The means of eye tracking variables were analyzed using the nonparametric Mann-Whitney U test to determine whether they differed statistically based on whether participants had received landscape architecture education. The means of the four eye tracking variables differed significantly between the two groups (Table 4). The number of fixations among participants who have received or are receiving landscape architecture education is significantly higher than among participants without education in this field (Table 5). However, the total fixation duration, average fixation duration, and time to first fixation variables were lower in the group receiving landscape architecture education. These findings reveal that the visual perception process can vary depending on the education received or the level of expertise. A high number of fixations means that individuals with landscape architecture education examined the landscape elements in the photographs shown to them in a more detailed and systematic manner. It is thought that the spatial reading skills acquired as a result of the courses taken and the practical work carried out during the education process may have increased these participants' visual scanning skills regarding environmental elements. This situation means that individuals educated in landscape architecture evaluated a greater number of landscape components in the scenes shown to them with shorter fixations. On the other hand, the relatively low total and average fixation time in these participants means that individuals who have received landscape architecture education can process the visual details in the scenery shown to them more quickly and effectively. In addition, the low duration until the first fixation indicates that these individuals can experientially identify spatial patterns in visual scenes more quickly.

Table 4. Results of the mean comparison test for eye tracking variables

Eye tracking variable (LA education)	Test	Statistics	p-value
Number of fixations	Mann-Whitney U	29129	0.006
Total fixation time (seconds)	Mann-Whitney U	28194	0.001
Average fixation duration (seconds)	Mann-Whitney U	21737	< .001
Time until first fixation (seconds)	Mann-Whitney U	30383	0.046

Table 5. Mean and standard error values of eye-tracking variables at the level of groups with and without landscape architecture education

Eye tracking variable	Group	N	Mean	Std. error
Number of fixations	Has not received LA education	260	21.86	0.241
	Has received/is receiving LA education	260	22.55	0.259
Total fixation time (seconds)	Has not received LA education	260	7.83	0.075
	Has received/is receiving LA education	260	7.37	0.091

Average fixation duration (seconds)	Has not received LA education	260	0.37	0.005
	Has received/is receiving LA education	260	0.33	0.003
Time until first fixation (seconds)	Has not received LA education	260	0.54	0.018
	Has received/is receiving LA education	260	0.51	0.021

4. Conclusion and Recommendations

In studies measuring visual perception in urban green space planning, data is typically collected using traditional methods such as questionnaires, interviews, or observation. However, these methods can be limited in terms of achieving objective results. In this context, eye-tracking technology is an important complementary tool in urban green space planning in terms of revealing how individuals perceive landscapes or which elements they pay more attention to. The results of this study show that when eye-tracking is used in conjunction with traditional approaches, it enables a more comprehensive analysis of visual quality perception in both quantitative and qualitative terms.

The difference in landscape evaluation scores between GVI categories has shown that a 25% green fabric ratio may be a psychological threshold in landscape perception. It was observed that the evaluation scores given by participants dropped significantly in photographs below this ratio. Therefore, maintaining green texture above a certain ratio is important for increasing visual satisfaction in urban green spaces. Correlations between GVI and landscape evaluation variables reveal that green appearance is linked not only to ratio but also to qualities such as visual integrity and color balance.

When examining the relationships between the proportions of landscape elements in the photographs and landscape evaluation variables, it was observed that the presence of trees and shrubs created a positive perception, while hardscape or other structural elements created a negative perception. It is understood that participants found spaces with a natural character, balanced with plant material, and where structural landscaping was not dominant to be more aesthetically pleasing from a visual perspective. The results of the eye-tracking analysis revealed that individuals who had received or were receiving landscape architecture education examined the scenes with a greater number of fixations, but for relatively shorter periods of time. This situation shows that participants, who have gained visual and aesthetic skills through their landscape architecture education, scan the environmental elements in the photographs more systematically. Considering the preliminary results of the study, it is understood that the use of eye-tracking technology in conjunction with traditional data collection methods can provide a physiological basis for urban green space planning and design decisions.

Thanks and Information Note

This conference paper utilizes data and findings obtained from project number 124K606, supported by TÜBİTAK under the 3005 program. The paper complies with national and international research and publication ethics. Ethics committee approval for this study was obtained from the Ordu University Social and Human Sciences Research Ethics Committee,

dated October 30, 2024, with decision number 2024-157. All authors contributed equally to the paper.

Abstract

Children's Playgrounds are among the most significant environments where physical and cognitive development takes shape, and the foundations of freedom are established. These playgrounds provide experiential spaces that support imagination, develop motor skills, and strengthen the sense of security. Children who merge their games with imagination may become the captain of a ship or an inseparable part of nature. Within this process, the feeling of safety is their most fundamental right. To ensure that playgrounds are designed with safety in mind, specific criteria must be established. At this point, safety standards serve as guiding frameworks. Safety standards aim to prevent possible accidents by defining measurement ranges and limitations for playgrounds and equipment. While national standards demonstrate similarities, they also present significant differences in content. This study seeks to reveal the effects of different safety standards on design and functionality. Two of the most widely applied global standards, TS EN and ASTM, were selected for comparison. Based on these standards, the design outcomes of playgrounds and equipment were evaluated through both visual and conceptual analysis. The findings obtained from this process were directly associated with design practice, and two distinct models were developed. The research highlights how playground design is directed by safety norms. At the scale of equipment, the overall site, and design criteria, the balance between safety and creativity was critically discussed. Differences between standards were found to play a decisive role in shaping playground design in terms of aesthetics, functional diversity, and experiential richness.

Keywords: Children's playground, safety, safety standards, creativity balance, design process

1. Introduction

Play nurtures children's imagination and enables them to develop their creativity. At the same time, it offers children the opportunity to gradually build self-confidence and a sense of independence by making their own decisions and interacting with their surroundings (Polat, Doğan & Şahin, 2022). In order for children to grow into healthy individuals, it is of great importance for the future of society to create physical environments that ensure their fundamental needs and rights, support play opportunities, and prioritize safety (Onay & Kuş Şahin, 2019).

Throughout history, in line with social transformations and technological advancements, play—having a fundamental place in child development—has constantly evolved, renewing its spatial organization, formal structure, tools and materials, as well as its expressive language (Kahya Canlı & Demirarslan, 2020). Whether play takes place indoors or outdoors leads to differences in the types of materials and equipment used. These spaces, which play a key role in children's processes of experiencing their environment—particularly outdoor playgrounds—gain importance as environments that support these developmental processes in a more natural and

interactive way (Kaya & Alıncak, 2024). In contrast, traditional playgrounds dominated by elements such as swings, slides, and sandpits tend to promote more individual play behaviors and mainly contribute to the development of children's gross and fine motor skills (Başaran Uysal, 2013). In addition to improving gross and fine motor skills, playgrounds that are associated with specific and/or different themes through developing technology also contribute to children's mental development (such as imagination, empathy, and social/communication skills). Furthermore, ensuring a safe play experience within the play–child relationship established in playgrounds is of great importance.

Due to deficiencies in design and supervision in children's playgrounds, risks such as falling, entrapment, and collision may occur; therefore, safety principles have become an integral part of the design process in organizing playgrounds (Sarıaslan Senyen & Erdoğan, 2019). The play equipment that supports children's physical development must be diverse and sufficient to meet the developmental needs of different age groups and must be designed and implemented in accordance with relevant safety standards (Aklıbaşında, Tırnakçı & Özhancı, 2018).

When the standards related to playground elements are examined, it is understood that—regardless of the type or nature of the equipment—the primary consideration in the design, installation, and use processes of a playground should be safety (Sarıaslan Senyen & Erdoğan, 2019). The standards used in children's playgrounds in Turkey have been shaped by adapting the regulations valid in Europe. Accordingly, the previously applied TS 5219 and EN 71 standards have been replaced by TS EN 1176 and TS EN 1177, which have entered into force (Ulaş & Ayan, 2016). The TS EN 1176 standard, which contains comprehensive provisions regarding the safety of equipment used in children's playgrounds, consists of a total of eleven sections covering different types of equipment as well as installation and maintenance processes (TS EN 1176-1, 2023).

While TS EN 1176 is valid in Europe and Turkey, ASTM F1487 is applied in the United States (USA) as the primary reference standard concerning playground safety. The ASTM F1487 standard defines nationally recognized safety requirements for equipment used in public playgrounds, based on the injury risk criteria determined by the U.S. Consumer Product Safety Commission (CPSC) (ASTM International, 2025).

The fundamental approaches and safety priorities on which these two standards are based shape the formal design of playground equipment, material selection, fall height criteria, and risk management parameters through different methodologies. Therefore, in the design of children's playgrounds, not only the level of safety but also the quality of play experience, spatial diversity, and the degree of creativity are directly influenced by these standards.

This research aims to examine the effects and limiting aspects of the TS EN 1176 and ASTM F1487 safety standards—used in playground design—on creative design processes, within the scope of two separate playground models designed according to the respective values of these standards. By comparing the effects of standards on design decisions, it seeks to reveal the balance between safety and design freedom. The designs are constructed with a simplified approach, free from excessive detail, to clearly and visibly present the differences between the two standards.

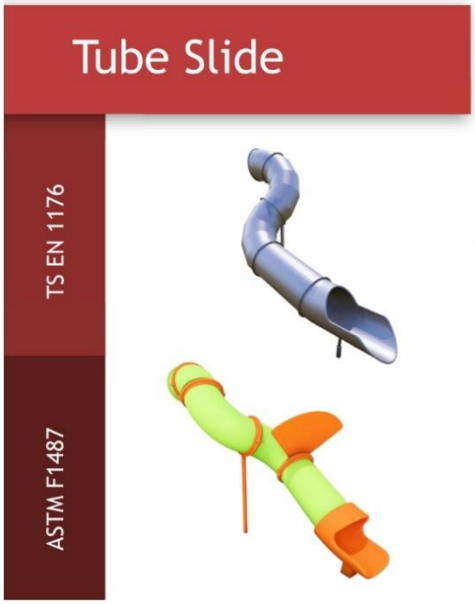
2. Materials and Methods

This research consists of five main sections: determination of the research purpose, examination of the relevant materials identified in line with this purpose, determination of the research limitations, formation of the findings, product design, and visualization.

The aim of the research is to examine the effects and limiting aspects of the standards **TS EN 1176 – Playground Equipment and Surfacing: Safety Requirements and Test Methods** (Turkish Standard European Norm 1176) and **ASTM F1487 – Standard Consumer Safety Performance Specification for Playground Equipment for Public Use** (American Society for Testing and Materials F1487), which are used in playground design, on creative design processes within the scope of two separate playground models designed according to the respective values of these standards. The playground design was constructed with a simplified approach—free from excessive detail—to clearly and visibly reveal the differences between the standards. Accordingly, by comparing the effects of the standards on design decisions, the study aims to reveal the balance between safety and design freedom.

The main materials of the research, **TS EN 1176** and **ASTM F1487,** were obtained from the official websites of the relevant institutions. For a comparative analysis between the two standards, a detailed review was conducted; and based on the initial assessments, it was observed that the diversity of product groups and the broad scope and content addressed by the standards were extensive. Therefore, in order to define the scope and limitations of the study, basic design elements included in a complex playground structure—where the differences between the two standards can be most clearly observed—were selected. These include **tube slides, stepped ladders, inter-platform transition elements, railings, and barriers.** These selected design components were comparatively analyzed between the two standards, and the findings obtained were evaluated through comparative tables supported by visual materials.

The design was developed based on the **"Puzzle" concept**. The reason for selecting this concept lies in the fact that although both standards adopt the same ultimate goal of ensuring safety in children's playgrounds, they present different approaches to achieving this objective. Much like the differently shaped pieces of a puzzle, both standards share similar principles but diverge in terms of their methods of application and design orientations. To represent this situation, a **common platform symbolizing the intersection point of the two standards** was designed and named the **"Standard Platform."**



Based on the findings obtained from the analysis and the determined design concept, two separate playground groups were designed according to the respective standards. The designs were modeled using **SketchUp**, and **product and component renderings** were produced using **Lumion**. Additionally, in order to support site layout and visualization, **Google's artificial intelligence software Gemini** was utilized for generating visual representations.

3. Findings and Discussion

The TS EN 1176 and ASTM F1487 standards aimed at ensuring safety in children's playgrounds were compared, and similarities and differences between the two standards were revealed through their design principles, risk prevention approaches, and component criteria. The examinations conducted within the scope of the research showed that the standards are quite extensive in terms of scope and content; therefore, it was not possible to include all articles in the design process. For this reason, the study focused on four fundamental design elements—tube slides, stepped ladders, inter-platform transition elements, and railings and barriers—

where the differences between the standards could be most clearly observed. The designs were prepared with a simplified approach to demonstrate how these differences emerge both visually and functionally.

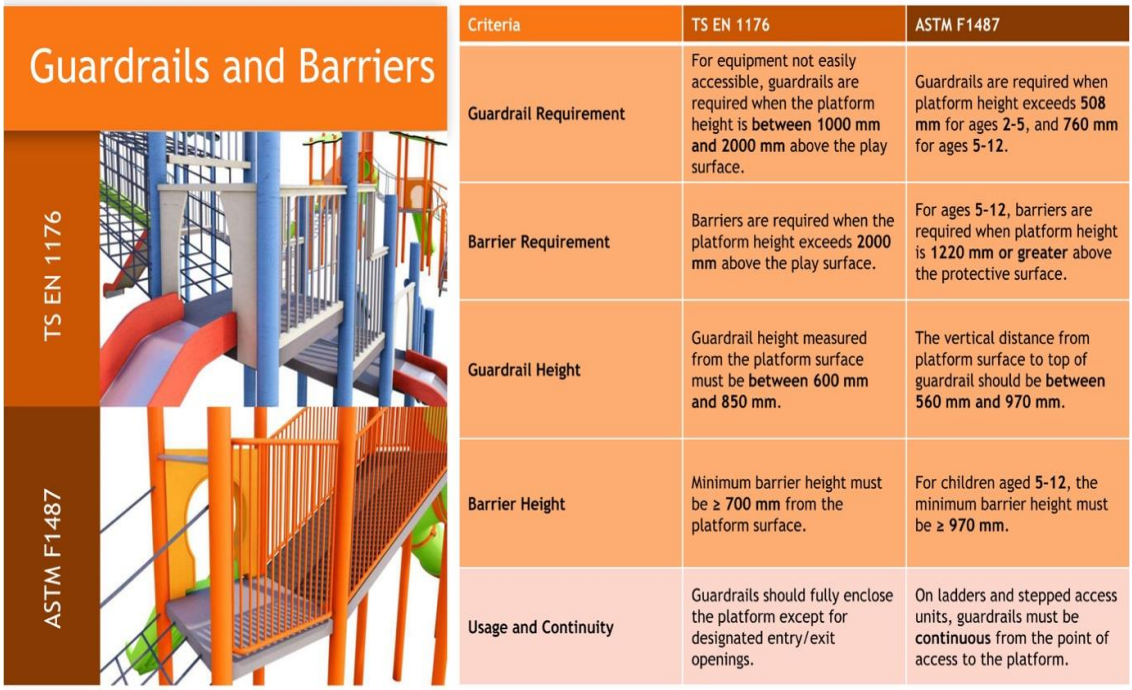
In the tube slide design, according to the two standards, a total of eight design criteria were identified: transition platform, sliding slope, entry section, sliding channel width, exit section length, fall height, slide protection, and supporting structure. The application details of these criteria as specified in the standards are presented in Figure 1. The design criteria in which differences were observed between the two standards are indicated in different colors on the table.

Criteria	TS EN 1176	ASTM F1487
Transition Platform	A transition platform must be provided. The depth is generally ≥ 350 mm.	The depth of slide transition platforms shall be at least 360 mm.
Sliding Slope	The angle of the sliding section relative to the horizontal should not exceed approximately 40°.	No part of the sliding surface shall be steeper than 50° relative to the horizontal.
Entry Region	A handrail or guiding element must be provided to assist the user in moving into the sitting position.	A handhold, head piece, or protective guiding element is required to direct the user into the correct sitting position.
Slide Bedway / Internal Width	For tunnel slides, the minimum internal height and width of the sliding surface must be at least 750 mm.	For tube slides, the internal diameter must be 580 mm or greater.
Exit Region Length & Slope	The exit section must have a slope between 5° and -10°, with a minimum length of 300 mm.	The exit section must have a slope between 0° and -10°, with a minimum length of 280 mm.
Fall Height Measurement	The fall height is measured from the protective surfacing to the start of the sliding section.	The reference fall height for a fully enclosed slide tube is taken as 2130 mm.
Slide Protection (Upper Guarding)	No guard is required on the slide body itself; protection must comply at the platform level (guardrail/barrier criteria).	A protective guard must extend 970 mm above the slide surface, covering a 645° arc around the entry.
Support Structure	Support posts may remain accessible in the free space.	Support structures of tube slides must be designed to minimize opportunities for climbing.

Figure 1. Differences between the two standards in tube slide design (Adapted from TS EN 1176 and ASTM F1487)

In the comparison of safety standards applied in tube slide design, the design criteria of sliding channel width, fall height, and slide protection stand out. According to the TS EN standard, the inner height and inner width of the sliding surface must be at least 750 mm (TS EN 1176-3, 2010). In the ASTM standard, the internal diameter is required to be 580 mm or more. Regarding fall height, in the TS EN standard, the distance from the protective surface to the starting point of the slide is taken as reference, while in the ASTM standard, the tube protection height of 2,130 mm is taken as reference. For slide protection, the TS EN standard does not require any protection on the upper part of the slide; it only stipulates that the barrier and railing criteria of the starting platform must be met. In contrast, the ASTM standard requires protection extending 970 mm above the upper surface of the slide, covering an arc of 645°.

In the design of stepped ladders, according to the two standards, there are six design criteria: step height and depth, ladder width, slope, handrail and railing, step spacing, and fall prevention measures. The application details of these criteria as specified in the standards are presented in Figure 2.



Criteria	TS EN 1176	ASTM F1487
Step Height & Depth	Minimum tread depth should be ≥ **110 mm** to provide sufficient standing area.	Vertical rise between steps must be < **229 mm**; minimum tread depth ≥ **178 mm**.
Ladder Width	No fixed dimension, but the ladder is generally recommended to match the width of the access platform.	If double-sided access is provided, the total ladder width must be > **910 mm**.
Slope	Ladder inclination should remain consistent.	A series of steps used for ascent or descent should have a slope ≤ **50°** relative to horizontal.
Handrails & Guardrails	The height of the guardrail measured from the stepping or platform surface must be **between 600 mm and 850 mm**.	Continuous handrails shall be provided on **both sides** of ladders, ramps, and stepped access systems with multiple steps.
Step Openings / Risers	Open risers are permitted; however, openings should be < **30 mm**.	Vertical openings between steps shall not exceed **230 mm**.
Fall Protection Measures	Barriers are required if the accessible platform height exceeds **600 mm** above the play surface.	Any step located **1220 mm** above the protective surface requires a protective barrier.

Figure 2. Differences between the two standards in stepped ladder design (adapted from TS EN 1176 and ASTM F1487)

In the comparison of safety standards applied in the design of stepped ladders, the design criteria of slope, step spacing, and fall prevention measures are prominent. According to the TS EN standard, it is stated that the slope of the ladders must have a fixed value, although no numerical value is specified. In the ASTM standard, however, it is defined as a series of steps used for ascent and descent, having a slope of 50° or greater relative to the horizontal plane. Regarding step spacing, the TS EN standard does not require the risers of the steps to be closed; however, if the risers are closed, the gap must be less than 30 mm. In the ASTM standard, the vertical spacing between steps must not exceed 230 mm. For the fall prevention criterion, according to TS EN, when the platform is more than 600 mm above the play surface, access must be provided through barriers. In the ASTM standard, all steps with a height of 1,220 mm above the protective surface must include a protective barrier.

When the requirements and dimensional ranges of guardrails and barriers are examined, they are analyzed according to design criteria such as the necessity of guardrails, the necessity of barriers, guardrail height, barrier height, and usage. The application details of these criteria as specified in the standards are presented in Figure 3.

Criteria	TS EN 1176	ASTM F1487
Guardrail Requirement	For equipment not easily accessible, guardrails are required when the platform height is **between 1000 mm and 2000 mm** above the play surface.	Guardrails are required when platform height exceeds **508 mm** for ages **2-5**, and **760 mm** for ages **5-12**.
Barrier Requirement	Barriers are required when the platform height exceeds **2000 mm** above the play surface.	For ages **5-12**, barriers are required when platform height is **1220 mm or greater** above the protective surface.
Guardrail Height	Guardrail height measured from the platform surface must be **between 600 mm and 850 mm.**	The vertical distance from platform surface to top of guardrail should be **between 560 mm and 970 mm.**
Barrier Height	Minimum barrier height must be ≥ **700 mm** from the platform surface.	For children aged **5-12**, the minimum barrier height must be ≥ **970 mm.**
Usage and Continuity	Guardrails should fully enclose the platform except for designated entry/exit openings.	On ladders and stepped access units, guardrails must be **continuous** from the point of access to the platform.

Figure 3. Differences between the two standards in guardrail and barrier design (adapted from TS EN 1176 and ASTM F1487)

In the comparison of safety standards applied in guardrail and barrier design, the criteria of usage requirement and application height stand out for both components. According to the TS EN standard, the use of guardrails is required for equipment that is not easily accessible, with a platform surface height between 1000 mm and 2000 mm, whereas in the ASTM standard, the requirement is defined based on age groups: for the 2–5 age group, when the platform height exceeds 508 mm, and for the 5–12 age group, when it reaches 760 mm. When this criterion is considered for barriers, according to the TS EN standard, a barrier must be provided when the equipment that is not easily accessible exceeds 2000 mm from the play surface, while in the ASTM standard, this value corresponds to a height of 1220 mm or more above the protective surface for the 5–12 age group.

In terms of application height, the TS EN standard specifies that the height to the upper part of the guardrail, measured from the platform and from the surface of the ladder or ramp, must be no less than 600 mm and no more than 850 mm. In the ASTM standard, the vertical distance to the top surface of the guardrail is between 560 mm and 970 mm. Regarding barrier application height, the TS EN standard states that the height to the top of the barrier, measured from the surface of the platform, ladder, or ramp, must be at least 700 mm; according to the ASTM standard, this value must be at least 970 mm for surfaces used by children aged 5 to 12 years.

When flexible and non-flexible platform transition elements are examined within the scope of the two standards, it has been observed that they are brought together with different structural components and are classified under general criteria but not defined as separate topics. Platform transition elements, within the context of general design criteria, have been analyzed through parameters such as surface slope in horizontal net crossings, side protection height, mesh spacing, barrier requirement, passage width, guardrail system, surface characteristics, and bridge classification. The application details of these criteria as specified in the standards are presented in Figure 4.

Criteria	TS EN 1176	ASTM F1487
Surface Slope (Angle of the Net Surface)	Horizontal net transitions are permitted when the surface slope is ≤ 45°.	Net transitions may be used instead of climbing elements when the slope does not exceed 50°.
Side Protection Height	The vertical height from the transition surface to the top of the guardrail or barrier must be ≥ 700 mm.	The vertical distance from the foot support surface to the top of the protective barrier must be ≥ 970 mm.
Net Mesh Opening Size	Maximum mesh opening: ≤ 230 mm.	Maximum mesh opening: ≤ 230 mm (same requirement).
Barrier Requirement	Barriers are required when the transition height exceeds 1000 mm, with minimum barrier height ≥ 700 mm.	Barriers required when fall height exceeds 1200 mm, with protective height determined by child age group (commonly ≥ 970 mm for ages 5-12).
Transition Width	Recommended minimum clear width: ≈ 700 mm.	Minimum clear width: ≥ 910 mm (may be reduced to 810 mm over short distances).
Guardrail Height Along Transition	Vertical height from the walking surface to the top of the guardrail should be 600-700 mm.	Vertical height from the walking surface to the guardrail top should be 560-970 mm.
Barrier Requirement Based on Height	Barriers are required when the transition height exceeds 1000 mm, with barrier height ≥ 700 mm.	Barriers are required when fall height exceeds 1200 mm, with barrier height determined by age group (≥ 970 mm for ages 5-12).
Surface Characteristics	Non-slip, water-draining surface with foot support projections recommended.	Non-slip, water-draining surface required.
Slope and Classification	Transition walking surfaces must not exceed 38°; beyond this, the surface is classified as a climbing element.	Surfaces with a slope > 30° are no longer considered a play surface, but become climbing elements.

Figure 4. Differences between the two standards in platform transition elements (adapted from TS EN 1176 and ASTM F1487)

In the comparison of flexible platform transition elements, the criteria of side protection height and barrier requirement stand out. According to the TS EN standard, the side protection height must be 700 mm or greater, measured from the tube passage surface to the top of the barrier or guardrail, whereas in the ASTM standard, this value is measured as ≥ 970 mm from the foot level. Regarding the barrier requirement, according to TS EN, barriers are mandatory for transitions exceeding 1000 mm in height. In the ASTM standard, barrier requirements are defined based on fall height when the value exceeds 1200 mm.

In the comparison of non-flexible platform transition elements, the criteria of passage width, guardrail system, and barrier requirement stand out. According to the TS EN standard, the minimum recommended passage width is 700 mm, while in the ASTM standard, the minimum clear width is 910 mm, and for short-distance transitions, it is measured as 810 mm. The

guardrail height in the TS EN standard must be between 600 mm and 700 mm, whereas in the ASTM standard, this value ranges between 560 mm and 970 mm. The barrier requirement in the TS EN standard is mandatory when the height exceeds 1000 mm, while in the ASTM standard, the use of barriers is defined according to age group when the fall height exceeds 1200 mm.

In bridge classification, according to the TS EN standard, when the slope on bridges and transition surfaces exceeds 38 degrees, the element is no longer considered a bridge but is classified as a "climbing element." Similarly, according to the ASTM standard, surfaces with a slope greater than 30 degrees are not regarded as "play surfaces" and are classified as climbing elements.

As a result of the comparative analyses conducted, it has been observed that there are significant differences between the TS EN 1176 and ASTM F1487 standards in the criteria related to the design elements addressed within the scope of the study. In order to present these differences systematically, both the quantitative and qualitative definitions of the two standards were evaluated through comparative tables (Figures 1–4). In light of the findings obtained, a subsequent design process was carried out to reveal not only the technical differences but also their potential impacts on user experience, design aesthetics, and designer creativity, and to visualize these differences more concretely. The design process was conducted by creating two separate designs based on the differences identified between the two standards (Figure 5).

Figure 5. Playground equipment design based on the differences between TS EN and ASTM standards

In the design process, how the criteria and parameters specified in the standards were reflected in the selected design elements was systematically examined. In line with these examinations, the playground design was carried out based on the results of the comparative analyses presented above. The design was modeled in the SketchUp program, and product and component renderings were produced using the Lumion program. The component render visuals of the product are presented in the comparative tables given above (Figures 1–4).

In the design, the materials used were selected in accordance with the regulations adopted and inspected by the relevant manufacturers, and the design elements included in the playground were structured and scaled appropriately for production. Additionally, since the design was carried out within the framework of a specific concept, visualization was performed using the artificial intelligence tool Gemini to simulate the perceptibility of the comparison between the two standards within a real environment (Figure 6).

Figure 6. Real-world view of playground equipment designed according to the standards

Through the visualization study, the process of the designed playground model has contributed not only to the evaluation of the design at the conceptual, plan, and model scale, but also to the assessment of potential implementation scenarios in the future.

4. Conclusion and Recommendations

Safety is one of the most defining and limiting elements in the design process of children's playgrounds. In this context, TS EN 1176-1:2023 and ASTM F1487-21 are the two primary reference documents that are recognized as valid in both Turkey and Europe as well as in the United States, containing the most comprehensive regulations on playground safety. Both standards aim to minimize risks such as falling, entrapment, impact, and access through the use of master (probe) tests developed based on child anatomy and behavioral patterns and defined by measurable dimensional values. Through these testing methods, specific spacing intervals, barrier heights, platform distances, and surface inclinations have been scientifically standardized.

However, these safety requirements also establish mandatory frameworks that can restrict creativity for playground designers. Even when a designer pursues aesthetics, functionality, and innovation, each element must remain within certain dimensional limits; platform heights, slope ratios, barrier heights, and mesh openings are required to comply with the standards. This situation particularly narrows the boundaries of design in play components that involve high fall potential or are constructed with flexible materials (such as nets, ropes, or bridges). Nevertheless, the purpose of the standards is not to inhibit creativity but to encourage innovative solutions within the boundaries of safety.

On the other hand, it is evident that neither of the two standards is detailed enough to cover all possible design variations. Especially in contemporary design approaches involving net climbing structures, flexible transitions, or themed and hybrid play constructions, there are gaps in the standard texts where direct equivalents are not provided. At this point, the evaluation of designs often depends on the interpretive judgment of supervisory bodies or experts; thus, the same design may be interpreted differently across various implementations. Consequently, the interpretive sections of the standards create uncertainties for both designers and manufacturers during the processes of technical compliance and safety certification.

In conclusion, TS EN 1176 and ASTM F1487 standards constitute the fundamental framework that defines the balance between creativity and safety in children's playgrounds. While these standards ensure safe play environments, they also allow designers to pursue originality and aesthetic value within certain boundaries. However, this measurement-based system grounded in test methods needs to be continuously updated to support the development of flexible and innovative designs aligned with contemporary play concepts. The evolution of these standards to consider not only mechanical safety but also the quality of play experience and the design freedom that supports children's physical, social, and cognitive development is of great significance for the future of playground design.

Abstract

Rapid technological advancements today are reshaping urban life and spatial production processes, bringing flexibility, mobility, and user-centered experiences to the forefront. In this context, the Archigram group, emerging in the 1960s, developed radical, experimental, and technology-centered architectural visions as alternatives to modernist planning paradigms. Radical architectural projects such as Plug-In City, Walking City, Instant City, Living Pod, Cushicle, and Suitaloon placed modularity, portability, and individual freedom at the core of architectural design. Archigram's utopian vision represents not only the technological imagination of its era but also a critical, creative, and innovative perspective on future urban living scenarios. This study examines the intersections between Archigram's modular and mobile spatial concepts and contemporary urban design practices that prioritize sustainability, flexibility, and user-centered approaches. Emergency housing solutions after disasters, climate-induced migration, and smart city applications are evaluated as contemporary reflections of Archigram's vision. Furthermore, AI-assisted methods were employed to visualize future-oriented urban design proposals. This approach enables a contemporary reinterpretation of Archigram's utopian vision through modern technologies and highlights the potential of AI as an experimental research and design tool in architecture and urban planning. The study also emphasizes the necessity of addressing the impact of new technologies—such as AI and augmented reality—on spatial design, promoting social participation, and developing innovative, climate-resilient urban models. In conclusion, Archigram's experimental projects serve as a powerful and transformative source of inspiration, guiding equitable, sustainable, and participatory design approaches to address today's complex urban challenges.

Keywords: Archigram, modularity and mobility, technology and urban design

1. Introduction

In contemporary society, the acceleration of technological advancements has significantly reshaped urban life and urban culture. This transformation, encompassing physical, social, cultural, and technological dimensions, transcends the traditional boundaries of the concepts of human–space–time. Within this context, questions such as how urban spaces should be configured, how individuals will experience these spaces, and how the social structure will be influenced by this transformation occupy an important place in the research and practice agendas of architecture and urban planning disciplines (Seymen Aksu & Yalçıner Ercoşkun, 2022).

It is anticipated that the cities of the future will evolve into focal points shaped by technological developments and defined through futuristic visions. Accordingly, various inquiries have been made regarding the extent to which technology can be integrated into urban design, and these inquiries have paved the way for innovative projects that push the boundaries of their time.

Integrating technology not only into buildings but also into social life, public spaces, and the processes through which individuals gain autonomy has become a fundamental approach. The objective of this understanding is not merely to produce buildings or physical environments, but to employ technology to transform individuals into participants of a more liberated, interactive, and dynamic mode of living. In this way, technology transcends being merely an instrumental component in the production of space and becomes an active element of social transformation and individual experience. This approach is particularly evident in the design vision of the Archigram group (Fernandez Rubio, n.d.).

Formed through the collaboration of Warren Chalk, Dennis Crampton, Ron Herron, Peter Cook, David Greene, and Mike Webb, the British group Archigram emerged in the 1960s as an intellectual platform where new ideas in architecture were generated, debated, and disseminated, fostering an experimental mindset that proposed radical tendencies in design (Wilkinson, 2023).

Archigram—its name derived from the combination of "architecture" and "telegram"—was initially founded as a magazine, but soon evolved into an intellectual movement that marked a significant turning point in the history of architecture (Figure 1). Rejecting conventional approaches to architecture, its founders adopted a more flexible, dynamic, and experimental design perspective. Questioning historical heritage and traditional architectural practices, Archigram sought to transform architecture by drawing inspiration from popular culture, exuberant visual narratives, and the emerging technological opportunities of the period (Gardinetti, 2024).

Figure 1. Cover images from Archigram 4 (left) and Archigram 8 (right) (Architecture & Design Community, 2025)

Radical Architectural Concepts of Archigram and Their Potential in Urban Design

Emerging in the 1960s under the strong influence of Modernism, the Archigram group adopted a radical stance in architecture by developing a dynamic, speculative, and flexible approach that challenged the rationalist and static planning paradigms of the period. The cities, social

environments, and intellectual atmospheres in which the members were raised shaped their architectural production, while the technological, social, and ideological transformations of the modern era profoundly influenced Archigram's experimental approach. The group argued that the city could not be defined by static and rigid boundaries, advocating instead for portable and transformable architectural proposals developed at the intersection of technology, individual needs, and popular culture, thereby transforming architecture into a forward-looking field of critical inquiry. In this respect, Archigram addressed unresolved issues of Modernism in creative ways, leaving a significant theoretical legacy for contemporary architectural thought. Today, rapid urbanization, mass migration, climate crises, and technological advancements necessitate the design of cities that are flexible, sustainable, and user-centered. Within this context, the principle of modularity introduced by Archigram in the 1960s has resurfaced in contemporary architecture through prefabricated structures, temporary housing solutions, and sustainable residential systems. Portable and mobile living units developed for emergency settlements following disasters and climate-induced migration closely align with Archigram's "moving city" concept. Additionally, through the widespread adoption of data-driven smart city applications, Archigram's technology-integrated urban vision is being reinterpreted in new ways, finding both theoretical and practical resonance in contemporary urban planning approaches. The group's key projects that exemplify its radical approach in architecture include Plug-In City, Walking City, Instant City, Living Pod, Cushicle, and Suitaloon (Somer, 2006). To illustrate the formal and conceptual diversity of these designs, English-language prompts were prepared and an AI-assisted design process was employed, generating spatial interpretations of these visionary architectural concepts.

2. Plug-in City

Plug-in City is an experimental urban system proposal developed by the Archigram group between 1962 and 1964, consisting of a synthesis of small-scale projects and conceptual ideas. The themes discussed in Issues 2 and 3 of the Archigram magazine during this period received positive feedback, and Peter Cook articulated this process as follows: "It was therefore inevitable that we should investigate whether the entire urban environment could be programmed and structured to adapt to change." Plug-in City was first published in 1964 in Issue 4 of the Archigram magazine. This work emerged as a speculative series of proposals designed for change, envisioning a computer-controlled urban system in which removable components would unite under a megastructure service framework. The system adopts a linear rather than circular form. However, as these linear structures expand and develop over time, their short-term accessibility to the surrounding rural settlements (villages, hobby houses, etc.) may diminish. Archigram designed Plug-in City as a connective network capable of integrating small-scale rural structures dispersed across Europe. In doing so, the proposal envisioned providing equal access not only to the urban center but to all lands and natural resources. The system's most significant characteristic is its capacity to "continuously construct and reshape itself." This dynamic structure is made operable through a monorail line that runs above the grid system (Figure 2). The monorail not only transports passengers but also carries cranes. These cranes are capable of moving modular components attached to the grid vertically, horizontally, and diagonally. In this way, spaces with various functions—from living units to parking structures—can be flexibly integrated into the system according to the "plug-and-play" principle (Tsigkouni, 2012).

Figure 2. A sectional view of Plug-in City illustrating its structural components (Tsigkouni, 2012).

Flexible and Modular Architecture

'A futuristic cityscape with flexible, modular buildings that can expand or shrink, dynamic architecture made of lightweight materials, structures that resemble plug-in capsules, minimalistic design with high-tech interfaces — vibrant colors, blue sky, utopian feel.'

Based on the information provided above, sample visualizations were generated using Lookx AI. The biomorphic and spherical structural forms depicted in these images are shaped by the radical visions of the Archigram group—particularly inspired by the flexible, modular, and ephemeral characteristics of the Plug-in City concept. These designs represent high-tech and autonomous living units independent from existing urban morphology, while simultaneously reflecting contemporary tendencies toward flexibility, adaptability, and personalization in urban planning. The capacity of AI to materialize such a vision can be regarded as a new methodological tool for exploring the potential of future sustainable and adaptive architectural solutions through an interdisciplinary approach (Figure 3).

Figure 3. AI-generated design: flexible and modular architecture.

3. Walking City

The concept of the Walking City, designed by Ron Herron, describes a structure resembling a robot capable of movement through its telescopic legs. This structure is not merely about the relocation of architectural components; rather, it signifies the capacity of the urban whole to move spatially (Figure 4). Free from attachment to a fixed location, this flexible system can reposition itself in response to needs, crises, resources, and opportunities, thereby demonstrating that the city is not dependent on a static physical setting. The character of such

a structure is boundless, and its movements are inherently unpredictable (Tutkun & Demirkan, 2023).

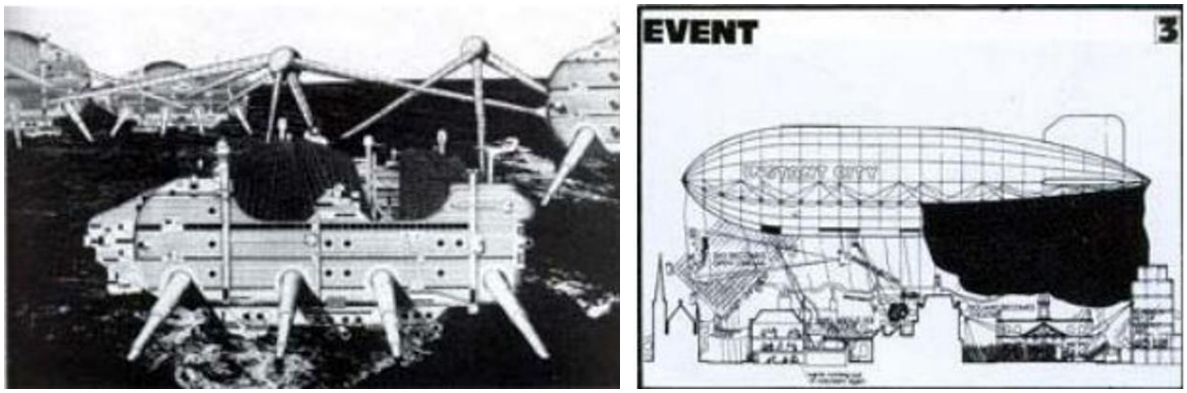

Figure 4. A sectional view of Plug-in City illustrating its structural components (Tsigkouni, 2012).

Mobile Urban Units

'A visionary mobile city with walking robotic buildings, movable housing units with wheels or legs, portable urban systems, a surreal blend of technology and architecture, inspired by Archigram's Walking City — bright, imaginative, sci-fi aesthetic.'

Based on the information provided above, sample visualizations were generated using Lookx AI. The mobile, spherical, and biomorphic units depicted in Figure 5 symbolize, in line with Archigram's vision, an autonomous, self-sufficient, and flexible mode of existence rather than a fixed and hierarchical urban structure. The wheeled and modular design emphasizes these units' capacity for spatial adaptation and relocation, challenging conventional notions of permanence in settlement. The ability of artificial intelligence to materialize this radical concept holds the potential to revive philosophical and architectural debates on limitless urbanization and life in perpetual motion. This study contributes to contemporary research examining the relationship between urban mobility and capsule architecture.

Figure 5. AI-generated design: mobile urban units

4. Instant City

Developed in 1970, the concept of Instant City was designed as a flexible organism capable of responding to the variable and immediate needs of urban inhabitants. Lacking a fixed structure,

this city can be shaped according to the desires and current conditions of its users (Figure 6). Instant City allows urban spaces to transform instantly in response to user requirements, providing flexibility and rapid adaptation. The project integrates inflatable and lightweight structural units through trailer modules, combining bridges, towers, support systems, scaffolding, audiovisual screens, projection equipment, and various electronic systems into a cohesive whole. Conceived as a temporary and dynamic urban model, the design draws inspiration from a circus structure that operates in one location for a limited time before relocating, thereby maintaining its mobility (Akgül, 2006).

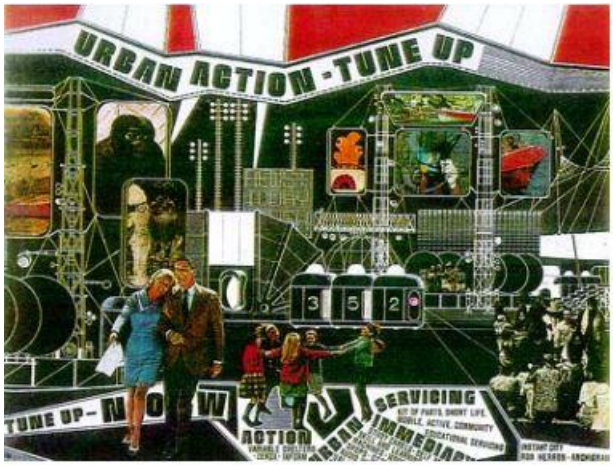

Figure 6. Instant City (Akgül, 2006)

Integration of Technology and Daily Life

'A high-tech living space where architecture is seamlessly integrated with digital technology, interactive walls, wearable smart devices, and intelligent building systems — futuristic but cozy environment, sleek design, cybernetic landscape.'

Based on the information provided above, sample visualizations were generated using Lookx AI. These images depict a public space defined not by traditional structural components, but by information, media, and temporary lighting. Large illuminated screens highlight a scenario in which the flow of information and ephemeral cultural events becomes more central than the architectural form itself. This parallels Archigram's pursuit of creating an urban environment centered on "events" or "experiences," rapidly assembled and dismantled. The space presents a hybrid landscape in which walls function not only as physical boundaries but also as dynamic communication surfaces. AI's interpretation emphasizes the transient and information-intensive nature of urban spaces, offering a significant contribution to contemporary discussions on digital public realms (Figure 7).

Figure 7. AI-generated design: Integration of Technology and Daily Life

5. Living Pod

Living Pod is a technology-integrated living unit concept developed by the Archigram group, focusing on individual life (Figure 8). The concept is expressed as a portable and modular capsule, defining the occupant's living space with maximum functionality in a minimal area. Advocating the idea that space should be mobile and transformable rather than fixed and permanent, this design radically challenges traditional notions of housing. Living Pod represents one of the early examples of user-centered, adaptive, and flexible spatial organization, proposing personalized micro-living environments that can be shaped according to an individual's lifestyle (Beşlioğlu, 2014).

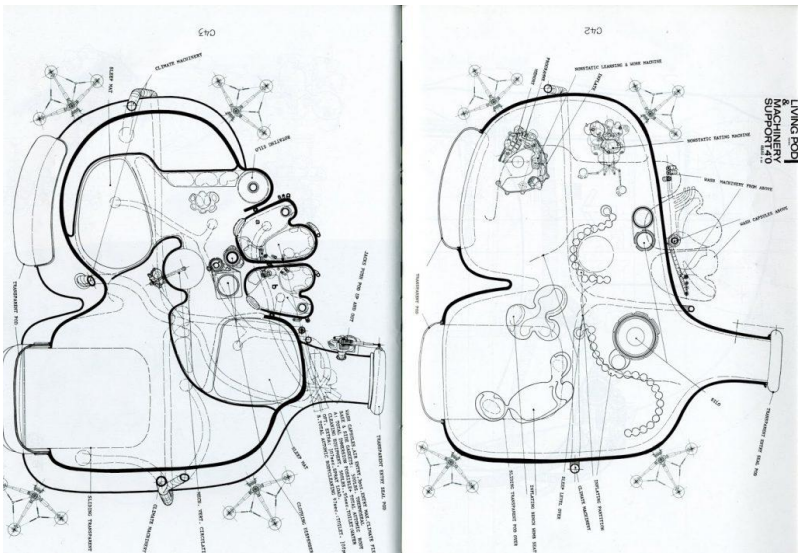

Figure 8. Living Pod (URL1)

Sustainable and Self-Sufficient Systems

'A green, futuristic neighborhood with solar panels, vertical gardens, and water recycling systems — eco-architecture with self-sufficient pods or capsules, surrounded by nature, combining organic forms with technology — clean, bright, hopeful atmosphere.'

Based on the information provided above, sample visualizations were generated using Lookx AI. The depicted vertical and curvilinear structures represent not only modular units but also

an ecological urban fabric interwoven with dense vegetation. In addition to the traditional Living Pod emphasis on technology and autonomy, these capsules incorporate biophilic design elements, reinforcing a symbiotic relationship between humans and nature. AI's interpretation merges contemporary architectural trends—such as urban farming, green façades, and vertical forestry—with the Living Pod's vision of individualized and flexible living, exploring the potential of future eco-autonomous living units. This study offers a novel solution to challenges of limited resources and high-density urban settlements through the lens of Archigram's radical philosophy (Figure 9).

Figure 9. AI-generated design: Sustainable and Self-Sufficient Systems

6. Cushicle

Cushicle is another radical living unit concept developed by Archigram member Michael Webb in 1966. Designed as a wearable living system, Cushicle is a compact structure that can be carried like a backpack and, when unfolded, transforms into a functional living space (Figure 10). It includes a sleeping area, food storage, and environmental control systems, thereby addressing concepts of individual freedom, mobility, and independence within the architectural context. This system is conceived to enable a person to live autonomously without dependence on the surrounding environment, and it serves as a significant example reflecting the impact of technological advancements on architecture during the latter half of the 20th century (Webb, 1966).

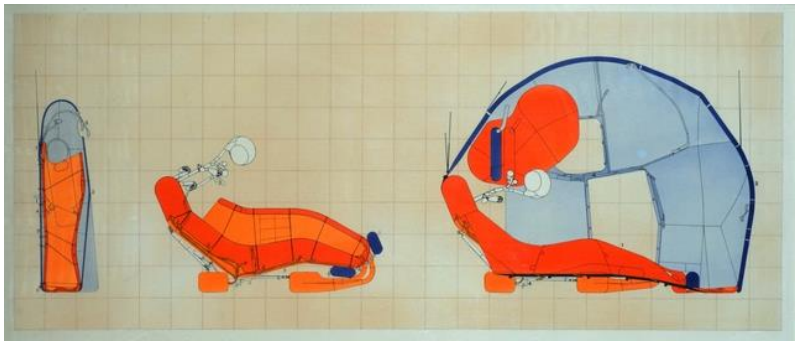

Figure 10. Cushicle (URL2)

Flexible Cities and Service Nodes

'Visualize Michael Webb's 1966 Cushicle concept as a contemporary urban design vision. The urban design features a dynamic, fluid public space filled with modular service nodes and charging stations where Cushicle users can temporarily 'plug in' and receive technological services. In this space, inflatable, transparent Cushicle units expand from their backpack form into personalized, capsule-like living environments. The ground and service nodes are covered in a futuristic, grid-like, technology-focused pattern. The atmosphere should blend the aesthetic of 1960s Futurism (Pop Art influences) with contemporary high-tech. A night or twilight setting, dominated by neon lights and pneumatic structures, emphasizing individual freedom and urban flexibility.'

Based on the information provided above, sample visualizations were generated using Lookx AI. In Figure 11, the inflatable, transparent, and individual living/rest units offer a contemporary interpretation of Cushicle's core concept: a personal habitat that meets individual needs and is portable anywhere. These designs create temporary and customized micro-spaces within public areas such as city squares, reflecting the individual's desire for autonomy from environmental conditions. The soft, illuminated, and almost ambient forms of the units emphasize the tension between digital interaction and personal space.

Figure 11. Flexible Cities and Service Nodes

7. Suitaloon

Suitaloon, also developed by Michael Webb, is another wearable living space concept that can be considered within the same thematic framework as Cushicle (Figure 12). Derived from the combination of "Suit" and "Balloon," this concept envisions a portable, inflatable dwelling unit that envelops the human body. Suitaloon is conceived as an architectural structure that directly engages with the human body and functions as its extension. In this respect, it advocates viewing space not only as a functional entity but also as an experiential and personal extension. By integrating technology with the human body, this design invites a reconsideration of architecture and living space as fluid and boundary-defying concepts (Webb, 1966).

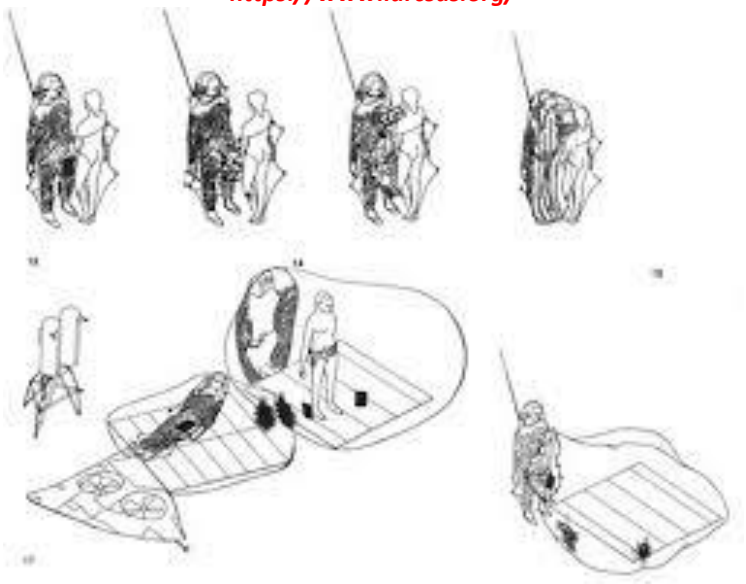

Figure 12. Suitaloon (URL3)

The Future of Urban Privacy and Fluid Spaces

'The city features a modular and lightweight infrastructure that adapts to the dynamic and fluid movements of individual Suitaloon users. People navigate urban spaces or temporarily 'settle' within their transparent or semi-transparent inflatable 'balloon' dwellings that envelop their bodies. These Suitaloons create personalized micro-environments. The city landscape is filled with high-tech, modular walking platforms, inflatable architectural elements, and light trails indicating energy flows. The atmosphere is futuristic, slightly dystopian yet emphasizing individual freedom, set at night or dusk. A strong contrast between neon colors and organic inflatable forms prevails.'

In Figure 13, the inflatable, illuminated, and spherical units evoke the concept of Suitaloon transforming from a wearable shell for individual shelter and environmental interaction into a full-scale spatial installation. Transparency and lighting convert these units into striking and temporary installations within the urban landscape, while positioning the user as a protected and autonomous presence against the backdrop of the modern metropolis. This design effectively visualizes architectural tendencies that challenge the necessity of fixed forms and blur the boundaries between personal and public space.

Figure 13. The Future of Urban Privacy and Fluid Spaces

8. Conclusion

This study examined the theoretical legacy of modularity and mobility—radical architectural concepts developed by the Archigram group in the 1960s—on contemporary urban design paradigms through AI-assisted visualization. In the context of rapidly changing urban needs, technological advancements, and global challenges such as the climate crisis, the visionary projects of Archigram—including Plug-In City, Walking City, Instant City, Living Pod, Cushicle, and Suitaloon—were materialized using AI-based design tools to explore their potential relevance to current urban planning and architectural practice.

The resulting visualizations offer a contemporary reinterpretation of Archigram's philosophy. The principle of modularity has been redefined beyond prefabrication, temporary shelter solutions, and adaptive housing systems, integrating biophilic design elements (as seen in the Living Pod interpretation) and high-tech infrastructure (as in Plug-In City) to create self-sufficient and ecological systems. The AI-generated images reinforced the notion that urban fabric need not operate within fixed, rigid boundaries but can function according to a megastructure logic, allowing detachable, plug-in, and rapidly transformable components.

The concept of mobility emphasized not only physical relocation—as exemplified by the robotic mobility of Walking City—but also the fluidity and temporality of urban experience and spatial functions. The visualization of Instant City highlighted the capacity to generate an "atmosphere" or "event" rapidly assembled and dismantled, structured more around information, media, and temporary occurrences than traditional architectural form. The interpretations of Cushicle and Suitaloon integrated architecture with the human body, demonstrating how personal freedom and urban privacy could be achieved through digital and pneumatic micro-environments. This approach presents a radical challenge to conventional notions of settlement, offering a theoretical counterpart to today's individualized and perpetually mobile lifestyles.

Methodologically, the use of tools such as Lookx AI should be regarded as a new interdisciplinary interface for materializing futuristic and speculative architectural concepts. AI demonstrates the potential for a novel research and design methodology in architecture and urban planning by synthesizing complex philosophical and architectural visions with rapidly evolving aesthetic and technological trends. This approach makes the design process more speculative, prototype-driven, and extends beyond traditional drawing techniques.

In conclusion, while Archigram's vision was nourished by the technological optimism of the 1960s, its proposed adaptive, flexible, and user-centered urban spaces exhibit strong theoretical alignment with contemporary demands for sustainability, adaptability, and personalized experiences. This study underscores that the cities of the future should be designed as dynamic systems based on continuous change and interaction rather than fixed forms, and that AI-based visualization constitutes a critical tool for understanding and disseminating such futuristic urban visions.

obozkurt@nku.edu.tr (Responsible Author)

Abstract

Gaziköy is a coastal settlement in the Şarköy district of Tekirdağ. Preserving much of its authentic architectural heritage, Gaziköy is currently protected under both urban and archaeological site status. Traditional wooden houses constitute one of the most significant components of the settlement's architectural heritage. Despite various natural and human-induced threats, the village continues to preserve authentic examples of wooden structures. The aim of this study is to evaluate the current problems of timber decay in Gaziköy houses and to discuss their effects on the sustainability of the rural fabric. The research is based on field observations, non-destructive wood material analyses, and data compiled from previous survey drawings. The analyses revealed that wooden elements such as structural frames, floors, roofs, and façades have deteriorated due to physical factors, biological decay, and human-induced problems. These issues affect not only the durability of the buildings but also the integrity of the settlement pattern and the continuity of its cultural identity. The study emphasizes that ensuring the sustainability of the rural fabric requires integrating appropriate conservation methods for wooden materials into holistic rural heritage management strategies. The continuation of traditional repair techniques, the involvement of the local community, and the implementation of sustainable tourism policies are highlighted as essential steps for the long-term preservation of Gaziköy's wooden houses and the rural environment they shape.

Keywords: Gaziköy houses, timber decay, conservation, rural heritage, sustainability

1. Introduction

Gaziköy, a coastal settlement located in the Şarköy district of Tekirdağ, stands out as one of the most significant rural heritage areas of the region with its authentic architectural fabric and multilayered cultural structure. Since the Ottoman period, the settlement has developed around economic activities such as viticulture, olive cultivation, and fishing, traces of which still characterize the local landscape and social life today.

Gaziköy is among the few settlements that have preserved a large part of their original architectural heritage. The village is protected under both *urban conservation* and *archaeological site* status, and there are forty-one registered examples of civil architecture within the settlement (Özer et al, 2023). This situation demonstrates that Gaziköy possesses values that must be preserved not only in terms of architectural heritage but also with respect to cultural continuity and rural lifestyles.

Timber plays a crucial role in shaping the civil architectural identity of the settlement. The timber-framed houses are distinguished by the use of locally sourced wooden materials in structural components such as load-bearing systems, floors, and roofs. However, the timber elements in these houses are increasingly affected by physical, biological, and human-induced factors, leading to progressive material degradation. These problems threaten not only the structural integrity and lifespan of individual buildings but also the coherence of the rural fabric and the continuity of its cultural identity.

The aim of this study is to examine the problems related to the timber material used in Gaziköy houses and to evaluate their impact on the sustainability of the rural fabric. While documenting

the deterioration processes of timber, the study also seeks to discuss appropriate conservation approaches necessary for transmitting the traditional rural environment to future generations.

2. Materials and Methods

This research was conducted in Gaziköy, a settlement located within the Şarköy district of Tekirdağ province. Within the scope of the study, timber structures that have retained their authenticity were selected based on their preservation status, material integrity, and representativeness within the overall settlement pattern. During the field survey, the current conditions of the buildings were documented through photographs, and deteriorations observed in façades, floors, roofs, and load-bearing structural elements were recorded. Previously prepared measured drawings (rölöve), registration documents, and data from the Tekirdağ Cultural Inventory were also evaluated as supplementary sources.

Non-destructive observation techniques were employed in identifying timber-related problems. On-site examinations were carried out to detect signs of moisture, cracks, deformation, and biological deterioration in wooden components. No microscopic or chemical analyses were performed; instead, assessments were based on visual observations and comparative literature data. This approach enabled the collection of reliable information without causing damage to the original material of the registered buildings.

The data obtained from the fieldwork were classified according to types of deterioration. The findings were then analyzed to discuss the conservation issues of Gaziköy houses within the broader context of rural heritage sustainability.

3. Historical and Cultural Context of Gaziköy

Gaziköy is an important coastal village located on the shores of the Marmara Sea, at the foothills of the Ganos Mountains. It has witnessed continuous settlement from antiquity to the present day. Known as *Ganos* in ancient times, the settlement demonstrates a remarkable historical continuity supported by archaeological findings and epigraphic evidence. The discovery of tomb stelae, ceramic kilns, and the remains of religious structures in the area reveal the archaeological significance of Gaziköy (Bülbül, 2019).

Figure 1. Gaziköy settlement (tr.wikipedia.org)

During the Ottoman period, Gaziköy became known for its agricultural production—particularly viticulture and olive cultivation—as well as for its rich marine resources. From the late 19th century onward, the region also drew attention for its mining potential. According to Özkan (2023), between 1876 and 1950, petroleum and coal exploration activities in and around Gaziköy directly influenced the settlement's economic and social structure. These diverse

economic activities contributed to the formation of a multilayered rural fabric where agricultural production coexisted with early industrial enterprises.

Today, Gaziköy is protected as both an urban conservation site and an archaeological site. In 2016, the Edirne Regional Council for the Conservation of Cultural Heritage designated the village as an "urban conservation area," during which forty-one examples of civil architecture were officially registered (Özer et al., 2023; Arkeolojik Haber, 2016). Furthermore, in 2021, the Tekirdağ Metropolitan Municipality approved a 1/5000-scale Conservation-Oriented Master Zoning Plan for Gaziköy (Tekirdağ Metropolitan Municipality, 2021). These decisions demonstrate that the village holds a multifaceted protection status encompassing both its archaeological and architectural heritage.

In recent years, projects initiated by local authorities have also attracted attention. Within the framework of the "Heritage Workshop" (Miras Atölyesi) initiative of the Tekirdağ Metropolitan Municipality, the restoration of numerous houses in Gaziköy and its surroundings has been planned (Anonymous, 2019). These initiatives emphasize that Gaziköy should be regarded not merely as a remnant of the past, but as a living component of sustainable rural heritage.

4. Use of Timber in Gaziköy

Gaziköy houses are timber-frame structures built upon stone ground floors, reflecting the characteristic architectural features of the coastal settlements of Tekirdağ. These houses, mostly two-storey dwellings, are adapted to the region's topography and are situated on sloping terrain (Figure 2). Their floor plans are typically organized around a central sofa, with rooms symmetrically arranged around this core. A significant portion of the building stock in Gaziköy was constructed between the late 19th and early 20th centuries, reflecting local production techniques and traditional material practices.

Figure 2. Mümin Pala House, Gaziköy

The timber-frame system, widely used in traditional Turkish architecture, also forms the principal construction technique in Gaziköy houses. In this system, the structural framework is composed of wooden posts, beams, and diagonal braces, while the spaces between them are filled with adobe, brick, or stone (Çobancaoğlu, 2003). This method was preferred in earthquake-prone regions because it provided both lightness and flexibility. Stone foundations were generally used at the junction between the frame and the ground, preventing moisture from coming into direct contact with the wooden elements (Saydamer, 2014).

In the Gaziköy examples, stone masonry is typically used on the ground floor, while timber-frame construction is applied on the upper levels (Figure 3). This stratified construction approach offers a solution that is well adapted to both the material diversity and climatic conditions of the region.

Figure 3. Stone masonry on the ground floor, timber-frame walls on the upper floor, Gaziköy

Timber floor beams play a crucial role in the structural integrity of the houses. As shown in Figure 4, the floors are formed by wooden boards placed over timber beams. The ceilings, on the other hand, are usually plain and finished with simple wooden laths (Figure 5). Similar structural systems are also common in other traditional settlements across the Thrace region (Pala Azsöz, 2022).

Figure 4. Floor beam construction detail, Gaziköy

Figure 5. Ceiling and wall details, Gaziköy

The roofs are hipped and covered with traditional alaturka clay tiles. Timber rafters and purlins carry the roof loads. On the façades, timber components are used not only as structural elements but also as aesthetic features. Wooden craftsmanship is prominently displayed in the design of bay windows, overhangs, eaves, and window frames. Similarly, in other traditional houses of Tekirdağ and its surroundings, façade surfaces are finished with either wooden cladding or lime plaster.

The types of timber used in the construction of Gaziköy houses are closely related to the region's natural vegetation. In the Thrace region, oak (*Quercus*), pine (*Pinus*), and chestnut (*Castanea*) are the most commonly used local species (Saydamer, 2015). Owing to their durability and workability, these species were preferred for both load-bearing and finishing elements.

To enhance resistance against the region's humid maritime climate, some examples show that wooden surfaces were protected with traditional oil-based paints or covered with lime-based plasters. These practices aimed to extend the material's lifespan by reducing direct exposure to air and moisture.

In Gaziköy houses, timber stands out not only as a structural component but also as an expression of craftsmanship. Handcrafted yet modest wooden details can be observed in doors, windows, and ceilings. The console brackets beneath bay windows, the carved window surrounds, and the projecting eaves are key features defining the architectural character of the region. These details are not only aesthetically motivated but also structurally functional: for instance, the wide eaves protect wooden façades from rainfall, while the brackets support the overhangs. Thus, every timber element in Gaziköy houses carries both technical and cultural significance.

5. Timber Material Problems

In Gaziköy houses, timber constitutes the main component of the structural frame as well as the flooring, roofing, and façade elements. However, by its very nature, timber is highly susceptible to both environmental and human-induced factors. This vulnerability has led to various forms of deterioration that threaten the authenticity and integrity of the buildings. Similar issues observed in traditional wooden structures across Türkiye have also been identified in the case of Gaziköy (Perker & Akıncıtürk, 2006; Kartal, 2016).

Due to its hygroscopic nature, timber is sensitive to fluctuations in environmental humidity and temperature. Changes in moisture content trigger swelling, shrinkage, and cracking behavior (Ridout, 2004). In Gaziköy, which is located in close proximity to the sea, high humidity levels and salt-laden air cause deformation and surface deterioration in timber elements. In addition, UV radiation leads to color fading and thermal degradation on sun-exposed façades (Figure 6). Although physical deterioration develops gradually, long-term neglect may result in cross-sectional loss of load-bearing elements. Deflections observed in floor beams and eaves are typical indicators of such deformation.

Figure 6. Surface greying caused by weathering and UV exposure on a timber façade in Gaziköy

As an organic material, timber is also vulnerable to biological degradation. The most common types of decay observed in Gaziköy houses are caused by fungi and insects. Wood-decay fungi (*Basidiomycetes*) decompose cellulose and lignin, leading to a weakening of the fiber structure. Brown rot, particularly prevalent in water-exposed areas, is the most common type of fungal decay. Figure 7a shows a floor element darkened and deformed due to brown rot, while Figure 7b illustrates fungal deterioration in a roof structure. The decay, exacerbated by human neglect and abandonment, has spread through ceilings and floors, eventually causing structural collapse.

(a) **(b)**

Figure 7. (a) Example of a floor deformed by brown rot fungus in Gaziköy. (b) Attic timber structure deformed due to moisture and fungal infestation

Additionally, channels formed by wood-boring insects and termites cause significant cross-sectional loss in structural members (Bozkurt, 2013). Gaziköy's humid climate supports the life cycle of these biological organisms, accelerating the overall decay process.

One of the most evident problems observed in Gaziköy's wooden buildings is the lack of maintenance. In long-abandoned or unused houses, roof leaks, broken gutters, and uncontrolled vegetation growth contribute to rapid timber decay (Pala Azsöz, 2022). Moreover, improper repair attempts—such as the use of cement-based plasters, plastic paints, or incorrectly

dimensioned timber reinforcements—block the natural breathability of the material and accelerate deterioration (Figure 8). In some cases, interventions made during the re-functionalization of buildings also damage the original fabric. Such practices pose a critical threat to the holistic sustainability of the rural identity.

Figure 8. (a) PVC window inserted into a stone wall with brick infill; (b) fiberboard covering used to conceal moisture damage on ceiling; (c) old wooden door reused as support for stairs and ceiling structure

6. Conclusion and Recommendations

Gaziköy is one of the few coastal settlements in Tekirdağ that has largely preserved its authentic wooden housing fabric. The construction techniques, craftsmanship, and spatial organization of these buildings clearly reflect the rural way of life and the material knowledge of their period. However, the analyses reveal that the timber material has suffered significant damage over time due to physical, biological, and human-induced factors. This condition threatens not only the lifespan of individual structures but also the integrity of the rural fabric. Therefore, the timber-related problems observed in Gaziköy's traditional buildings demonstrate that conservation should not be limited to physical restoration alone but should instead be approached through a holistic heritage management framework. Within this framework, multidimensional conservation principles should be developed, ranging from material-based approaches to community involvement.

Material-based conservation approaches play a fundamental role in the sustainability of Gaziköy's traditional wooden structures. Conservation interventions should be compatible with the original material and technical characteristics of the buildings. Non-destructive analytical methods should be prioritized in diagnostic and intervention processes. Moreover, studying the mechanical properties of local tree species and ensuring their sustainable use in restoration practices are crucial both ecologically and structurally.

Education and the participation of skilled artisans constitute another indispensable component of the conservation process. The expertise of local carpenters and woodworkers should be documented and integrated into academic and training programs. Establishing local workshops in collaboration with universities, municipalities, and the Regional Council for the Conservation of Cultural Heritage would sustain the transfer of traditional craftsmanship from master to apprentice. In this regard, "the Miras Atölyesi" (Heritage Workshop) initiative

represents an important step; however, its activities have not been adequately maintained to ensure long-term sustainability.

From the perspective of sustainable rural heritage management, Gaziköy's rural landscape should be regarded not only as an architectural heritage area but as a living cultural landscape. Restoration policies should be supported by economic models that allow local residents to sustain their livelihoods, such as eco-tourism, handicrafts, and small-scale accommodation initiatives. In the implementation of the Conservation-Oriented Development Plan, it is essential to strengthen local participation mechanisms alongside environmental sustainability principles.

Finally, continuous research and documentation are vital for the preservation of Gaziköy's wooden architectural heritage. Documentation studies concerning the architectural, material, and functional characteristics of the buildings should be periodically updated. The integration of photographs, drawings, measured surveys, 3D scans, and archival materials will enable the establishment of a long-term monitoring system. This will not only facilitate the tracking of material deterioration but also ensure that future conservation decisions are grounded in scientific evidence.

Ultimately, the preservation of timber in Gaziköy signifies not merely the repair of physical structures but also the safeguarding of rural lifestyles, collective memory, and local identity. Therefore, sustainable conservation strategies must place both material science and cultural continuity at their core, ensuring that the authentic identity of Gaziköy is preserved within the principles of holistic heritage management.

Thanks and Information Note

This study was enriched by the valuable contributions of many students who participated in the Surveying and Restoration Project course conducted between 2016 and 2024 in the Ganos Region. Their dedication, fieldwork, and documentation efforts have been an essential part of this research. I sincerely thank all of them for their commitment and collaboration.

Abstract

Adaptive reuse, also referred to as re-functionalization, is an established approach that aims to adapt existing buildings to contemporary requirements while preserving their historical and architectural values. Within this framework, the conversion of historical buildings into libraries stands out as a practice that combines social benefit with heritage conservation. This study compiles and examines cases classified according to the original functions of historical buildings (e.g., religious structures, industrial facilities, palaces and public buildings, bank buildings, and military barracks), focusing on the strategies employed in their transformation into libraries. The analysis addresses aspects such as spatial reconfiguration, structural reinforcement, accessibility, integration of technical infrastructure (climate control, acoustics, lighting, fire safety), placement of collections and user programs, as well as conservation principles including minimal intervention, reversibility, and the legibility of the relationship between new and old. The findings demonstrate that the constraints and opportunities inherent in original functions distinctly shape transformation strategies, thereby providing architects, planners, and cultural heritage experts with decision-supportive principles and comparative insights for adapting historical buildings into libraries without compromising historical integrity.

Keywords: Adaptive reuse (re-functionalization), historical buildings, library, conservation principles

1. Introduction

Any kind of architectural work built for shelter or other purposes is defined as a structure (TDK, 2022). A structure is also defined as a whole formed by many building materials that protects its contents from adverse external conditions, and structures can be classified according to many criteria. In this context, accommodation structures (hotels, etc.), healthcare structures (hospitals, pharmacies, etc.), religious structures (mosques, churches, synagogues, etc.), commercial structures (business inns, shops, etc.), social structures (theaters, coffeehouses, cinemas, etc.), transportation structures (roads, bridges, ports, airports, etc.), water structures (dams, water canals, etc.), sports structures (indoor sports halls, stadiums, etc.), educational structures (libraries, schools, etc.), monuments (Çanakkale Martyrs' Memorial, Anıtkabir, etc.), residences (houses, apartments, etc.), and industrial structures (factories, etc.) are among the main types of structures widely referenced in the literature (Güner and Yüksel, 2016).

Today, rapid changes in social, cultural, and technological fields have caused many structures to no longer fulfill their original functions. Therefore, various types of structures that have fallen out of use over time are being re-evaluated and reorganized with contemporary techniques in line with today's needs. This process is called "adaptive reuse" or "refunctionalization," which means bringing structures back into use with new functions. The adaptive reuse approach stands out as a significant method at the intersection of architecture, interior architecture, and conservation disciplines.

Adaptive reuse, or refunctionalization by another name, is a concept that dates back to ancient times. Wong cites historical examples of this approach, such as the use of a cave as a living space or animal hides as clothing. This concept is directly related to many practices such as adaptation, addition, alteration, conservation, transformation, expansion, maintenance, modernization, reconstruction, renovation, rehabilitation, relocation, repair, replication, restoration, and strengthening, and should be addressed in conjunction with and as part of these processes. Examples of adaptive reuse can be found everywhere today. Especially structures with cultural heritage value undergo remarkable transformations in line with contemporary approaches shaped by economic concerns. In this context, old schools are converted into residences, prisons into hotels, industrial facilities into art studios, and places of worship into restaurants, thus being used with new functions (Wong, 2017). The refunctionalization of historical buildings is not only a process of structural transformation but also of great importance in ensuring cultural continuity, preserving urban identity, and maintaining collective memory. Especially structures reused with public and cultural functions such as libraries bring together the architectural heritage of the past with today's understanding of information sharing.

The Turkish Language Association (TDK) defines the concept of a library as "an institution that collects, organizes, and effectively provides access to all kinds of recorded information sources such as books, films, records, etc., in accordance with its founding purpose and mission" (TDK, 2022). Although the term library often evokes spaces with books and study desks, today there are many different types of libraries shaped according to technological needs and designed with contemporary methods. The Turkish Librarians' Association (TKD) emphasizes that libraries should no longer be seen merely as places where books are stored and lent, but rather as active centers of social interaction, cultural transformation, and information sharing (TKD, 2023).

Although studying is an individual act, education has historically been a collective phenomenon. Therefore, educational structures (schools, libraries, faculties, study halls, study centers, private teaching institutions) have served and continue to serve as spaces for collective study throughout the centuries. The need for collective study continues today. For this reason, refunctioning spaces—especially as libraries that respond to a public demand—is socially and culturally beneficial.

2. Materials and Methods

This study was conducted based on the qualitative research method. Qualitative research is a term that encompasses various methods involving its own specific techniques such as narrative analysis, ethnographic study, and content analysis (Aydın, 2023). In fact, it would not be incorrect to characterize this research as a typological approach. Typological thoughts and actions assume two things: first, the recognition and discovery of basic types; second, the ability to see things in complementary relationships. The discussion of type and typology can encourage a way of looking at the built environment; while helping us to recognize and discover basic types, it also enhances our ability to perceive differences and similarities by noticing the invisible connections between architectural works (Güney, 2007). For this purpose, the original functions of some historical buildings that have been converted into libraries were first identified in the study (Figure 1).

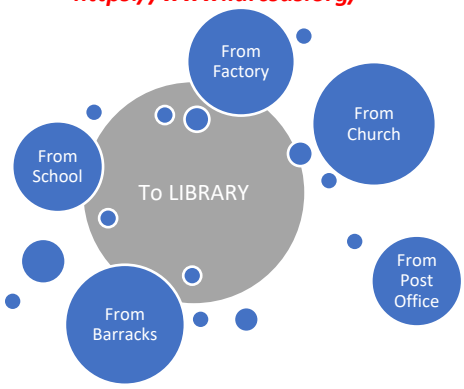

Figure 1. Original functions of some historical buildings converted into libraries (created by the author)

Subsequently, these historical buildings identified through a literature review were classified according to the building category corresponding to their original functions, based on their intended purposes at the time of construction (Figure 2).

From Industrial Building to Library	• Adams Street Library **(Brooklyn, USA)** • Afife Batur Library **(İstanbul, Türkiye)** • Cemil Meriç Library **(Antalya, Türkiye)** • İstanbul Bilgi University Library **(İstanbul,Türkiye)** • LocHal Library **(Tilburg, Netherlands)**
From Administrative or Public Building to Library	• Çorum Former Municipality Building Library **(Türkiye)** • Gürün Public Library–Women's House **(Sivas, Türkiye)** • Idea Exchange **(Ontario, Canada)** • Neude Utrecht Library **(Utrecht, Netherlands)**
From Educational Building to Library	• Historical Atatürk Primary School Library **(Balıkesir, Türkiye)** • James Baldwin Media Library **(Paris, France)** • Bibliotheek Aalst - Utopia **(Aalst, Belgium)**
From Religious Building to Library	• Athy Community Library **(Kildare, Ireland)** • Virgin Mary Church Library **(Kayseri, Türkiye)** • IGI Library **(Liberec, Czech Republic)** • House of Literature - Maison de la littérature **(Québec, Canada)** • Selexyz Dominicanen Bookstore **(Maastricht., Netherlands)**
From Commercial Building to Library	• Biblioteca Salaborsa **(Bologna, Italy)** • Kansas City Central Library **(USA)**
From Civil Building to Library	• Kressbronn Library **(Kressbronn am Bodensee, Germany)** • Heybeliada Public Library **(Islands-Istanbul, Türkiye)** • Transformation of Old House into Capsule Hotel and Library **(Zhejiang, China)**
From Military Building to Library	• Gendarmerie Station Library **(Antalya, Türkiye)** • Baby and Child Library in Döşemealtı **(Antalya, Türkiye)** • Rami Library **(İstanbul, Türkiye)**

Figure 2. Classification of historical buildings converted into libraries (Created by the author)

The classified examples were examined using a descriptive method in line with the established analysis criteria. These criteria include spatial reconfiguration, structural reinforcement, accessibility, technical infrastructure integration, and conservation principles.

The analysis results reveal how the original function guides transformation strategies across different building types, offering insights for conservation and design practice. Furthermore, the classification and inclusion of these buildings—converted into libraries—into the literature

according to their original functions will demonstrate that the information regarding what needs to be done before, during, and after the adaptive reuse process may vary depending on the original function. In this way, the data obtained can be analyzed in a more systematic and comparable manner based on the aforementioned classification.

3. Findings and Discussion

It is observed that a large number of buildings that have lost their original function in our country and around the world have been reintegrated into social life through contemporary library use. Due to its functions of providing access to information and serving as a public gathering space, the library has become a frequently preferred target function in the re-evaluation of idle buildings from different periods and typologies. Since every building is initially designed for a specific purpose of use, during the process of re-evaluating these buildings as libraries, the original function generates both limiting conditions and new spatial and symbolic possibilities for the designer at many scales, such as spatial organization, structural system, openness, and circulation layout.

Figure 3 shows the global distribution of building examples that have been converted into libraries. According to the literature review, it has been determined that in Canada, the USA, France, the Netherlands, Germany, the Czech Republic, Belgium, Italy, Turkey, and China, many buildings with different original functions—such as factories, churches, school buildings, post office buildings, and barracks—and often of historical significance, have been converted into libraries (Figure 3).

Figure 3. Countries with buildings converted into libraries through adaptive reuse around the world (Created by the author based on the literature review of buildings converted into libraries)

Most adaptively reused buildings possess cultural, historical, aesthetic, artistic, rarity, or folkloric values. Buildings that embody one or more of these values are considered architectural heritage. According to ICOMOS, architectural heritage is defined as buildings and groups of buildings of various scales and characteristics that are the common property of humanity, that must be transmitted to the future with their original qualities preserved, and that should be protected in accordance with integrated conservation principles (ICOMOS 2013). The groups

of historic buildings that possess these values, require preservation, and have been renewed through conversion into libraries are examined in this study under seven categories: industrial, administrative, educational, religious, commercial, civil, and military.

3.1. Buildings Converted from Industrial Structures into Libraries

Following the Industrial Revolution, especially during the 1930s under statism policies, many industrial buildings were constructed in various countries but gradually lost their functions over time. Urbanization, pressure from land value, and economic transformations have placed these areas at risk of disappearance. However, since the 1970s, these buildings have begun to be regarded as "industrial heritage," and the idea that they should be preserved as part of urban identity has gained importance. In this context, international organizations such as UNESCO, DOCOMOMO, ERIH, ICOMOS, and its sub-unit TICCIH have been operating to document and preserve industrial heritage (Genç, 2023).

These industrial buildings that have lost their function have begun to be used for different purposes. Due to their nature as industrial structures, their wide spans and open spatial layouts make them suitable for adaptive reuse in functions that require multi-user occupancy, such as libraries, hotels, social centers, and museums. These buildings, which represent industrial heritage with their architectural qualities, also gain value when they are designed by prominent architects. Instead of demolition and reconstruction, adaptive reuse should be adopted as a primary strategy, and cultural continuity should be considered. Today, industrial buildings can be re-evaluated through reuse by being converted into museums, art studios, offices, residences, schools, and multifunctional buildings (Cantell, 2005). Examples of industrial buildings converted into libraries are frequently encountered both in Turkey and abroad.

One such example is a historic building in Brooklyn, dating back to 1901, which has served various functions over the years, from a torpedo factory to a recycling facility. Today, the ground floor of this adaptively reused industrial building functions as a library. The building also includes residential units and commercial spaces. Designed by the WORKac team, this library preserves the dialogue between old and new along the brick perimeter walls, which contrast with a series of pixelated murals inspired by the layered history of the building. The fifteen-meter-high windows surrounding the library support a series of open spaces that connect to a porous volume and an elevated children's area. The volume, clad in MDF with a custom CNC-milled pattern, offers suitable environments for stroller parking and book storage within its wide and curved openings; the elevated section provides young visitors of the library with the opportunity to view the Manhattan skyline, East River, and Main Street Park from the main reading room (Karakoç, 2022). This design decision highlights the importance of designing spaces not only to meet physical needs but also to address users' psychological needs, demonstrating that the designer has provided emotional comfort to encourage users to spend more time in a comfortable environment.

Another example is the LocHal in Tilburg, the Netherlands, which was converted from a locomotive workshop into a library and now houses Bibliotheek Midden-Brabant (public library), Kunstloc Brabant (cultural and arts research center), and Brabant C (cultural and creative industries investment fund) units (Döğerlioğlu, 2019).

It is also known that a section of the historic Hasanpaşa Gasworks, which ceased functioning as a factory in 1993, has been converted into a library. Originally a coal gas plant, Hasanpaşa Gasworks was refunctioned with two main functions in mind: a museum and a library, and was

organized into museum and library buildings. In this context, the museum buildings were designed as an activity hub incorporating temporary exhibition spaces, a science center and workshop, a bookstore, and a museum shop, and were included in the functional scheme as "Museum Buildings"; the library was planned to operate in connection with shared workspaces and a café. The former compressor building (Building F) of the gasworks was transformed into the Afife Batur Library, serving as a library and quiet study area. The ground floor consists of a reception desk, library, and research sections. Concrete pedestals are surrounded by bookshelves, and the niches between them are used as research and reading areas. The research areas include high tables with eight computers, while the reading areas feature free seating units. Work desks have been placed in front of the façade openings to benefit from natural light. The upper floor was designed as a free study area with tables along the central axis and a stepped seating arrangement along an inner wall. User comfort was enhanced with movable side tables and storage niches (İtez, 2022).

Another example is the Cemil Meriç Library located in Antalya (Figure 4). The building was converted from the transformer building of a former yarn weaving factory into a library. The building consists of a ground floor and a basement; the lower floor is mainly equipped with book storage units and accommodates the administrative unit. On the ground floor, study areas, wet areas, and a café section were arranged, and the system room was also located on the ground floor (Aydın, 2025).

Figure 4. Cemil Meriç Library (Antalya, Türkiye)-Photo Source (Aydın, 2025- Author archive)

Another example that can be examined is the Istanbul Bilgi University Library. It was converted from the buildings of the Silahtarağa Electric Power Plant, which ceased functioning in 1983 and holds the status of industrial heritage. Since 2004, conservation and adaptive reuse efforts have been carried out by Nevzat Sayın Architectural Services. Until 2013, only dismantling and reinforcement were undertaken in two boiler rooms, after which boiler rooms 4 and 6 were transformed into the faculty of architecture. The library integrated into this educational facility serves as a good example of the adaptation of industrial buildings into spaces for education and knowledge (İtez 2015).

When all these examples are considered, a common point can be observed in the adaptive reuse of industrial buildings. Due to their large spaces and multi-building complexes, while a part of the complex is used as a library, other parts offer opportunities to be used with different functions such as museums, exhibition areas, science centers, and galleries.

3.2. Buildings Converted from Administrative or Public Structures into Libraries

Administrative buildings previously used as municipal or party headquarters, or buildings such as post offices open to public use, have also been adaptively reused and started to function as library buildings.

The 100-year-old historic post office building in Utrecht, the Netherlands, was converted into the Neude Library by Zecc Architecten and Rijnboutt. In this way, the city gained a space for reading books, studying, listening to music, drinking coffee, or simply relaxing. The Art Deco-style building bears the signature of architect Joseph Crouwel, who was influenced by the Amsterdam School. With its large parabolic ceiling, yellow glazed stones, and figures symbolizing continents, the building now serves a multifunctional public use such as reading, studying, listening to music, and socializing (Merdim, 2020).

The conversion of an old post office into a library in Canada differs from the previous example in the Netherlands in that it does not contain book storage or reading areas. Idea Exchange, instead of shelves filled with books, includes spaces for makers, sound and film studios, a children's discovery center, a café, and an event hall. For this reason, it is referred to as "Canada's first bookless library." The Canadian architecture firm RDHA added glazed volumes to the historic post office in Cambridge, Ontario, and transformed the building into a community center (Merdim, 2019).

The historic stone building in Çorum, originally built as a library in 1923 and used as a municipal building since 1960, was restored through a comprehensive restoration process and regained its original function. With this transformation, carried out in line with the principles of cultural heritage preservation and continuity of public use, the building now serves as an information access center under the name "Nation's Library," providing 24/7 service (Ceylan, 2023; Ceylan 2024).

Information about the building in Gürün, Sivas, which was used as a public library for a period, is somewhat ambiguous. It is said that the building was constructed by CHP and has definitively functioned as a party building since 1936. According to one study, it was built as a Rüştiye (Ottoman secondary school) (Zor and Bilget Fataha, 2022: 421), while another study suggests that it was built as a People's Party building in 1923 and used as a middle school for two years (Öz, 1999: 237–238). (cited in Gündoğan Baldık, 2025).

It has been inferred from documents that the building was constructed by CHP in 1935, served as a party building in 1936, and as a community center and community center library in 1939. From 1946 to 2006, the building served as the "District Public Library," and since 2006, it has been serving the public as the "Women's House." Although it functioned as a library for a period, it is no longer used as a library today (Sivas Provincial Directorate of Culture and Tourism, 2024). (cited in Gündoğan Baldık, 2025).

3.3. Buildings Converted from Educational Structures into Libraries

Education is defined by the Turkish Language Association (TDK) as "direct or indirect assistance, inside or outside of school, in helping children and young people acquire the knowledge, skills, and understanding necessary to take their place in social life and to develop their personalities; upbringing" (TDK, 2022). The buildings in which the evolving understanding of education and instruction comes to life are called educational buildings.

Schools, faculties, libraries, study centers, private teaching institutions, and various course halls can be considered educational buildings.

The transformation project carried out by Atelier Associer in the 19th district of Paris involves the conversion of a high school building from the 1970s into a media library and reception center. The existing structure of the building was preserved, decontaminated from asbestos, and subjected to a comprehensive cleaning process. Prefabricated elements such as reinforced concrete columns, beams, slabs, and façade panels were restored; components obtained through selective dismantling were reused on-site. These interventions re-established the spatial order of the building and enhanced surface quality, enabling the creation of high-quality public spaces suitable for contemporary use (Leblebiciler, 2025).

The Utopia building, designed by KAAN Architecten in the city of Aalst in the Flemish region, is a high-quality transformation project that integrates contemporary architecture with cultural functionality. Located within the fragmented fabric of the city's streets and squares, the building occupies an area of 8,000 m² within the structural shell of a former military school and serves as both a city library and an academy of arts. While the building's exterior presents a simple appearance compatible with its surroundings through its red brick cladding, the interior is shaped by an architectural narrative that promotes collective learning and cultural production. Open and permeable spatial arrangements support individual and collective learning processes, thereby strengthening the public character of the building. In this context, Utopia stands out as a contemporary cultural structure integrated into urban life on both physical and intellectual levels (URL1, 2018).

The Atatürk Primary School building, located in the district of Burhaniye in Balıkesir, Turkey, and bearing the characteristics of a historical structure, was reintegrated into public life with the function of a library following a comprehensive restoration process. Constructed in 1908 as a Military Recruitment Office under the leadership of local notables and with public contributions, the building was modified in 1916 to meet educational needs and transferred to the Ministry of National Education, hosting educational activities under various names. Throughout its historical process, the building bore the names Kutluili Mektebi (1916), Boys' School and Kuvâ-yı Milliye Hospital (1919), Numune Mektebi (1923), Şükrü School (1924), First School (1926), and finally Atatürk Primary School (1946), reflecting a multi-layered history of education and healthcare. With the construction of a new 10-classroom building in 1990 by philanthropist Faruk Kızıklı, this historic structure continued to serve as an annex to the school. As a result of the restoration work carried out under the leadership of the Balıkesir Governorship in 2022, the building's original architectural fabric was preserved and transformed into a contemporary Culture, Art, and Education Center. This transformation constitutes a significant example in terms of both the preservation of cultural heritage and the sustainability of collective memory (URL 2; URL 3).

3.4. Buildings Converted from Religious Structures into Libraries

Structures such as churches, mosques, synagogues, etc., that serve a religion and are used by people for worship in accordance with their beliefs are called religious buildings. Structures in which worship takes place are also referred to as temples or sanctuaries (TDK, 2022). The loss of function and reuse stories of buildings often emerge as a result of various migrations or conquests (Wong, 2017). Especially in the case of religious buildings, due to migration or conquest, a structure that does not align with the beliefs of the newly arrived community loses

its function and becomes idle. These idle structures can be repurposed with various functions such as restaurants, libraries, or hotels.

In the town of Athy, Ireland, the historic Dominican Church, which had been closed since 2015, was adaptively reused as the Athy Community Library following an official opening held at the beginning of March. The new library preserved the original atmosphere of the historic structure and was transformed into a creative space in terms of both aesthetics and functionality. Thus, the Dominican Church was reintegrated into urban life not only as an architectural backdrop but also as a public space that sustains collective memory and supports cultural production (URL 4; URL 5).

In the city of Liberec, Czech Republic, an idle Roman Catholic presbytery building was also adaptively reused as a new public library. The interventions, carried out while preserving the existing structure, ensured the sustainability of architectural heritage and provided an open, accessible cultural space for city residents. Thus, the building was evaluated not only as a physical transformation but also as a spatial manifestation of social and cultural revitalization (Cive, 2023).

Maison de la littérature was opened to the public in 2015 following a comprehensive renovation process. The historical origin of the building dates back to 1848, when it was initially constructed as a Methodist church named Wesley Temple serving the Anglophone community. In 1944, it was adaptively reused by the prestigious Institut Canadien du Québec, which has a 175-year history in French literature, as a flagship library and conference campus. After losing this function in 1999, the building remained idle for a long time before being reintegrated into urban life as a public library. This process represents a good example of the evolution of a historic building into a space that serves cultural production while preserving its multilayered identity (Khan, 2024; URL 6).

The Dominican Church, built approximately 700 years ago and currently home to the Selexyz Dominicanen bookstore, is a noteworthy example of the adaptive reuse of religious architectural heritage. Bearing distinct traces of the Gothic style and with its historical structure preserved during renovation, the building played a central role in urban life for centuries through its religious function; however, after the end of its sacred duties, it was transformed into a cultural and commercial space. Although the structure is not a library and should not be analyzed as such, it is considered worth mentioning as an aesthetic and functional solution in the context of its adaptive reuse into a bookstore—a function closely related to that of a library—and its opening to contemporary use. This transformation is regarded as a qualified intervention that ensures architectural continuity and contributes to cultural sustainability (Lo, 2015; Hassan, 2023).

Figure 5. Virgin Mary Church Library (Kayseri, Türkiye)- (Aydın, 2025- Author archive)

Another example of a structure converted into a library is the Church of the Virgin Mary (Figure 5). The former church building is located in Kayseri, Turkey. Having lost its original function, the building was used over time for various purposes such as a sports hall, warehouse, and gendarmerie station. Although interventions such as paint and other applications that did not align with the character and history of the building were made over time, the structure was cleaned of unnecessary additions during its conversion into a library and was adaptively reused (Aydın, 2025).

3.5. Buildings Converted from Commercial Use to Libraries

Commerce is defined as the buying and selling of products, goods, etc.; trade (TDK, 2022). The word commercial refers to anything related to commerce. Commercial buildings can simply be listed as business inns, shops, and shopping malls. Like other types of buildings, commercial buildings may lose their function over time. It is also possible to encounter commercial buildings with historical value, just like other structures.

Buildings such as banks and currency exchange offices, where there is no direct sale of products but where money transactions occur frequently, can also be considered commercial buildings. For example, Salaborsa has long been the central hub of economic life in Bologna, Italy; stock exchange transactions, market activities, and commerce took place there. After World War II and until the 1960s, Salaborsa became a modern sports facility, hosting basketball and even boxing matches. Today, the building functions as a library, and its modernist interior design of glass and iron makes it unique. The documents it offers are not limited to books and newspapers but also include comics, CDs, maps, audiobooks, and much more (Belli, 2021; URL 7).

The city library located in Kansas City, USA, is also a building that has been converted from a bank into a library. The former bank vault now houses the Stanley H. Durwood film collection, while the 11-meter-high ceilings of the old bank add grandeur to the main reading room. However, the idea of converting a bank into a library may be a more challenging adaptive reuse compared to other buildings, especially in terms of accessibility (for example, fully integrating the vault room into the transformation during renovation).

3.6. Buildings Converted from Civil Use to Libraries

Civil architecture today evokes structures that are not produced by the state and are not used for public purposes. Within a hierarchy of preservation that prioritizes significant buildings belonging to the state/public—especially religious and military ones—the possibility of civil

architecture belonging to ordinary citizens becoming an object of preservation is generally only feasible if it represents the best of its kind (VEKAM, 2014).

The transformation project carried out by Steimle Architekten in the town of Kressbronn am Bodensee, Germany, is an example of the adaptive reuse of rural civil architectural heritage. Located in the village center near the municipal building and festival hall, the former barn structure was converted into a library and community center, equipped with angled vertical shutters on the façade. During the transformation process, the original character of the building was preserved; its structural simplicity and material language were reinterpreted in harmony with the new functions. This intervention enabled the creation of a public space that supports both spatial continuity and local identity. Thus, the building evolved into a cultural hub that responds to current social needs while serving as a memory space bearing traces of the past (Merdim, 2020).

The transformation project carried out by Atelier tao + c in Zhejiang Province of the People's Republic of China involves the redesign of a 232-square-meter historic building in the village of Qinglongwu in the Tonglu region with the functions of a capsule hotel, bookstore, and library. This old structure, with a wooden frame and mud plaster, is positioned to face the mountains to the south and east, and the village road to the north. The greatest challenge in the design process was to ensure openness and spatial continuity for public functions within a limited physical space while preserving the privacy of the accommodation areas. Atelier tao + c addressed this challenge through architectural organization and spatial transitions, creating a balanced layout within the building that supports both social interaction and individual use. This approach serves as an exemplary case in terms of architectural adaptive reuse and spatial integration in a rural context (Merdim, 2020).

The historic mansion located in the Princes' Islands of Istanbul, which began serving as a public library in 1968, was kept open for over thirty years through the devoted efforts of Fevzi Yılmaz until 2001. Like many public libraries in Turkey, this structure survived with limited resources and undertook a modest public function by providing essential reference materials to island students and offering a place to study by the stove. After 2001, the library was partially kept open through volunteer support and short-term assignments, but due to the insufficiency of these efforts, it struggled to survive until 2008 and was eventually completely abandoned. During this period, the status of the library's collection became uncertain, and the space turned into a significant void in terms of preserving cultural memory (Demirhan, 2024; URL 8).

Although there are not many examples of the adaptive reuse of structures referred to as civil architecture, there are mansions and residences in our country that should be preserved. The most important issue in the adaptive reuse of these buildings is to ensure proper promotion of the repurposed structure and to resolve matters such as accessibility and transportation. Otherwise, sustainability may not be achieved with the newly assigned function.

3.7. Buildings Converted from Military Use to Libraries

ICOFORT (International Scientific Committee on Fortifications and Military Heritage) was established in 2005 under ICOMOS (International Council on Monuments and Sites) to address military heritage and fortification elements. The committee carries out activities related to the preservation, identification, restoration of military heritage and fortifications, the development of international cooperation, raising awareness, promoting scientific studies, and encouraging maintenance and repairs ("Committee", 2022). In line with the committee's initiatives, a

significant step was taken in 2021 when the guiding principles concerning fortifications and military heritage were adopted at the ICOMOS General Assembly ("ICOMOS Guidelines", 2022; cited in Armağan, 2022). Within this scope, the study examines the conversion of a gendarmerie station, a service building affiliated with the same station, and a military barracks into libraries.

The building located in Döşemealtı district of Antalya, formerly a gendarmerie station, remained idle for many years before being restored by the Ministry of Culture and Tourism and converted into a public library for young people. During the opening ceremony, photographs from the building's derelict period were exhibited, creating a visual memory of the transformation process. The renovated structure offers a contemporary space for learning and socializing for young users, contributing to the cultural infrastructure of the region (Çınar, 2025). The service building affiliated with the same station was also renovated and opened for use as a two-story Baby and Children's Library (URL 9).

Located in Eyüpsultan, Istanbul, the Rami Library offers cultural, artistic, and educational experiences to visitors of all ages through modern library services and the "living library" concept. With its 250-year history dating back to the Ottoman era, the Rami Barracks underwent comprehensive restoration in 2023 and became one of Istanbul's largest and among Europe's notable library complexes. As a result of restoration and adaptive reuse efforts carried out by the Republic of Turkey Ministry of Culture and Tourism, the Rami Barracks, which dates back to the 18th century, was redesigned as a multifunctional library complex. The structure was planned as a comprehensive public space catering to users of all age groups; in addition to baby, children, youth, and adult libraries, it includes specialized libraries, an archive unit, a café, workshop areas, a theater hall, and gallery spaces. With a total seating capacity of 4,200, the complex offers not only access to information but also a versatile platform for cultural production and social interaction (Gürbüz, 2023; URL 10).

Open to users of all ages, the structure was designed as an inclusive and holistic public space that promotes intergenerational learning. In this context, the project aims to produce a knowledge ecosystem that supports cultural continuity and keeps collective memory alive (Akgün, 2025). Additionally, Rami Library is recognized as Turkey's first library to receive a sustainability certificate. It can be confidently stated that the library underwent a successful adaptive reuse process, as the Sustainability Certificate—granted on December 30, 2022, by Biosphere, a program accredited by the Global Sustainable Tourism Council—is held by only 56 facilities worldwide (URL 11).

4. Conclusion and Recommendations

The study is fundamentally based on two concepts: adaptive reuse and the library. Adaptive reuse is seen as significant for disciplines operating in accordance with the principles of architecture, interior architecture, and conservation. While adaptive reuse contributes to economic, social, and architectural development, it also safeguards cultural and collective memory. This study demonstrates that converting historic buildings into libraries constitutes a sustainable and culturally meaningful conservation strategy.

Comparative analyses show that each building type carries its own constraints and opportunities; these characteristics guide the design and transformation process. Therefore, the balance between conservation and adaptation must be established with respect for the original character of the building. Such projects extend the life cycle of heritage structures, transforming

them into dynamic spaces that respond to the cultural and intellectual needs of contemporary society. The study offers guiding principles for architects, interior designers, cultural heritage experts, and anyone interested in the concept of adaptive reuse, focusing on processes that preserve historical integrity.

The analyses conducted reveal that the original function of each historic building significantly influences the adaptation strategies and spatial organization followed during its conversion into a library. For instance, religious buildings, due to their monumental spatial character and symbolic atmosphere, generally require minimal physical intervention; it is important that the new function remains legible within the existing sacred context. In some cases, religious buildings are adaptively reused through the addition of an annex. In this way, the historically, religiously, and spiritually significant parts of the building are preserved with minimal interference, and the space is opened for use.

In contrast, industrial buildings, with their wide spans and flexible layout plans, allow for more experimental and contemporary design interpretations. Administrative and public buildings, due to their strong representational value and rich interior details, require balanced interventions. The adaptive reuse of commercial buildings demands a careful process of structural reinforcement and accessibility adaptation due to their solid and compartmentalized layout schemes, while military buildings, often composed of repetitive modular units, are suitable for reorganization in line with library programs. Among the categories, the conversion of educational buildings into libraries is perhaps the most straightforward and easily achievable renovation.

Since libraries are educational structures by function, conversion projects from schools or faculties into libraries represent a compatible functional choice due to the similarity in building type. In the case of civil structures such as mansions, residences, and buildings constructed for individual use in agricultural and rural areas—like barns, stables, and granaries—structural reinforcement must be carried out with greater care, as aging and potential construction limitations and oversight deficiencies during the building phase, especially in our country, may have led to overlooked issues. Additionally, for these small spaces, problems such as insufficient area based on user numbers, lack of visibility, and consequently the creation of underutilized spaces may arise.

Abstract

Neighbourhood markets are social and traditional trading spaces that reflect cultures, provide a platform for social interaction, and bring together large numbers of people living in the same city according to their production and consumption habits. Markets are not merely places where shopping is done, serving commercial and economic purposes, but also urban spaces that reflect and perpetuate the local and traditional culture, daily activities, and habits of the community in which they are located. In different cultures, street markets hold significant potential in the context of urban culture production. In our country, markets are examined under two headings depending on the area in which they are established. The first is open markets established randomly on streets and avenues, while the second is markets consisting of closed or semi-open spaces, often established by local authorities for this purpose, known as covered markets. This study, which stems from the problem of markets in the second category in our country being used on certain days of the week and remaining inactive on other days, investigates what functions could be integrated into these markets and how the sustainability of these markets can be ensured. Markets from different cultures were examined in terms of their spatial and functional characteristics in order to identify potential functions that could be assigned to these markets, ensure their sustainability, and offer various design proposals. The marketplaces examined were designed and approached using an interdisciplinary approach. This research highlights the local and cultural importance of markets and offers recommendations for marketplace structures to be built in our country.

Keywords: Bazaar, indoor marketplace, production of space, space of consumption, traditional market

1. Introduction

As a social product, the production process of space is based on the actors involved in the production process, the relationships between them, and the daily life practices of the people living in that space. In a sense, space is the result of a reciprocal relationship process that contributes to the formation of society and is created by society, and we can only access real information about space to the extent that we can understand this relationship. Space is a social product, and what makes space what it is are the diverse relationships that form within that space (Lefebvre, 2014).

Marketplaces, which have existed in cities since the agoras of ancient times, represent the world's oldest shopping tradition. Weekly markets, set up at various locations in cities on specific days of the week, serve as both an alternative and a complement to shopping centers and established bazaars. They are preferred by many users due to their positive features, such as catering to various income levels, offering consumers choices, and being easily accessible (Özgüç ve Mitchell, 2000).

Marketplaces are temporary or permanent shopping venues established on specific days of the week at locations easily accessible to the public. Neighbourhood markets, on the other hand, are traditional shopping venues typically set up on one day of the week at specific locations within the city. While the primary purpose of traditional neighbourhood markets, which are urban spaces, is shopping, the consumption that takes place in these spaces differs from the consumption habits of the contemporary capitalist system. In addition to their economic and commercial functions, markets provide opportunities for encounters, communication and interaction, sharing and togetherness, offering spatial potential in public and social terms (Uzgören, 2021).

Street markets have developed by creating temporary spaces for consumption and socialising that stand out for their sensory and emotional richness. While it is debatable whether street markets can be considered "architectural", despite their open-air locations, changing forms and lack of infrastructure, street markets create a sense of enclosure and intimacy and a sense of place through their lights, sounds and occupation of space. Even when realised through "makeshift" (geçici, derme çatma) and "improvised" (doğaçlama) means, street markets possess the potential to "place-making" (Kelley, 2020).

Street markets are not merely shopping venues for the community; they are perceived as public spaces where the city's users, sellers, consumers and visitors develop their own understanding of physical space and specific spatial routines, both physically, mentally and symbolically. (Gvion, 2017).

Street markets are urban spaces in a global sense. Although street markets are typically small-scale and located in accessible public areas, they significantly influence the quality of urban spaces. Street markets have the potential to represent local culture. In other words, street markets are urban cultural spaces. Alongside shopping activities, they are a visible urban culture that enriches the city's public life by enabling users to interact with each other and experience different products, cultures and various activities (Kamarudin et al., 2015).

Markets are commercial and economically based spaces, but they are not merely places for shopping; they are urban spaces that reflect the culture, traditions, daily activities and habits of the community in which they are located.

Markets have taken on many different forms in different geographical areas and therefore different cultures, being used in various spatial configurations from streets to squares and from town squares to water surfaces. Consequently, it can be said that marketplaces around the world exhibit a rich diversity. Marketplaces are classified in different ways by different researchers in the literature.

According to Öztekin (2009), marketplaces can be classified as follows:

According to their location:

- Linear markets: A market typology consisting of two rows facing each other, formed by sales units lined up side by side along a linear axis on a street or avenue.
- Area markets: These are markets established by local authorities with defined boundaries.

According to their roof;

- Open markets: This is a market typology where the sales units and circulation areas are not covered by a roof. Temporary covering systems are used by sellers.
- Covered markets: These are markets where both the sales units and circulation areas are covered by a permanent roof. Only the top of the market area may be covered, or the side surfaces may also be covered.

According to when they are set up;

- Periodic markets: These are markets set up at regular intervals in a specific place. Weekly markets are an example of this group.
- Permanent markets: These are markets set up every day without interruption in a specific location.

According to the product sold;

These are markets where a specific product group is sold. The market is named after this product or product group. Livestock markets are an example of this group.

According to Heathcott (2019):

- Linear type: This is the most common market typology, involving a simple, linear layout along a street or road.
- Circuit type: This is a settlement type that starts at one point in the city and branches out to other streets and roads. The branches may be connected to each other, creating continuity, or they may be disconnected.
- Cluster type: Clustered markets are arrangements of various sales units that come together in different forms.
- Contour type: This is a settlement pattern that emerges when sales units follow the natural or man-made features of the city. This could be a roundabout or a traffic island, or it could be the shape of a valley or street itself.
- Hybrid type: This is when two or more of the other typologies come together to form a hybrid typology. For example, a market displaying the characteristics of both the linear and cluster types at the same time.

There are five street market typologies.

According to Liu (2024);

- Nodal bazaars: These are markets that adapt to the conditions of their surroundings, such as the natural environment, traffic and crowds. Their spatial arrangements are flexible, they have no clear boundaries and they evoke a strong sense of community. They are usually located in part of city squares or along extensions of streets and avenues.
- Linear bazaars: These refer to market areas that have developed from traditional streets or were built later as part of rural tourism. Such markets are integrated with the streets and function as a natural part of the transport system. The flexible layout of the streets and their natural extensions bring vitality to the market. The shops lining the street and the stalls on both sides establish a complementary relationship. Fixed shops provide storage, rest, water, and electricity facilities to mobile stalls, while the stalls increase visitor traffic, boosting the sales potential of the shops. Like point markets, linear markets also gather human flow along transport routes and create an intimate spatial scale. This arrangement offers visitors the

opportunity to experience different spatial experiences along the street and encourages a desire to explore. The most distinctive feature of linear markets is the linear arrangement of the space.

- Area bazaars: These refer to large-scale market areas that have developed in close proximity to each other, often growing out of point or linear markets, with their interiors divided by roads. Their spatial layout is flexible, often combining both point and linear market forms. The layout of these markets is generally scattered, with weak spatial connections between different market sections and no clearly defined boundaries for these areas.

According to Kamarudin et al. (2015);

Street markets vary according to their location in the city's open spaces. There are two general types of street markets found in different countries: permanent and temporary street markets.

- Permanent street market: Permanent street markets are daily street markets that are open continuously every day or on specific days of the week or month. These markets typically sell vegetables, meat, poultry, fish, and other daily goods for local residents to purchase. Permanent street markets usually have fixed stalls where sellers rent their own stalls.
- Temporary street market: Temporary street markets are set up for seasonal events, festivals and special days and are usually held in a public area of the city. Although certain streets are temporarily occupied by market vendors to sell special products based on local culture, events and festivals held at the market, temporary street market events add vibrancy to the urban environment. (Abdulazeez and Pathmanathan, 2015; Medina, 2002; akt. Kamarudin et al. 2015).

Street markets have serious negative effects on accessibility, the construction of illegal structures, traffic congestion, solid waste production, car accidents and the deterioration of urban aesthetics (Adedeji et al., 2014). In this sense, locating markets in spaces designed and built for this purpose eliminates these negative effects.

2. Materials and Methods

This study, which stems from the problem of markets consisting of enclosed or semi-enclosed spaces, mostly established by local authorities in our country specifically to serve this function, being used only on certain days of the week and remaining unused on other days, investigates what functions could be integrated into these markets and how the sustainability of these markets can be ensured.

This study was conducted to identify potential functions that could be assigned to market structures, to ensure the sustainable use of market structures, and to present various design proposals in this context. Market structures from different cultures were examined in terms of their spatial and functional characteristics. The marketplaces examined were approached from an interdisciplinary perspective and designed accordingly.

The research highlights the importance of markets in terms of local identity and cultural memory; it also offers guiding recommendations for the design of market structures to be built in Turkey in the future.

3. Findings and Discussion

3.1. Targ Blonie Market

The renovation project for the market in Blonie, a small town near Warsaw, the capital of Poland, was carried out by Aleksandra Wasilkowska Architectural Studio (Table 1). The

market, where the local community has maintained its centuries-old tradition, provides access to affordable and high-quality food sold directly by producers and farmers. It was decided to renovate the market to address its poor comfort standards and lack of basic market infrastructure, and the project was completed in 2022 (Ott, 2023).

Table 1. Targ Blonie Market (Ott, 2023)

Project:	Targ Blonie Market
Location:	Blonie, Varşova, Polonya
Architect:	Aleksandra Wasilkowska Architectural Studio
Project Year:	2022

A mixed-use public space combining two social functions: market and park, has been created. Multi-functional white canopies that reflect sunlight and provide shelter from rain have been planned (Figure 1) (Ott, 2023).

Figure 1. Targ Blonie Market canopies (Ott, 2023)

When the market closes, the wood-panelled display units serve as seating elements, and the market area can be used for various events (Figure 2). Small-scale structures for administrative, commercial, and service units have been designed on the outer perimeter of the white canopy (Figure 3) (Ott, 2023).

Figure 2. When the market closes, display units with wooden cladding that will serve as seating elements (Ott, 2023)

Figure 3. Small-scale structures built on the outer edges of the white canopy (Ott, 2023)

At the centre of the market, a play area and seating units have been designed for children (Figure 4). Around the structure, there is an access road to facilitate product delivery, as well as open stalls for the mobile trade of vehicles and agricultural products. Furthermore, the market and its surroundings have been planned at the same level, designed to ensure accessible and safe movement for all users (Ott, 2023).

Figure 4. Children's play area and seating units designed to serve the park function integrated into the market (Ott, 2023)

Green islands were designed around the roofs and pavilions to provide food and shelter for birds and insects, while also aiming for the trees to provide shade for the open trading points. Rainwater from the roof is collected to water the plants and seep into the soil (Figure 5). (Ott, 2023).

Figure 5. The green islands of the market (Ott, 2023)

Various street furniture, lighting fixtures, white circular information boards, bicycle racks, rocks, bird and insect houses, a bar and seating areas have been designed to create a sense of unity. Serving various functions, the public space microclimate improves, strengthens micro-entrepreneurship, and aims to increase the city's resilience in the event of a pandemic, food, and climate crises by providing users with access to locally produced food outdoors (Ott, 2023).

3.2. Mercado Municipal de Braga

The project to renovate and expand the Braga Municipal Market, which has been in use since the 1950s, with the aim of preserving and continuing its architectural and cultural heritage, was designed by the Apto Arquitectura architecture office and completed in 2020 (Table 2) (Figure 6) (Moreira, 2023).

Table 2. Mercado Municipal de Braga (Moreira, 2023)

Project:	Mercado Municipal de Braga
Location:	Braga, Portugal
Architect:	Apto Arquitectura
Project Year:	2020

Figure 6. Mercado Municipal de Braga entrance facades (Moreira, 2023)

With the new structure added to the existing one, the previously scattered functional distribution of the market has been reorganised, circulation areas have been designed around a central square, thus enabling users to perceive and experience the space as a whole, see and reach all market stalls from the square, and strengthening buyer-seller communication. (Figure 7) (Moreira, 2023).

Figure 7. Mercado Municipal de Braga indoor circulation areas (Moreira, 2023)

The market has two pedestrian entrances located at different corners of the building. One of these entrances is planned as the main entrance, while the other is the secondary entrance. The entrances are strategically positioned. The main entrance door, placed diagonally at the corner of the square plan, directs users to the square and secondary circulation areas. Circulation within the market has been carefully planned, which helps to minimise crowding. Stalls selling fresh fruit and vegetables are located in the center of the market, and this area has been designed to be the focal point of the market (Figure 8). Shops, restaurants, kitchens, and other commercial establishments surround the market area (Moreira and Concatto, 2023). Thus, the distribution of different types of businesses and various consumer goods offers visitors alternatives to explore.

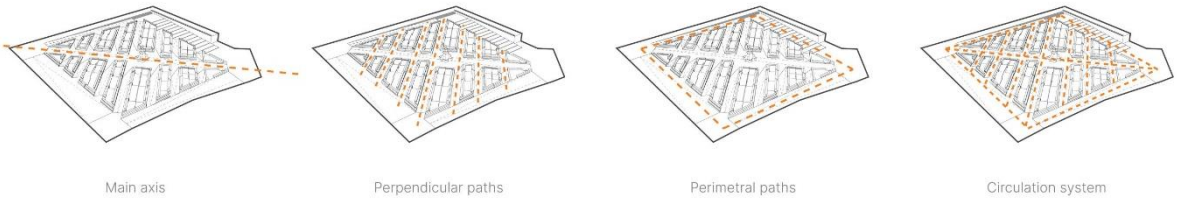

Figure 8. Mercado Municipal de Braga circulation diagram (Moreira, 2023)

The functions within the market include fruit and vegetable sales areas, flower sales areas, fish sales areas, butchers, kitchens, waste bins, live animal sales areas, information points, loading and unloading areas, dining areas, and multi-purpose rooms (Figure 9) (Moreira and Concatto, 2023).

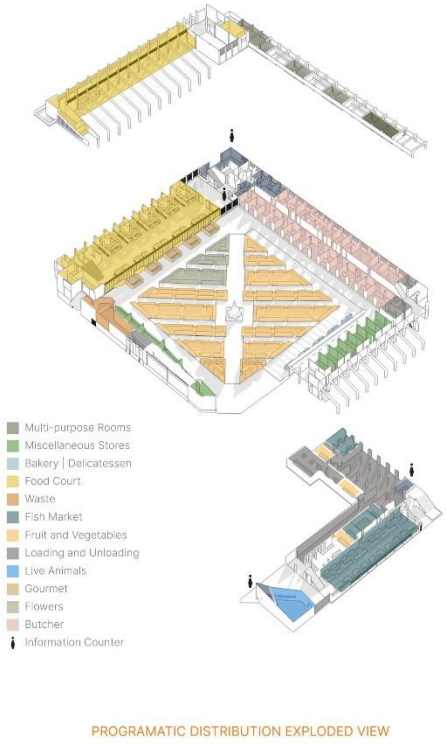

Figure 9. Mercado Municipal de Braga functional diagram (Moreira, 2023)

Service units and technical areas are separated from areas with high consumer traffic. The spaces where the loading and unloading processes of products are carried out have been consolidated into a single area, and a waste disposal process has been established. A food and beverage space has been integrated into the market to both generate revenue for the market and turn it into a center of attraction (Figure 10) (Moreira, 2023).

Figure 10. Cafe designed in conjunction with the Mercado Municipal de Braga (Moreira, 2023).

The building's location on sloping terrain has resulted in level differences within the interior space, which have guided the interior design, with different heights connected by stairs and ramps (Figure 11). (Moreira and Concatto, 2023). This has removed barriers to movement, created an accessible interior for disadvantaged users, and facilitated logistical operations.

Figure 11. Ramps and staircases designed to connect level differences within an interior space (Moreira, 2023)

Parametric design methods were utilised to balance the scale of the space and create a dynamic interior, and wooden ceiling elements were designed using this method (Figure 12). The truss system, which forms the structure's load-bearing framework, controls light while incorporating a rainwater drainage system and supporting the wooden ceiling elements and glass. The aim is to design and construct the market as a fast, technically accurate, and economically sustainable structure (Moreira, 2023).

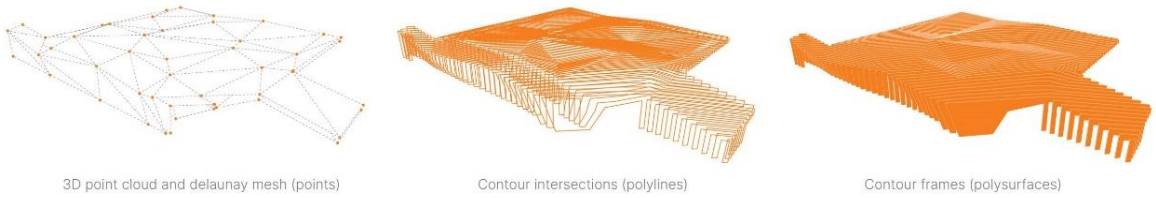

Figure 12. Wooden ceiling elements designed using the parametric design method and characterising the space (Moreira, 2023)

The roof system, composed of non-structural wooden beams, contributes to the interior space in many ways. The glass roof allows natural light into the interior, while the parametric wooden beam system ensures that natural light is controlled. Acoustic comfort is provided by the sound changing direction when it hits the wooden beams. Furthermore, the geometry of the interior space facilitates the circulation of air through convection (Figure 13) (Moreira and Concatto, 2023).

Figure 13. The passive sustainability contributions of wooden ceiling elements to the space, such as air circulation, controlled intake of natural light and acoustics (Moreira, 2023)

The fundamental spatial configuration of the structure consists of a steel support system for the glass roof and non-structural wooden beams (Moreira and Concatto, 2023).

Braga Market brings together the present and the past while preserving a significant part of its original structure. It also stands out for its spaciousness and capacity to host various activities, including a fish market and a variety of restaurants. Furthermore, strategically placed information stands within the interior guide visitors. The market offers a smooth and enjoyable shopping experience by organising different sectors together. The project not only preserves the old market but also promotes better working conditions and efficient commercial activities, acknowledging the critical role played by the market's vendors in the local economy and the preservation of traditions. Therefore, Braga's market is not just a trading center, but also a place that encapsulates the history, culture and economy of the region. By preserving the past and investing in the future, it has become not just a place of trade, but also a symbol of respect and appreciation for fishermen and merchants, shaping the city's identity (Moreira and Concatto, 2023).

3.3. Tula Farmers Market

The Tula Farmers' Market project, located in the city of Tula, the capital of Russia's Tula Oblast, was designed by the 8 Lines architecture office and constructed in 2017 (Table 3) (Figure 14). The architectural form of the farmers' market reflects the idea that each farmer is first and foremost an individual and that when they come together, they form a rural cooperative (Maggiora, 2019).

Table 3. Tula farmers market (Maggiora, 2019)

Project:	Tula Farmers Market
Location:	Tula, Tula, Russia
Architect:	8 Lines
Project Year:	2017

Figure 14. Tula Farmers Market entrance facade (Maggiora, 2019)

Tula Farmers' Market includes sales areas for farm products and agricultural supplies, a cafeteria, a product quality control laboratory, a play area, a space for various events, a relaxation area, sanitary facilities, offices, storage areas, and workshops. These functions ensure that the market is not merely a place of trade, but also a social hub where connections are made, projects emerge, and interactions occur. Additionally, a small area has been designed in front of the building for temporary art installations (Figure 15) (Maggiora, 2019).

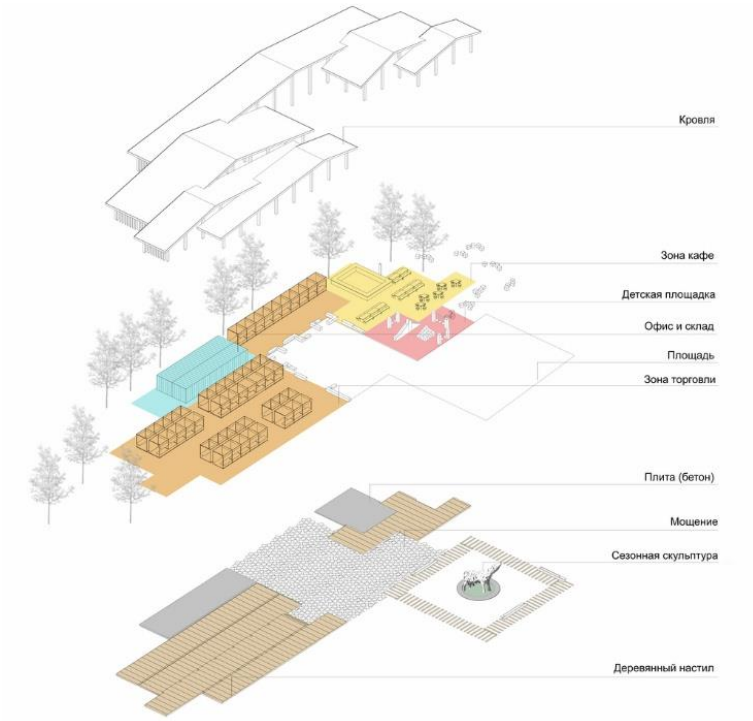

Figure 15. The architectural form of Tula farmers' market reflects the idea of rural cooperation, where each farmer is an individual and they come together and functional diagram (Maggiora, 2019).

Tula farmers' market offers a unique shopping experience with its interior space within a spatial unity. (Figures 16, 17).

Figure 16. Semi-open spaces of Tula Farmers Market (Maggiora, 2019)

Figure 17. Interior of Tula Farmers Market (Maggiora, 2019)

The Tula Farmers' Market project was awarded the prize for the best wooden architecture of the year in the 'Wooden Public Buildings' category at the 2018 'Archiwood' competition (Maggiora, 2019).

4. Conclusion and Recommendations

Markets can be defined as consumption areas that play heterogeneous roles and reveal the commercial, social and cultural characteristics of societies. This study discusses what architectural qualities could animate market structures as urban cultural spaces and offers recommendations in this regard. These recommendations aim to prevent market structures from becoming idle by ensuring that markets can also be used when markets are not held. The findings obtained from the markets examined within the scope of the research are as follows:

It is seen that the markets examined were designed with a concept, and their architectural forms reflect an idea. It can be stated that the architectural form of the Tula Farmers' Market, in particular, reflects the idea of rural cooperation formed when farmers come together, with each farmer being primarily an individual, and that this form is highly compatible with the function of the structure and makes it unique.

Each of the markets examined has been designed as accessible spaces for disadvantaged users such as disabled people, the elderly, and children. Targ Blonie Market and its surroundings have been planned at the same level, thus creating an accessible and safe shopping environment for all users. Due to the sloping terrain of Braga Municipal Market, the level differences created in the interior have guided the market's design, with different level heights connected by ramps, thus creating an accessible market for users from all groups.

The circulation and direction of the markets examined within the scope of the study are found to be legible, and the stalls are found to be locatable. Circulation at Braga Municipal Market is designed to enable users to perceive and experience the space as a whole, to see and reach all market stalls from the square. In addition, information stands have been placed inside the market to guide visitors.

Landscaping can be considered an element that enhances visitor comfort in markets. Arrangements such as landscaping, the design of seating units, the provision of a pedestrian-friendly environment, and the presence of shaded areas will make markets more desirable. Mehta (2013) found that seating areas are one of the most important elements in 'keeping people in public spaces' (Kamarudin et al. 2015). This means that seating units in markets are important for facilitating the shopping experience of users, encouraging them to spend more time in the market, and allowing them to rest.

The markets examined were designed and conceived to serve not only shopping but also various other functions. Seating elements and a children's play area were designed at the centre of Targ Blonie Market, thus creating a mixed public space that combines two social functions: market and park. Furthermore, when the market is not in operation, the wood-clad display units (sales stalls) serve as seating elements, enabling the market area to be used for various events. An integrated food and beverage venue has been designed to make Braga Municipal Market a centre of attraction. Tula Farmers' Market, on the other hand, includes sales areas for agricultural materials and farm products, along with a cafeteria, play area, relaxation area, product quality control laboratory, sanitary facilities, offices, storage, and workshops.

When designed correctly, markets have the potential to draw users away from shopping centres, where they meet various needs in one place, towards marketplaces. Markets should be designed to encourage interaction and be interactive between users, sellers and visitors, with units supporting social activities. This ensures that markets remain vibrant with the presence of the local community and host interesting local events, thereby sustaining cultural values. Markets can also become important social spaces where various public events are held. When properly designed, markets will attract visitors from other countries, contribute to trade and cultural tourism in the region, and become a meeting and socialising point for the community.

Other functions that can be integrated into markets include:

- Children's play areas
- Cafeterias
- Units where users can consume the products they have purchased
- Seating and relaxation areas
- Exhibition units
- Various gastronomy-related events and festivals
- Open-air film screenings
- Various children's activities
- Local cultural events, fairs

Markets should be designed as flexible, openable and closable, adaptable to current conditions, experience-oriented spaces that can serve various functions.

Abstract

Landscape Performance Assessment (LPA) presents a research approach in which the environmental, social, and economic benefits of implemented landscape design are supported by quantitative data on their contributions to sustainability. Supported by the Landscape Architecture Foundation (LAF), LPA focuses on landscape areas with the potential to demonstrate high performance. Performance findings inform the design process, helping to design more sustainable and high-performing landscape areas as well as to improve/redesign existing areas. When the 210 studies published by LAF are examined, it is noteworthy that no assessment study has yet been conducted in Türkiye and that it is not a common research approach in the fields of practice and academia. This study aims to focus on LPA studies and to examine conceptual relationships through the method of content analysis. It has been investigated which performance themes and design strategies most frequently produce the reported benefits, the relationship between the identified performance themes and design strategies, and which concepts are sought in defining a high-performing project. The analyses, within a conceptual framework, provided a perspective on the design of high-performing landscape areas through the relationship established between performance themes and design strategies. As a result of the research, recommendations have been developed regarding which themes, design strategies, and concepts should be included in the design of high-performing landscape areas in Türkiye and in future participation LPA studies. This research not only provides a reflection for landscape design in Türkiye but also offers an important framework that supports studies in other countries.

Keywords: Conceptual approach, landscape performance, landscape design, sustainability, design process

1. Introduction

Today, landscape architects face significant and complex challenges such as providing climate-resilient landscape spaces, coping with rapid urbanization, adapting to natural disasters, conducting ecological restoration of degraded urban areas, managing water resources, addressing urban growth, and integrating ecological knowledge into design process (Yang et al., 2016; Barnes et al., 2025). In response to the environmental issues of the 21st century, the field of landscape architecture continues to expand and transform through interaction with numerous professional disciplines, while the need and demand for stronger justification of actions in design and planning studies have also increased (Swaffield & Deming, 2011). In this context, design plays a crucial role in addressing environmental issues and achieving sustainability (Çelik, 2013).

In order to effectively address these challenges, landscape architects increasingly require empirical information, reliable evidence, and research to inform design and support decision-making processes in the planning, design, and management of landscape spaces (Brown & Corry, 2011; Meijering et al., 2015; Yang et al., 2016). However, decision-making processes

in contemporary landscape architecture practice often rely on beliefs and experience-based approaches (Brown & Corry, 2011; Shen et al., 2023). Landscape architecture is an evidence-based design discipline that depends on reliable data to advance and guide design practices (Luo, 2014). Therefore, evaluating the outcomes of implemented design and planning projects is crucial for the creation of successful landscape spaces, as it enables the determination of the accuracy of design approaches and the assessment of their environmental, social, and economic values through quantitative research (Luo, 2014; Yang et al., 2016).

The Landscape Performance Series (LPS) measures the outcomes of sustainable development across three benefit areas – environmental, social, and economic – and utilizes the quantitative data collected to inform future design practices (Luo, 2014). The Landscape Architecture Foundation (LAF) defines the concept of landscape performance as *"a measure of the effectiveness with which landscape solutions fulfill their intended purpose and contribute to sustainability"* ("Landscape Architecture Foundation (LAF)", n.d.). Regardless of how sustainability is defined, sustainable development and landscape are inseparable entities. In this context, landscape performance plays a significant role (Shen et al., 2023) and regards sustainability as one of the primary objectives of design and planning project (Ndubisi et al., 2015). Within the scope of LPS studies, LAF established the Case Study Investigation (CSI) Program in 2011 to support practitioners working collaboratively with academic and student research teams. The LPS and CSI initiatives aim to promote the design of project with performance objectives, the documentation of project goals and design intentions, and the systematic collection of performance data (Barnes, 2024).

Understanding landscape performance provides critical insights for the creation of future high-performance and resilient landscape design projects by informing the shaping of design objectives and supporting the appropriate selection of spatial and functional design principles and elements (Aydınlı, 2017; Özdil, 2018; Güler, 2019). Consequently, such feedback can aid in the management of landscape spaces, indicate the need for improvements to enhance low-performing or underperforming areas, or suggest the necessity for redesigning certain landscape areas (Chen, 2024). Therefore, it is essential to investigate the conceptual transitions and potential implications of performance outcomes produced within the scope of LPS for the landscape architecture design process.

This study focuses on 210 landscape design projects evaluated within the CSI Program under the LPS framework. The aim was to identify and relate the generated benefits, performance themes, and design methods in order to highlight the design concepts that should be considered in defining a high-performance project. Accordingly, recommendations have been developed regarding which performance themes and design methods should be incorporated into projects to achieve high-performance landscape designs in Türkiye.

2. Materials and Methods

This study, which presents a research approach focused on design, is structured around four main components: the formulation of the research aim and questions, the establishment of the sample area, the development of evaluation criteria for the data analysis process, and the analysis of the data.

The aim of this study is to examine the benefits generated in Landscape Performance Assessment (LPA) studies using a content analysis approach. Specifically, the study seeks to identify the most frequently addressed performance themes in LPS studies, the design methods

applied in the evaluated projects, the relationships between the applied design methods and the performance themes, and the concepts to be considered in defining a high-performance project. In addition, based on the findings, the study aims to provide conceptual recommendations regarding which performance themes and design methods should be incorporated into the design process to achieve high-performance landscape designs in Türkiye. Accordingly, the four research questions developed are presented below. These are:

- **RQ$_1$:** *What are the most frequently addressed performance themes in Landscape Performance Assessment studies from environmental, social, and economic perspectives?*
- **RQ$_2$:** *What design methods are applied to generate environmental, social, and economic benefits in Landscape Performance Assessment studies?*
- **RQ$_3$:** *How are the applied design methods in Landscape Performance Assessment studies associated with specific performance themes?*
- **RQ$_4$:** *What concepts should be considered in the design process to define a high-performance project based on Landscape Performance Assessment studies?*

The content analysis method was selected for analyzing the materials and addressing the research questions. Content analysis is a research technique that uses written or textual documents within their context to obtain reproducible and valid inferences, providing new sights, enhancing the researcher's understanding of specific ideas, and/or informing practical actions (Krippendorff, 2004, p.12). Janis (1943-1965) classified research methods within content analysis into three categories: (1) Pragmatic content analysis, which categorizes the possible causes or effects of signs present in the text; (2) Semantic content analysis, which categorizes the signs in the text based on their meanings; and (3) Sign-instrument analysis, which categorizes signs according to their psychophysical characteristics (Krippendorff, 2004, pp.44-45). According to these definitions, the semantic content analysis method is deemed most suitable for the purpose of this study.

The unit of analysis for this study was determined as the reports of LPA studies supported by the LAF. LPA reports are publicly accessible through the *"Case Study Brief"* database on the official LPS website (https://www.landscapeperformance.org/). Accordingly, all 210 CSI reports published between 2010 and 2024 constitute the sample of this study.

A coding scheme was developed for the analysis LPA reports. This scheme was informed by guidelines developed by the American Society of Landscape Architects (ASLA) and the LAF. Specifically, the references used were *Landscape Architecture Technical Information Series (LATIS), A Landscape Performance – Metrics Primer for Landscape Architects: Measuring Landscape Performance on the Ground* (McCoy, 2018) and *Evaluating Landscape Performance: A Guidebook for Metric and Methods Selection* (Canfield et al., 2018). The performance themes defined for environmental, social, and economic benefits in these guides were used as indicators in the coding scheme. The resulting coding scheme is presented in Figure 1.

Figure 1. Performance themes and coding (adapted from Canfield, et al. 2018 & McCoy, 2018)

The texts included in the LPA reports were examined during the analysis phase. However, texts provided under heading such as "*uncertain benefits," "features," "additional information," "lessons learned," "cost comparison," "limitations,"* and *"supplementary information"* were not included in the analysis. This exclusion is due to the fact that findings reported under these headings cannot be considered definitive benefits within the scope landscape performance. Inferences drawn from the texts in the reports were marked on the coding scheme, while no marking was made when no inference could be identified. Additionally, the outcomes of landscape designs can be evaluated under one or multiple performance themes. This is because, unlike building which are closed systems, landscape are open systems, and the implemented designs can generate diverse performance outcomes. An example of marking under single and/or multiple performance themes is presented in Figure 2. The analysis was conducted by a single coder in a one-time evaluation of the reports.

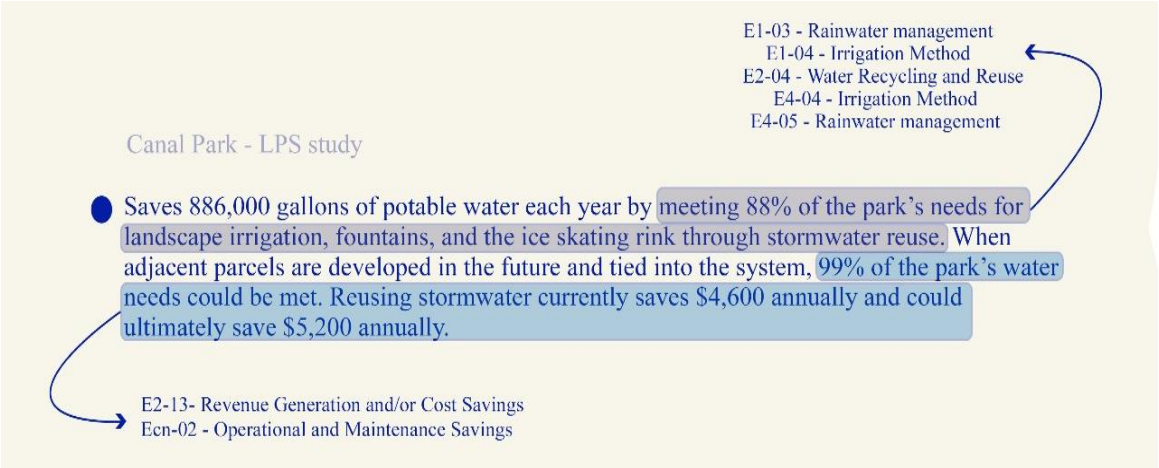

Figure 2. Linking and coding texts with Performance themes (adapted from Salazar, 2015)

Based on the coding scheme developed from the analysis, a frequency analysis was conducted. The results of the analysis are presented both textually and visually (e.g., diagrams, tables). This approach enabled the identification of performance themes to be prioritized in high-performance landscape projects, the most frequently used design methods, and the relationship between these methods and performance outcomes, thereby revealing the key concepts to be considered in creating high-performance landscape designs. Using the resulting conceptual map, recommendations were developed for the design and implementation of high-performance landscape areas in Türkiye.

3. Findings and Discussion

The LAF continues its efforts to inform landscape architecture design through LPS studies and to promote the development of an evidence-based design approach. The 210 LPS studies conducted under the CSI Program between 2010 and 2024 represent a significant source of knowledge and information. The fact that this knowledge has been generated across different countries, regions, and project types contributes to the diversity of the data produced. Upon examination, 32 project types were identified, including parks/open spaces, courtyards/squares, and coastal redevelopment. The landscape design projects included in the 210 LPS studies evaluated in this research correspond to the project types listed in Table 1 below.

Table 1. Distribution of projects by type in LPS studies ("Landscape Performance Series (LPS)", n.d.)

Project Types	Total	Project Types	Total
01. Coastal Redevelopment Project	**28**	17. Park/Open Area	**90**
02. Community	**6**	18. Playground Area	**6**
03. Conference/Retreat Center	**2**	19. Rainwater Management Facility	**24**
04. Courtyard/Square	**29**	20. Recreation Trail	**11**
05. Garden/Arboretum	**11**	21. Retail	**6**
06. Golf Course	**1**	22. School/University	**30**
07. Health Facility	**9**	23. Single-Family Home	**5**
08. Holiday Village/Hotel	**5**	24. Sports Facility	**1**
09. Hybrid Development	**3**	25. Stream Restoration	**15**
10. Industrial Park	**1**	26. Street Landscape	**19**
11. Multi-family Housing	**4**	27. Transportation	**8**
12. Municipal/Government Facility	**7**	28. Urban Agriculture	**4**
13. Museum/Cultural Center	**8**	29. Wetland Creation/Restoration	**18**

15. Office	**7**	31. Youth/Community Center	**3**
16. Other	**4**	32. Zoo	**1**

In this section of the study, 210 LPS studies were analyzed using the content analysis method, and answers were sought for the four research questions (RQ_1, RQ_2, RQ_3, and RQ_4). During the research process, each LPS study was coded once, and the analysis of the most frequently

addressed performance themes is presented in Figure 3. For the investigation related to the first research question, a total of 3,399 data entries were processed. The data were analyzed based on three dimensions: frequency of use within each theme, within each benefit category, and across all themes. Environmental benefits were divided into five subcategories, each containing distinct or overlapping performance themes. This categorization led to variations in the results of category-based analyses within the environmental benefit category. However, similar category-based calculations could not be applied to the social and economic benefit categories, as each theme in these categories represents a unique and independent topic.

Performance Benefit	Performance Theme	Code	Frequency of Occurrence in Total LPS Studies (n=210)	Rate of Occurrence within Theme (%)	Rate of Occurrence within Benefit Category (%)	Overall Occurrence Rate (%)

Figure 3. Most frequently addressed Performance themes in LPS studies

A total of 614 data entries were recorded under the environmental benefit category. Accordingly, the most frequently addressed performance themes within each environmental subcategory are listed below:

- ***Within the Soil/Land (E1) performance theme*****,** the most frequently addressed topics were stormwater management (E1-03), habitat quality and biodiversity (E1-13), and irrigation method (E1-04).
- ***Within the Water (E2) performance theme*****,** the most frequently addressed topics were stormwater quantity (E2-02), reduction and efficiency of irrigation demand (E2-03), and stormwater quality (E2-01).
- ***Within the Vegetation (E3) performance theme*****,** the most frequently addressed topics were reducing stormwater runoff and promoting infiltration (E3-03), acting as a carbon sink (E3-06), contributing to improved air quality (E3-02), and providing habitat, food, and shelter for wildlife (E3-12).
- ***Within the Carbon, Energy, and Air Quality (E4) performance theme*****,** the most frequently addressed topics were stormwater management (E4-05), carbon sequestration and avoidance (E4-12), and air quality (E4-08).
- ***Within the Materials and Waste (E5) performance theme*****,** the most frequently addressed topics were reuse and recycling of materials (E5-01) and waste reduction (E5-02). Since this theme is associated with two sub-performance themes, a comparison was made to identify which of the two was more frequently addressed.

A total of 895 data entries were recorded under the social benefit category. Accordingly, the most frequently addressed performance themes were identified as activity and health (S-04), preference (S-02), and spiritual enrichment (S-11). In the economic benefit category, a total of 330 data entries were recorded. The most frequently addressed performance themes within this category were operations and maintenance savings (Ecn-02), economic development (Ecn-07), and property value (Ecn-01). Across the benefits categories, a total of 2,174 data entries were recorded under the environmental benefit category. Within this category, the most frequently addressed performance themes were stormwater management (E4-05), stormwater management (E1-03), and stormwater quantity (E2-02). The values in the social and economic categories correspond to the same themes identified above. Among all performance themes and the 3,399 total data entries, the most frequently addressed themes were E4-05, E1-03, and E2-02, all of which are associated with the environmental benefit category.

The realization of each theme may result from the implementation of one or more design methods. The investigation addressing the second and third research questions examined the design methods applied and their relationship with the performance themes, as presented in Figure 4.

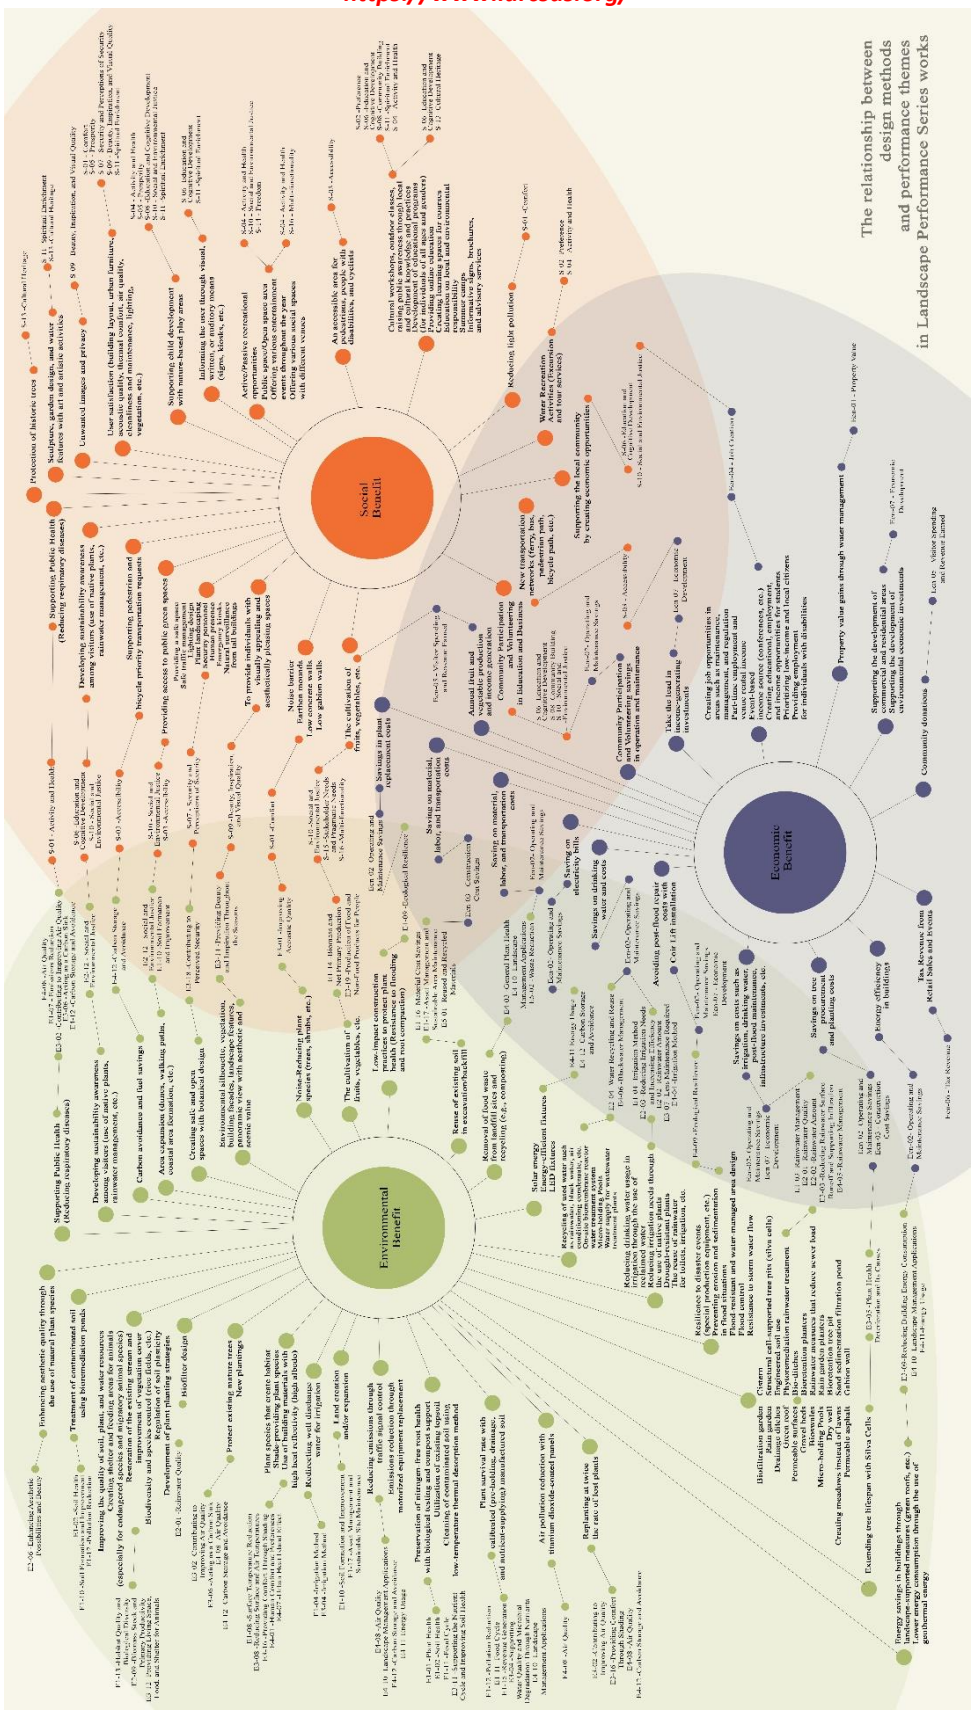

Figure 4. Landscape design methods and their relationship with Performance themes

The visual highlights the prominent design methods. This focus was chosen because, considering the diversity of project types presented in Table 1, factors such as project location, economic investment, natural and cultural values, and the needs of both the community and the city lead to significant variation in design approaches. When the findings related to research question RQ_1, RQ_2, and RQ_3 are correlated, it is observed that many of the design methods are primarily implemented within the scope of environmental benefits.

4. Conclusion and Recommendations

In contemporary practice, creating landscape spaces that address environmental challenges, provide high-quality living environments, and manage and/or enhance existing resources represents a crucial spatial quality within a sustainable life cycle. Therefore, designing high-performance landscapes within the framework of sustainability not only contributes to environmental benefits but also facilities the emergence of social and economic gains. Aligning high-performance landscape design with performance themes occurs through the implementation of specific design methods that respond to designer and client goals. Generally, performance themes such as *stormwater management, reduction of irrigation demand, activity and health, operation and maintenance cost savings, and construction cost savings* are developed through the design and implementation process. However, certain themes – *such as providing habitat and food for wildlife, preference, comfort, sense of place, property value, and economic development* – represent performance outcomes that can be assessed after the landscape design has been implemented. Ultimately, the creation of a high-performance landscape depends on the success of the project's implementation. The LPS evaluates and measures this success by quantitatively assessing the environmental, social, and economic benefits generated by the implemented design.

When the LPS studies published between 2010 and 2024 are evaluated as a whole, it becomes evident that the evaluation process has evolved and its scope has expanded over time. The growing understanding of the purpose of performance assessments conducted by researches, along with their significant contributions to the field of sustainability, has been further supported by advances in technology and the increasing variety of research methods. This demonstrates that LPA is not a static field of study. Moreover, the performance outcomes published within an open-access database that includes the results of CSI projects serve as a valuable professional resource across academia, education, and practice. The analysis of these performance results provides critical insights for the design process, supporting the creation of more sustainable and high-performing landscapes as well as the enhancement or redesign of existing sites. Accordingly, this study explores the conceptual transitions and reflections from landscape performance assessment to design practice, contributing to a deeper understanding of how performance-based evaluation informs and shapes contemporary landscape design.

Based on the responses to the research questions, the most frequently addressed performance themes in the environmental, social, and economic benefit categories were identified as stormwater management (E4-05/E1-03/E2-02), activity and health (S-04), and operations and maintenance savings (Ecn-02), respectively. Analysis across all performance themes further highlighted the prominence of stormwater management (E4-05/E1-03/E2-02) within the environmental benefits category. As noted in most studies, one reason for the prominence of stormwater management is its support through local and regional regulations. However, identifying the most frequently addressed themes does not imply that other performance themes are unimportant. In practice, performance themes generated by the implementation of one

design method can function independently, while the application of another method may contribute to or reinforce additional themes. Consequently, all performance themes are directly or indirectly interconnected under the umbrella of sustainability. Therefore, future landscape designs should incorporate a broader range of performance themes, and the design methods applied to achieve these themes should be carefully examined and evaluated.

Due to the extensive and detailed nature of design methods, the approaches applied in the studies were addressed only at a conceptual level. The conceptual map presented in Figure 4 provides guidance on the methods that can be implemented in the design of a high-performance landscape. It is observed that design methods are most frequently applied within the environmental benefit category, which can be attributed to the fundamental goal of landscape architecture: creating natural and livable spaces for people through the use of natural resources and materials. As an example, within the stormwater management theme, parameters such as site grading and vegetation used in the design of rain gardens serve functions including water direction, infiltration, flow attenuation, treatment, and storage. Additionally, the water stored in rain gardens contributes to operations and maintenance cost savings for the landscape while mitigating the destructive effects of flooding during heavy rainfall, thereby creating a safe environment for users. This functional system also fosters cognitive development and environmental awareness among individuals.

In most LPS studies, the design methods applied are not fully specified; however, some studies provide textual and/or visual support (e.g., technical drawings, plans, renders, real-world images). The sharing of materials that illustrate the design and its details may depend on the design firms and clients involved. Nevertheless, presenting research findings within the CSI framework, supported by design methods and analyses, can help readers interpret the information, integrate it into the design/implementation process, enhance it, or develop new solutions. Therefore, establishing a clear and standardized framework for presenting LPS studies would facilitate future academic and professional work in the field.

Based on the analyses and findings, a high-performance landscape can be defined as follows:

"It should be a space designed with foresight not only for today's resources but also for those of the future. Such spaces effectively manage water resources, enhance habitat quality and biodiversity, reduce water use and demand, act as a carbon sink, provide habitat and foraging opportunities for wildlife, improve air quality, reuse existing materials, and minimize waste generation. They offer users a variety of active and passive recreational opportunities, support individual and public health, provide diverse choices and encourage people to prefer the space. These landscapes enrich individuals spiritually and foster spaces with strong social interactions. At the same time, they contribute to operational and maintenance cost savings, support economic development in the surrounding area, and enhance property values."

In conclusion, based on the analyses conducted, the study identifies the themes, design solutions, and concepts that should be incorporated in the design of high-performance landscapes in Türkiye and in future participation in LPS studies. Designing high-performance landscapes in Türkiye will contribute to sustainability goals at both local and national levels and will lay the foundation for creating resilient and high-quality living environments. This research not only provides a reference for landscape design practices in Türkiye but also offers a valuable framework that can support studies and applications in other countries.

Abstract

The use, planning, and experience of urban spaces are radically transforming with the rapid development of digital technologies. Urban recreation areas, impacted by this situation, are not only spaces where users spend their free time but are also transforming into hybrid social spaces by integrating with digital technologies. They are integrating digital technologies such as virtual reality (VR), augmented reality (AR), and mobile applications to increase functionality, accessibility, and interactivity. VR applications are used in the planning process of urban recreation areas to gather the ideas and opinions of different users through virtual simulations and to enable users with other disabilities to experience the spaces in a digital environment. AR technologies provide interactive information about cultural elements, historical textures, and plant species. Gamified experiences also enable more active use of urban recreation areas. Mobile applications also personalize user experiences within areas, such as orientation, event calendars, density information, and health and sports tracking, and support more efficient use of the spaces. This study investigates the integration of virtual reality (VR), augmented reality (AR), and mobile applications in urban recreation areas. The contributions and opportunities offered by these digital technologies have been evaluated. The study highlights how integrating digital technologies into urban recreation areas in sustainable urban planning will provide an innovative perspective, improving the functionality of spaces and the quality of social life in cities.

Keywords: Urban recreation areas, virtual reality, augmented reality, mobile applications

1. Introduction

Society moving away from rural areas and towards urban areas has increased the population in cities, causing pressure on the urban structure. Society has started to experience physical, social, and psychological pressures within urban life. However, in the cities they live in, their environment is rapidly becoming depleted and polluted by developing technology. This situation leads to psychological, personal, and physical deterioration in people. The need for recreation has emerged in society to escape this pressure (Uzun & Müderrisoğlu, 2010). This recreation need felt by society consists of the' social and personal benefits. It comes to the fore with the benefits it provides for social integration and solidarity and the formation of democratic societies. It also responds to personal benefits such as gaining mental health, socialization, creativity, improving physical health, developing personal skills and abilities, providing economic impact, and ensuring work efficiency and success (Belli & Gürbüz, 2012). At this point, recreation areas in urban areas (Figure 1) come to the fore in meeting the recreation need. These areas offer activities held in open or closed areas in the city center. People can access these activities easily in short periods and immediate surroundings (Eren & Koçyiğit, 2020). They are seen as basic public spaces where they meet their physical, psychological, and social

needs. They play an important role in experiencing urban belonging, socialization, and physical activities (Whyte, 1980). City squares, city parks, theme parks and gardens, and museums are examples of urban recreation areas (Yavuz & Altınay, 2016).

Figure 1. Sample applications of urban recreation areas (Url-1; Url-2)

The use and experience of urban recreational spaces have been evolving in recent years due to increasing urbanization, digitalization, technological advancements, and diversified user expectations. In this regard, digital technologies such as virtual reality (VR), augmented reality (AR), and mobile applications stand out for their rich potential in experiencing and using public spaces.

Virtual Reality (VR) technologies are computer-generated three-dimensional artificial environments that evoke the senses through visual, auditory, and textural cues. Users, wholly or partially isolated from the physical world, can spend time in virtual environments using specialized devices such as VR headsets, gloves, and head-mounted displays (Slater & Sanchez-Vives, 2016). Augmented reality (AR), on the other hand, provides users with a realistic experience by integrating data generated by transferring visual, auditory, and other sensory content from the real world into a digital environment. Unlike VR, it does not immerse the user in an entirely virtual environment but superimposes virtual objects onto the real environment (Azuma, 1997; Billinghurst et al., 2015). Mobile applications encompass software programs designed to run on portable devices. They are a part of mobile information technologies widely used in many areas such as communication, commerce, education, and entertainment. They enable users to interact via touchscreens, voice commands, or sensors (Kim, 2008; Gao et al., 2014). Ultimately, digital technologies such as VR, AR, and mobile applications enable users to experience, interact, and participate. Proper design and delivery of these technologies can increase individual well-being and contribute to cities' sustainable goals.

2. Integration of Virtual Reality (VR), Augmented Reality (AR) Technologies, and Mobile Applications into Urban Recreation Areas

Literature on integrating digital technologies such as VR, AR, and mobile applications into urban recreational area is ongoing. With the integration of these technologies into urban spaces;

- **VR technology (Figure 2)** allows users to transform urban recreational spaces fully into virtual environments. This allows users to experience physical spaces digitally. It will also

enable individuals with access restrictions to access public spaces through virtual simulations (Slater & Wilbur, 1997). Enabling the introduction of urban parks or cultural landscapes through virtual tours contributes to preserving and sharing natural and cultural heritage (Bekele et al., 2018).

Figure 2. VR technology (Url-3)

- **AR technologies (Figure 3)** offer users an "enriched" experience by adding digital layers to physical spaces (Azuma, 1997; Milgram & Kishino, 1994). AR-supported navigation systems in urban recreation areas facilitate the discovery of natural walking routes and can strengthen environmental education by providing interactive information about plant and animal species (Billinghurst & Kato, 2002). Gamification applications using these technologies also contribute to users' more active exploration of urban spaces and increased levels of physical mobility (Laato et al., 2023).

Figure 3. AR technology (Url-4)

- **Mobile applications** play a significant role in the sustainable management of urban recreational areas. Location-based services allow users to learn about park density, access online event calendars, and provide instant feedback (Yang et al., 2025). Mobile health and

exercise applications also support the health-focused functions of recreational areas by encouraging physical activity among park users (Pereira, 2024).

3.Conclusion

Within the scope of the study, the integration of Virtual Reality (VR), Augmented Reality (AR) and mobile applications was examined in the context of supporting urban recreation areas with digital technologies. Findings from the literature indicate that these technologies not only enrich the user experience but also have the potential to increase participation, strengthen urban identity, and contribute to sustainability goals. VR technologies, in particular, are a powerful tool for users to experience spaces, pre- and post-design simulations, and interactive exploration. By adding digital layers to the physical environment, AR technologies provide information, guidance, and cultural content to individuals using urban recreation areas. Mobile applications, in turn, facilitate the accessibility, interaction, and user-focused services in urban recreation areas, enabling a broader audience to reach. Combining these technologies offers city residents and users more inclusive, interactive, and innovative recreation experiences.

Furthermore, collecting and analyzing user data through digital integration enables the development of participatory and data-based decision-making mechanisms in urban planning processes. However, resolving issues such as technical infrastructure, cost, digital inequality, and privacy are critical to the sustainable implementation of these technologies. Consequently, integrating VR, AR, and mobile applications into urban recreational spaces is a key tool in building smart, user-centric cities of the future. Therefore, interdisciplinary collaboration among urban designers, municipalities, and technology developers is essential to the success of this integration.

Abstract

Urban recreation areas are essential spaces where society meets its social, physical, and spiritual needs and strengthens social solidarity and integration. They are indispensable components of urban life. Rapid urbanization, coupled with increased population density, spatial fragmentation, and social alienation, limits city residents' communication and interaction and weakens social ties. Urban recreation areas, which host a wide range of activities such as squares, parks, community gardens, walking and cycling paths, and cultural and artistic activities, bring together individuals of different genders, ages, languages, religions, races, cultural backgrounds, and socioeconomic backgrounds, enabling them to share experiences. They foster communication and interaction among individuals and support disadvantaged groups' participation in urban life. Thus, social integration is achieved by ignoring social differences. Social solidarity and integration are the coming together, acting together, and uniting urban areas, communities, and individuals towards a common purpose, goal, value, and responsibility. This study explores and examines how urban recreation areas contribute to social solidarity and integration in national and international literature. The study emphasizes that urban recreation areas are places where individuals spend their free time and are strategically crucial for social solidarity and integration sustainability. In this respect, the study will provide a new perspective on the literature and urban planning and management.

Keywords: Urban recreation areas, social solidarity, integration

1. Introduction

Urban recreation areas, planned and designed to meet society's social, physical, and cultural needs, offer opportunities for individuals to spend their free time through their open and closed spaces (Figure 1). They encompass many areas such as community gardens, squares, parks, playgrounds, and sports facilities in cities (Chiesura, 2004). These areas are considered spaces where physical and psychological needs within society are met and sociocultural platforms where social relationships are developed and social integration is strengthened. The stress of today's urban life, the intense workload, long working hours, and individuals' tendency towards individualism can limit their ability to socialize and integrate (Gehl, 2011). In this regard, urban recreation areas provide opportunities for individuals of different genders, ages, races, languages, religions, cultures, and socioeconomic backgrounds to come together and interact. In this way, they support social cohesion, social solidarity, and integration (Peter et al., 2010).

Figure 1. Sample applications of urban recreation areas (Url-1; Url-2)

Social solidarity and integration in urban areas is the coming together, acting, and uniting of individuals in a society towards common goals, objectives, values, and responsibilities (Putnam, 2000). It mediates the formation of trust and social bonds among individuals. It is a fundamental dimension of social cohesion. Trust is associated with perceptions of cooperation and equality (Dragolov et al., 2016). It increases social resilience in times of crisis. It is one of the most fundamental elements facilitating compliance with implemented welfare and health policies (Borkowska & Laurence, 2021). It reflects inclusive social values by supporting the coexistence of communities with different languages, religions, cultures, ethnicities, and socioeconomic characteristics (Doreian & Fararo, 2012). It increases social solidarity and integration by forming emotional bonds, a sense of belonging, and community loyalty between society and individuals (Hu et al., 2023).

Considering the contribution of urban recreation areas to social solidarity and integration (Figure 2), they serve as spaces where communities spend their free time and as social platforms where social interaction is fostered and a sense of trust and belonging is developed. They directly contribute to social solidarity and integration. The diversity of activities and spaces they accommodate increases interaction among different socio-cultural and economic groups. Thus, they reinforce mutual trust and solidarity among individuals. They strengthen ties between communities (Cattell et al., 2008). They create opportunities for interaction and encounters in cities with multicultural characteristics. They encourage intercultural harmony. They facilitate social interactions between residents and individuals from different cultures (Seeland et al., 2009). They foster social belonging and neighborhood identity. Urban recreation areas designed at the neighborhood level foster a sense of belonging among individuals and strengthen community ties. They also increase mutual trust among users and support social integration (Francis et al., 2012). It enables the experience of cultural diversity. This, in turn, increases inclusiveness by reducing social conflicts (Low et al., 2005).

Figure 2. Examples of social solidarity and integration in urban recreation areas (Url-3; Url-4; Url-5)

2. Sample Applications

In this part of the study, randomly selected urban recreation areas were discussed, and their orientation towards social solidarity and integration was explained.

- **New York – Bryant Park (Figure 3)**

In the 1970s and 1980s, Bryant Park was perceived and known as an area where users felt unsafe, crime rates were high, and social exclusion was widespread. This resulted in the park's weakness in terms of social solidarity and integration (Whyte, 1980). William H. Whyte's 1980 study, "The Social Life of Small Urban Spaces," referenced the park's redesign. The study investigated how people behave in public spaces and what physical arrangements encourage social interaction. Attention was paid to implementing activity formats to increase social interaction and foster participation among diverse communities (Madden, 2010). Strategies for social integration were developed. Free and accessible activities, emphasizing open public space, and security and belonging were prioritized.

Figure 3. Bryant Park- New York (Url-6; Url-7)

- **Barselona – Parc Güell (Figure 4)**

Designed by Antoni Gaudí between 1900 and 1914, the project was initially planned as a residential garden project but was never completed, eventually gaining a new function as a public park. It was created based on the idea that social relationships would be strengthened and spaces harmonious with nature could bring people together (Kent & Prindle, 1993). Located at the park's center, "Plaça de la Natura" was planned as a public meeting and interaction area. It serves as a social space that can be used for collective events. Its multifunctional structure contributes to the coming together of people from different social classes and strengthens social integration. The structures adorned with mosaics within the park functioned both aesthetically and to establish a shared cultural identity (McNeill, 2000). Over time, transforming it from private property into public space reflected a more inclusive approach to public space by reducing social inequalities (Arias-Sans & Russo, 2016).

Figure 4. Parc Güell- Barcelona (Url-8; Url-9)

- **Zurich – Urban Forests and Parks (Figure 5)**

Since the 19th century, it has been one of the cities that has planned public green spaces as a tool for social integration. The municipality defines green spaces as nature conservation, social gathering, democratic sharing, and recreation (Seelan et al., 2009). It embraces the principle of public space open to all. Different social classes are encouraged to share the same spaces. It is a city with a high immigrant population, and its urban forests and parks provide a platform for diverse ethnic groups to integrate (Kabisch & Haase, 2014; Haase et al., 2017).

Figure 5. Rieterpark- Zurich (Url-10)

- **İstanbul – Maçka Demokrasi Park (Figure 6)**

The park emerged as part of the green belt project planned around the İnönü Gezi Park and Dolmabahçe Valley in the 1950s as part of the urban development activities (Tekeli, 2009). Known as Makça Park, it was redesigned after September 12, 1980, and renamed Democracy Park. This transformation allowed the park to function as a recreational space, a political memorial, and a social gathering space (Kuyucu, 2014). Its central location makes it a common space, enabling diverse socio-economic groups to unite. This increases the park's potential for social integration. It hosts various events to strengthen the solidarity practices of citizens (Erkip, 2000).

Figure 6. Maçka Demokrasi Parkı- Türkiye (Url-11)

3. Conclusion

In conclusion, as in the examples above, urban recreation areas not only serve the functions necessary for society to utilize its leisure time but also serve as a tool for establishing cultural and social relationships, fostering the integration of ethnic differences, and fostering and strengthening social harmony. Therefore, in planning these areas, it is crucial to consider functions that foster aesthetic, ecological, and social solidarity and integration.

Abstract

Indoor air contamination is primarily caused by three mechanisms: occupant bio-effluents, building product emissions, and external pollutant ingress. These hazards introduce adverse agents causing specific health problems, often linked to insufficient awareness among design and user groups. Evaluating Indoor Air Quality (IAQ) pollutants during design and operation requires simulation tools that concurrently integrate complex factors. Accurate assessment necessitates understanding each tool's characteristics, as results depend significantly on regional climate, construction materials, occupant profile, and ventilation strategy. Tools derive calculations from IAQ limit values defined by the national standards of their country of development. This study comparatively evaluates four accessible IAQ simulation tools: CONTAM (USA), MODELICA (Canada/Asia), IA-QUEST (Canada), and EPA's IAQX. CONTAM was identified as the most current, largely due to its integration with other programs and 2D drawing capabilities. Given the tools' reliance on specific national data, utilizing a simulation tool tailored to local conditions is expected to yield more accurate results.

Keywords: Indoor air quality, indoor air pollutants, simulation tool, CONTAM

1. Introduction

Indoor air can be contaminated due to the biological and physiological actions of occupants and as a result of building products. This contamination in Indoor Air Quality (IAQ) directly affects the health of the space occupant. Risk groups, particularly the sick, the elderly, and children, are more severely affected. These effects may be short-term or can lead to long-term health problems.

Studies concerning Indoor Air Quality (IAQ) have increased in developed countries in recent years. This is due to the rise in Sick Building Syndrome and building-related illnesses. While there are studies and measurement stations regarding outdoor air quality in our country, the number of studies conducted within the scope of Indoor Air Quality (IAQ) is insufficient. An examination of the Ulusal Tez Merkezi determined that the number of thesis studies conducted within the scope of Indoor Air Quality (IAQ) is insufficient. A total of 26 Master's and PhD theses were written up to September 2025.

Regulations and standards concerning Indoor Air Quality (IAQ) exist both in our country and globally. These regulations, which aim to determine the limit values of Indoor Air Quality (IAQ) pollutants, may vary according to the local characteristics of countries. These limit values are employed in the simulation tools used to simulate Indoor Air Quality (IAQ). When evaluating the results of a simulation tool, it must be remembered that the limit values used in the tool are country-specific. If the tool is to be used in a different country, attention must be

paid to the similarity of the climatic and geographical features. Thus, the closest result can be achieved.

The simulation tools used to measure Indoor Air Quality (IAQ) possess various distinct features. Advantages such as library diversity, offering the possibility of two-dimensional (2D) drawing, and integration with different programs play a role in the selection of the simulation tool. The user should identify the strengths of these tools and determine the most appropriate simulation tool for their study.

1.1. Indoor Air Quality and Indoor Air Pollutants

Indoor air, which is composed of atmospheric gases from the external environment, contains certain ratios of nitrogen, oxygen, argon, and carbon dioxide. In addition to these gases, the air contains very small amounts of neon, helium, methane, krypton, hydrogen, xenon, nitrogen dioxide, and ozone (Tünay & Alp, 1996; Vural & Balanlı, 2005). As a result of natural actions occurring in the atmosphere, the ratios of the air's components remain constant. As long as this balance is maintained, the air is considered to be "of high quality."

According to the title “Ventilation for Acceptable Indoor Air Quality” in the ASHRAE 62-1989 Standard: “It is air in which there are no known pollutants at harmful concentration levels determined by authoritative bodies, and in which 80% or more of the occupants are not expressing dissatisfaction with the air quality” (Aslan, 1997).

To ensure comfort conditions, a human requires an average of 25 to 39 m^3 of air per hour. During respiration, oxygen from the air is consumed, producing carbon dioxide and water vapor. The amount of oxygen required by an individual is related to their weight, age, nutrition, and actions (Balanlı, 2007; Darçın, 2008).

Both short- and long-term exposure to Indoor Air Pollution can lead to various health problems, including respiratory diseases, heart diseases, cognitive deficiencies, and cancer. The World Health Organization estimates that 3.8 million people die globally each year due to illnesses related to harmful IAQ originating from dirty cookstoves and fuels (WEB 1, NIEHS, 2025).

IAQ is directly related to occupant health and comfort. Ensuring its protection requires maintaining its control. This monitoring can be achieved through solutions applied during the design or utilization phases, such as particle control (filtration), ventilation control, and pressurization (Aslan, 1997).

The main physical properties of air are related to temperature, humidity, air movements, pressure, and radiation from the atmosphere. Temperature, humidity, and air movements gain importance in terms of IAQ (Gültekin, 2001). The World Health Organization stated that for indoor air to provide comfort conditions, the temperature should be 19-23 °C, the relative humidity 40-60%, and the air velocity 0.1 m/s (WHO, 1987).

Temperatures between 20-26 °C in the indoor environment remain within the comfort limits for most people. However, complaints about building-related illnesses increase above 22 °C. This is because the emission of Volatile Organic Compounds (VOCs) from building materials increases at temperatures between 20-26 °C (Hays et al., 1995; Gültekin, 2001).

Air pollution is constituted by the accumulation of pollutants—which can compromise the composition of air and mix with it from various sources—to a level that affects living organisms (Balanlı, 2007; Darçın, 2008). Indoor air is known to be contaminated in three ways: as a result of the biological and physiological actions of occupants, by air pollutants originating from

building products, and by the ingress of pollutants from the external atmosphere into the building (Balanlı & Taygun, 2005; Ceylan, 2011).

Darçın classified indoor air pollutants as follows (Darçın, 2014):

- According to their Physical Properties: gases/vapors, particulates (Table 1),
- According to their Chemical Properties: organic, inorganic,
- According to their Sources: originating from outside the building, from building products, from the space occupant/actions,
- According to their Health Effects: causing cancer, non-cancer illnesses, and Sick Building Syndrome,
- According to their Origin: natural and artificial.

Table 1. Classification of Indoor Air Pollutants According to Their Physical Properties (Darçın, 2014)

Indoor air pollutants in the form of gas/vapor:	Carbon monoxide, carbon dioxide, nitrogen monoxide, nitrogen dioxide, sulfur dioxide, radon, ozone, mercury, Volatile Organic Compounds (VOCs), polycyclic aromatic hydrocarbons
Indoor air pollutants in the form of particulates (PM):	• Fibers: asbestos, vegetable fibers, rock wool, glass wool • Metals: lead • Biological pollutants: viruses, bacteria, mold fungi, pollens, arthropods, skin flakes
Some pollutant groups:	Various waste groups resulting from combustion (smoke, etc.), pesticides

The concentration of the pollutant in the form of gas and vapor is determined by volume or weight. For volume determination, the unit ppm (parts per million), which indicates the gas volume in one million total volume, or ppb (parts per billion), which indicates the pollutant volume in one billion total volume, is used (Tichenor, 2006; Ceylan, 2011). Particulates, on the other hand, are substances dispersed in the air in solid and liquid states. They can be removed from the area where they are suspended due to reasons such as sedimentation, diffusion, and evaporation (Velicangil, 1985; Gültekin, 2001).

According to their size, particulates are classified as:

- PM_{10} (coarse particulates): those with diameters between 10 µm and 2,5 µm
- $PM_{2,5}$ (fine particulates): those with diameters smaller than 2,5 µm,
- $PM_{0,1}$ (ultrafine particulates): those with diameters smaller than 0,1 µm (Darçın, 2014).

Ventilation can be defined as the clean air taken into the indoor environment of the building from the outside environment (Öztürk et al., 2005). The purpose of providing ventilation in a building is the occupant's need for breathing and protection from indoor air pollutants. For the building to be adequately ventilated by natural methods, external air of suitable quality must reach the building, this air must be introduced into the building via the building envelope, sufficient and appropriate air circulation must be ensured within the building, and the contaminated air must be expelled from the building (Darçın & Balanlı, 2012). The types of ventilation systems are indicated in Figure 1.

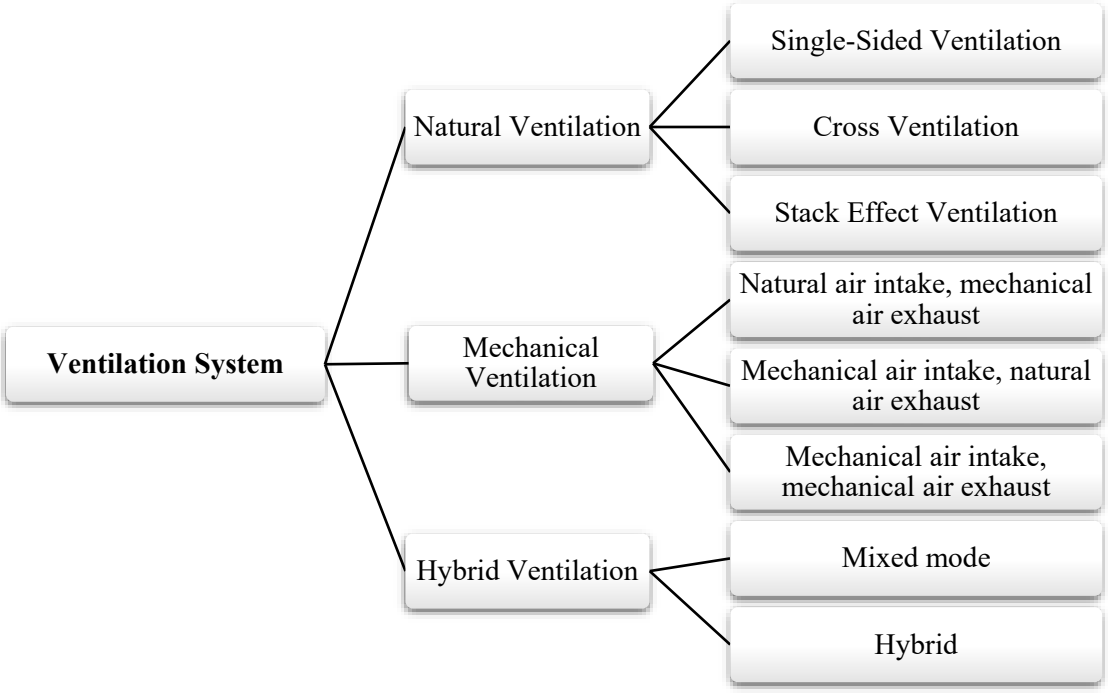

Figure 1. Types of Ventilation Systems.

1.2. Effects of Indoor Air on Human Health

Indoor air pollutants, given the formation of specific conditions, can generate different types of health problems in humans, who are the principal occupants of the building (Darçın, 2014). In children, the immune, respiratory, digestive, nervous, and reproductive systems have not completed their development. The rate at which airborne Particulate Matter (PM) reaches the lungs may be higher in children compared to adults (Maeseno, 2013; Ertürk, 2017).

Indoor air pollutants can be classified based on their effects on occupant health as: toxic (poisonous), carcinogenic (causing cancer), mutagenic (causing genetic effects), allergenic (causing allergies), irritant (affecting respiration and vision), and infectious (Cengiz Yılan, 2008). Bulgurcu also classified indoor air pollutants in the context of their health effects as: irritant, asphyxiant, narcotic, poisonous, pathological-allergenic, and carcinogenic (Bulgurcu, 2015). According to this classification:

- Volatile Organic Compounds (VOCs): irritant, asphyxiant, narcotic, poisonous, carcinogenic,
- Formaldehyde, biological pollutants, environmental tobacco smoke, polycyclic aromatic hydrocarbons, asbestos, and radon: irritant, carcinogenic,
- Pesticides and lead: irritant, poisonous, carcinogenic,
- Carbon dioxide and carbon monoxide: asphyxiant,
- Nitrogen dioxide and sulfur dioxide: irritant,
- Radon: determined as carcinogenic.

Another illness caused by Indoor Air Pollution is Sick Building Syndrome (SBS). Symptoms begin shortly after the occupant enters the building and cease shortly after they leave. Although the causes of Sick Building Syndrome cannot be determined definitively, one accepted hypothesis is that certain air pollutants, present as a mixture at low concentration levels in the indoor air, cause the discomfort symptoms associated with SBS (EPA, 1994).

Pollutants thought to be associated with SBS are listed as (Bernstein, 2008):

- dust,
- Volatile Organic Compounds (VOCs),
- endotoxins, and
- molds.

Furthermore, the discomfort caused by odors generated by indoor air pollutants, falling under the scope of cacosmia (bad odor syndrome) which can be observed in occupants inside the building, is also considered one of the causes of SBS (Balanlı, 2012; Darçın, 2014).

1.3. Regulations and Standards Related to IAQ in Our Country and Worldwide

There are several regulations and standards in our country and worldwide that determine the limit values for indoor air quality. Some of these include:

- Türkiye Air Quality Assessment and Management Regulation (2008),
- National Air Quality Index,
- ASHRAE (American Society of Heating, Refrigerating and Air-Conditioning Engineers) Standard,
- European Union Standards,
- World Health Organization Standards,
- Limit values determined by the TOBB Türkiye Climatization Council IAQ Commission (2025).

The limit values for indoor air pollutants have been determined through these regulations and standards. These limit values vary (Table 2). The Türkiye Air Quality Assessment and Management Regulation determines the limit values for outdoor air pollutants. However, it is kept within the scope because a healthy IAQ cannot be achieved in an environment where the outdoor air quality is poor. Most spaces in Türkiye are ventilated using natural ventilation. Therefore, outdoor air pollutants are also observed indoors.

The National Air Quality Index was established by adapting the EPA Air Quality Index to our national legislation and limit values. The air quality index is calculated for five basic pollutants. These are: Particulate Matter (PM_{10}), carbon monoxide (CO), sulfur dioxide (SO_2), nitrogen dioxide (NO_2) and ozone (O_3) (Istanbul Air Quality Monitoring Center, WEB 2, 2025).

ASHRAE is an international society that focuses on heating, cooling, and air-conditioning. Founded in 1894, ASHRAE aims to advance human well-being through sustainable technology for the built environment. The society and its members focus on building systems, energy efficiency, IAQ, refrigeration, and sustainability in the industry (ASHRAE, WEB 3, 2025).

The main purpose of the European Union's air quality standards is to assess the exposure of humans and vegetation to pollution, to evaluate the actions carried out by competent authorities to reduce pollution or maintain air quality, and to inform the public about air quality (IBB Department of Environmental Protection and Control, WEB 4, 2025).

The World Health Organization (WHO), in its guidance documents published in 2000 and 2005, recommended exposure levels (concentrations and durations) for which there is no evidence of adverse effects on human health and vegetation (IBB Department of Environmental Protection and Control, WEB 5, 2025).

The Limit Values Working Group was established within the TOBB Türkiye Climatization Council IAQ Commission. The members of the LVWG examined the literature regarding indoor environment emission sources, concentrations in schools, the health effects of these emissions, and existing limit values. They identified the indoor air pollutants to be addressed and made recommendations for limit values for schools in Türkiye (Sofuoğlu et al., 2025).

Table 2. Comparison of Regulations and Standards

	TAQAMR	NAQI	ASHRAE	EUS	WHOS	TCCS
SO_2 (Sulfur dioxide)	350 µg/m³ (hourly)	380 µg/m³ (hourly)	x	350 µg/m³ (hourly)	500 µg/m³ (10minutes)	x
NO_2 (Nitrogen dioxide)	200+20 µg/m³ (hourly)	260 µg/m³ (hourly)	x	200 µg/m³ (hourly)	200 µg/m³ (hourly)	100 ppb (hourly)
NOx (Nitrogen oxide)	x	x	x	200 µg/m³ (annual)	x	x
PM_{10} (Particulate Matter Pollutant)	50 µg/m³ (24-hour)	60 µg/m³ (24-hour)	50 µg/m³ (short-term)	50 µg/m³ (24-hour)	45 µg/m³ (24-hour)	45 µg/m³ (8-hour)
$PM_{2,5}$ (Particulate Matter Pollutant)	x	12 µg/m³ (24-hour)	x	25 µg/m³ (annual)	5 µg/m³ (annual)	15 µg/m³ (8-hour)
Pb (Lead)	0.5 µg/m³ (annual)	x	x	0.5 µg/m³ (annual)	0.5 µg/m³ (annual)	x
	TAQAMR	**NAQI**	**ASHRAE**	**EUS**	**WHOS**	**TCCS**
C6H6 (Benzene)	5 µg/m³	x	x	5 µg/m³	5 µg/m³	5 µg/m³ (8-hour)
CO (Carbon Monoxide)	10.000 µg/m³ (8-hour)	10.000 µg/m³ (8-hour)	10.000 µg/m³ (short-term)	10.000 µg/m³ (8-hour)	10.000 µg/m³ (8-hour)	9 ppm (8-hour)
O_3 (Ozone)	120 µg/m³	120 µg/m³	235 µg/m³	120 µg/m³	100 µg/m³	70 ppb

	(8-hour)	(8-hour)	(short-term)	(8-hour)	(8-hour)	(8-hour)
Arsenic	0.006 µg/m³ (annual)	x	x	0.006 µg/m³ (annual)	0.006 µg/m³ (annual)	x
Cadmium	0.005 µg/m³ (annual)	x	x	0.005 µg/m³ (annual)	0.005 µg/m³ (annual)	x
Nickel	0.02 µg/m³ (annual)	x	x	0.02 µg/m³ (annual)	0.02 µg/m³ (annual)	x
Benzo(a)pyrene	0.001 µg/m³ (annual)	x	x	0.001 µg/m³ (annual)	0.001 µg/m³ (annual)	x

2. Materials and Methods

The scope of IAQ includes the building system, the materials used to construct the building, the materials brought into the building by occupants and visitors, the occupants' actions within the building, and 'Heating, Ventilation, and Air Conditioning (HVAC) and air filtration systems' (Yan, Song et al., 2008). Evaluating all these factors that arise during the utilization phase requires design tools capable of considering all these factors simultaneously. Various simulation tools are utilized to assess IAQ.

This study will examine four different IAQ simulation tools. These simulation tools were chosen due to their ease of access and the distinctions they offer:

- CONTAM in the USA,
- MODELICA in Canada and Asia,
- IA-Quest software in Canada are used to simulate IAQ.
- EPA's IAQX (Simulation Tool Kit for Indoor Air Quality and Inhalation Exposure) simulation software is also available.

3. Findings and Discussion

CONTAM was developed by government employees at the National Institute of Standards and Technology (NIST, 2020). CONTAM is intended for use in the field of air flow and pollutant dispersion in buildings. The software is a methodology used to calculate air flows and pollutant transfer within a building. The calculations are based on a simplified model of actual buildings.

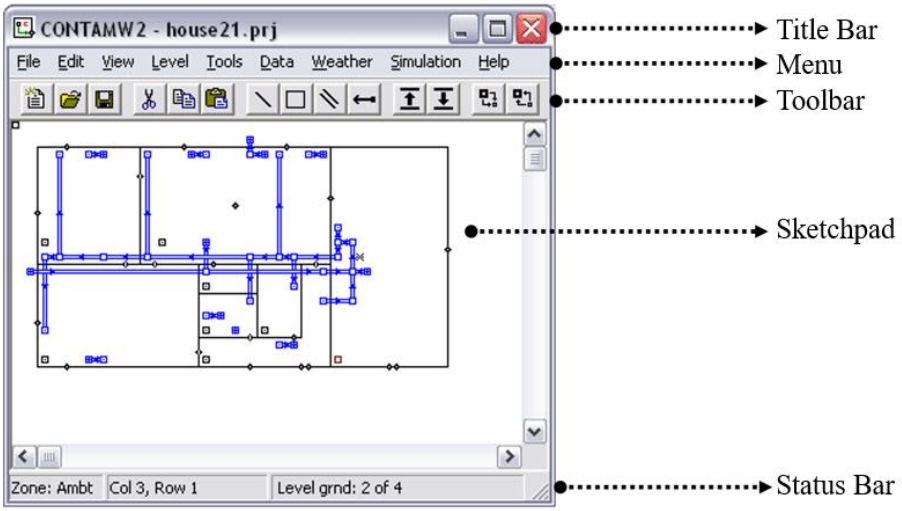

Figure 2. Interface of the CONTAM Software (WEB 6, 2025)

The use of CONTAM to analyze indoor air flow or pollutant transfer involves five distinct steps:

1. Building Idealization: Creating an idealization or a specific model of the building.
2. Schematic Representation: Creating a schematic representation of the idealized building using the ContamW SketchPad to draw the building components.
3. Defining Building Components: Collecting and entering the data associated with each of the building components represented in the SketchPad.
4. Simulation: Selecting the type of analysis desired, setting the simulation parameters, and generating the simulation.
5. Saving Results: Reviewing the simulation results and saving selected portions of the results.

CONTAM can also be integrated with EnergyPlus. EnergyPlus is a whole building energy simulation program used by engineers, architects, and researchers to model both energy consumption (for heating, cooling, ventilation, and lighting loads) and water use in buildings (EnergyPlus, WEB 7, 2025). CONTAM can be combined with EnergyPlus to perform air flow and heat transfer simulations (NIST, 2020).

The following are transferred from EnergyPlus to CONTAM:

- Zone temperatures,
- Ventilation system airflow rates,
- Outdoor airflow fractions for outdoor airflow controllers,
- Exhaust fan airflow rates,
- Energy recovery fan airflow rates,
- Outdoor environmental data, including temperature, barometric pressure, wind speed, and wind direction, obtained from the EnergyPlus weather (.epw) files.

The following are transferred from CONTAM to EnergyPlus:

- Zone airflow rates,
- Interzone airflow rates obtained via airflow paths,
- Control values exposed through the CONTAM control network (e.g., a signal calling for ventilation airflow due to a high pollutant level).

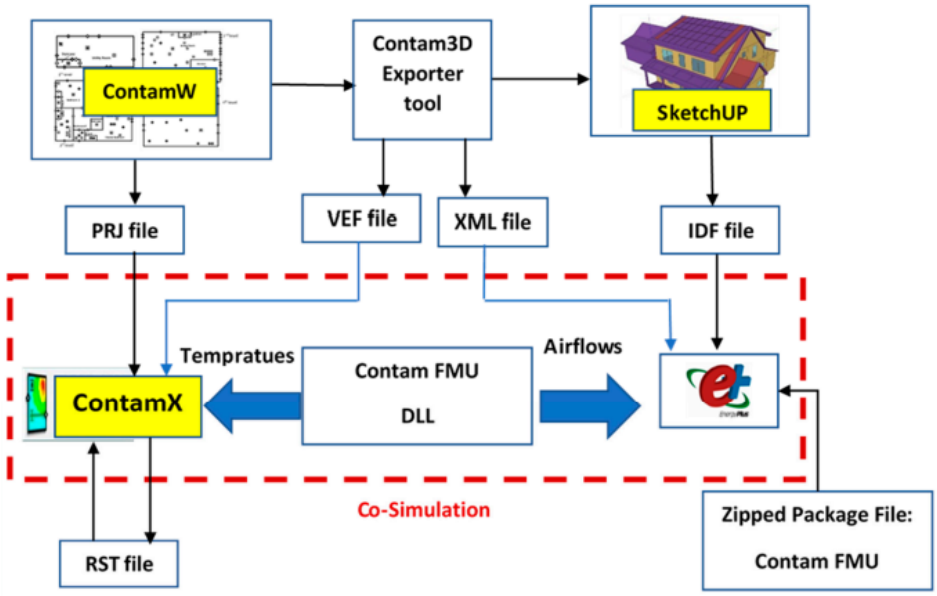

Figure 3. CONTAM-EnergyPlus Relationship (Heibati et al., 2019)

Modelica was developed to support the research and development of building energy and control systems. Primary applications include control design, energy analysis, and model-based study. It was developed by Canada and Asian countries.

It is a language that supports the connection of components governed by mathematical equations to facilitate modeling. It provides object-oriented structures that facilitate the reuse of models and can be readily used to model complex systems containing mechanical, electrical, electronic, magnetic, hydraulic, thermal, control, electric power, or process-oriented sub-components (Modelica, 2023). Many free libraries are available on the Modelica website. Previous versions can also be accessed from the site. Information about books written for the software and universities where courses are taught can be accessed.

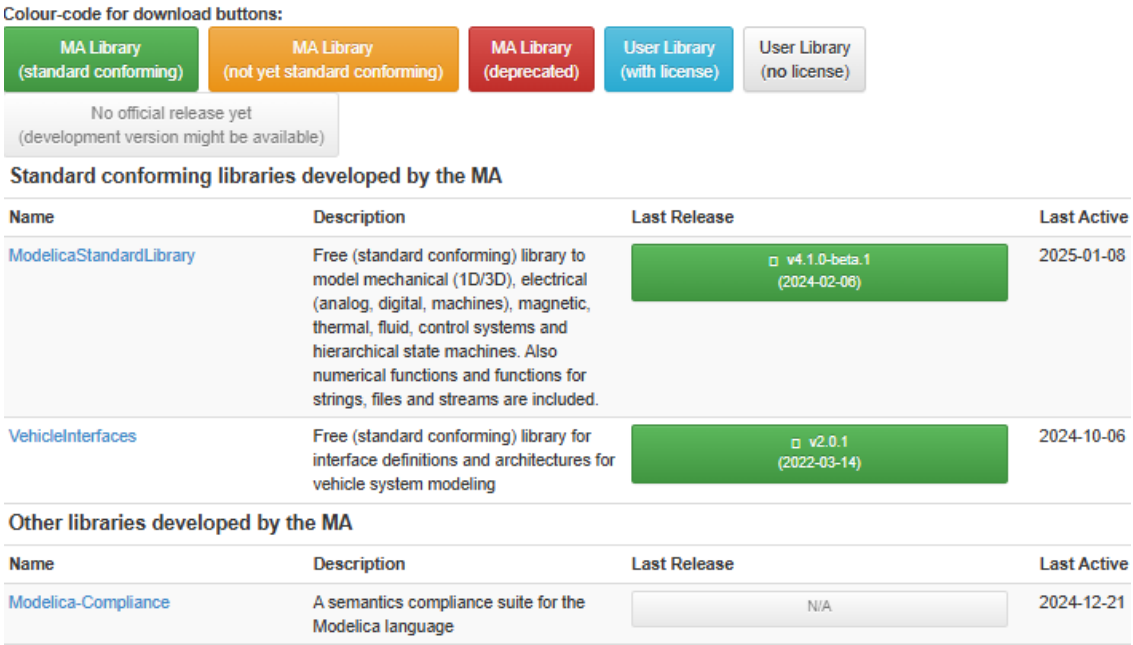

Figure 4. Modelica Libraries (Modelica Library, WEB 8, 2025)

IA-Quest (Indoor Air Quality Emission Simulation Tool) includes a materials database that allows for the selection of materials based on low emissions and contains their measured emissions. Furthermore, the tool aids in quantifying the impact of low-emission materials and effective ventilation strategies on IAQ by estimating the emission of Volatile Organic Compounds (VOCs) from building materials and furniture. It was developed in Canada.

The IA-Quest software consists of two parts: a database and a simulation component:

- The database provides information on health-relevant target Volatile Organic Compounds (VOCs) from building materials commonly used in Canada.
- The simulation component calculates pollutant concentrations that may arise due to emissions from the materials present in a room with a known ventilation rate and schedule. The emission properties of the materials are obtained from the database within the software (NRCC, WEB 9).

To simulate the indoor air concentrations of chemicals originating from building materials, occupants must possess the following information (NRCC, WEB 9):

- The volume of the space,
- The ventilation rate and schedule,
- Materials (selected from the database),
- For each material: the exposed/emitting surface area,
- Simulation duration.

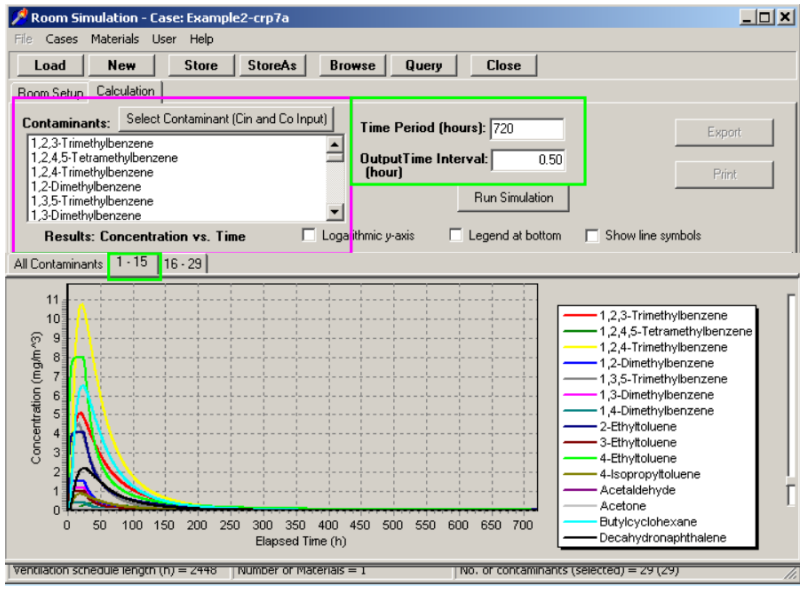

Figure 5. Interface of the IA-Quest Software (Won, 2008)

IAQX (Simulation Tool Kit for Indoor Air Quality and Inhalation Exposure) is a Microsoft Windows-based IAQ simulation tool. In addition to performing traditional IAQ simulations that calculate pollutant concentrations, IAQX can estimate the adequate ventilation rate when specific air quality criteria need to be met.

The outputs provided by the program include:

- Estimation of Volatile Organic Compound (VOC) emissions from solvent-based indoor coating materials based on product formulation,
- Indoor solvent spills,

- VOC emissions from carpets,
- Particulate Matter (EPA, 2000).

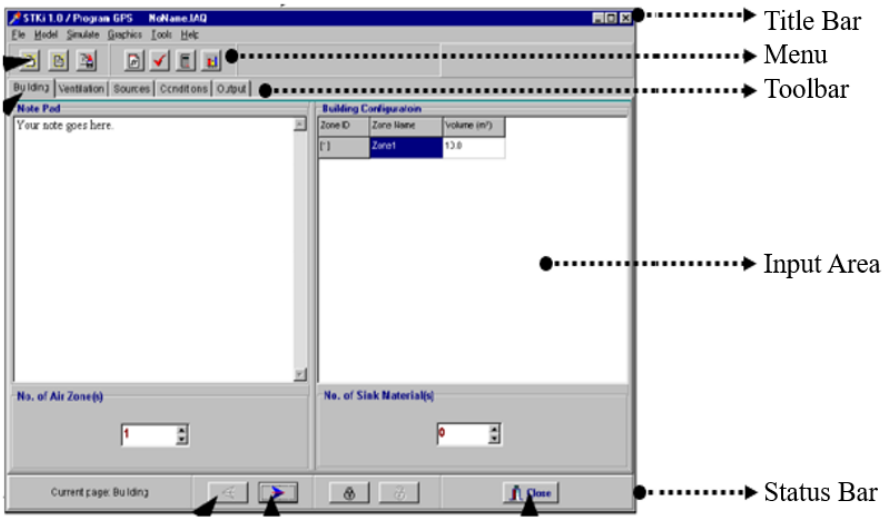

Figure 6. Interface of the IAQX Software (EPA, 2000)

IAQ is directly related to human health. The exposure of the occupant group to pollutants in the indoor air poses a threat to their health. These health problems can be biological as well as having psychological effects. At this point, the designer must detail solutions that will enhance IAQ. Thereby, a portion of the pollution that may arise during the utilization phase will be eliminated. The occupant must also make conscious choices regarding the ventilation of the space and the control of actions performed within it, with the same level of awareness.

All simulation tools used to measure IAQ examined within the scope of this study are freely accessible. 2D drawing can only be performed in the CONTAM tool. All simulation tools except IA-Quest have a manual. Each program possesses a strength from the perspective of the occupant:

- CONTAM: Stands out due to its 2D drawing capability, integration with TRNSYS and EnergyPlus programs, and possession of video content.
- MODELICA: Stands out due to having the largest library.
- IA-QUEST: Stands out due to having an extensive materials database.
- IAQX: Stands out due to its manual introducing the program (Table 3).

Table 3. Comparison of Simulation Tools Used Within the Scope of IAQ

	CONTAM	MODELICA	IA-Quest	IAQX
Country/ Institution	USA	Canada and Asian Countries	Canada	EPA
Cost (Paid/Free)	Free	Free	Free	Free
2D Drawing Capability	2D Drawing is available	x	x	x
Guide	+	+	x	+

4. Conclusion and Recommendations

IAQ is a significant architectural factor that can affect the health of the occupant group. Indoor air can be contaminated as a result of the biological and physiological actions of the occupant, as well as originating from building products. The designer must take into account the effect on IAQ when determining the materials to be used in the building design during the production phase. Various simulation tools can be utilized to perform this calculation. These simulation tools can be used to determine indoor air pollution during the utilization phase as well as the design phase.

CONTAM in the USA, MODELICA in Canada and Asia, and IA-Quest software in Canada are used to simulate IAQ. EPA's IAQX (Simulation Tool Kit for Indoor Air Quality and Inhalation Exposure) simulation software is also available. These simulation tools were chosen due to their ease of access and the distinctions they offer.

All examined software programs are freely accessible. No other software is integrated with another program except CONTAM. Detailed manuals are available for all simulation tools except IA-Quest. Modelica has the largest library and provides access to publications/university courses on its official website. The IA-Quest simulation tool includes a more extensive materials database. The manuals for CONTAM, Modelica and IAQX contain information on how to use the software and its interface.

All simulation programs possess a unique advantage compared to the others. CONTAM has been determined to be the most current simulation tool due to its integration with other programs and the possibility of 2D drawing. However, it is considered that the interface of all simulation tools, including CONTAM, needs to be updated and developed. However, real-time monitoring of this data by the occupant could be enabled by providing 3D integration.

There is no simulation tool produced in Türkiye. A simulation tool specific to Türkiye could be developed by creating a more user-friendly and modern interface design and by expanding the materials inventory. The limit values set for IAQ pollutants in the regulations should be utilized in these tools. Since simulation tools are developed considering the climatic data and material properties of countries, more accurate results can be achieved with a simulation tool specific to Türkiye.

Abstract

Since the early 2000s, two data collection methods—terrestrial laser scanning and photogrammetry—have been increasingly utilized in various fields of scientific research. These methods play a particularly significant role in the documentation of excavation sites and historical structures in archaeology. This study aims to conduct a detailed architectural documentation of an underground structure, discovered during the 2022 excavation season at the Kaletepe in the ancient city of Miletos, which must be evaluated together with the cistern it contains. For this purpose, tacheometry measurement techniques, terrestrial 3D laser scanning, and both terrestrial and UAV-supported photogrammetry will be employed. The intended outcome of this study includes the creation of architectural drawings, high-resolution 3D models, and orthophotos, which will provide a foundational basis for subsequent archaeological architectural research. In achieving this, the study first defines the fundamental theoretical concepts and applied measurement methods. It then presents the preparatory steps and methodological approaches for data collection. The collected data are comprehensively analyzed through a comparative evaluation using Metashape and Reality Capture software. Additionally, the study includes architectural

documentation of the structure, consisting of a niche corridor accessed by stairs and a cistern, using a combination of traditional measurement and photogrammetric methods.

Keywords: Miletus/Kaletepe, underground cistern, photogrammetry, terrestrial laser scanning, 3D Model

1. Introduction

Miletus is an ancient harbor city located on the western coast of Anatolia, near the mouth of the Maeander River. The archaeological remains of the city lie approximately 3 kilometers north of the modern village of Balat in Didim, Aydın. Although today it is situated about 10 kilometers inland, in antiquity Miletus owed its prosperity to its strategic location and four well-protected harbors, which made it a prominent center of trade and colonization. Because of this strategic importance, the city was besieged and conquered multiple times by various powers, but its eventual decline was brought about by the silting of the Maeander River. Sharing the same fate as its neighboring Ionian League cities—Priene and Myus—Miletus lost its maritime connection during the Early Christian period as its harbors silted up, leading to a decline in economic vitality and gradual abandonment (For further information, see Gorman, 2001; Greaves, 2002; Niewöhner, 2016).

The area known as Kaletepe, or alternatively Theater Hill, lies to the northwest of the city, between the ancient Theater Harbor and the Lion Harbor. Kaletepe, which began to serve as a residential area from the early periods onward, shows evidence of significant erosion in its southern section even prior to the Hellenistic and Roman periods, while archaeological data from the western and northern plateaus are comparatively more coherent. Excavations conducted in the northern part of the hilltop have yielded postholes indicative of Early Archaic structures, despite the scarcity of earlier material remains apart from a few fragments of Mycenaean and Geometric pottery. The archaeological record suggests that this area was predominantly used as a residential quarter from the Archaic period through the Byzantine and Ottoman eras (For further information, see Kleiner, 1961; Kleiner, 1964; Fildhuth, 2015; Müller-Wiener, 1982) (Fig. 1).

Figure 1. Miletus in Asia Minor, and Kaletepe/Theater Hill in the city plan (Filduth, 2015, p. 163-164)

The researches initiated in 2021 also focused on these residential quarter located north of the area referred to as Kaletepe or Theater Hill. One of the most striking discoveries made during the 2022 excavation season was a cave—previously described rather briefly as a ‘cellar/storeroom’ by the 1961 excavation team—along with an adjoining cistern (Kleiner, 1961, p. 46-48). During the two-week survey within the cave, 12 steps leading into an inner corridor enabling access to deeper sections of the structure were revealed. The most striking

feature of this formation, apart from the stairs totally carved into the natural limestone bedrock, the corridor, and the niches located on both sides of it, is the large underground cistern added to the building. Separated from the cave by a brick-built wall most likely added in a later period, the cistern stands out for its tall masonry walls, the high-quality mortar used in its construction, and the finely plastered surface of its broad dome (Teraman Hepdinçler, 2024, p. 90-94).

The intended function of this underground structure will be clarified through the archaeological assessment of the limited number of small finds recovered from the site, alongside comparative analyses with the extensive body of literature on ancient hydraulic installations. Furthermore, the detailed architectural documentation obtained in this study provides a basis for generating new hypotheses concerning the structure's form, construction phases, and potential functions.

2. General Information

2.1. Topographic Documentation

The primary objective of this study is to conduct a detailed topographic documentation of the cistern and its adjoining corridor with niches. As the term suggests, this documentation aims to ensure the precise measurement and recording of an existing structure. Regardless of the historical period to which the structure belongs, all constructive and aesthetic features—along with deformations, damages, alterations, and restorations that have occurred over time—must be systematically documented (Busen, Knechtel, Knobling, Nagel, Schuller & Todt, 2017). Traditionally, documentation has been understood as the measurement and recording of the existing condition, or as a 'graphic survey' of the current state. Architectural record drawings represent a carefully selected and differentiated presentation focusing on the essential elements of the structure. This selective process requires informed interpretation based on knowledge of historical construction techniques, architectural styles, interior decorations, and materials. Thus, architectural documentation is not merely the production of plans and drawings but also a process of knowledge acquisition, in which information is communicated through meaningful visual representation. In the light of technological advancements, the concept of documentation today should be approached from a broader perspective. Laser scanning technologies and modern photogrammetric methods provide new opportunities for documentation, and the modern understanding of architectural recording now encompasses not only traditional measured drawings but also a range of digital outputs. There is no universally applicable ideal method for all structures; rather, the methodological approach must be calibrated to local conditions and specific project requirements. For the documentation of the structure at Miletus, a combination of tacheometric surveying, terrestrial 3D laser scanning, and both ground- and UAV-based photogrammetry was employed. The intended outcome of this work includes the creation of high-resolution 3D models and orthophotos, which will form a foundational basis for architectural drawings and subsequent archaeological studies of the structure.

2.2. Photography

A fundamental requirement for accurate photogrammetric reconstruction is the availability of high-quality photographic data. Image resolution defines the precision of the details recorded in a photograph. In general, higher resolution increases accuracy in photogrammetric analysis, as it provides the computer with more detail for matching. Therefore, the most suitable choice is a high-resolution, full-frame camera capable of capturing images in RAW format, which offers the advantage of full control over image processing. The ideal focal length of a lens for photogrammetry depends on several factors, including the size and distance of the object, the

desired level of detail, physical accessibility, and the type of camera used. In general, a lens with a medium focal length is the most appropriate choice for photogrammetric purposes.

2.3. Photogrammetry

Photogrammetry is the technique of obtaining 3D information through the recording, measurement, and interpretation of image data. The measurements are made indirectly on images of the object rather than directly on the object itself. This is a measurement method based on a mathematical model of central-perspective imaging. The shape or position of an object is determined through the reconstruction of light rays, where each image point P′, together with the projection center O′, defines a spatial direction extending toward the corresponding object points. If the actual imaging geometry of the camera — namely, the interior orientation— and the position of the recording system in space — namely, the exterior orientation— are known, each image ray can be precisely defined in three-dimensional space. The intersection of at least two homologous and spatially distinct image rays forms a three-dimensional object point. Depending on the number of images, these methods can be classified as single-image photogrammetry, stereophotogrammetry or multi-image photogrammetry. When examined according to the location and distance of image acquisition, they can be further subdivided into space photogrammetry, aerial photography, terrestrial photogrammetry, close-range photogrammetry, underwater photogrammetry, and macro photogrammetry (Luhmann, 2018).

2.4. Total Station

A total station is a surveying instrument used to record points in 3D. This device measures and records polar coordinates -horizontal angle, zenith angle, and horizontal distance- from the position of the instrument. When both the instrument height and the target prism height above ground level are defined, the height difference relative to the ground elevation can also be accurately calculated. In modern total stations, distance and angle measurements are performed electronically. If the device includes a microprocessor, automated measurements, evaluations, and digital data transfer are also possible. Depending on the quality of the instrument, measurement accuracy can reach centimeter or even millimeter precision.

2.5. Laser Scanning

Another measurement method is 3D laser scanning. In this method, the surroundings are rapidly scanned with laser pulses in a surface-based manner. As a result, a large number of systematically arranged 3D points -known as a point cloud- are obtained. Various outputs can be derived from this 3D point cloud. The range of applications is broad, extending from simple measurements to the generation of 2D plans, the creation of 3D models, and even the transfer of data into augmented reality (AR) environments. In terrestrial applications, depending on the type of device, the measurement range is limited to a few hundred meters, whereas in airplane or drone-supported applications, a more comprehensive area can be recorded. Similar to photogrammetry, the locally referenced point cloud can be transferred into a larger coordinate system using tie points (Resnik & Bill, 2018).

2.6. Software

The Leica Cyclone FIELD 360 mobile application enables the creation of three-dimensional datasets in the field using the BLK360 Laser Scanner and allows data registration to be completed with the Leica Cyclone REGISTER 360 Post-Processing Software. Users can

automatically collect, merge, and verify scanning and visual data on-site. Once the modeling is complete, the 3D model can be prepared for export and subjected to further processing. Agisoft Metashape and Epic Games Reality Capture are software solutions for 3D reconstruction. These programs use photogrammetry as an evaluation method to automatically generate data from images, point clouds, or textured 3D models, and they produce georeferenced orthophotos. CloudCompare is a cross-platform, open-source application developed for processing point clouds and 3D geometries, including triangular meshes. The software's original purpose was to enable the fast and efficient comparison of high-density point clouds.

2.7. Hardware

A Nikon D810 camera combined with a Nikon 20mm F1.8 lens was used for recording image data. A Leica Viva TS15 total station was employed to determine the coordinates of the tie points. The instrument provides an angular measurement accuracy of 2" (0.6 mgon) for horizontal (Hz) and 3" (1 mgon) for vertical (V) measurements. Due to its compact design, a Leica BLK360 laser scanner was used. This device is a 3D scanner equipped with an integrated spherical imaging system and a thermographic panoramic sensor system. It can be connected to a tablet or smartphone via local network, allowing for on-site data pre-processing or single-scan operations at the touch of a button. For aerial photography, a DJI Mavic 2 Pro drone was used. The device features a 35 mm lens with a 77° field of view, a 20 MP camera, and a 1" CMOS sensor. Fieldwork operations were supported by a Dell Precision 7740 workstation equipped with an Intel Xeon E-2286M 9th generation processor (8 cores / 2.4 GHz), an NVIDIA Quadro RTX 4000 graphics card, 64 GB DDR4 SDRAM-ECC 2667 MHz memory, and two SSD drives with 512 GB and 1 TB storage capacities.

3. Application

3.1. Tacheometric Measurement

Firstly, based on preliminary data, the distribution of reference points in the area was planned as a sketch. Due to vegetation and deep shadows, the visibility of some reference points was occasionally reduced, causing minor deviations from the actual plan. To ensure visibility during drone flights, markers approximately ten times larger (about 30×30 cm) than those typically used indoors were employed and fixed in place. In indoor areas with limestone walls, the reference markers were wedged between tree roots, while on the cistern walls -where humidity was particularly high- temporary markings were made using wax-based paint (Fig. 2).

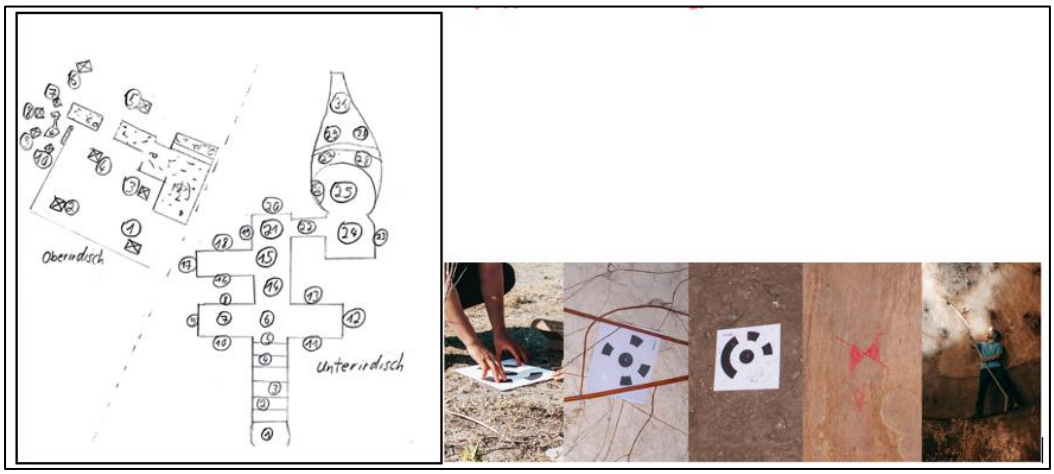

Figure 2. Sketch of reference points

A file containing previously established reference points was uploaded to the Leica TS15 total station, and the coordinates were recorded in the WGS 84 / UTM Zone 35N (EPSG: 32635) coordinate system, which was also used in this project. The total station was positioned by performing a free station setup based on four known points. Since the line of sight to all points was not always clear, the instrument was repositioned several times using repeated free station setups. The most challenging locations for establishing stations were the stairwell leading down to the cistern and the cistern itself. Access to the cistern was quite narrow, which restricted the field of view toward the reference points. This limitation was taken into account during the planning of the reference points, and additional markings were made specifically to facilitate the free station setup of the total station inside the cistern. In total, 10 reference points were measured above ground and 35 below ground, all of which were planned to be used later for georeferencing (Fig. 3).

Figure 3. Total station setup procedures

3.2. Photogrammetric Data Acquisition Process

To minimize harsh contrasts in the image data, the photogrammetric recording was planned to take place on a cloudy day. However, since the weather forecast predicted clear skies throughout the entire measurement campaign, it was decided to carry out the shooting before sunrise. In preparation for image acquisition, the day before the survey, the shading covers over the excavation trenches were removed so that both the trenches and the excavation area could be included in the capture. Image recording began with UAV flights at an altitude of approximately 20 meters. The drone first conducted a circular flight around the excavation area, followed by detailed image captures at an altitude of approximately 5–10 meters using cross-grid mapping. To ensure maximum consistency between aerial and terrestrial image datasets, immediately after the flight, images of the exterior area up to the cistern entrance were taken with a DSLR camera. The documentation started with general overview photographs of the corridor leading to the cistern, providing reference orientation. Subsequently, photographs parallel to the floor and walls were taken, followed by oblique-angle shots and finally close-up images of specific sections. Inside the cistern, the images were captured along circular trajectories, using automatic camera focusing at 3-second intervals. Before each shot, the target area was illuminated with a flashlight to ensure proper focus. In total, approximately 2,400 ground-based photographs and 360 aerial photographs were captured (Fig. 4).

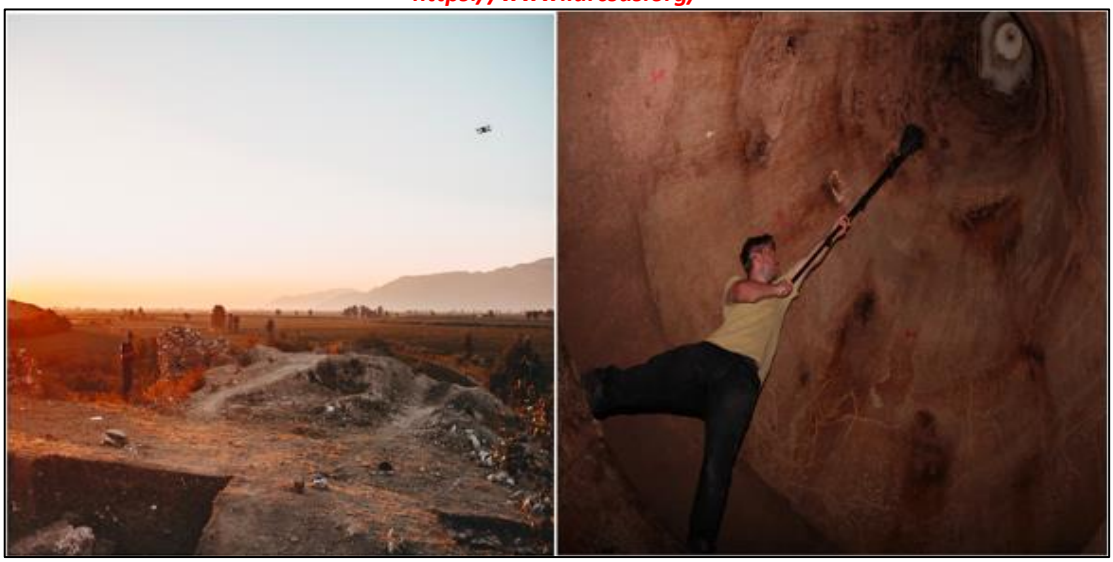

Figure 4. Photogrammetric data acquisition process

3.3. 3D Laser Scanning

In addition to photogrammetric imaging, terrestrial laser scanning was also carried out. The scanning operations began outdoors, with the distance between individual scans set at approximately 1,5 meters. This distance was reduced to 0,5 meters in the underground corridor with stairs and in the cistern, which was the focal area of the study. A total of 114 medium-resolution scans were performed. During the scanning process, the scans were correlated with each other and pre-registered (Fig. 5).

Figure 5. 3D Laser Scanning Process

4. Pre-Processing of Data

4.1. Radiometric Corrections of Image Data

In the first step, a catalog for the raw image data was created in Adobe Lightroom, and image summaries were calculated. Each photograph was then examined individually, and all blurry or under -or overexposed images were removed. To ensure as homogeneous lighting as possible within the database, automatic exposure correction was applied to all photos. Subsequently,

each image was reviewed again, and occasional color corrections were made, which was particularly necessary in the entrance area where natural light was still present. Finally, all photographs were exported in full resolution in JPEG format.

4.2. Processing of Laser Scanning Data

The laser data were processed using Leica Cyclone Register 360 software. For this purpose, the data were directly transferred from the Leica BLK 360 to the software via a local network connection. During the initial import, it was observed that most of the connections were highly inaccurate or provided insufficient overlap; the average accuracy of the connections at this stage was approximately 8 cm. Consequently, the connections between each scan position were analyzed and overlaps were adjusted. The overall alignment of the scans was then optimized. As a result, the strength of the connections (from 35% to 73%), overlap rate (from 43% to 80%), and accuracy (from 8 cm to 2 cm) were significantly improved.

To obtain the most detailed and complete 3D representation of the structure, it was planned to merge the laser scanning point cloud with the photogrammetric dataset. However, the distortions described above became the determining factor for excluding the laser data from further processing. As a test, an attempt was made to merge the point clouds obtained from the laser and photogrammetric datasets using Reality Capture and Agisoft Metashape software. For this, it was necessary to load and re-register the laser scanning positions separately in both programs. Reality Capture failed during the registration phase, successfully registering only 6 out of 85 scans. In Metashape, the registration was completed without any issues. However, a problem arose during the merging of the laser scanning and photogrammetric point clouds and manual tie points were required to align them. To this end, it was planned to use the reference points employed in the photogrammetric process. However, since the laser data lacked RGB information, accurately identifying the corresponding reference points proved highly challenging, and their exact centers could not be precisely located. Once the reorientation was completed, the point clouds were merged, but the laser scan data showed a slight misalignment. Moreover, since the photogrammetric point cloud was already very dense, the laser scanning data did not add significant value. All these factors led to the decision to proceed without using the laser data (Fig. 6-7). The final point cloud consists of approximately 357 million points and was exported in LAS and E57 formats (Fig. 8-9).

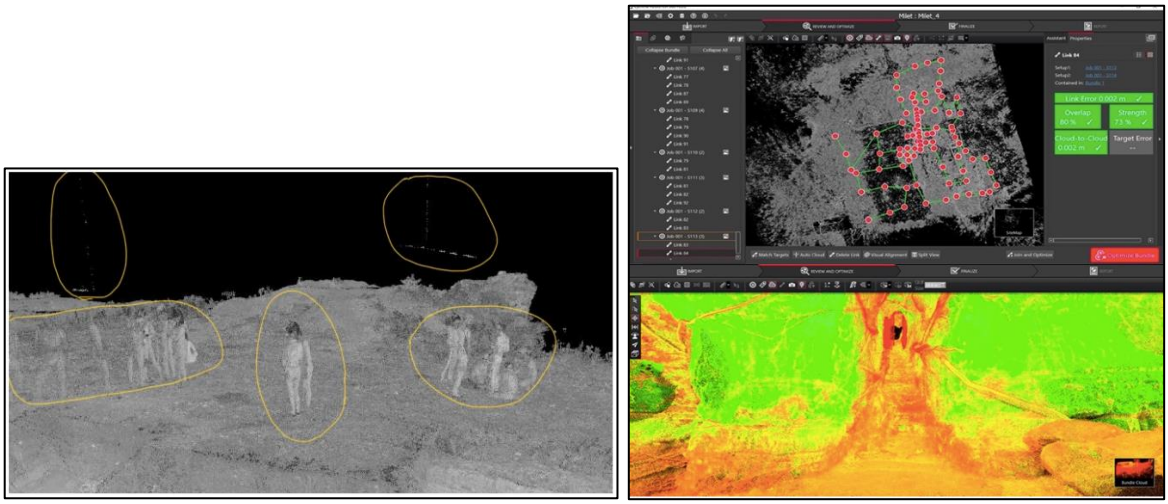

Figure 6-7. Data processing

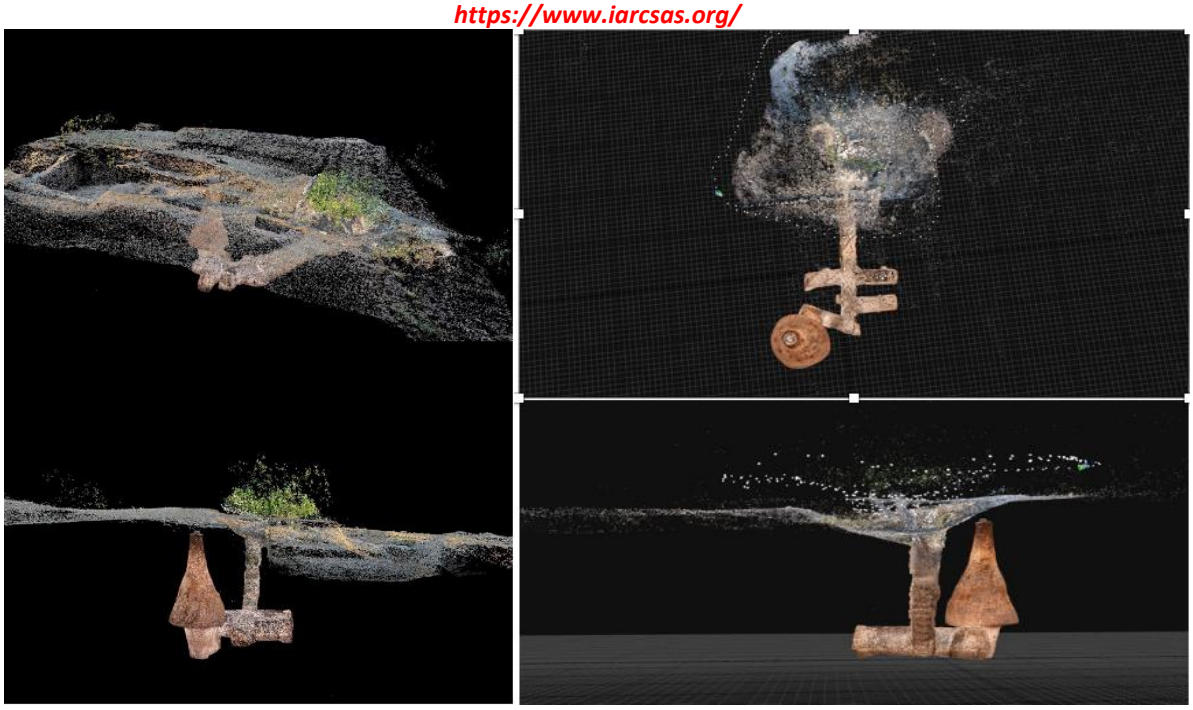

Figure 8-9. Final point cloud data

5. Photogrammetric Evaluation

The photogrammetric evaluation was carried out using Agisoft Metashape and EpicGames Reality Capture software. Metashape was used for the creation of orthomosaics, while Reality Capture was employed for 3D reconstructions. The orthomosaics presented in the figures were generated with a pixel size of 1 mm (Fig. 10-15). Due to the large amount of data, the 3D reconstruction was divided into 4 subsections. The models were exported in OBJ format and also published via the NIRA web viewer (Fig. 16).

Figure 10-11. Plan view and cross-section along the cistern

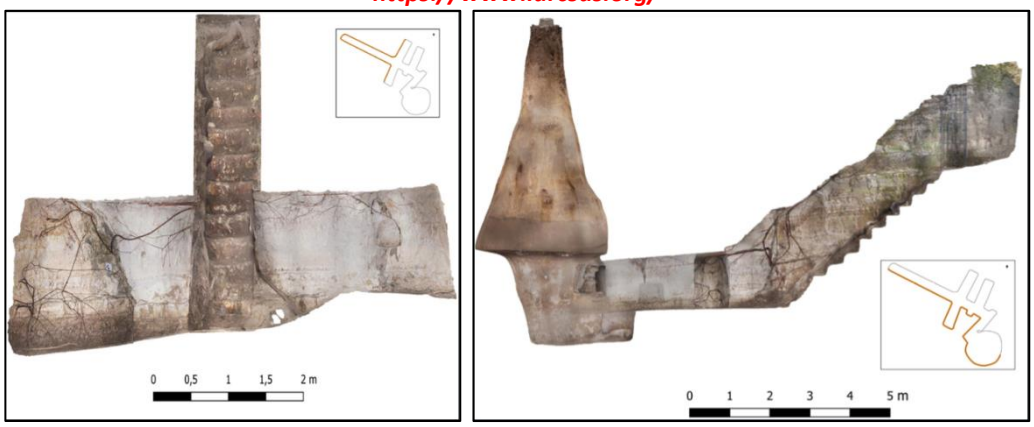

Figure 12-13. Cross section along the front niches and the staircase, and longitudinal section along the staircase

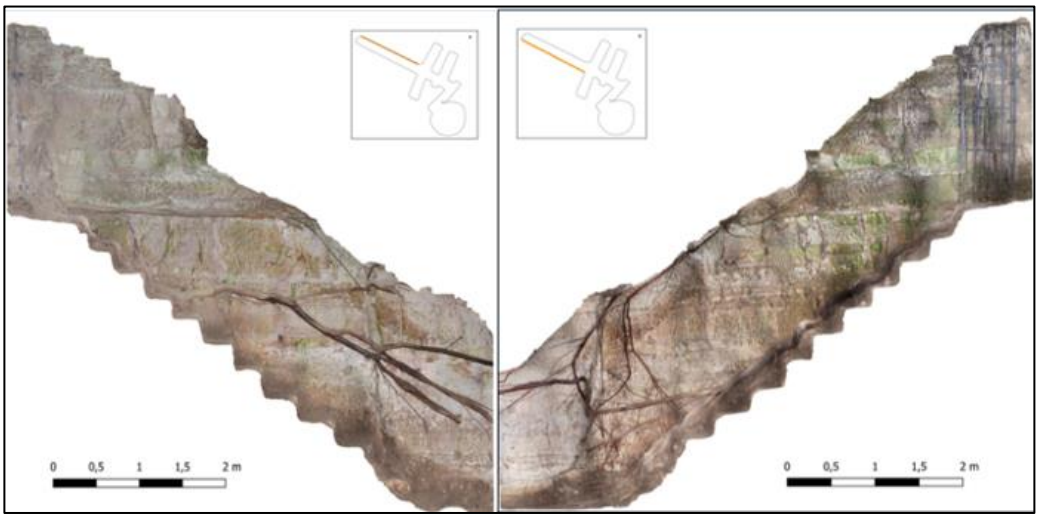

Figure 14-15. Detail views of the north and south walls of the staircase

Figure 16. Segmented 3D models

6. Architectural Documentation

Traditional speleological surveying methods were employed for the architectural documentation of the structure, and sketch drawings, as well as clinometer and compass readings were carried out. In order to complete the photogrammetric modeling and make the relationship between the above-ground structures and the cistern more comprehensible, photographs of the surface structures were also taken, marking the end of the fieldwork (Fig. 17).

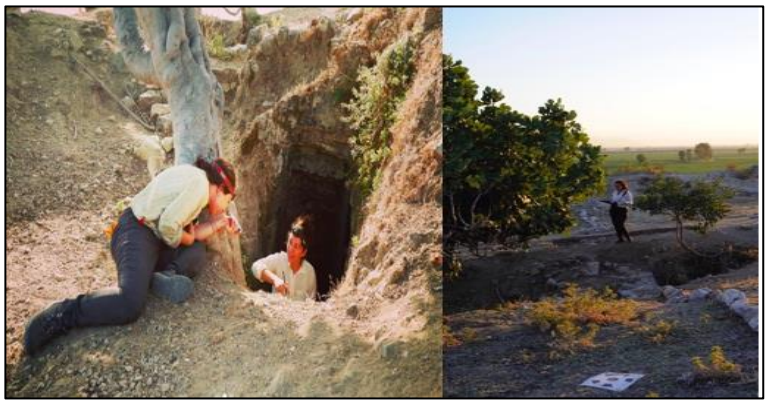

Figure 17. Architectural documentation process

After the completion of the fieldwork, the measurements obtained through traditional methods were entered into the Walls program, and base drawings were prepared. In Reality Capture and Agisoft Metashape, orthophotos were generated from point cloud data created by uploading the coordinates of the control points into the system, enabling architectural drawings to be produced (Fig. 18-19).

Once the orthophotos were finalized, measurements were verified on the photographs. Several points measured in the field were compared with the orthophotos, and drawings were initiated in AutoCAD. During the import of orthophotos into the program, special attention was paid to ensure that embedded GPS data were preserved (Fig. 19-20).

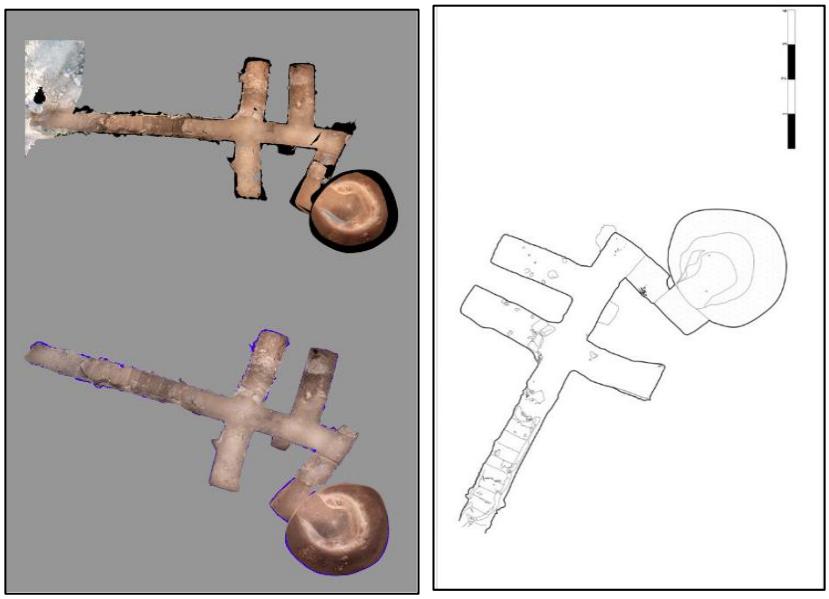

Figure 18-19. Orthoimages prepared for drafting and CAD drawings in AutoCAD

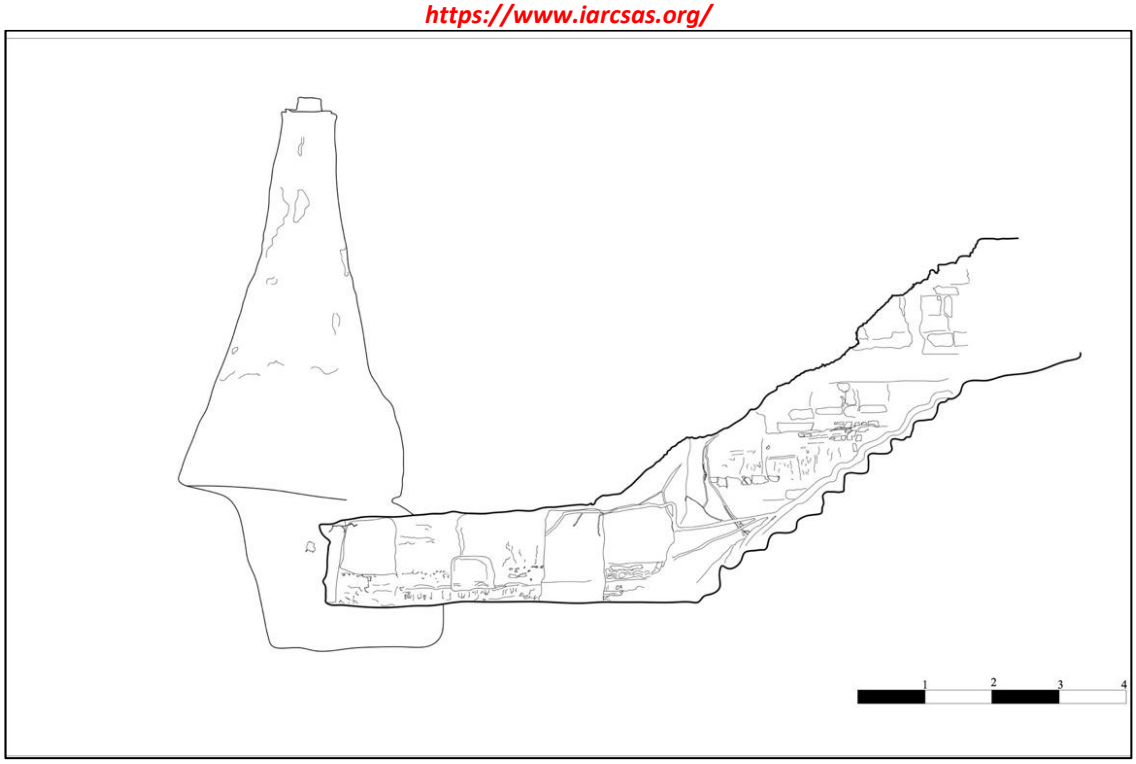

Figure 20. Final Drawing produced in AutoCAD

7. Conclusion and Recommendations

In the documentation of the structure, terrestrial and UAV-assisted photogrammetry were employed, and a terrestrial laser scan was additionally conducted using the Leica BLK 360. As the resulting model did not yield satisfactory results, these data were not used in subsequent processing steps. The execution of the photogrammetric survey ensured the acquisition of high-quality base data, from which high-resolution point clouds, textured 3D models, and orthomosaics could be generated.

The collected data provided a basis for comparing the photogrammetric analyses performed in Agisoft Metashape and Epic Games Reality Capture. The test series demonstrated that both programs have certain advantages and disadvantages: Reality Capture processes data much faster and can produce more complex results, but it frequently encounters error messages or interruptions. It can be said that improvements are needed in the visualization and editing of the results produced with this software. In contrast, Metashape generates less dense point clouds and meshes, requires longer processing times, but stands out as a more stable program, offering advantages in orthomosaic creation and 3D model editing. Desired results can be obtained with both software packages; however, each has its software-specific limitations. Nevertheless, both methods will continue to serve as important components in future projects. Considering that technological advancements have led to the optimization of processing algorithms and the development of more powerful computer components, facilitating the handling of large and complex datasets, it can be concluded that the methodology for architectural documentation will continue to evolve dynamically in the future.

Thanks and Information Note

This research was supported by the Scientific Research Projects Unit (BAP) of Mimar Sinan Fine Arts University (Project No: 2023-25). I would like to express my gratitude to

the Coordination Unit for their support. Part of the data presented in this study was also included in the master's thesis titled "Bauaufnahme einer antiken Zisterne auf der archäologischen Grabung in Milet, Türkei" (N. Techow, 2024), submitted to the Berliner Hochschule für Technik.

The article complies with national and international research and publication ethics. Ethics Committee approval was not required for the study. All authors contributed equally to the article.

Abstract

Architecture has been defined in various ways and scopes throughout history. At this point, it has relationships with many disciplines on experimental or theoretical planes. Cinema is one of many disciplines related to architecture. While architecture becomes an image of representation in reflecting reality for cinema, cinema is an important field of experimentation for architecture. In cinema, reality and believability are two important concepts in terms of establishing a connection between the viewer and the film. The viewer strengthens their perception of time and space through small images and symbols within the film. At this point, the film's questions of reality and believability are left behind, and its impact on the viewer is greater. The concepts of architecture and space are also important in this regard. This study evaluates the country of Numenor in The Lord of the Rings: The Rings of Power series, adapted from J.R.R. Tolkien's The Lord of the Rings book. The aim of the study is to highlight the importance of the subject in terms of the reflection of architecture's role in cinema on the audience and its relation to reality. Within the scope of the study, the country of Númenor was analyzed in terms of different spaces. At this point, a visual analysis method was applied using scenes to be used in the study. The cinematic spaces of Númenor were examined using specific parameters within the scope of architectural literature. The parameters used in the analysis were established as scale, material, form language, lighting, and perception. These parameters enabled a comprehensive evaluation of the scenes from a spatial and perceptual perspective.

Keywords: Architecture, cinema, Numenor, space

1. Introduction

Architecture is a discipline that works in conjunction with various other disciplines, exchanging contributions with many of them at this point. In addition to all this, the relationship between cinema and architecture is far ahead of others in terms of their contribution to each other. While cinema offers approaches that shed light on the future for architecture, architecture strengthens cinema's credibility with the audience and, in this way, causes the exchange of data between the audience and the director to develop. The reflection of various architectural elements in cinema is key to understanding the past, present, and future from the viewer's perspective. The viewer avoids questioning the film's reality with elements found in the past or present and becomes tightly bound to the fictional universe and plot created.

The relationship between cinema and architecture has been one of mutual influence and development since the very inception of cinema as a concept, rather than simply a progression from cinema to architecture. In her book, Katherine Shonfield states that she brings films into the field of architecture in terms of their visual, conceptual, and methodological aspects. She argues that films are created every day in cities, buildings, and rooms, and that every day architects and urban planners make decisions about cities, buildings, and rooms, and that their areas of expertise are the same, only that they live in different worlds (Shonfield, 2000). Walter

Benjamin, in his essay "The Work of Art in the Age of Mechanical Reproduction," which focuses on architecture and film, states that both art forms are actually based on the sense of touch. Benjamin emphasizes that the flow of cinema transforms individuals from spectators into disembodied observers and experiencers. Both architecture and cinema indicate a kinesthetic way of experiencing space, and images stored in memory are shaped as tactile retinal images (Benjamin, 1993). At this point, spaces are also considered an important tool. In cinema, elements contained within spaces allow for the observation of time, circumstances, sociology, and socio-economic conditions. Materials, designs, colors, and styles that reveal period traces in architecture are important elements within spaces.

In the field of architecture, the purpose of creating volume with vertical and horizontal elements is to ensure the creation of a sense of space. Perception describes the expression and reflection of experiences as part of the formation of space (Arayıcı, 2018). In other words, for space to be formed in a perceptual sense, it does not need to be a closed box. With the advancement of technological capabilities today, creating a sense of space is much easier. Various computer programs can be used to create non-existent spaces, or sets prepared in studio environments can be enriched with spaces prepared in various computer environments thanks to equipment such as green screens. The elements that constitute space are listed as natural space, artificial space, and mixed space, depending on the nature of the elements that limit the space. In addition, the area created by enclosing part of the physical space with walls and ceilings is called interior space, while the area outside this is called exterior space (Altan, 1993).

In cinema films, locations are divided into two categories: physical locations and fictional locations. Fictional locations are further divided into physical fictional locations and virtual fictional locations. Physical locations are spaces that can be perceived on a plane along with their materials, spaces whose existence we are certain of through all of our senses. Physical spaces can be described as areas that actually exist, are perceived by the senses, comply with human ergonomics and anthropological rules, and are constructed in real places for a specific purpose (Karaduman, 2021). Fictional spaces are spaces that exist in the imaginary world and have no connection to reality. Kavut defines fictional space as a space that exists outside of the time in which one is present and cannot be translated into reality (Kavut, 2021). At this point, it can also be defined as spaces that do not exist in real life but are prepared with vertical and horizontal structural elements in reality or in a computer environment. Physical fictional spaces can also be defined as spaces that do not exist in reality but are not confined to computer environments and drawings. These spaces are also physically present in the sets created using models or visual elements. The architectural elements desired in the set environment are discussed using various design sketches. Once the design is decided, it is produced by creating technical drawings. In fact, the same steps are applied in a manner similar to the process of creating real locations. Decorations are then built in the set where they are needed. Since these locations are used in the performing arts, they are usually produced on a one-to-one scale. However, they can also be produced on a smaller scale depending on the purpose in the film. Virtual fictional locations, on the other hand, are locations that cannot exist in reality. They are an important means of representation for the distant future or past on the timeline. Virtual fiction narrates events that humanity may encounter or has encountered in the past, present, or future. It is an effort to learn the truth or to imagine by taking people into the world of imagination (Büyükarman, Öztürk & Şahin, 2015). The depictions of the future, especially in science fiction films, can be predictive in terms of architectural space. At this point, when science fiction films from the past to the present are examined, it is clear that the predictions made for certain periods

have been proven in various ways. Along with this, it can also be defined as an important means of representation within fantasy cinema. Since many of the spaces depicted in these works cannot exist in reality, they are reflected to the audience through drawings made in a virtual environment, i.e., a computer environment. The spaces created do not undergo a production-related process. They exist in computer environments. For this reason, it is not possible to perceive them physically. The concept of cinematic space is also quite important in the continuation of these definitions. The concept can be defined as the design of a space in a film, approached from a general framework, whether virtual or physical. All types of set design, including outdoor, indoor, or virtual spaces created throughout the film, are included in this definition. Throughout the filming, in addition to spatial elements, all kinds of equipment, including the camera and shooting angles, ensure that the viewer internalizes the film and views events from a powerful perspective in terms of perception. As mentioned at the beginning, the concept of cinematic space also plays a very important role in bringing the viewer closer to reality. While the imaginary universe that the author of the film wants to reflect is supported in various ways, it is provided in various visual wholes to strengthen the viewer's perception. At this point, geographical conditions and architectural elements are important tools of representation. When viewers can establish a close relationship with reality and achieve integrity, the film becomes impressive for them. Along with the concept of cinematic space, the concept of cinematic memory is also important in this context. The concept can be defined as the strengthening of the perception of reality for viewers through the use of real architectural elements in spaces that do not exist in reality and are produced in various ways.

2. Materials and Methods

Viewers can establish a strong connection with reality by observing details such as real-world architectural elements and various geographical landscapes in cinematic settings. As a result, viewers can establish a connection between the film and reality and believe that the events in the film could have taken place at specific times and locations. For this reason, a strong perceptual relationship can be established between the film and the viewer. The elements that cause the connection with reality are usually processed as stimuli in small points in the background. At this point, the elements mentioned are evaluated within the scope of certain parameters. Scale is an important parameter in revealing the relationship that the space establishes with individuals. In monumental spaces, concepts such as pressure, authority, and power are conveyed to users (Ching, 2014). Material is also an important parameter. It provides clues about the culture and nature of the society in which the space is located. Furthermore, different materials are fundamental reasons for the variation in perception within spaces (Zumthor, 2006). Another parameter is form. It is important in terms of examining the characteristics and aesthetic concerns of the space. The arrangement of architectural elements, proportions, and style choices provide an opportunity to evaluate the identity of the space (Ching, 2014). Another parameter is lighting. Natural and artificial light have a significant effect on the perception of space. As a result, dramatic, oppressive, authoritarian, or similar aspects of the space emerge (Zumthor, 2006). Finally, perception is an important parameter. It emerges through the influence of other parameters. Through this parameter, the spirit of the space, user experience, and sensory effects are evaluated (Norberg-Schulz, 1980). These real-world elements, present in cinematic spaces, not only strengthen the audience's perceptual engagement with the plot but also increase their belief in visual elements. Therefore, the concept is particularly important for works in the fantasy or science fiction genres. According to Juhani Pallasmaa, cinematic space has the ability to evoke feelings such as fear, tension, and

pain in the viewer. It can revive the viewer's forgotten memories. For this reason, the viewer's relationship with reality can be strengthened (Pallasmaa, 2007). The Lord of the Rings film is one of the most important works reflecting the concepts mentioned above. There are thesis studies evaluating the film, and within the scope of this study, the country of Numenor from The Lord of the Rings: The Rings of Power series, which reflects the events that developed in the years before the films and is a current series, will be discussed. Although J.R.R. Tolkien does not provide extensive information about the city in his work, it has been constructed by designers in a manner consistent with Middle-earth, the universe created by Tolkien. The city, which has a strong connection to reality between the viewer and the work, is an important example within the scope of this study.

3. Findings and Discussion

Númenor is an island city that emerged in the middle of the Western Sea as a gift to humanity for the suffering they endured, following the war against the evil Lord Morgoth, where humans and elves lived together. The island is shaped like a five-pointed star. At its center lies a mountain called Meneltarma, considered sacred by the Númenóreans. Only the king or queen is permitted to speak upon this mountain. Furthermore, Númenor is regarded as having significant potential due to its rich mineral deposits, powerful forests, and abundant food sources. Many rich plant species unknown and non-existent in Middle-earth are found in abundance in Númenor. In short, it is clear that the Valar bestowed all their riches upon this island, a gift to humanity. The White Tree, one of the important symbols of this wealth, will later become a symbol in the cities of Gornor and Arnor, which will be built by humans. The White Tree has been regarded as a representation of the continuation of life, the abundance of resources, and freedom from extinction in Númenor's history. The fact that the Queen of Númenor, who responded negatively to the requests of the Elf Princess Galadriel, realized she had made a wrong decision when the leaves of the White Tree scattered and changed her mind is also a valuable example of the importance of this issue.

3.1. Entrance to Numenor

In the story, Elendil, Lord of Númenor, who rescued Lady Galadriel, is taking her to Númenor. In this context, Númenor appears before the audience depicted for the first time. Between two mountains with enormous trees at their peaks, the coastal city of Romenna in Númenor can be seen (Figure 1).

Figure 1. Entrance to Numenor. *The Lord of the Rings: The Rings of Power* (2022), Episode 3, 07:00.

As you enter the valley, you encounter enormous human figures carved into the rocks on the mountain slopes (Figure 2).

Figure 2. Entrance to Numenor. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 07:35

There is a large bridge near the city whose structure is supported by massive columns. The columns on the bridge are covered with equally massive sculptures, creating a sense of harmony with the valley. Ornaments similar to those on the tower continue along the bridge. (Figure 3).

Figure 3. Entrance to Numenor. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 08:04

Numenor is an island nation with a layered structure. The massive columns adorned with sculptures, frequently observed marble surfaces, stone texture, and color palette largely align with the characteristics of the Neoclassical architectural movement (Figure 4). As a result, the table has been created in this manner according to the specified parameters. (Table 1).

Figure 4. Entrance to Numenor. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 08:25

Table 1. Spatial Analysis of City Entrances (The Lord of The Rings: The Rings of Power, 2022)

ENTRANCE TO NUMENOR				
				
SCALE	**MATERIAL**	**FORM**	**LIGHTING**	**PERCEPTION**
It is a valley formed by sculptures between two mountains on a large scale.	The stonework and entrance bridge feature gold-detailed column carvings.	As you approach the valley, there is a monumental bridge and tower. Along with this, there is a symmetrical arrangement of monumental structures throughout the valley.	There is a torch in the welcome tower to signal ships approaching the city across the valley. However, there is no other light source besides natural light.	The monumental structures and colossal statues in the valley represent the city's splendor and grandeur.

3.2. Port

There are many boats in the harbor. Blue marble and paint are used in places on the walls surrounding the harbor. Vertical lines find their place in many places in magnificent and imposing shapes. As this is a port city, chaos and noise prevail in the harbor areas. Various barrels and sacks are scattered around (Figure 5). Numenor is a country where trade is conducted and fertile lands are abundant.

Figure 5. Port. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 08:50

3.3. Street Texture

In the streets of Numenor, stone textures and blue paint are frequently preferred. As Numenor is an island nation, choices such as the sun, stars, and blue color—considered sacred as guides—are consistently used. Minimalist decorations are also found along the city streets. Hanging plants are used in some places. Various ground elements are observed along the streets. Irregular cobblestones are used on the street surfaces. (Figure 6).

Figure 6. Numenor Streets. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 09:10

In the sections closer to the square, larger blocks of stone are used. Decorative and period-style fixtures are used on the walls for street lighting. Shops where crafts are made are observed on the ground floors of the buildings in the square (Figure 7).

Figure 7. Numenor Streets. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 10:09

In Numenor, establishments such as bars and bakeries welcome their guests at tables and chairs placed on the streets. The venue is painted in blue and white. Wooden details are frequently used. The dining tables are also made of wood. Other shops and streets in the city can also be seen in this scene. Along with blue and white, yellow is used to represent the sun on the Numenor flag. The tables and chairs are covered with fabrics featuring various local symbols. In addition, plants are used at various points in the venue and at certain locations on the street where the venue is located. (Figure 8).

Figure 8. Numenor Streets. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 31:39

The streets in the outlying areas of the city are almost entirely dominated by stone masonry when compared to other streets. The use of paving stones is evident on the ground. Furthermore, stone masonry is also used on the wall surfaces (Figure 9). As a result, the table has been created in this manner according to the specified parameters (Table 2).

Figure 9. Numenor Streets. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 32:22

Table 2. Spatial Analysis of Numenor Streets (The Lord of The Rings: The Rings of Power, 2022)

STREET TEXTURE				
				
SCALE	**MATERIAL**	**FORM**	**LIGHTING**	**PERCEPTION**
These are generally medium and small sized venues.	The streets of Numenor are dominated by stone. Marble is also used at certain points to adorn doorways. Hanging plants are frequently found along the streets.	It is a symmetrical arrangement surrounding the city square in a simple and classical style.	Ornate, art deco style fixtures were used on the walls for street lighting.	In certain areas, a perception has been created that streets that are understood to be secluded but close to the city square are densely populated and used by everyday people.

3.4. City Square

Numenor City Square appears to be built on a large area. Stone and marble constitute the majority of the surface materials in this space. A structure that appears to be significant among

the elements above is covered with blue tiles up to a certain height, and sculptures have been placed in front of it to highlight its aesthetic appeal. This structure possesses enormous dimensions far exceeding human scale and detailed carvings created with geometric forms. (Figure 10).

Figure 10. City Square. *The Lord of the Rings: The Rings of Power* (2022). Episode 4, 07:22

3.5. Numenor Palace

This palace, which frequently uses stone and marble textures befitting the splendor of Númenor, stretches from the edge of the valley to its peak. The semicircular opening on the front facade of the palace opens onto a courtyard featuring the White Tree, one of the important symbols of Númenor. From this area, there is a water flow extending down to the lower valley (Figure 11), (Figure 12), (Figure 13).

Figure 11. White Tree. *The Lord of the Rings: The Rings of Power* (2022). Episode 4, 01:03:41

Figure 12. Numenor Palace. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 10:13

Figure 13. Numenor Palace. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 10:21

Inside the palace, there is a circular area surrounded by magnificent columns. The interior of the columns is used as a gathering place for Numenor meetings, while the outer area serves as an entrance corridor (Figure 14).

Figure 14. Numenor Palace. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 10:32

One side of the corridor faces the open assembly hall, while the other side consists of a closed wall. Blue paint is visible along the wall surface, and a wide door is visible in one section of the wall. There are carvings on the door. To the right and left of the door, there is a protrusion separate from the wall surface. This area appears to be covered with cream-colored marble. Continuing from the entrance corridor, there is a staircase leading to the aforementioned gathering space. It is evident that the entrance to the gathering space is a few meters lower than the entrance corridor. Marble cladding is used on the areas on the right and left sides of the entrance staircase. At the turning points of the marble cladding, there are gold-detailed carvings (Figure 15).

Figure 15. Numenor Palace. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 11:05

The space is predominantly characterized by marble and blue paint textures. Marble is used in areas intended for customization, such as the columns and the queen's throne. As seen on the entrance stairs, gold detailing adorns the marble surfaces throughout the space. Behind the queen's throne, curtains with burgundy and gold details are used. A large chandelier is used above the throne. Along with this, marble is used on the floor, which is at a different level from the throne. A burgundy carpet is placed on the marble floor. Light is seen coming from certain places to some of the people in the space. Therefore, it is clear that there are openings in certain sections of the ceiling (Figure 16).

Figure 16. Numenor Palace. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 11:59

The dome is encircled by gold-embellished bands. Additionally, protrusions made of marble cladding are located on both sides of the opening. These marble cladding surfaces feature gold-detailed embellishments. The marble flooring surrounding the right and left sides of the space consists of a few centimeters of elevation difference. The floor line is completed in the section where the opening is located (Figure 17).

Figure 17. Numenor Palace. *The Lord of the Rings: The Rings of Power* (2022). Episode 4, 03:59

Gold-colored chandeliers are used to illuminate this space. Transparent white material is used at the points where the chandelier light is emitted. The connections are also made of gold-colored chains (Figure 18). As a result, the table has been created in this way according to the specified parameters (Table 3).

Figure 18. Numenor Palace. *The Lord of the Rings: The Rings of Power* (2022). Episode 4, 03:56

Table 3. Spatial Analysis of Numenor Palace (The Lord of The Rings: The Rings of Power, 2022)

NUMENOR PALACE				
				
SCALE	**MATERIAL**	**FORM**	**LIGHTING**	**PERCEPTION**
It is monumental in scale, and individuals appear quite small in comparison to the structure.	The gold details on the marble and columns are the standout materials for this space.	The entrance axis of the building features oval lines. Meanwhile, the space where the Queen's throne is located occupies a circular area. The palace is designed around a central system.	There is a powerful light coming from the dome at the center of the space. It is evident that there are openings in the ceiling of the space. Additionally, it is used in classic chandeliers.	By designing the space around an oval axis and placing the Queen's throne at its center, it reinforces the perception of power and authority.

3.6. Library

The library is generally a quiet and dark structure. Although dark tones are generally preferred, red is also used in the wall details. Documents rolled up are placed on black metal shelves. Small fixtures in metallic black are used for lighting. Above the red wall surface is a painting depicting prominent figures of the Elf race attending the library's opening. Immediately in front of it is a table made of dark wood (Figure 19).

Figure 19. Library. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 34:30

3.7. Prison

Numenor Prison consists of small dungeons built around a large hall. A large statue occupies the center of the hall. Large, ornate columns surround the statue. The surfaces are generally marble with a blue color reminiscent of ocean waves. Stone is used for the walls inside the dungeons. There is no light except for a small light source coming from the hall. Inside the dungeons, there are narrow windows through which natural light can enter. The dungeon doors are also made of iron and have ornate frames (Figure 20), (Figure 21).

Figure 20. Prison. *The Lord of the Rings: The Rings of Power* (2022). Episode 3, 54:23

Figure 21. Prison. *The Lord of the Rings: The Rings of Power* (2022). Episode 4, 11:29

The prominent locations of Númenor are compiled in the table below along with specific parameters. The locations were examined in terms of scale, material, form language, lighting, perception, and atmosphere (Table 4).

Table 4. Analysis Table Based on Spatial Parameters (The Lord of The Rings: The Rings of Power, 2022)

SPACE	SCALE	MATERIAL	FORM	LIGHTING	PERCEPTION
CITY ENTRANCE	Large Scale	Stone Texture	Symmetrical Array	Natural Light Source	Magnificence
PORT	Large Scale	Stone Texture and Wooden Skeleton	Functional and Distributed Array	Natural Light Source	The Wealth of Port Trade
STREET TEXTURE	Medium and Small-Scale Spaces	Stone Texture	Scattered Array	Natural Light Source and Ornamental Metal Lighting Fixture	Suitable for Daily Life
CITY SQUARE	Large-Scale Public Spaces	Stone Texture	Symmetrical Array	Natural Light Source and Ornamental Metal Lighting Fixture	Social Unity
NUMENOR PALACE	Monumental Scale	Stone Texture and Gold Embroidery	Center-Focused Array	Natural Light Source and Ornamental Metal Lighting Fixture	Magnificence and Power
PRISON	Small Scale	Stone Texture	Symmetrical Array	Natural Light Source and Torch	Atmosphere of Darkness and Loneliness
LIBRARY	Medium Scale	Metallic Surface and Wood Texture	Asymmetrical Array	Natural Light Source and Ornamental Metal Lighting Fixture	Rich Source

4. Conclusion and Recommendations

Within the scope of this study, the locations belonging to the city of Numenor depicted in The Lord of the Rings: The Rings of Power series were evaluated in terms of scale, material, form, lighting, and perception parameters. As a result, it was observed that the credibility of

completely fictional locations from the viewer's perspective is enhanced not only by visual aesthetics but also by the use of historical and architectural elements.

In this context, the presence of period architectural traces in spaces causes the viewer to situate the story within a historical timeline. Although the design elements in spaces do not directly refer to a specific period, they suggest the existence of a historical process to viewers. For example, metallic surfaces evoke associations with the beginning of the industrial age, while stone and wood-textured surfaces remind viewers of the architectural styles of earlier periods. In this context, even if architectural details are not specifically emphasized for particular periods, they reinforce viewers' belief in the narrative by evoking various reminders in their historical memory.

The data obtained as a result of all this shows that cinema is not just a backdrop for events, but an important tool for strengthening the bonds with the audience in terms of credibility. It is clearly demonstrated that architectural elements contribute to the credibility of cinematic spaces. Furthermore, the use of period symbols and styles in spaces plays an important role in making fictional spaces appear real to the audience.

Abstract

The construction industry has reached a critical stage, accounting for almost 40% of global energy use and greenhouse gas emissions. Steel structures offer major sustainability benefits, including a high strength-to-weight ratio, flexibility, industrial production suitability, and recyclability, yet they also produce significant carbon emissions throughout their life cycle. Integrating Building Information Modeling (BIM) in early design stages is therefore crucial to embed sustainability within digital design processes, as traditional methods remain insufficient to meet environmental goals. This study examines the integration of BIM and Life Cycle Assessment (LCA) to assess sustainability in steel bridge and tower projects. BIM consolidates multidisciplinary data into a single 3D model, while LCA quantifies environmental impacts such as carbon footprint, energy use, and waste generation.Six case studies were analyzed: 1915 Çanakkale, Osman Gazi, and Yavuz Sultan Selim Bridges in Türkiye, and Akashi-Kaikyo (Japan), Russky (Russia), and The Blade (Saudi Arabia), using A1–A5 life cycle modules. Results show 10–25% carbon reductions, 8–22% energy savings, and 10–20% lower maintenance costs, extending service life by up to 20 years. Findings highlight the importance of early digital simulations for material and energy optimization. To encourage BIM–LCA adoption in Türkiye, the study recommends regulatory incentives, green financing tools, professional training, and digital twin integration to advance sustainable steel construction.

Keywords: BIM, LCA, sustainability, steel structures, carbon emissions, energy efficiency

1. Introduction

1.1. Background of the Study

The construction sector accounts for 34% of global energy consumption and 37% of CO_2 emissions from energy use (IEA, 2023; UNEP, 2022). These alarming figures underline the industry's decisive role in global climate action. Steel structures, particularly bridges and high-rise towers, are fundamental components of contemporary engineering due to their exceptional strength, flexibility, and adaptability to industrial production methods.

Yet, the environmental cost of steel production, characterized by energy-intensive processes and substantial CO_2 emissions, poses significant challenges to sustainability.

In this context, sustainable design practices have become indispensable. The increasing adoption of Building Information Modeling (BIM) provides opportunities for early-stage environmental analysis and optimization. BIM enables a data-driven design process in which environmental parameters such as embodied carbon, energy use, and material quantities can be monitored and optimized from the conceptual phase onward. When combined with Life Cycle Assessment (LCA), BIM extends its scope beyond visualization and coordination, enabling quantitative evaluation of a project's sustainability performance.

1.2. Problem Statement

Although steel structures are inherently recyclable—reaching up to 90% recyclability rates—the potential for sustainability optimization is often underutilized. In many cases, sustainability considerations are incorporated only in later stages, after design decisions are already finalized. This delayed approach limits opportunities to minimize embodied carbon, energy consumption, and material waste.

Traditional design workflows focus primarily on structural safety and cost-effectiveness, with limited integration of environmental data. As a result, critical decisions regarding material selection, transportation, and construction logistics are made without holistic evaluation of their life cycle impacts. Consequently, the construction sector faces persistent challenges in aligning economic efficiency with environmental sustainability.

1.3. Research Aim

The purpose of this study is to investigate the environmental, economic, and operational impacts of BIM–LCA integration in large-scale steel projects and to perform a comparative analysis between Turkish and international case studies. Specifically, the research aims to:

- Quantify reductions in carbon emissions, energy use, and maintenance costs through BIM–LCA integration.
- Compare the performance of Turkish mega bridge projects with international counterparts.
- Identify the contribution of digital tools—such as BIM, LCA, and digital twins—to enhancing sustainability outcomes.

1.4 Significance of the Study

This research contributes to Türkiye's goal of achieving net-zero carbon emissions by 2053. The study emphasizes that the integration of BIM and LCA enables early, data-driven decision-making, which can yield measurable improvements in environmental and economic performance. Moreover, it highlights the importance of digital transformation in construction, offering a framework through which engineers, contractors, and policymakers can coordinate sustainability strategies more effectively.

1.4. Literature Review

1.4.1. Building information modeling (BIM) and sustainability

Building Information Modeling (BIM) represents a paradigm shift in the construction industry. As a process integrating all project disciplines within a shared digital model, BIM facilitates collaboration, reduces information loss, and enables accurate simulation of real-world performance. Beyond coordination and visualization, BIM has evolved into a critical sustainability tool.

According to Azhar (2017), BIM provides a platform for early-stage energy simulations, carbon footprint assessments, and material optimization, allowing designers to make informed choices that minimize environmental impact. The use of parametric modeling enables automatic recalculation of quantities and energy consumption as design changes occur. These capabilities transform sustainability from a post-design verification process into an integral design driver.

Research by Wang and Chong (2022) further demonstrates that integrating BIM with life cycle cost analysis can reduce operational costs by 10–20%. In steel construction, where prefabrication and modular assembly are common, BIM supports precise material estimation, waste reduction, and improved logistics—all of which contribute to environmental and financial sustainability.

1.4.2. BIM Applications in Steel Structures

Steel structures stand out for their durability, strength-to-weight ratio, and recyclability. However, they are also energy-intensive to produce. Ding (2020) reported that steel production contributes substantially to global industrial carbon emissions. Early-stage integration of BIM helps mitigate these impacts by enabling optimization of prefabrication, transport, and on-site assembly.

For example, in the Akashi-Kaikyo Bridge project in Japan, digital modeling was later incorporated into an existing traditional design, enabling post-construction data integration and maintenance tracking. In Russia's Russky Bridge, BIM-based simulations were used to assess aerodynamic behavior under extreme wind loads, improving both safety and efficiency. In Saudi Arabia, *The Blade* tower project leveraged BIM-integrated digital twin systems and IoT-based monitoring, achieving a 22% improvement in energy efficiency (Lu et al., 2021).

These examples show that BIM not only enhances constructability but also provides measurable sustainability gains through performance monitoring, resource optimization, and lifecycle management.

1.4.3. Integration of BIM and LCA

The integration of BIM and Life Cycle Assessment (LCA) enables lifecycle-based computation of carbon emissions, energy consumption, and waste generation using data extracted from BIM models. International standards—namely ISO 14040/44 and EN 15978—structure the building lifecycle into distinct modules: A1–A3 (product stage: raw material supply, transport, and manufacturing), A4–A5 (construction process: transport to site and installation), B1–B7 (use stage: operation, maintenance, repair, replacement, refurbishment, operational energy and water use), C1–C4 (end-of-life: deconstruction, transport, waste processing, and disposal), and D (benefits and loads beyond the system boundary, including recycling and reuse) (EN 15978, 2011).

Abanda and Byers (2016) show that rigorous data mapping between BIM elements and LCA datasets can improve the accuracy of carbon accounting by up to 15%. Complementarily, Ding (2020) reports that in large-scale projects, BIM–LCA integration can reduce environmental impacts by 10–25%. These findings underline the value of linking model-based quantities (e.g., structural steel tonnage, connection types, coating systems) to environmental datasets to produce consistent and traceable results across project stages.

1.4.4. Digital Twin Technologies and the Internet of Things (IoT)

In recent years, digital twin technologies have extended the capabilities of BIM by creating a live, cyber-physical representation of the asset. Through IoT sensors, condition monitoring, and analytics, digital twins enhance operational efficiency and sustainability during the use phase. Lu et al. (2021) demonstrate that integrating digital twins can lower maintenance costs by up to 20% through predictive and condition-based strategies. In *The Blade* project, a BIM-integrated digital twin with IoT-supported monitoring achieved a 22% reduction in energy consumption and transitioned maintenance planning from periodic to data-driven practices.

This continuous feedback loop allows operational decisions (e.g., HVAC scheduling, façade control, or structural health monitoring) to be optimized in near real time.

1.4.5. Research Gaps in the Literature

A review of the extant literature highlights several gaps:
• **Scale and typology:** Most BIM–LCA studies focus on buildings; research for mega-scale steel bridges and towers remains limited.
• **Empirical validation:** Many contributions are theoretical or simulation-based; real-world case studies with measured outcomes are scarce.
• **Integrated ecosystems:** Studies that jointly examine BIM–LCA with digital twins and IoT are emerging but still few in number, limiting best-practice consolidation and benchmarking.

2. Materials and Methods

2.1. Research Approach

This study adopts a comparative case study approach combining both qualitative and quantitative methods.The aim is to evaluate the effects of BIM–LCA integration on the sustainability performance of steel structure projects.The research does not involve direct modeling or software-based LCA calculations.
Instead, it focuses on the systematic collection, analysis, and comparison of existing project data.Therefore, the study is based on secondary data analysis.

Six mega steel structure projects were selected as case studies: 1915 Çanakkale Bridge, Osman Gazi Bridge, Yavuz Sultan Selim Bridge, Akashi-Kaikyo Bridge (Japan), Russky Bridge (Russia), and The Blade Tower (Saudi Arabia).

These projects were chosen to represent different geographical regions and levels of digitalization maturity, enabling a comparative assessment of BIM–LCA applications and their environmental outcomes.

2.2. Data Collection Process

In the first stage, technical, environmental, and operational data were collected for the six selected projects.
Data were obtained from official government reports, academic studies, and technical bulletins published by engineering firms.

- For Turkish projects (1915 Çanakkale, Osman Gazi, Yavuz Sultan Selim): Data were gathered from the *Ministry of Transport and Infrastructure's Mega Projects Reports*, publicly available project documents, engineering presentations, and national academic proceedings.

- For international projects (Akashi-Kaikyo, Russky, The Blade): Data were derived from case studies published in *Journal of Cleaner Production*, *Automation in Construction*, and *Sustainable Cities and Society*, as well as from environmental impact assessment (EIA) reports.

All data were categorized under four main headings:

1. **Material usage:** steel quantity, section type, production process.
2. **Energy consumption:** energy used during production, transport, and erection.

3. **Carbon emissions:** reported embodied carbon values ($kgCO_2$/ton).

4. **Operational indicators:** recycling rate, maintenance frequency, and service life.

2.3. BIM–LCA Integration (Theoretical Framework)

In this study, BIM–LCA integration was not applied directly through software, but rather analyzed conceptually based on documented real-world applications in literature.

In general, BIM–LCA integration occurs when quantitative data (material quantities, transport distances, energy data) extracted from a BIM model are imported into an LCA calculation system.
In this study, that process was analyzed through previously documented case studies rather than direct modeling.

The level and purpose of BIM use in each project were examined:

- In some cases, BIM was used mainly for design coordination and quantity take-off,
- In others, it was used for environmental analysis, energy simulations, and digital twin applications.

These varying levels of BIM implementation were compared with the reported LCA outcomes (such as carbon emission reduction and energy efficiency improvements). Thus, the impact of BIM–LCA integration on environmental performance was evaluated indirectly through existing datasets rather than primary calculations.

2.4. Software and Tools

No BIM or LCA software was directly used during the study. However, to define the methodological framework, commonly referenced software tools in similar studies were acknowledged:

- Autodesk Revit: Used for BIM modeling and quantity extraction.
- One Click LCA: Used to transform BIM data into environmental impact calculations following EN 15978 standards.
- Excel & SPSS: Used for organizing, analyzing, and visualizing collected numerical data.

These tools were not directly applied in the analysis but are cited as the methodological foundation for the study's comparative approach.

2.5. LCA Modules

The scope of the LCA analysis followed the EN 15978 standard, focusing mainly on A1–A5 modules:

- A1–A3: Material production and embodied carbon.
- A4: Transport and fuel consumption.
- A5: Construction site activities and waste generation.

Additionally, C and D modules (recycling and recovery potential) were only qualitatively evaluated, not quantitatively analyzed.

2.6. Comparative Case Analysis

The collected data were comparatively analyzed based on environmental, economic, and operational performance indicators.

Evaluation criteria:

1. **Environmental Performance:** carbon emissions ($kgCO_2$/ton), energy consumption (MJ), recycling rate (%).
2. **Economic Performance:** material cost, maintenance and operational expenses.
3. **Operational Performance:** service life, maintenance frequency, digital twin integration.
4. **Sustainability Contributions:** waste reduction, reuse potential, carbon management practices.

All data were normalized (e.g., emissions per ton of steel) and ranked by performance levels. It was observed that projects with higher BIM implementation levels, such as *The Blade* and *Akashi-Kaikyo*, achieved significantly better environmental performance. This indicates a clear correlation between digitalization maturity and sustainability performance.

2.7. Validation through Literature

The findings were compared with results from prior studies, such as Ding (2020) and Lu et al. (2021), which reported 10–25% carbon emission reductions through BIM–LCA integration. The consistency between these findings confirms that the present study aligns with both academic literature and real-world evidence.

3. Findings and Discussion

3.1. Carbon Emissions

BIM–LCA assessments showed considerable variation in carbon emissions across projects, primarily reflecting differences in steel quantities, structural systems, and logistics. The large Turkish bridges—1915 Çanakkale, Osman Gazi, and Yavuz Sultan Selim—demonstrated high embodied carbon due to substantial steel tonnages and complex erection sequences. By contrast, *The Blade* exhibited lower net emissions after optimization, supported by model-based coordination, energy-focused design choices, and operations-stage efficiency measures enabled by its digital twin.

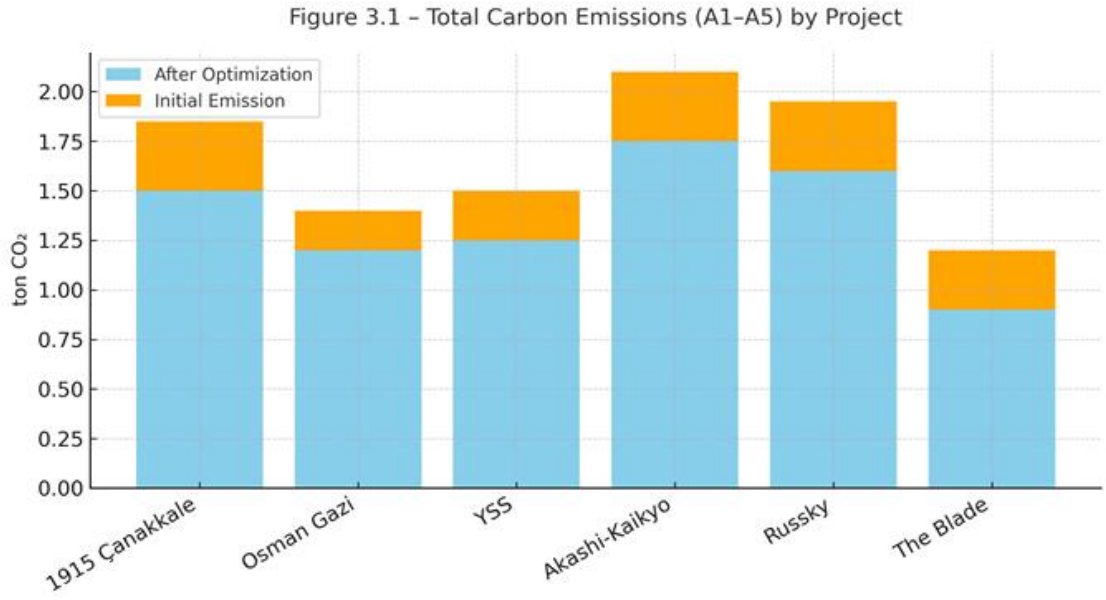

Figure 3.1. Total Carbon Emissions (A1–A5) by Project.
As indicated in Figure 3.1, the **largest post-optimization reduction—25%—was observed in *The Blade***, corroborating literature-reported ranges for large projects.

3.2. Recycling Rates

Steel's recyclability strongly supports circularity objectives. Across the analyzed projects, recycling rates ranged from 70% to 95%.

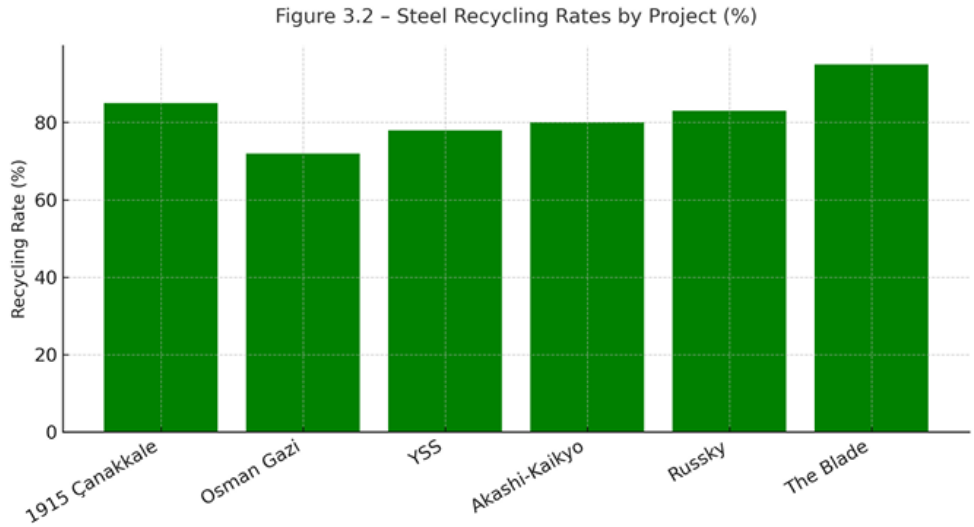

Figure 3.2. Steel Recycling Rates by Project (%)

Figure 3.2 shows that ***The Blade*** **achieved the highest recycling rate (95%)**, while **Osman Gazi** recorded the lowest (72%). Differences reflect procurement strategies, local recycling infrastructure, and specification requirements for recycled content.

3.3. Energy Efficiency Gains

Energy performance gains attributable to BIM-enabled optimization and, where applicable, digital twin operations varied across cases.

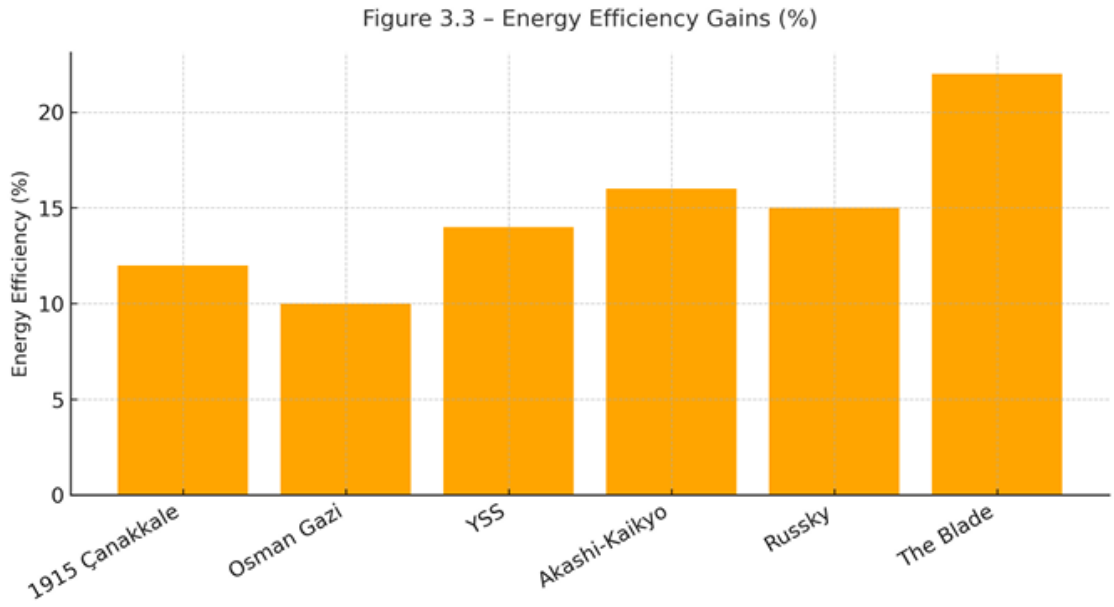

Figure 3.3. Energy Efficiency Gains (%)

As seen in Figure 3.3, ***The Blade*** **achieved the highest energy efficiency improvement (22%)**, whereas **Osman Gazi** registered approximately **10%**, pointing to divergent scopes of digitalization and operations-stage monitoring.

3.4 Discussion

The six case studies represent a spectrum of technological maturity and institutional contexts. In Türkiye, BIM is predominantly applied for coordination, clash detection, and construction planning—yielding time/cost benefits and improved constructability. In contrast, international cases—particularly *The Blade*—demonstrate extended digitalization, including digital twins, IoT integration, and AI-assisted energy monitoring, which translate to measurable operational sustainability gains.

When compared with literature, the observed carbon reduction levels (15–25%) align with Ding (2020) and Lu et al. (2021). Turkish bridges achieved ~15–20% reductions, whereas *The Blade* reached ~25%. This spread can be attributed to:

- **Regulatory frameworks and certification regimes** (e.g., LEED/BREEAM alignment driving documentation and continuous monitoring),
- **Supply chain capabilities** (availability of low-carbon steel, EPD coverage, and recycling infrastructure),

- **Digital maturity** (extent of BIM use beyond geometry—data standards, LCA mapping quality, and live operational feedback loops).

While Turkish mega bridges are remarkable engineering achievements, sustainability-focused data integration is still evolving. Consolidated national standards and public procurement incentives could accelerate practices such as low-carbon material selection, data-rich BIM execution plans, and mandatory lifecycle reporting.

4. Conclusion and Recommendations

4.1. Conclusion

This study confirms that BIM–LCA integration in steel structures can deliver substantial environmental and economic benefits. The case analyses indicate potential carbon reductions of 15–25%, recycling rates of 70–95%, and energy efficiency gains of 10–22%. Importantly, BIM–LCA proves valuable not only at the design stage but across construction and operations, functioning as a comprehensive sustainability management framework. Comparative results also reveal that performance is shaped by technology, institutional capacity, and regulatory context. While Turkish projects leverage BIM primarily for schedule and cost control, international exemplars show how standardized data protocols, certification alignment, and operations-driven digitalization can elevate environmental outcomes. Achieving the full potential of BIM–LCA will therefore require coordinated action across policy, finance, and education.

4.2. Recommendatıons

To mainstream BIM–LCA in steel projects, the following actions are recommended:

1. **Regulatory Integration:** Mandate BIM-based LCA in design submissions and align with **EN 15978** and recognized green certification systems (LEED, BREEAM). Require disclosure of embodied carbon (A1–A5) and, where feasible, end-of-life scenarios.

2. **Green Finance:** Deploy carbon credits, green bonds, and preferential financing to de-risk sustainability investments and prioritize low-carbon procurement.

3. **Technology Enablement:** Encourage digital twin deployment with IoT sensors and analytics/AI for continuous performance tracking (energy, condition, and carbon dashboards).

4. **Operational Circularity:** Require recycling and reuse plans in project execution, including targets for recycled content, take-back schemes, and traceable waste management.

5. **Capacity Building:** Establish BIM–LCA-focused university curricula and professional training; develop national BIM execution guidelines emphasizing LCA data structures, dataset mapping, and EPD usage.

Ultimately, BIM–LCA constitutes a powerful lever for achieving sustainability goals in steel structure projects. Realizing its benefits at scale depends on a holistic approach that couples digital technologies with policy instruments, financial incentives, and skills development.

Abstract

Disasters cause physical destruction, creating an urgent need for shelter. Meeting this need quickly and effectively in the post-disaster period and providing living comfort for disaster victims is of great importance. To this end, public institutions develop standardized housing projects to enable rapid post-disaster housing production. While these projects offer advantages in terms of speed and cost efficiency, they often overlook local climatic conditions, leading to long-term problems in environmental comfort. This study aims to evaluate the impact of climatic and regional differences on disaster housing design and the adequacy of standardized housing projects in this context. The research examines projects proposed for the provinces of Diyarbakır, Erzurum, Elazığ, Konya, Manisa, Adana, Bursa, and Ordu, located in different climate regions. Standard housing plans recommended by the Republic of Türkiye Ministry of Environment, Urbanisation and Climate Change were assessed in terms of compact massing, spatial organization, facade orientation, natural ventilation, and energy efficiency, considering climate and geographic context. The results show that standardized projects are insufficient in terms of regional and climatic adaptation. In hot and dry climates, the lack of natural ventilation and shading strategies is notable, while in cold climates, facade designs increase heat loss. In conclusion, although standardized housing projects allow rapid and cost-effective responses to post-disaster shelter needs, neglecting climatic conditions reduces long-term quality of life for users. Therefore, post-disaster housing production should prioritize plan types that are sensitive to local climatic conditions and ensure sustainable environmental comfort, alongside speed and cost considerations.

Keywords: Disaster Housing, Standardized Projects, Regional Differences, Climatic Adaptation, Environmental Comfort

1. Introduction

Disasters are defined as natural, technological, or human-induced events that directly affect human life, settlement patterns, and social structures; cause physical, economic, and psychological losses; disrupt normal living conditions; and cannot be managed with local resources alone. Due to its geographical location, position on an active tectonic belt, diverse geological/topographical characteristics, and the coexistence of various climatic zones, Türkiye is exposed to multiple natural disasters, particularly earthquakes.

Disasters such as earthquakes, floods, landslides, and wildfires not only result in physical destruction but also generate profound social, economic, and psychological impacts (Limoncu

& Bayülgen, 2005; Yılmaz, 2021). In the post-disaster period, achieving both spatial and individual recovery is possible only through rapid, effective, and sustainable interventions by relevant state institutions. In this context, meeting shelter needs involves not merely providing a physical dwelling, but also re-establishing living quality, safety, and comfort conditions in a sustainable manner.

Standardized housing projects, commonly employed in post-disaster reconstruction, often lead to significant problems due to the neglect of climatic differences across regions. Owing to its latitudinal position, Türkiye accommodates multiple climatic zones. This climatic diversity requires parameters such as temperature, humidity, wind direction, precipitation, and solar exposure to be considered in spatial organization, material selection, and building form. Consequently, applying the same housing typology in different climatic regions may be unsuitable in terms of both energy efficiency and indoor comfort. The country's broad geographical characteristics therefore necessitate a design approach that responds to regional environmental conditions and is compatible with diverse climate types (Ç. B. Dikmen, 2011; Kısa Ovalı, 2019; Koca, 2006). For instance, in cold climates, compact layouts that minimize heat loss and orient toward the south are key design principles, whereas in hot-dry regions, courtyard-based, permeable, and shaded spatial arrangements are essential for balancing indoor temperatures. In highly humid areas such as the Black Sea Region, natural ventilation, facade openings, and breathable materials become crucial. However, when standard designs are implemented without considering such climatic requirements, users are forced to inhabit thermally and psychologically uncomfortable spaces, while energy consumption and maintenance costs increase (Ç. B. Dikmen, 2011; Kısa Ovalı, 2019; Koca, 2006).

Therefore, the main objective in post-disaster housing design should not be limited to ensuring structural safety; it should also focus on developing housing types that are compatible with local climatic data, adopt passive design strategies, offer high energy efficiency, and prioritize user comfort. An approach that does not overlook climatic differences will enable the reconstruction of post-disaster living environments in a sustainable and healthy manner (Ç. B. Dikmen, 2011).

In Türkiye, the production process of permanent post-disaster housing is carried out through an institutional division of responsibilities among the Disaster and Emergency Management Presidency (AFAD-Afet ve Acil Durum Yönetimi Başkanlığı), Republic of Türkiye Ministry of Environment, Urbanisation and Climate Change (ÇŞİDB-Çevre ve Şehircilik İklim Değişikliği Bakanlığı), and the Housing Development Administration (TOKİ-Toplu Konut İdaresi). While AFAD is responsible for initial response, process coordination, and needs assessment, ÇŞİDB and TOKİ take part in the design and construction phases of the housing projects (Url-1; Url-2). In post-disaster housing production, TOKİ and ÇŞİDB employ standardized "type projects," which offer advantages in terms of cost and construction speed. However, these projects are often limited in their ability to reflect socio-cultural, geographical, and climatic differences. Although this approach accelerates the production process, it generates long-term disadvantages regarding climatic adaptability, comfort conditions, and the energy efficiency of the built environment (N. Dikmen, 2011; Kuz, 2021).

In this study, a literature review focusing on climate and energy-efficient design in post-disaster housing production was conducted in the Scopus, Web of Science (WoS), and ScienceDirect databases using the keyword "permanent post-disaster housing." Examination of the retrieved abstracts revealed that climatic assessments predominantly concentrate on temporary shelter

units, whereas studies on permanent housing largely remain limited to material- and heat-transmission-based analyses such as wall layers and building envelope properties. For this reason, studies addressing climatic performance aspects—such as daylighting, ventilation, and heating—in standard housing projects, even if not directly situated within the post-disaster context, were also included. This approach expanded the scope of the literature to enable the evaluation of climate-related design decisions in permanent post-disaster housing.

Bilgili (2023) selected a standard 2+1 housing project designed by TOKİ and analyzed its natural ventilation performance across five different climatic regions in Türkiye. The study assessed indoor airflow based on dominant wind direction and speed, comparing the effectiveness of natural ventilation across climates. The findings revealed that the same housing typology performs differently in terms of natural ventilation depending on the climatic context. While natural ventilation yielded favorable results in hot-dry, hot-humid, and temperate-humid climates, it was found to be insufficient in temperate-dry zones and problematic in cold-dry regions due to the necessity of wind-protected design. These results clearly indicate that implementing standardized projects without considering climatic conditions does not ensure equal efficiency across different regions (Bilgili, 2023).

Dikmen (2011) conducted an extensive survey with residents of mostly single-storey permanent houses built in rural areas through two different production models: state-led standardized projects after the 1995 Dinar (Afyonkarahisar) earthquake, and the participatory "Assistance to Those Who Build Their Own House" model after the 2000 Çankırı earthquake. The findings revealed that although users generally found the houses functionally adequate, they expressed significant dissatisfaction regarding thermal comfort and heating performance, which resulted in high energy/fuel consumption. The fact that user satisfaction with heating was higher in Dinar compared to Çankırı, despite both settlements being constructed without reference to climatic parameters, further demonstrates the lack of climate-responsive design in post-disaster housing (N. Dikmen, 2011)

Scientific studies consistently emphasize that climatic adaptation must not be overlooked in post-disaster housing production or in the implementation of standardized housing projects.

In Türkiye, the production of permanent post-disaster housing falls under the authority and responsibility of the central government. Within this framework, the state implements three primary methods for the construction of permanent housing: direct construction by ministries and government agencies, procurement of services from the private sector through tenders, and the "Assistance to Those Who Build Their Own House" (KEYY-Kendi Evini Yapana Yardım) model. In the first two methods, the constructed dwellings are allocated to disaster victims through low-interest loans or grants. In the KEYY model, users are encouraged to build their own houses, while the state provides financial assistance and technical support throughout the process. This approach aims to ensure the active participation of disaster-affected households in the reconstruction process (Savaşır, 2008). The central government may apply these methods individually or simultaneously in post-disaster housing delivery, and it adopts multiple production models such as mass housing, core housing, and user-participatory housing (AFAD, 2024; Savaşır, 2008).

The Disaster and Emergency Management Presidency (AFAD-Afet ve Acil Durum Yönetimi Başkanlığı) was established in 2009 under the Ministry of Interior. AFAD coordinates all phases of disaster management, including preparedness, emergency response, and post-disaster recovery. Its core responsibilities include the provision of temporary shelter, damage

assessment, determination of beneficiary eligibility, and planning of permanent housing production in disaster-affected areas (AFAD, 2024).

In 2011, the Ministry of Public Works and Settlement and the environmental units of the Ministry of Environment and Forestry were merged to form the Ministry of Environment and Urbanization. In 2021, its name was changed to Republic of Türkiye Ministry of Environment, Urbanisation and Climate Change (ÇŞİDB-Çevre ve Şehircilik İklim Değişikliği Bakanlığı) (Url-3). The Ministry undertakes multi-dimensional roles in pre-disaster preparedness, response, and recovery phases, including damage assessment, debris removal, infrastructure restoration, and housing production. It directly participates in the process by providing technical guidance and coordination during site selection, planning, and design phases of housing projects. Additionally, it oversees regulatory compliance and coordinates housing production either through tenders or direct implementation in collaboration with TOKİ and AFAD. The Ministry also promotes community involvement through the KEYY model, enabling disaster victims to take an active role in constructing their own dwellings (ÇŞİDB, 2022; Url-1).

The Housing Development Administration of Türkiye (TOKİ-Toplu Konut İdaresi) was established in 1984 under the Mass Housing Law No. 2985 with the aim of planning and supporting housing production. Initially operating under the Prime Ministry, TOKİ was transferred to the Republic of Türkiye Ministry of Environment, Urbanisation and Climate Change (ÇŞİDB-Çevre ve Şehircilik İklim Değişikliği Bakanlığı) by Presidential Decree No. 703 on 09.07.2018. TOKİ develops housing, infrastructure, and social facility projects both domestically and internationally, and undertakes the construction of housing and related infrastructure in disaster-affected areas. In cooperation with AFAD and the Ministry, it carries out large-scale housing production in a short time in accordance with approved projects, functioning as one of the key actors in post-disaster recovery. In addition, it plays an active role in housing finance, urban transformation, and the preservation of vernacular architecture(T.C. Resmi Gazete, 1984; Url-2).

Standardized “type project” applications, frequently preferred in post-disaster housing production, offer significant advantages in terms of accelerating construction and reducing costs. Particularly in large-scale interventions, standardized spatial solutions provide practicality for implementing institutions faced with the need for rapid production (Savaşır, 2008). However, this approach often fails to adequately consider climatic and regional differences and excludes user participation from the design process, which can lead to critical problems. Type projects are typically architectural schemes replicated nationwide without regard to geographical, climatic, or cultural context. As a result, the dwellings may not align with the climatic conditions, geography, socio-cultural structure, or household lifestyle patterns of the region in which they are built.

For instance, when identical window openings, facade orientations, or material selections are applied in regions with different climatic conditions, significant losses in both energy efficiency and spatial comfort may occur. Thus, in post-disaster planning processes, adopting design approaches that account not only for speed and cost efficiency but also for climatic characteristics plays a critical role in ensuring the sustainability of housing. This study aims to examine the extent to which regional climatic conditions are taken into consideration in the design of permanent post-disaster housing in Türkiye, and to evaluate the compatibility of province-specific prototype projects with the climatic and environmental characteristics of their respective regions.

2. Materials and Methods

The study initially intended to evaluate the housing projects of two main institutions responsible for post-disaster housing production in Türkiye: the Housing Development Administration (TOKİ-Toplu Konut İdaresi) and and the Republic of Türkiye Ministry of Environment, Urbanisation and Climate Change (ÇŞİDB-Çevre ve Şehircilik İklim Değişikliği Bakanlığı). However, due to the lack of sufficient data on TOKİ projects, the analysis was limited to the post-disaster housing models proposed by the ÇŞİDB.Within the scope of the analysis, provinces representing different climatic regions of Türkiye were selected. Erzurum was chosen for the cold climate region; Diyarbakır for the hot-dry climate; Bursa and Ordu for the temperate-humid climate; Konya and Elazığ for the temperate-dry climate; and Adana and Manisa for the hot-humid climate.

The study first involved a literature review to establish the evaluation criteria, which were defined based on geographical region and climate type. In line with these criteria, pilot provinces representing different regional and climatic characteristics were selected, and the ÇŞİDB standard housing types in these provinces were examined in terms of building form, facade configuration, and plan layout.

The primary evaluation parameters, derived from the literature, are geographical regions and climate types. Türkiye's geographical regions were classified into seven main zones at the First Turkish Geography Congress held in 1941, as shown in Figure 1: Mediterranean Region, Eastern Anatolia Region, Aegean Region, Southeastern Anatolia Region, Central Anatolia Region, Black Sea Region, and Marmara Region (Url-4).

Figure 1. Geographical Regions of Türkiye (Url-5)

According to the classification proposed by Zeren (1959), the climate of Türkiye is divided into five regions: cold, temperate-humid, temperate-dry, hot-humid, and hot-dry (Figure 2). In establishing these climate categories, the seasonal and daily temperature patterns of the regions, as well as their year-round relationship with humidity, were taken as the primary criteria. For instance, although they differ in temperature characteristics, the Marmara Region, the Black Sea coast, and the coastal areas of the Aegean and Mediterranean exhibit humid climatic conditions due to the influence of maritime effects. In contrast, moving inland from the coastal zones, the increasing dominance of continentality—especially where mountain ranges block maritime influence—results in predominantly dry climatic conditions.

Another reason why climate regions do not fully overlap with the geographical regions of Türkiye is the variability in humidity levels shaped by the interaction of maritime and continental effects. Additionally, factors such as elevation differences, the orientation of mountain ranges, and the movement pathways of cold and warm air masses contribute to the

emergence of different temperature and climate classes even within the same geographical region (Kısa Ovalı, 2019; Koca, 2006).

In this study, the pilot provinces were selected based on the Sample Post-Disaster Housing Projects published on the official website of the Republic of Türkiye Ministry of Environment, Urbanisation and Climate Change (ÇŞİDB-Çevre ve Şehircilik İklim Değişikliği Bakanlığı), taking both climate regions and geographical regions into account. The initial aim was to select two provinces from each climate region; each located in a different geographical region. However, all of the provinces listed under the hot-dry and cold climate regions on the Ministry's website (Url-6) are located within a single geographical region; therefore, only one province was selected from each of these two climate regions. On the other hand, since the temperate-humid, temperate-dry, and hot-humid climate regions include provinces distributed across different geographical regions, two provinces were selected from each of these categories.

The Ministry provides alternative architectural projects for different provinces, including single-storey, multi-storey, 2+1, and 3+1 housing types. For the purpose of ensuring a consistent and comparable analysis, only the 2+1 units within multi-storey buildings were included in the evaluation. As presented in Table 1 the selected provinces are: Erzurum representing the cold climate region, Diyarbakır representing the hot-dry climate region, Bursa and Ordu representing the temperate-humid climate region, Konya and Elazığ representing the temperate-dry climate region, and Adana and Manisa representing the hot-humid climate region. The locations of these selected provinces are marked on the climate regions map in Figure 2.

Table 1. Criteria for Selection and Pilot Provinces

	Marmara Region	**Black Sea Region**	**Aegean Region**	**Mediterranean Region**	**Central Anatolia Region**	**East Anatolia Region**	**Southeastern Anatolia Region**
Cold Climate Zone						Erzurum	
Temperate-Humid Climate Zone	Bursa	Ordu					
Temperate-Dry Climate Zone					Konya	Elazığ	
Hot-Humid Climate Zone			Manisa	Adana			
Hot-Dry Climate Zone							Diyarbakır

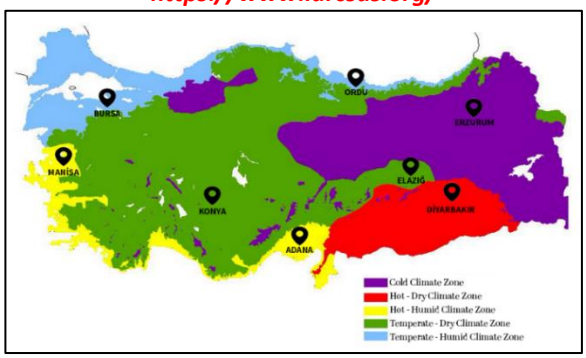

Figure 2. Climate Zones and Location of Pilot Provinces (Produced by the author using data from Koca, 2006)

3. Findings and Discussion

Under this heading, the design parameters according to climatic regions are first explained, and the standard floor plans of the multi-story 2+1 post-disaster housing units in the eight selected pilot cities are examined and evaluated within the climatic and geographical context. The assessment primarily focuses on building mass form, spatial organization, and facade orientation. Since none of the typified projects include an indication of facade orientation, it is not possible to make direction-based evaluations regarding facades or balconies. Therefore, facade orientation has been excluded from the scope of analysis, and the evaluation has been limited to mass form and spatial organization. The facade layout has been partially reviewed in a direction-independent manner.

In the hot-dry climate zone, the province of Diyarbakır experiences extremely hot and dry summers and cold winters. Daily and annual temperature differences, as well as solar radiation levels, are high throughout the year. The elevation of the provinces in the Southeastern Anatolia Region ranges between 500–1000 m, and the topography is generally flat or slightly undulating. In this region, the design strategy at the scale of building form and spatial organization should aim to reduce solar heat gains and enhance natural ventilation during the summer, while maximizing solar gains during the winter. The building form should be compact and preferably organized around an inner courtyard. In terms of spatial layout, to minimize heat exposure, facades should be narrow and spaces deeper in plan, while the transparency ratio on the west and south facades should be reduced (Ç. B. Dikmen, 2011; Dizdar, 2009; Kısa Ovalı, 2019).

In the hot-humid climate zone, represented by Manisa and Adana, summers are hot and highly humid. Therefore, the primary design objective is to reduce excessive heat gains in the summer while ensuring continuous air movement to improve indoor comfort. Since the south and west facades are exposed to the highest levels of solar radiation, the size of openings on these facades should be minimized, and effective shading devices should be used to control solar exposure. Planning interior spaces to remain open to prevailing winds increases cross-ventilation and prevents humidity buildup. Additionally, buildings should be positioned with sufficient spacing to avoid blocking natural airflow, enabling passive cooling at the settlement scale (Ç. B. Dikmen, 2011; Dizdar, 2009; Kısa Ovalı, 2019).

In the cold climate zone, represented by Erzurum, the long and severe winter conditions necessitate minimizing heat losses while maximizing solar heat gains. Accordingly, buildings should be designed in compact forms, with increased transparency on the south facade and buffer spaces such as storage rooms or stairwells located on the north side. Roofs should have

steep slopes to prevent snow accumulation, and the building envelope must be thick and well insulated. In the spatial organization, primary living spaces should be oriented to the south, whereas secondary functions should be located on the north to support energy-efficient use (Ç. B. Dikmen, 2011; Dizdar, 2009; Kısa Ovalı, 2019).

In the temperate-dry climate zone, represented by Elazığ and Konya, the diurnal temperature difference is high, with hot summers and cool winters. Summer design strategies should benefit from the cooling effect of prevailing winds, whereas in winter, the goal is to increase solar heat gains. Compact and attached building layouts help prevent heat loss while supporting solar exposure. Large transparent surfaces are not recommended, as they lead to excessive heat gain in summer and excessive heat loss in winter. Buildings should be oriented toward the south or southeast, and both roofs and exterior walls should be well insulated. Buffer spaces such as storage rooms or windbreaks should be placed on the north side to improve thermal comfort (Ç. B. Dikmen, 2011; Dizdar, 2009; Kısa Ovalı, 2019).

In the temperate-humid climate zone, represented by Bursa and Ordu, annual temperature fluctuations are low, yet humidity levels are high. This requires a design approach that promotes both ventilation for cooling and reduced humidity effects. Spatial organization should remain open, allowing continuous airflow through appropriately positioned openings. Shading devices and wide eaves should be integrated to protect facades. Window openings should be sufficiently large to benefit from summer breezes, and interior depth should be designed to balance solar gains (Dikmen, 2011; Dizdar, 2009; Kısa Ovalı, 2019).

3.1. Post-Disaster Housing Plans and Evaluation in the Cold Climate Region

The pilot province representing the cold climate region is Erzurum, located in the Eastern Anatolia Region of Türkiye. Figure 3 illustrates the standard floor plan of the post-disaster housing unit in Erzurum. The plan consists of two identical apartments symmetrically arranged around a central stair core. Overall, the layout is compact and linear; however, the living room facade is recessed slightly from the main building line, creating an indentation. The central core accommodates only the staircase, providing separate entrances to each unit.

An examination of the spatial organization reveals that each apartment includes an entrance hall, corridor, kitchen, living room, two bedrooms, a bathroom, a WC and one balcony. From the entrance hall, direct access is provided to the living room, kitchen and corridor; the corridor, in turn, distributes to the two bedrooms, bathroom and WC. The single balcony of the unit is connected to the kitchen.

With respect to facade organization, although each room contains more than one opening, all openings are positioned on a single facade, preventing cross-ventilation.

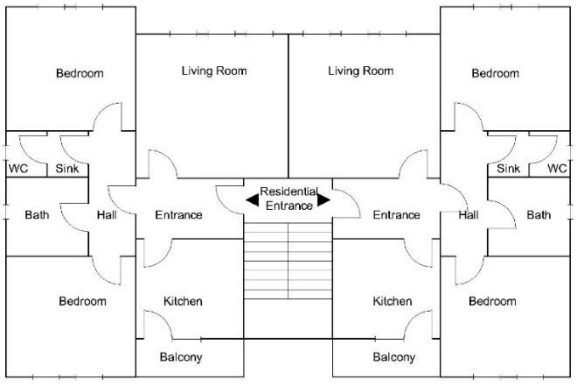

Figure 3. Erzurum Post-Disaster Housing Typical Floor Plan

Erzurum is located in Türkiye's cold climate zone, where compact building massing, southward orientation, buffer spaces on the northern facade, and high thermal insulation are considered key design strategies. The plan generally aligns with a compact, linear configuration; however, the recessed living room facade—while contributing to visual articulation—may increase heat loss. In addition, the stair core, entrance hall, and corridor lack access to natural ventilation. Since all windows face a single direction, cross-ventilation is not possible. Nevertheless, given the region's low humidity levels, this limitation may not constitute a critical drawback.

3.2. Post-Disaster Housing Plans and Evaluation in the Temperate-Humid Climate Region

The pilot provinces representing the temperate-humid climate region are Bursa, located in the Marmara Region, and Ordu, located in the Black Sea Region. The standard floor plan of the Bursa post-disaster housing unit, shown in Figure 4 consists of two apartments symmetrically arranged around a central core. A compact and linear configuration has been adopted, avoiding projections and recesses in the plan layout. The central core accommodates both the elevator and staircase, with the apartment entrances placed symmetrically and positioned opposite one another.

An analysis of the spatial configuration shows that each unit contains a living room, kitchen, two bedrooms, a bathroom, a WC, a hall, an entrance vestibule, and two balconies. The living room and kitchen are located on the front facade and are directly connected to the balcony on this side. The bedrooms are positioned at the rear of the apartment, ensuring privacy. The second balcony is associated with one of the bedrooms. With regard to facade organization, all spaces except the bedrooms have openings on two orientations.

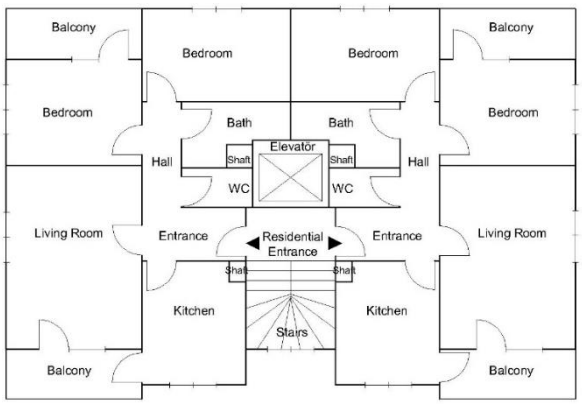

Figure 4. Bursa Post-Disaster Housing Typical Floor Plan

Bursa is located in the temperate-humid climate zone, where reducing indoor humidity and ensuring continuous air circulation are essential design considerations. The presence of two balconies in each unit, along with dual-aspect openings in all spaces except the bedrooms, enhances indoor air movement and enables cross-ventilation. This configuration also supports passive cooling through night ventilation. In particular, the dual-aspect layout of the living room and kitchen offers advantages in terms of natural ventilation and daylighting. However, the entrance vestibule, interior corridors, WC, and bathroom—being located adjacent to the central core—cannot benefit from natural ventilation; thus, cross-ventilation is limited to rooms facing the exterior facades.

The typical floor plan of the Ordu post-disaster housing unit is shown in Figure 5. The plan consists of two symmetrically arranged apartments organized around a central core. The building is formed by two compact masses connected through a smaller core volume, resulting in recessed areas on the front and rear facades at the core zone. At the center of the plan is a core containing a three-flight staircase and an elevator, with apartment entrances accessed from the floor hall connected to the core. Each apartment includes a living room, kitchen, bedroom, two additional bedrooms, WC, washbasin, bathroom, ventilation shaft, and two balconies.

From the perspective of spatial organization, common-use areas such as the entrance hall, kitchen, and living room are located near the entrance, while the bedrooms and children's rooms are placed further away. A night corridor separating these rooms from the living areas ensures privacy and acoustic comfort. The living room and kitchen are directly connected to the balconies. The placement of wet areas close to the core supports continuity of building services.

An examination of the facade organization shows that, except for the living room, all spaces are provided with a single-sided window opening. In the bedrooms and kitchen that open onto the balcony, an additional window on the same facade accompanies the balcony door.

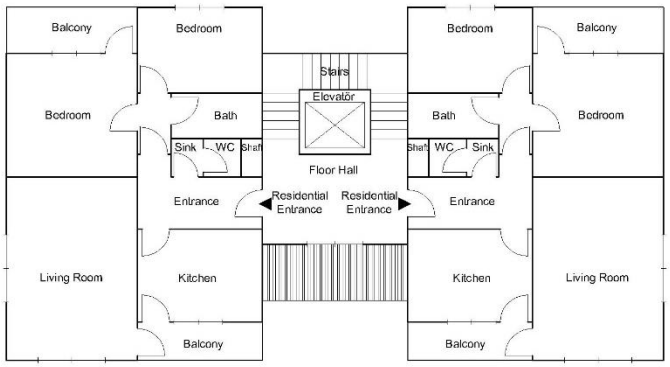

Figure 5. Ordu Post-Disaster Housing Typical Floor Plan

Ordu is located within a temperate and humid climatic zone, where moisture control and the provision of air circulation play a critical role in design. The placement of windows on two facades of the living room enables cross-ventilation. However, although the bedrooms could have been provided with openings on two facades, they are limited to single-sided windows, reducing the potential for cross-ventilation and creating a disadvantage in terms of indoor humidity distribution. The balconies on the front and rear facades contribute to the intake of prevailing winds at different times of the year, thereby enhancing natural ventilation efficiency. Since the bathroom, WC, and internal corridor are located away from the facade, they lack

natural lighting and ventilation. Conversely, the windowed facade of the floor hall allows the core area to benefit from natural daylight and air circulation.

3.3. Post-Disaster Housing Plans and Evaluation in the Temperate-Dry Climate Region

The pilot provinces representing the temperate-dry climate region are Konya, located in the Central Anatolia Region, and Elazığ, located in the Eastern Anatolia Region. Figure 6 illustrates the typical floor plan of the Konya post-disaster housing unit. The plan consists of two identical apartments symmetrically arranged around a central core. Overall, it features a compact and linear layout. The core accommodates the elevator, staircase, and atrium void, and is connected to each apartment via short and direct corridors.

An examination of the spatial organization reveals that each apartment includes a living room, kitchen, bedroom, children's room, bathroom, separate WC, washbasin area, entrance hall, and balcony. The living room and kitchen are positioned closer to the apartment entrance, while the bedroom and children's room are located further from it, enabling a functional separation between daytime living spaces and resting areas. The balcony is associated with the kitchen.

In terms of facade organization, all interior spaces receive light from a single direction, with openings located only on the front and rear facades; the side facades contain no openings.

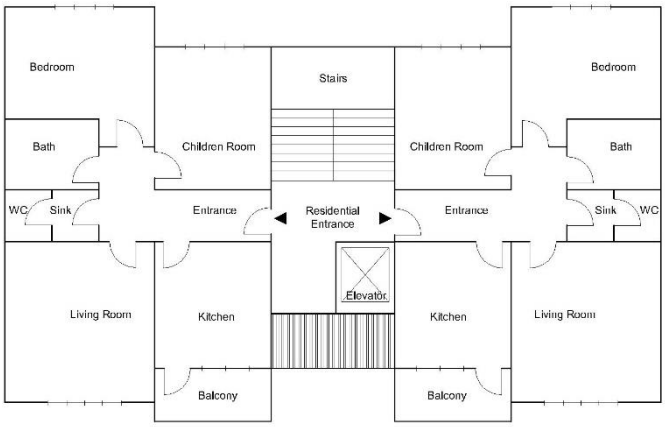

Figure 6. Konya Post-Disaster Housing Typical Floor Plan

Konya is located in a temperate–dry climate zone, characterized by high temperatures in summer, cold conditions in winter, and significant diurnal temperature variations. In such a climate, compact massing and appropriate solar orientation are of critical importance.

The Konya housing plan offers a linear and compact configuration, which is favorable in terms of energy efficiency. However, the presence of window openings solely on the front and rear facades, resulting in single-sided daylighting for all interior spaces, may lead to insufficient natural ventilation and daylight performance. The absence of openings on the side facades eliminates the possibility of cross ventilation, which may negatively affect indoor environmental comfort.

The floor plan of the Elazığ post-disaster housing unit is presented in Figure 7. The plan consists of two apartments symmetrically positioned around a central core. The layout is predominantly linear and compact, with no staggered or zigzag spatial arrangement.

At the center of the floor plan is a core containing the elevator, staircase, and service shafts. The entrances of both apartments open directly from this core into the entrance hall. Each

apartment includes a living room, kitchen, sitting room, bedroom, bathroom, washbasin area, WC, storage room, and entrance hall, as well as two balconies.

In terms of spatial configuration, the living room and kitchen are located on the front facade, near the entrance, together with the sitting room. The bedroom is positioned toward the rear of the plan, creating a functional separation between living and resting areas. Wet spaces are grouped adjacent to the service shafts. Additionally, small-scale storage spaces (pantries) are incorporated into the layout. The balconies are connected to the living room and bedrooms.

Window placement shows that openings exist on two facades. While the living room is served by windows on two adjacent facades, the remaining spaces receive daylight through a single window.

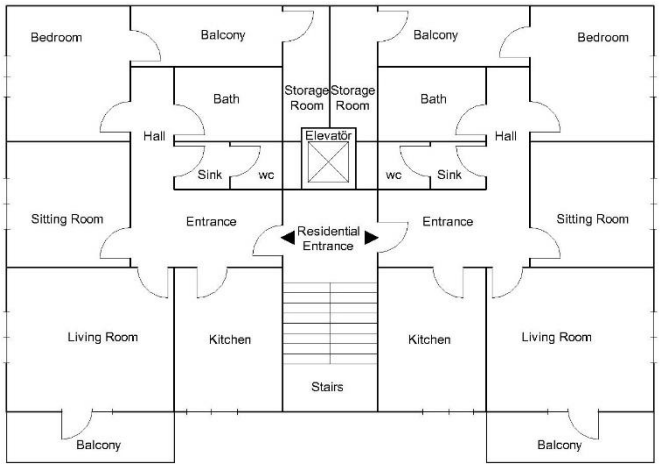

Figure 7. Elazığ Post-Disaster Housing Typical Floor Plan

Evaluation of the plan scheme indicates that the compact, linear, and symmetrical massing contributes to reduced heat loss, thereby improving thermal performance and lowering heating energy demand.

From the perspective of spatial organization, the central-core layout results in the bathroom and WC/washbasin areas lacking natural ventilation, whereas the storage room can be partially ventilated due to its direct connection to the balcony. The single-sided openings in most spaces limit cross ventilation. In a climate such as Elazığ—where night-time cooling enables natural ventilation and passive cooling—this restriction of cross ventilation may negatively affect user comfort.

3.4. Post-Disaster Housing Plans and Evaluation in the Hot-Humid Climate Region

The pilot provinces representing the hot-humid climate region are Manisa, located in the Aegean Region, and Adana, located in the Mediterranean Region. The typical floor plan of the Manisa post-disaster housing unit is presented in Figure 8. The plan consists of two apartments arranged symmetrically around a central core. Due to the projecting and recessed balcony forms, the overall plan geometry exhibits a partially indented–protruding massing. At the center of the plan is the core containing the elevator and staircase, from which the apartment entrances are accessed directly via short corridors. Each apartment includes a living room, kitchen, bedrooms, bathroom, WC, washbasin area, ventilation shaft, storage room, and two balconies.

Analysis of the spatial configuration shows that the living room is positioned on the front facade with a wide frontage and directly connected to the balcony, while the kitchen is placed closer to the entrance. The bedrooms and bathroom are located toward the rear of the plan to ensure privacy. The second room is designed to function as a sitting room, positioned to maintain a strong spatial relationship with the living room. One of the balconies is connected to the living room, while the other is associated with the bedroom. Furthermore, the storage space is accessed through the balcony adjacent to the bedroom.

Regarding window placement, it is observed that all spaces except the living room have single-sided openings; the living room, however, benefits from dual openings—one window and one door opening onto the balcony.

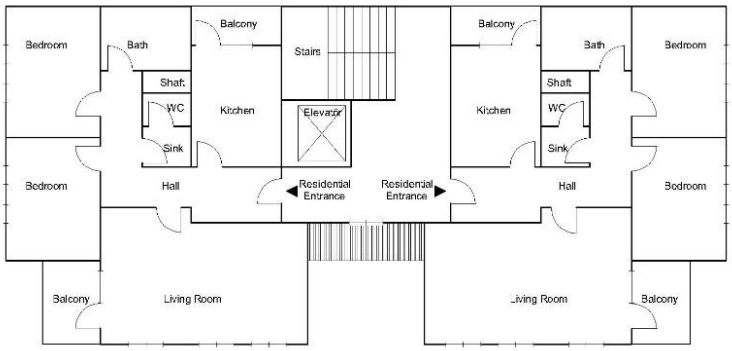

Figure 8. Manisa Post-Disaster Housing Typical Floor Plan

Manisa is characterized by hot and humid summers with limited annual temperature variation; therefore, reducing heat gain and ensuring natural ventilation are primary design goals. The recessed–projecting plan form contributes to passive cooling in summer by increasing exterior surface exposure and heat dissipation. Although this form may increase heat loss during winter, the cooling demand is more dominant in this climatic context, making the design strategy appropriate for summer conditions. The placement of openings on the front and side facades can help reduce solar heat gain when oriented effectively.

However, internal corridors and wet spaces are located away from the facade, preventing natural ventilation, and since most rooms are single-sided, cross-ventilation potential remains limited. In a city like Manisa—where night-time cooling can be used effectively—the lack of adequate ventilation strategies may negatively affect indoor comfort conditions.

The typical floor plan of the Adana post-disaster housing unit is presented in Figure 9. The plan consists of two apartments symmetrically arranged around a central core. In addition to the main core, there is a fire escape that is directly accessible from inside the apartment. Overall, the floor plan follows a compact layout; however, the recessed area created by the ground-floor entrance, which forms the outer facade of the corridor on the upper floors, partially deforms the compact form. The central core accommodates the staircase and elevator, while apartment entrances are accessed from the floor hall connected to this core. Each apartment includes a living room (combined with a dining area), kitchen, bedroom, children's room, bathroom, WC, two balconies, and a fire hall connected to the fire escape.

An analysis of the spatial configuration reveals that the entrance zone accommodates the foyer, kitchen, and living room—spaces associated with shared living and service functions. Private areas, such as the bedroom and children's room, are located farther from the entrance and

oriented toward the rear facades, ensuring functional separation between living and resting areas. Wet spaces are positioned near the central core to facilitate service shaft continuity and minimize plumbing runs.

Regarding facade organization, the kitchen on the front facade is almost entirely glazed, with the associated recessed balcony also enclosed by window surfaces. It is observed that all spaces except the children's room have single-sided window openings, while the children's room benefits from dual exposure through both a balcony door and an additional window on the adjacent facade.

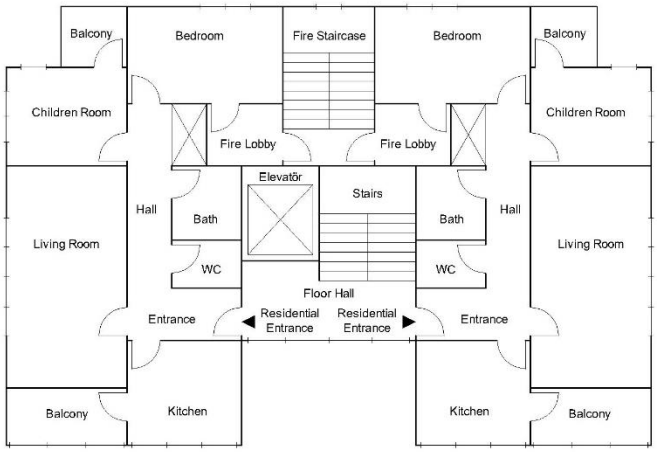

Figure 9. Adana Post-Disaster Housing Typical Floor Plan

Adana is located in the hot-humid climatic region, where minimizing solar heat gain and maximizing air circulation through cross-ventilation are key design priorities. Although the compact building form contributes to thermal gain, the relatively high window-to-wall ratio partially mitigates this effect. The recessed front facade and extensive glazing in the kitchen help reduce direct solar gain, while the overall compact massing of the building presents a disadvantage in other spaces by limiting heat dissipation. The dual-aspect openings in the children's room support cross-ventilation, whereas the single-aspect configuration of other rooms constrains airflow. Nevertheless, if internal doors are kept open, the potential for cross-ventilation throughout the dwelling can increase.

Because the bathroom, WC, and internal corridors are located away from exterior facades, these spaces lack natural lighting and ventilation. However, the presence of windows along one side of the floor hall provides daylight and ventilation to the core zone, enhancing its environmental performance.

3.5. Post-Disaster Housing Plans and Evaluation in the Hot-Dry Climate Region

The pilot province representing the hot-dry climate region is Diyarbakır, located in the Southeastern Anatolia Region of Türkiye. The typical floor plan of the Diyarbakır post-disaster housing block is illustrated in Figure 10. The plan is composed of four apartments symmetrically arranged around a central core. Unlike a linear layout, the spatial arrangement is formed by shifting the units relative to one another, generating recessed and protruding facades and interrupting the continuity of the building envelope.

The central core contains two elevators, a staircase, a refuse room, and service shafts, and provides access to each apartment through short distribution corridors. All four apartments on the floor follow the 2+1 typology, each comprising a living room, kitchen, bedroom, children's room, bathroom, separate WC, and entrance hall, along with two balconies. In the spatial configuration, the living room and kitchen are positioned closer to the entrance, while the bedroom and children's room are located farther away, ensuring a functional separation between living and resting zones. Wet spaces are organized close to the service shafts to facilitate plumbing efficiency. One balcony is connected to the kitchen, while the other is associated with the bedroom.

An examination of facade organization shows that each room contains only a single window opening, all oriented toward the same facade. Apart from the balcony attached to the bedroom, no openings are provided on the side facades, resulting in single-aspect apartments with limited daylight and ventilation potential.

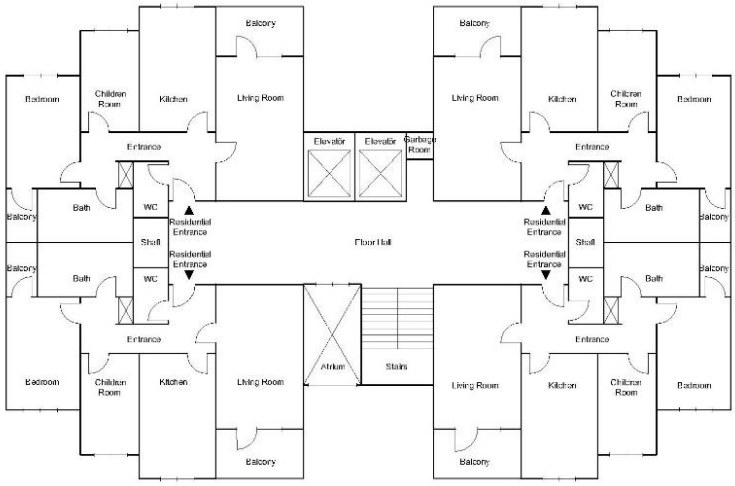

Figure 10. Diyarbakır Post-Disaster Housing Typical Floor Plan

From a massing perspective, the staggered positioning of the dwelling units is incompatible with a compact building form, leading to increased heat gain during summer and elevated heat loss in winter. This condition raises both heating and cooling loads, thereby increasing energy consumption, economic cost, and environmental impact. In terms of spatial organization, the centralized core and internal service zones—such as hallways, bathrooms, and WCs—lack direct access to exterior facades, making natural ventilation impossible. Furthermore, single-sided openings and single-orientation facade design severely restrict cross-ventilation throughout the apartments.

A climatic suitability assessment was conducted for the eight cities detailed above, and the results are summarized in Table 2 During the creation of the table and the evaluation process, housing designs in each city were analyzed according to climatic priorities. In cold climate regions, building mass and thermal retention were considered the primary design parameters, while other design criteria were of secondary importance. In contrast, in humid climates, ensuring cross-ventilation and even moisture distribution within interior spaces was evaluated as the determining criterion. The "suitability level" presented in Table 2 qualitatively classifies the performance of the designs in response to climatic conditions. Three categories were used in this classification. The term "partially suitable" indicates that the design meets certain climatic requirements but still contains some critical deficiencies. "Insufficient suitability"

denotes that the design partially responds to climatic conditions but performs poorly in key performance indicators. “Not suitable” indicates that the design conflicts with the recommended passive design principles for the respective climate zone. Based on the analyses conducted using this method, Erzurum, Elazığ, and Adana were determined to be partially suitable; Manisa and Konya were considered insufficiently suitable; and Ordu, Bursa, and Diyarbakır were found to be not suitable. Detailed explanations regarding the suitability levels presented in the table, as well as evaluations of the associated design parameters, are provided in the “3. Results and Evaluation” section of the study.

Table 2. Evaluation Findings of the Pilot Cities

	Erzurum	Ordu	Bursa	Elazığ	Konya	Manisa	Adana	Diyarbakır
Climate Zone	Cold	Temperate-Humid	Temperate-Humid	Temperate-Dry	Temperate-Dry	Hot-Humid	Hot-Humid	Hot-Dry
Plan / Mass Form	Central core, compact mass	Non-compact form	Linear compact mass	Predominantly compact mass	Predominantly compact mass	Non-compact linear form	Partially compact mass	Non-compact form
Positive Aspects	Compact form enhances heat retention	Living room cross ventilation	Compact mass and living room cross ventilation	Compact form provides energy efficiency; living room cross ventilation	Compact form provides energy efficiency	Indented form supports passive cooling	Compact form and some cross-ventilated spaces	Functional separation of spaces achieved
Negative Aspects	Recessed facades increase heat loss; single-aspect openings limit cross ventilation	Bedrooms single-aspect; limited cross ventilation and humidity control	Bedrooms single-aspect; limited cross ventilation and humidity control	Single-aspect spaces; passive cooling limited	Single-aspect openings in deep spaces limit daylight penetration and restrict cross ventilation	Single-aspect openings; cross ventilation and passive cooling limited	Compact form increases heat gain; single-aspect openings limit ventilation	Non-compact mass increases heat gain/loss; single-aspect openings limit ventilation; deep spaces reduce daylight
Climatic Suitability Level	Partially suitable	Not suitable	Insufficient suitability	Partially suitable	Insufficient suitability	Insufficient suitability	Partially suitable	Not suitable

Evaluation Note / Remarks	Focused on heat retention; cross ventilation limited	Humidity control and cross ventilation insufficient	Critical deficiency due to single-aspect openings; compact mass and living room cross ventilation present	Compact form advantageous; passive cooling limited but heating prioritized	Compact form advantageous; large spaces limited daylight	Passive cooling present; cross ventilation critically lacking	Positive and negative aspects balanced; moderately suitable	Non-compact form and facade openings inappropriate; deep spaces limit natural lighting

4. Conclusion and Recommendations

Disasters are phenomena that affect large populations and cause severe physical, social, and economic destruction within settlement systems. In a country like Türkiye, located on active fault lines and exposed to various climatic risks across its geographical regions, earthquakes in particular—along with floods, landslides, and wildfires—occur frequently and result in significant loss of life and property. One of the most urgent and fundamental needs that emerges in the aftermath of a disaster is shelter. Housing is not merely a physical necessity for protection; it also constitutes the primary space where social relations are established, daily life is sustained, and psychological recovery is supported. Therefore, ensuring the rapid, safe, and habitable provision of housing in post-disaster reconstruction processes is of vital importance. However, when post-disaster dwellings are produced rapidly without considering the climatic conditions, topography, or socio-cultural characteristics of the affected region, such housing often becomes dysfunctional over time and negatively affects users' quality of life. For this reason, the design of permanent post-disaster housing must be addressed not only through structural and engineering considerations, but through a multi-layered approach that incorporates spatial, geographical, and climatic suitability.

Post-disaster permanent housing should not only meet the physical needs of its occupants but also be compatible with the climatic conditions of its geographical location. Within the scope of this study, multi-storey 2+1 post-disaster housing typologies proposed by the Republic of Türkiye Ministry of Environment, Urbanisation and Climate Change were evaluated based on climatic data across different geographical regions of Türkiye. The aim of this study is to evaluate the suitability of standardized housing prototypes, frequently employed in post-disaster housing production, across different climatic regions, and to determine the extent to which these prototypes adapt to regional variations. Accordingly, eight provinces representing five major climatic zones of Türkiye were selected: Erzurum (Cold Climate Zone), Diyarbakır (Hot-Dry Climate Zone), Bursa and Ordu (Temperate-Humid Climate Zone), Konya and Elazığ (Temperate-Dry Climate Zone), and Adana and Manisa (Hot-Humid Climate Zone). The spatial plans were assessed by considering the climatic and geographical characteristics of each province, and the resulting findings were analysed. In the context of climate and geography, the plan analyses demonstrate that the standardized post-disaster housing prototypes predominantly follow compact and linear planning principles; however, they remain insufficient in offering spatial organizations optimized for climatic needs.

In cold-climate cities such as Erzurum, certain design decisions intended to reduce heat loss are partially observed; however, in Diyarbakır, which is located in a hot-dry climate zone, strategies that could mitigate excessive solar heat gain have not been sufficiently implemented. In Elazığ

and Konya, situated in a temperate-dry climate, the use of compact planning can be regarded as a positive step. Nevertheless, the placement of openings on a single facade restricts cross-ventilation and daylight penetration, thereby reducing indoor environmental comfort. In hot-humid regions such as Adana and Manisa, both the orientation of openings and the overall ventilation potential remain weak, while in temperate-humid cities such as Bursa and Ordu, partial improvements are observed in terms of shading and natural air circulation to counteract high humidity levels. However, the absence of facade orientation information in the project documentation raises questions regarding whether the design decisions are grounded in climate-responsive strategies.

Based on these findings, the general conclusion is that while standardized prototypes offer a practical solution for rapid and cost-effective post-disaster housing production, they do not incorporate passive design strategies compatible with local climatic conditions, resulting in low energy efficiency. Therefore, prioritizing speed of construction and economic feasibility alone is insufficient in the production of permanent post-disaster housing. Ensuring climatic responsiveness in design is of fundamental importance. Achieving this, however, requires addressing several technical and structural issues present in current practice. First, the prototype housing plans provided by the Ministry do not explicitly indicate building orientation, despite the fact that orientation is a primary parameter for assessing solar exposure, natural ventilation, and heat gain/loss. The absence of this information makes it difficult to evaluate whether the designs are genuinely climate-adaptive. Thus, clearly defining building orientation in the drawings and associating it with design decisions is essential for ensuring sustainability. Moreover, the presentation of standardized prototypes made available on the Ministry's online platforms varies in terms of language, scaling methods, and level of detail. This variation complicates both the analyses conducted in scientific studies and the decision-making processes of practitioners in the field. Adopting a unified presentation standard for these prototypes—defining clear criteria regarding drawing conventions, expression methods, and content depth—could effectively address this issue.

In conclusion, initiating a comprehensive standardization process for prototype housing within the Ministry would enhance both comparability and regional adaptability in post-disaster housing production. Developing alternative housing plans for each region that adhere to established standards and account for local climatic and geographical conditions not only streamlines the production process but also helps establish the foundations for a sustainable housing policy that is both livable and responsive to the local climate.

Abstract

This study focuses on the city of Isfahan and examines the interrelation between urban design, social inequality, and mental health by combining secondary evidence, official statistics, and public-health findings within the frameworks of social determinants of health, environmental stress, and salutogenic design. The research adopts a descriptive–correlational case-study approach; evidence was gathered using a PRISMA-based literature review from both international and Iranian databases, and analysis was completed through GIS and spatial statistical methods. Key limitations include reliance on secondary data and the absence of standardized neighborhood-level indicators. The findings indicate that the gradual erosion of the city's green heritage and human-scale structure has generated spatial inequalities in access to shelter, services, and restorative environments—approximately 55 % of the city's area falls into "deprived" or "highly deprived" categories. Public-health data reveal high levels of mental-disorder prevalence among target groups (44 % depression among university students; 28 % depression and 14 % anxiety among staff of Isfahan University of Medical Sciences). Satisfaction with urban green spaces shows a significant negative correlation with anxiety and depression levels ($\beta = -0.24$ and $\beta = -0.69$). Policy implications include integrating health equity into urban-planning frameworks, expanding community-based mental-health services, and applying green-justice criteria such as the 3–30–300 rule in underprivileged districts.

Keywords: Urban health equity, social determinants of mental health, salutogenic and restorative urban design, socio-spatial ınequality

1. Introduction

The WHO emphasizes that cities being the foremost health determinants, have a direct influence on health outcomes. Corburn & Cohen (2012) draw attention to the role of urban ecosystems like street networks, open areas, and the standard of housing. On the other hand, Ghaedrahmati et al. (2018) point at the unequal resource distribution and social segregation within cities as main factors causing health disparities and the increasing global population. This research takes a deep dive into the interconnections among urban design, social inequity, and mental health in Isfahan, Iran. The study underlines the role of environmental stressors, among which are noise, air pollution, overcrowding, and neighborhood safety, as major determinants of mental health and increasing in anxiety, depression, and other mental disorders as a result (Sarkar & Pujara, 2025). Though this connection has been widely investigated in the Global North cities, there is still a lack of understanding regarding the portrayal of these processes in non-Western urban areas. Isfahan's diverse history of urbanism and swift expansion give a good premise for research of the past and present urban development patterns. Meanwhile, one of the existing literature represents the deep spatial injustices in the access to urban facilities, and the other one the abnormal high mental health burden among the population

(Saraei, Ghafarian, & Dasta, 2020). In this context, the study aims to deliver place-specific knowledge, thus contributing to the enhancement of urban health equity. The research goal, which is an objective one, is to investigate how the features and characteristics of urban design contribute to the final stages of social inequalities and mental health in the urban area of Isfahan, Iran. In order to conduct the study properly and to achieve the above-mentioned research aim, the following questions have been formulated:

1. How could one characterize the major historical and contemporary, urban design elements and patterns that these neighborhoods or districts in Esfahan uniquely embody?

2. How are social differences especially with regard to accessibility to services, housing conditions, and income fairly spread spatially through Isfahan?

3. Could you kindly inform him/her about the prevalence of other chief mental health issues like anxiety and depression as well as the accessibility of services in Isfahan?

4. In principle, considering the outcome of any secondary data analyses, what connections could be drawn between specific urban design characteristics and the social inequality patterns and mental health results in micro-areal scales (for instance, neighborhoods and districts, and particularly in Isfahan)?

Besides involving urban planning, architecture, and landscape architecture, it also deals with the overall arrangement of space, aesthetic character, and performance of the structures, public places, transportation, and facilities (NYC DCP, 2024). The main principles of the design department are development that keeps people in mind; this means to create places for humans, the elderly, and children; the inclusion of green areas for parks and urban gardens that offer us nature in the city and habitat for wildlife, thus reducing carbon footprints, among others (Vaia, 2025; NYC DCP, 2024). Public spaces like the streets, the squares, and the parks are main areas where the civic life and social interaction take place. Their qualities are Accessibility, Safety, Inclusiveness, and Aesthetic. Urban design and architecture have a direct influence on the visual character of cities, while the public transport systems and facilities for walking, cycling, and using public transport that are equitably distributed enhance the mobility and come with the advantage of the lower carbon emissions. The provision of basic utilities such as water, energy, and communication networks forms the backbone of urban life and sustainability. According to the NYC Department of City Planning (2024), the mixed land-use neighborhoods that have good design, are walkable, and are located close to each other support people’s health through physical activity and social interaction.

Social Inequality in the Urban Fabric

Such divisions have their roots in fixed social structures that are based on class, race, gender, ethnicity, or other social categories (CUNY, 2021). In layman's terms, inequality is a disparity in a distribution while inequity is a disparity that is considered wrong, which is mostly the outcome of systemic hurdles or bias. Systemic and structural factors, such as educational levels, wealth distribution, types of occupations, and power relations, keep the differences going. Ideological supports, such as laws, policies, and cultural narratives, legitimize and reinforce the differences (CUNY, 2021). In cities, the inequalities are often seen through the lens of hidden structures that make up the social and economic landscape of the city. Such structures create neighborhoods with concentrated poverty and disadvantage. This unfair division of the city limits poor people's access to essential services and amenities while rich areas receive greater investment, thereby perpetuating their advantage. The Gini coefficient for income distribution,

the Index of Dissimilarity for residential segregation, concentration indices for health outcomes, and Geographic Information Systems (GIS) for mapping spatial patterns are among the tools used to measure urban inequalities (Ghanbari et al., 2013; Pourreza et al., 2018). With the help of these methods, one can have a glimpse of the uneven distribution of resources, opportunities, and health services among urban populations.

Urban Minds, Mental Health in the Built Environment

Mental health is the most important aspect of human well-being, which includes a variety of mental, emotional, social, and behavioral functions that vary throughout a person's life (Bitsko et al., 2022). Mental disorders are disruptions in cognition, emotion, or behavior that are so severe as to be each of the factors mentioned above, namely, psychological, biological, or developmental, being the underlying cause (CDC, 2022). Urban environments can be a double-edged sword for mental health. Urban areas have been found to have more people with mood, anxiety, and psychotic disorders than rural ones (Sarkar & Pujara, 2025). One of the major factors behind this scenario are psychosocial stressors such as social isolation, high perceived stress, and the fast pace of life along with environmental stressors like noise, air pollution, overcrowding, limited access to nature, and perceived lack of safety (WHO, 2025; CDC, 2022). Besides these, lifestyle factors like inactive lifestyle, poor diet, and sleeplessness also play an important role in determining the mental health outcomes (Sarkar & Pujara, 2025). The most common signs of mental health issues in cities include the number of people suffering from depression and anxiety, the levels of psychological stress, and the rates of suicides (Alijanvand et al., 2022; Nouhi Siahroudi et al., 2025). The main barriers preventing people from accessing and using mental health services are the high cost, distance, stigma, and lack of awareness (CDC, 2022). Urban challenges notwithstanding, the city can still be a safe haven, offering social connectivity, specialized medical care, culture, and job and education opportunities as advantages (Sarkar & Pujara, 2025). In line with the salutogenesis strategy, planning of the cities should lead the situation towards the areas rich in coherence, manageability, and meaningfulness, while also including ecological areas as support for stress reduction and psychological healing (Müller et al., 2023; Sarkar & Pujara, 2025).

Bridging the Concepts

Numerous theoretical frameworks present different views on the complicated interaction among urban planning, social inequalities, and mental health. One such framework is the Social Determinants of Health (SDOH), which stresses that health variations are determined by the environments where people are born, brought up, living, working, and eventually dying (Corburn & Cohen, 2012). Mental health inequality is largely impacted by urban design factors (like housing quality, walkability, and amenities) and social inequalities (such as income, education, and exclusion), and policies in other sectors also play a major role in shaping these determinants (Smith et al., 2024). Intersectionality theory sheds light on the interaction of overlapping social identities, like race, gender, and class, with the system of power that creates compounded disempowerment and health inequality (Iyer et al., 2022). The frameworks of environmental stress spotlights urban environmental features that are stressors—noise, pollution, overcrowding, traffic, unsafe areas and lack of green spaces—which have a greater impact on the poorer neighborhoods and thus raise the risks of anxiety, depression and psychological distress (Sarkar & Pujara, 2025). In contrast, autogenic and restorative environment frameworks examine urban design as a promoter of mental health and well-being. Salutogenesis emphasizes the creation of environments that are comprehensible, manageable,

and meaningful, while restorative design highlights the role of green spaces, safe public areas, aesthetically pleasing settings, and social interaction in alleviating stress and mental fatigue (Müller et al., 2023; Sarkar & Pujara, 2025). The THRIVES framework which stands for Towards Healthy Urbanism: Inclusive, Equitable, and Sustainable, is a new and unique approach that interweaves the above ideas and advocates the urban development of such that the whole human population would have their well-being improved while the environment and the social injustices entailed would be less (Pineo, 2020).

Various studies confirm that the way cities are designed determines, among other things, the level of stress and the availability of places for relaxation, the exposure to these factors being spatially mediated by social inequalities and the mental health of the population being influenced by this interplay. However, there are still some gaps that need to be filled: the majority of studies done so far are cross-sectional, thus cannot determine causality, and the evidence from non-Western contexts, particularly that of Isfahan, ~which is a city with a rich history and culture, is meager (Sui, Ettema & Helbich, 2022; Mahani et al., 2024). Future studies need to apply mixed methods and longitudinal designs, incorporate various data sources (qualitative experiences, socio-economic statistics, environmental metrics, and detailed mental health data), and aim at facilitating the evidence-to-action in urban policy (Pineo, 2020; Sui, Ettema & Helbich, 2022).

2. Methodology

This study takes a practical and integrative viewpoint to analyze the interaction of urban design, social inequality, and mental health in Isfahan, Iran. ~Due to the contextual complexity of these relationships, an in-depth case study method was selected to facilitate a complete understanding.~ The research uses a descriptive-correlational design, depending on secondary data synthesis instead of primary fieldwork, to create a multi-level picture of Isfahan's socio-spatial and health conditions.

The researchers employed the PRISMA method to gather secondary data from various international and Iranian databases (Scopus, Web of Science, PubMed, SID.ir, Magiran), which was a major step in assuring transparency and reliability.The search terms used were "urban design", "social inequality", "spatial justice", and "mental health". The analysis was also supported by official statistics from the Iranian Statistical Center and the Ministry of Health, as well as the review of urban master plans. The urban disparities were visualized and measured quantitatively by using Geographic Information Systems (GIS) along with the support of spatial statistical tools (e.g., Moran's I). Then these results were combined with the thematic qualitative synthesis of previous studies to interpret how the built environment influences the perceptions of inequality and well-being. The findings were examined through the theoretical perspectives of, for instance, the Social Determinants of Health, environmental stress, and salutogenic design. The major restrictions concern the secondary character of the data and the absence of uniform neighborhood-level indicators that would connect the design, socio-economic status, and mental health. The immobile nature of the official maps impedes the understanding of the residents' lived dynamics, while the differences in index definitions and time periods make it hard to compare studies. Such limitations make the results to be correlational instead of causal; however, they still reveal the existence of urban disparities in a systemic way.

3. Findings and Discussion

Isfahan comes with a rich history and a great reputation for the development of not only Iran but also world urbanism. It is a perfect place to study the relations among spatial form, social organization, and lived experience. The change of Isfahan from an early settlement to the present-day city has demonstrated how urban design has simultaneously supported and obstructed social justice and people's happiness. Isfahan situated on the central plateau of Iran and fed by the Zayandeh Roud River; its development reached the climax during the Seljuk era (11th-12th centuries CE) when it turned into the capital and gradually changed into a living urban core around Masjed-e Jame' Atiq and its adjacent bazaar. This urban structure, with its narrow streets, inward-looking courtyard houses, and harmonious public-private spatial distribution, was indicative of the sustainable and socially supportive model of Persian urbanism. The city had its peak during Shah Abbas I rule in 1598 when the Safavid planning formed the heart of a new urban structure via Naqsh-e Jahan Square, which was a representation of cultural richness, civic activities, and architectural harmony. Naqsh-e Jahan Square, containing the government (Ali Qapu Palace), religious (Sheikh Lotfollah and Imam Mosques), and commercial (Qeisarieh Bazaar) complexes, is a clear-cut synthesis of civic, spiritual, and economic functions. Official documents mark it out as a ceremonial as well as a leisure center and a mainstay of Safavid cultural and political identity. The square's orientation towards the historic bazaar points to a deliberate incorporation of the new royal order into the city's traditional urban heart.

Chaharbagh Avenue was one more major undertaking during this time, a linear boulevard that united the royal areas with the Zayandeh Roud River. This avenue was a mix of transportation, landscape, and social activities, which mirrored the Safavid concept of urban spaces that were both organized and pleasant. As shown in Figure 1, the historical urban layout of Isfahan illustrates the integration of civic, religious, and commercial functions. The demolitions of older buildings that often accompanied the urban expansion in the following centuries, were very different from the planning that characterized the Safavid period, which was based on addition and cohesion.

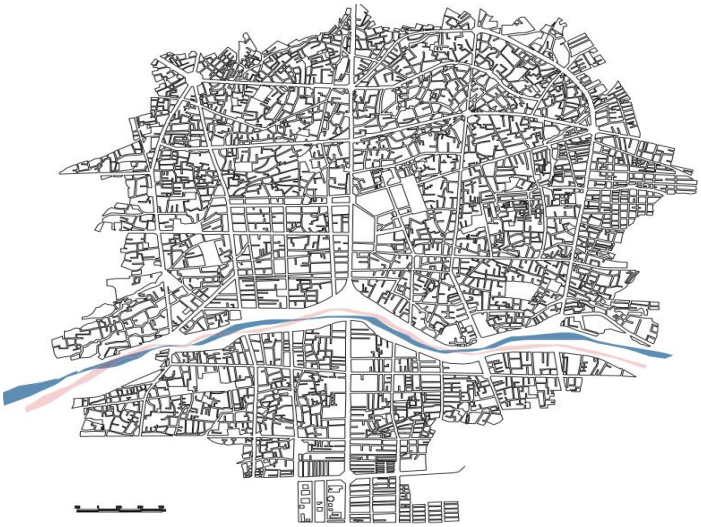

Figure 1. Urban Layout of Isfahan: A Historical City Map (Massachusetts Institute of Technology, n.d.)

Isfahan's traditional urbanism grandly displaying courtyard houses, breezy alleys, and marketplaces and squares as public spaces these concepts are usually overlooked in

contemporary design. The periodic difference in public space quality, accessibility to urban nature, walkability, and social interaction in between the old and newly developed areas is very important to understand the facts of spatial inequality. The city's planning throughout Isfahan's urban evolution highlighted the power plays of each period, determined the people's social structure and resource distribution. The city's transformation has undergone several phases Seljuk's organic centrality, Safavid's magnificence, Pahlavi's modernization, and today's urban sprawl creating a very complex and varied city in terms of both its physical and social systems. This historical flow sets up a basis to look at how the differences in density, housing types, proximity to services, and the quality of open and green spaces relate to the indicators of inequality (income, education, housing) and to the psychological issues of stress, anxiety, and depression. Thus, Isfahan's urban heritage that has been standing the test of time is a source of inspiration in making cities more sustainable and equitable through their development. Table 1, the highest residential density of 450 persons/ha, an 80/20 historic–modern fabric, and very little green space of only 5.2 m²/person are features of historic districts. The longest road network of 15.8 km and the largest green space of 8.0 m²/person are the characteristics of modern districts which still provide an environment that is less automobile-oriented. Peripheral districts have the lowest density of 150 persons/ha, the shortest road network of 9.3 km and the smallest provision of green space of only 2.5 m²/person. They also have a 90/10 modern fabric ratio. All these contrasts together point to the need for capacity and conservation challenges in the historic cores, modernization opportunities in the modern districts, and the periphery's amenity/connectivity deficits, targeted open-space provision, and transit-oriented development.

Table 1. Key Urban Design Features Across Different Districts of Isfahan (Author, 2025)

Urban Form Indicator	Historic District	Modern District		Peripheral District	
Residential Density (persons/hectare)	450	320	150	**Population**	**%**
Green Space per Capita (m²/person)	5.2	8.0	2.5	10.342.391	75.8
Road Network Length (km)	12.5	15.8	9.3	13.474.701	75.6
Historic/Modern Fabric Ratio (%)	80/20	30/70	10/90	15.702.851	75.0
Urban Form Indicator	Historic District	Modern District	Peripheral District	18.895.089	68.1

The Safavid legacy of urban planning which relied on the strategic utilization of the Zayandeh Roud River along with its “madi” channels provided Isfahan with a well-organized layout. On the other hand, urban sprawl, high-density population, and inadequate infrastructure are some of the problems the city is facing today, particularly in the areas outside and around the old city. Researches pointed out that the provision of public amenities like sports facilities is unequal across regions, which is a clear indication of injustice in this matter. Besides, the difference in

income levels makes it even harder to afford housing, thus the low-income people are being pushed into the areas where the houses are substandard and the services are poor Quantitative analyses have demonstrated very strong correlations between urban morphology, social inequality, and well-being. Research done in Isfahan in 2022 revealed that the more people were satisfied with the urban green spaces, the less anxious ($\beta = -0.24$, $p < 0.01$) and depressed ($\beta = -0.69$) they were. This protective connection survived the COVID-19 crisis, thereby highlighting the psychological advantages of green areas that are easy to access. In the United Kingdom the Persian Cohort Study provided national-level evidence, which confirmed that the mental health issues of low-income groups are more pronounced (concentration index = –0.012) and that gender and age are the major factors influencing this situation. In Isfahan, mental health problems are still a major issue, and the rate of depression among students has reached 44%. Furthermore, a study conducted in 2017 showed that around 60% of adults had experienced mental distress. The conditions of depression–stress (16.5%) and depression–anxiety (12%) are examples of how the vulnerabilities overlap. Suicide trends are one of the indicators of the mental health crisis: the ages 15-29 recorded the highest rates, and the methods of hanging and self-immolation were the most common respectively for men and women The distribution of suicide methods by gender is summarized (See Figure 2).

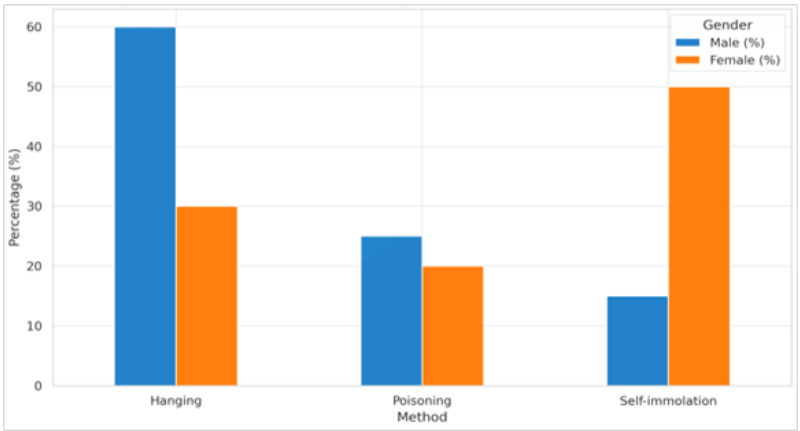

Figure 2. Common Suicide Methods by Gender in Isfahan Province (2013–2015) (Author, 2025)

According to national records, the period from 2010 to 2021 saw an average suicide rate of 8.14 per 100,000 people in Iran, where around 131 attempts occurred per 100,000. About 76% of the respondents stated the need for mental health assistance, but only 50% of them tried to consult a professional, mainly because of financial issues, lack of access to services, mistrust, and social stigma (Mohammadi et al., 2008). Urban planning factors in Isfahan only make matters worse. Areas with little greenery and no facilities for leisure, poor housing, and the residents' feelings of being polluted and slow public transport are the main causes of mental suffering, especially in low-income neighborhoods (Sui et al., 2022; Saraei et al., 2020; Asgari & Gholi Zadeh, 2020). Major barriers to mental health service utilization are illustrated, As shown in Figure 3, cost of services is the most frequently reported barrier, followed by access/distance and stigma (See Figure 3).

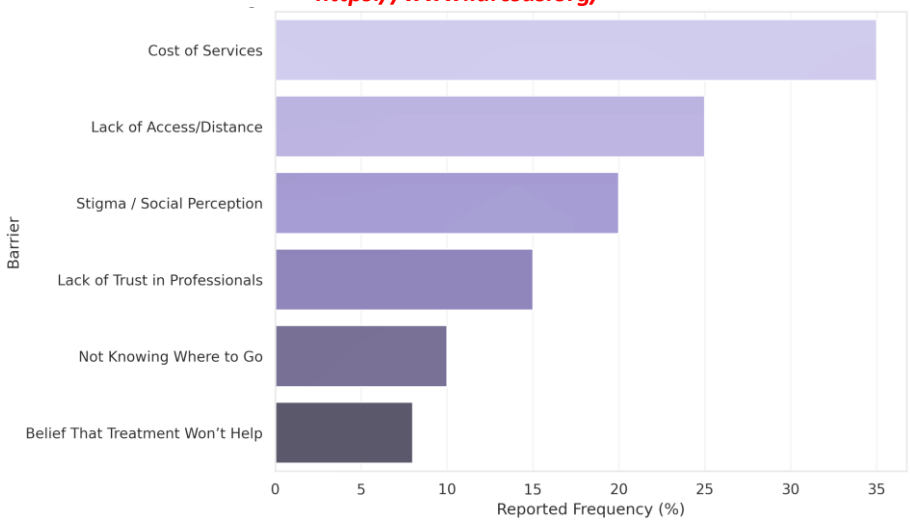

Figure 3. Barriers to Mental Health Service Utilization in Isfahan (Author, 2025)

The socio-economic inequalities which are geographically located within Isfahan's urban fabric, have a great impact on mental health disparities (Mahani et al., 2024). Urban design that promotes equity, such as easy access to parks, increased housing quality, and mental health services that cater to all, can alleviate these disparities and enhance the wellbeing of the whole community (Sarkar & Pujara, 2025; Asgari & Gholi Zadeh, 2020). There is a need for further detailed, neighborhood-level studies utilizing GIS tools to identify the complex spatial patterns of inequality and the effects on public health (Martens, 2017). In Figure 4, the highest prevalence is observed among IUMS students (≈45%), followed by IUMS employees (≈28–29%) and secondary school students (≈21–22%). Lower levels are seen in general adults with depression + stress (≈15–16%) and general adults with depression + anxiety (≈10–11%).

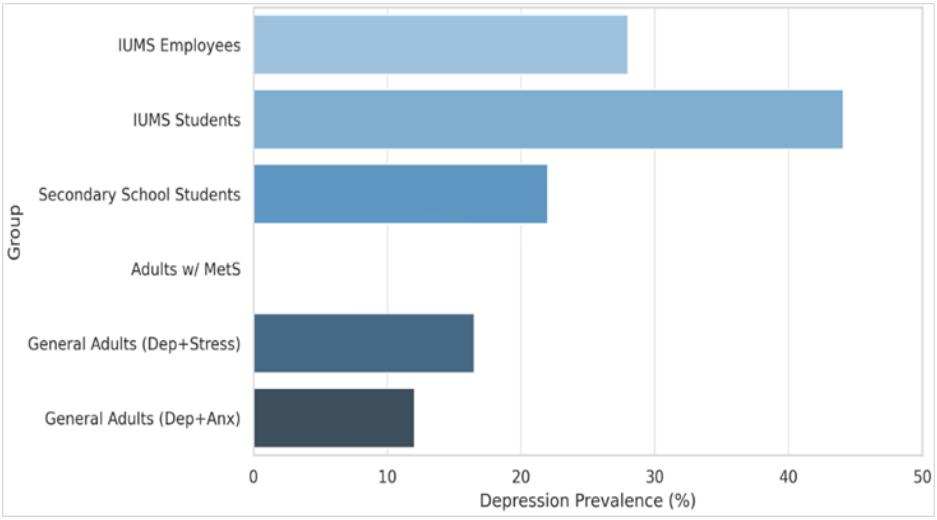

Figure 4. Depression Prevalence Among Different Population Groups in Isfahan (Author, 2025)

The HADS (Hospital Anxiety and Depression Scale) showed a 28% depression rate among the IUMS staff (Najafi, Rezaei, & Hashemi, 2022). Students at university had a 44.1% prevalence

based on the BDI (Ahmadi & Rezai, 2024), while high school students came up with a figure of 22% through the use of the CDI (Bazargan & Dehghani, 2023). Furthermore, the adult population with metabolic syndrome exhibited depression and anxiety levels that were higher than the ones recorded for the non-metabolic group (Shahrestanaki et al., 2012). The anxiety rate that was among the IUMS personnel was about 14% (Najafi, Rezaei, & Hashemi, 2022).Suicide, which is the most drastic expression of mental health issues, has raised a worrying issue in Isfahan. In the years 2013–2015, the most common methods of suicide were hanging, poisoning, and self-immolation, with men opting for hanging and women for self-immolation; it was mainly 15–29-year-olds who made up the majority of cases (Sharifi et al., 2024). Some places like Najafabad have been singled out for having particularly high mortality rates (Sharifi et al., 2023). The accessibility of mental health care is still very limited in some regions. Even though a large portion of the population, 76%, indicated that they required professional help for their mental health problems, the demand was not met as only 50% of the individuals opted for the treatment; similarly, among parents with mental disordered children, 81.3% were ready to seek help but only 55.4% opted for it (Mohammadi, Naghavi, & Zarafshan, 2008). The main obstacles consist of various issues related to logistics (high cost, distanced location, long waiting time, lack of information), people's perception of the situation (e.g. stigma, distrust of the professionals, doubts about the effectiveness of the treatment), and the unavailability of professionals in psychiatry and the high prices of mental health services (Mohammadi et al., 2008; Hosseini et al., 2023; Shakeri et al., 2022). All in all, these data suggest that there is a huge unmet demand for mental health services in Isfahan, including depressive disorders, anxiety, stress, and suicides, with cost, accessibility, and stigma comprising the main barriers. This underscores a critical gap between population needs and available mental health services (Alijanvand et al., 2022; Mohammadi, Naghavi, & Zarafshan, 2008). In the Table 2 Prevalence estimates are derived from different screening instruments (HADS, BDI, CDI) applied to distinct sub-populations (employees, university students, adolescents), and are therefore not directly comparable across rows (Afshar et al., n.d.; Karimi et al., 2021). Provincial suicide data refer to 2013–2015, whereas national suicide/attempt rates are aggregated for 2010–2021; temporal comparisons should be interpreted cautiously (Brief Lands, n.d.; Ahmadi et al., 2023). Barriers to care and service utilization figures are based on Iranian and Isfahan samples and document persistent cost, access, stigma, and trust constraints within the mental healthcare pathway (Mohammadi, Naghavi, & Zarafshan, 2008).

Table 2. Health Outcome Improvements by Building Type (Author, 2025)

Indicator	Finding / Data Point (Prevalence % or Rate)	Population Group / Context	Location	Source(s)
Depression Prevalence	28% (HADS)	IUMS Employees	Isfahan Province	(Afshar et al., n.d.)
	44.1% (BDI)	IUMS Students	Isfahan	("Prevalence of Depression in Iranian College Students," n.d.)
	22% (CDI)	Secondary School Students	Isfahan	(Karimi et al., 2021)
	Higher mean score in	Adults with/without	Isfahan	(Hosseini et al., 2012)

	adults with Metabolic Syndrome (HADS)	MetS		
	Pair-comorbidity with Stress: 16.5% (HADS)	General Adults	Isfahan Province	(Alijanvand et al., 2022)
	Pair-comorbidity with Anxiety: 12.04% (HADS)	General Adults	Isfahan Province	(Alijanvand et al., 2022)
Anxiety Prevalence	14% (HADS)	IUMS Employees	Isfahan Province	(Afshar et al., n.d.)
	Higher mean score in adults with Metabolic Syndrome (HADS)	Adults with/without MetS	Isfahan	(Hosseini et al., 2012)
	Pair-comorbidity with Stress: 10.23% (HADS)	General Adults	Isfahan Province	(Alijanvand et al., 2022)
	Pair-comorbidity with Depression: 12.04% (HADS)	General Adults	Isfahan Province	(Alijanvand et al., 2022)
Stress Prevalence	Pair-comorbidity with Depression: 16.5% (HADS)	General Adults	Isfahan Province	(Alijanvand et al., 2022)
	Pair-comorbidity with Anxiety: 10.23% (HADS)	General Adults	Isfahan Province	(Alijanvand et al., 2022)
Completed Suicide Rate	Methods: Hanging (esp. males), Burning (esp. females), Poisoning. Age: Peak 15-29 yrs.	General Population (2013-2015)	Isfahan Province	(Brief Lands, n.d.)
	Iran overall: 8.14 per 100k (9.1 M, 5.0 F)	National (2010-2021)	Iran	(Ahmadi et al., 2023)
Suicide Attempt Rate	Iran overall: 131 per 100k (128 M, 152 F)	National (2010-2021)	Iran	(Ahmadi et al., 2023)
Barriers to MH Service Use	Cost, inconvenient access, stigma, lack of trust are major barriers.	General Population / Patients (incl. Isfahan sample)	Iran / Isfahan	(Mohammadi, Naghavi, & Zarafshan, 2008)
MH Service Utilization	Low utilization despite need (e.g., only 50% of those wanting help sought it; 15.6% ever saw	General Population / Specific samples	Iran / Isfahan	(Mohammadi, Naghavi, & Zarafshan, 2008)

	psychologist/psychiatrist in another study).			
Mental Health Burden (DALYs)	Significant & increasing burden nationally from mental disorders (Depression, Anxiety highest).	National (1990-2019)	Iran	(National and subnational burden of mental disorders in Iran (1990–2019), 2020)
MH Professionals per capital	Data specifically for Isfahan not found in reviewed sources.	-	Isfahan	-

Sharifi et al. (2023) mention that some areas with higher localized suicide death rates in the Isfahan province, like Najafabad, have been reported. Overall, Ilam, Hamadan, and Kermanshah have the highest suicide rates, yet the problem continues to be serious all over the country (Sharifi et al., 2023). Access to mental health services is restricted. A national study indicated that 76% of the participants considered themselves in need of psychological support, but only 50% actually took the step to contact the help (Mohammadi, Naghavi, & Zarafshan, 2008). The same gap was observed among parents of children with mental health disorders—over 81% were ready to seek assistance, while just about 55% did. Finance, distance, time for processing, and lack of information about services were mentioned as the major barriers. Participants pointed out among other reasons that there was low trust in professionals, there was stigma, and there were doubts about the efficacy of treatment (Mohammadi, Naghavi, & Zarafshan, 2008). There were also structural difficulties, such as services not being affordable, side effects of medication, and stigma, which were mentioned in the context of qualitative research that was conducted among patients suffering from bipolar disorder in Isfahan (Hosseini et al., 2023). There is limited information available concerning the number of mental health professionals per capita in Isfahan (Shakeri et al., 2022). Philanthropy density was taken into account, though, in other provinces like Lorestan, while similar information for Isfahan was not accessible (Shakeri et al., 2022). National DALYs data reveal a huge increase in the mental disorder burden, particularly depression, anxiety, schizophrenia, and bipolar disorders, from 1990 to 2019 (Tehrani-Banihashemi et al., 2022). Also, one of the main reasons for this is the low mental health literacy (MHL) which is shown by the fact that the correlation of higher MHL with better life outcomes is strong (Sheikhi et al., 2022). However, merely 15.6% of the study participants ever went to see a mental health professional. Likewise, only a third of medical interns at Tehran during the pandemic resorted to psychological help (Khafri et al., 2022). Figure 5 Anxiety prevalence (%) across population subgroups. Bars display the point estimates of reported anxiety by group. The highest prevalence is observed among IUMS employees (≈14–15%), followed by general adults with comorbid anxiety–depression (≈11–12%) and general adults with anxiety plus stress (≈10–11%). Taken together, this evidence clearly indicates that there are considerable unmet mental health needs in the Isfahan area where depression, anxiety, stress, and suicide exist at high rates and are further intensified by barriers like cost, access, and stigma (Alijanvand et al., 2022; Mohammadi, Naghavi, & Zarafshan, 2008).

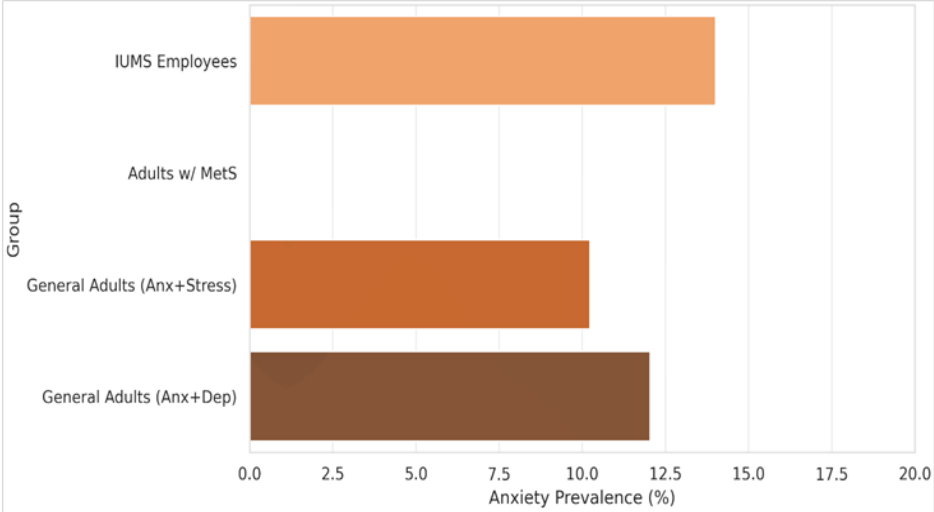

Figure 5. Anxiety Rates Across Socio-Demographic Groups in Isfahan and Comorbid Conditions (Author, 2025)

The negative impact on mental health in Isfahan is increased due to the geographical distribution of socioeconomic inequalities (Parrish et al., 2024). A significant part of the population suffers from poor mental health with high prevalence of depression, anxiety and suicide (Karimi et al., 2021), and at the same time, persistent barriers that make access difficult such as high cost, inaccessibility and stigma (Mohammadi, Naghavi, & Zarafshan, 2008) represent a critical public health issue. No public or green spaces may lead to less social interaction and thus less time for individuals to build social support, which could further raise the risk of people becoming isolated—a factor affecting mental health (Sarkar & Pujara, 2025). Isfahan's contemporary urban layout manifests inequality in resources and opportunities distribution (Martens, 2017). Such disparities might be the reason behind the mental health problems in the community and less use of mental health services (Karimi et al., 2021; Mohammadi et al., 2008). Therefore, the urban context of the city could be considered both a potential resource and a source of stress for the inhabitants (Chitsazzadeh & Farahani, 2021; Sarkar & Pujara, 2025). The mentioned conclusions are consistent with the Social Determinants of Health framework (Corburn & Cohen, 2012), the Environmental Stress Model, and the Salutogenesis concept which all point to the direction that built environments and social disadvantage affect people's well-being (Sarkar & Pujara, 2025; Müller et al., 2023). It is still so important to make mental health services more available by providing investment, financial support, primary-care integration, and running awareness campaigns (Mohammadi et al., 2008). This lack of data, which is related to the neighborhood level, connecting environmental design with socioeconomic and mental health outcomes has prevented a full causal analysis (Kiadaliri et al., 2013). One way to approach this issue would be through GIS-based spatial analyses that might reveal a connection between certain urban design features and health outcomes (Martens, 2017). Table 3, Social discrimination indicators by district in Isfahan (Ghaedrahmati et al., 2018). Values report unemployment rate (Historic 9.8%; Modern 7.5%; Peripheral 14.3%), income inequality via the Gini coefficient (0.32; 0.28; 0.41), healthcare service coverage (88%; 92%; 76%), and housing affordability rate (65%; 78%; 50%) across historic, modern, and peripheral districts, respectively. Note: higher Gini indicates greater inequality; for percentages, higher is better except for unemployment.

Table 3. Social discrimination Indicators by District (Ghaedrahmati et al. 2018)

Social Indicator	Historic District	Modern District	Peripheral District
Unemployment Rate (%)	9.8	7.5	14.3
Income Gini Coefficient	0.32	0.28	0.41
Healthcare Service Coverage (%)	88	92	76
Housing Affordability Rate (%)	65	78	50

Minor and inconclusive evidence that can be found in the current literature, however, indicate a pattern of spatial inequity that is very strong and well defined in Isfahan. In addition, the analysis of the urban fabric has uncovered differences that are present in the distribution of basic amenities and services. As an example, the public sports facilities are very unevenly distributed in favor of the central districts, whereas the urban peripheries suffer from a lack of such facilities (Saraei, Ghafarian, & Dasta, 2020). Because of the income gap that makes it difficult for people to afford housing, the poorest families are perforcedly segregated into neighborhoods with poor-quality housing and little resources. The injustice is aggravated by the socioeconomic factors. (Asgari & Gholi Zadeh, 2020) GIS research indicates that injustice in space is not evenly distributed among the municipal districts of Isfahan. The ideal method for spatially unjust situations to be represented would be one that includes both visual and quantitative characteristics. A good example is the research of Ghaedrahmati et al. (2018) showing the whole country mapped very clearly regarding social justice levels according to access to basic urban services fivefold combined indicator. The best usufruct areas, as depicted in the image, Indeed, urban resources are allocated extremely unevenly, judging by the areas that receive good and poor living conditions. The city is divided into neighbourhoods where the poor are concentrated, and in large parts of the city, especially in the outer and older, worn-out districts, people are being classified as impoverished or totally impoverished. This visual evidence makes the inequity distribution of urban resources very clear. In Figure 6, depression prevalence (%) across population subgroups. Bars indicate point estimates for each group. The highest prevalence is observed in IUMS students (≈45%), followed by IUMS employees (≈28–30%) and secondary school students (≈22–23%). Lower levels are seen in adults with metabolic syndrome (MetS) (≈14–15%), general adults with depression plus stress (≈12–13%), and general adults with depression plus anxiety (≈8–9%).

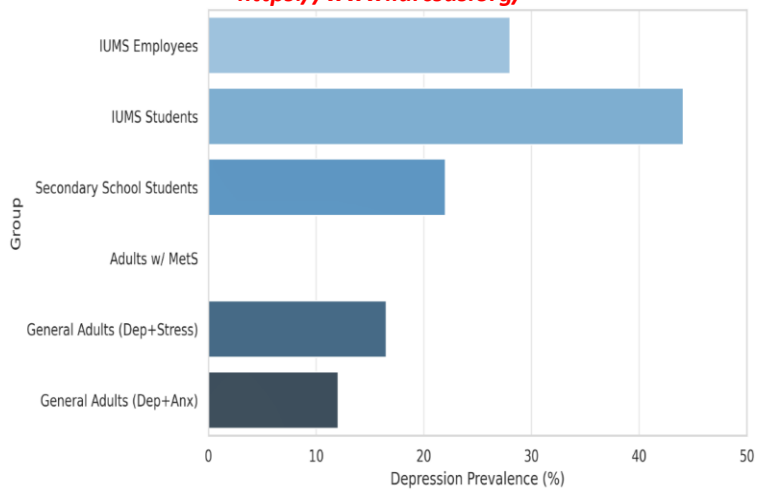

Figure 6. Equity in Space of Isfahan (Ghaedrahmati et al., 2018)

The areas where the dark color is present have a high level of enjoyment while the regions with lighter colors such as yellow and orange are the ones with less people having access to basic needs and thus the dark color is in the center of the city and the yellow and orange colors are in the outskirts. Source: Adapted from Ghaedrahmati et al. (2018). The spatial analysis is being expressed quantitatively through the summary in (Ghaedrahmati et al., 2018). Table 4 shows, area shares across four social-justice tiers are reported with defining characteristics: Enjoyment (5.3%): high access to health, education, recreation, and green space; Semi-Enjoyment (39.6%): moderate/good access with some gaps; Deprived (36.2%): limited access to multiple essential services; Fully Deprived (18.9%): critically low access to basic urban infrastructure and amenities.

Table 4. Levels of Spatial Inequality in Isfahan: The Opportunity Structure of its Municipal Districts (Ghaedrahmati et al. 2018).

Level of Social Justice	Area Percentage	Key Characteristics
Enjoyment	5.3%	High access to all services (health, education, recreation, green space).
Semi-Enjoyment	39.6%	Moderate or good access to most services, but with some deficiencies.
Deprived	36.2%	Limited access to multiple essential services.
Fully Deprived	18.9%	Critically low access to basic urban infrastructure and amenities.

When taking a closer look at the quantitative results, it comes to light that urban setting, inequality, and mental health are linked by statistically significant correlations. The less the positive views of urban green space (UGS) the more the anxiety ($\beta = -0.24$, $p < .01$) (Sarkar &

Pujara, 2025). Besides, the application of Global Moran's I in spatial analysis was a further step that confirmed the non-random distribution of social justice, as the Moran's Index of 0.515 ($z = 57.27$, $p < 0.001$) showed this with high- and low-inequality areas being clustered (Ghaedrahmati et al., 2018). The present-day urban environment divides people regarding access to services, sports facilities, and housing prices (Martens, 2017; Saraei et al., 2020; Asgari & Gholi Zadeh, 2020). Isfahan mental health studies have revealed high rates of gloom and anxiety (Alijanvand et al., 2022) among people who also face the barriers to care like cost, logistics, and stigma (Mohammadi et al., 2008). The scarcity of recreational areas and their unequal distribution signal a lost opportunity for the enhancement of well-being and equality (Müller et al., 2023). The case in Isfahan reveals that disparity in the availability of services, infrastructure, and health impacts are signs that health equity need be a fundamental part of urban planning. Besides, development projects and zoning laws should always be reviewed for their impact on social inequity and mental health. Policies that favor human-scale design, connectivity, mixed land use, and public amenities distribution among areas most in need will be the ones to make it certain that all communities draw benefits from urban growth (Higgins et al., 2020; New York City Department of City Planning, 2024).

The authors suggest that the access to greenery and public spaces should be given priority in the neighborhoods that are in most need in order to lower the risk for mental health (Sarkar & Pujara, 2025). The money must be spent on parks and plazas and areas for recreation that are either within walking distance or very close to public transit, thus making sure that the urban amenities are distributed equitably. Mental health care access equity can be achieved through the increase of community-based services, the incorporation of care into primary health systems, the reduction of fees, and the organization of stigma-reducing awareness campaigns (Mohammadi et al., 2008). Well-positioned services and interdisciplinary teams across urban planning, housing, transport, public health, and social services are crucial, with the help of the participatory planning process that involves local people (Chitsazzadeh & Farahani, 2021; Inclusive aspects of urban design, 2017). Isfahan does not consist of reliable datasets at neighborhood level which are already combined urban design, socioeconomic indicators, and mental health outcomes, and data at provincial level hides intra-city variability (Kiadaliri et al., 2013). Differences in survey methods and timelines continue to pose problems to comparisons and synthesis (Kiadaliri et al., 2013). GIS-based spatial analyses can link outside form (green place, street connectivity, building typologies) with inequality and health outcomes (Martens, 2017). Lastly, the analysis of the past infrastructure, for example, the mâdi water-distribution system, could unearth not only the cultural and practical aspects of social cohesion and well-being but also the needs of the people in that area (Chitsazzadeh & Farahani, 2021). Table 5 shows, health care and mental health as stakeholders in the relationship between common mental disorders and sources of health data (Author, 2025). Values report anxiety prevalence (Historic 22.4%; Modern 18.6%; Peripheral 29.1%),depression prevalence (14.7%; 12.0%; 21.5%), and suicide rate (per 100,000 population: 6.2; 4.5; 8.7). Main access barriers are qualitative summaries by district: Historic cost, stigma; Modern accessibility, cost; Peripheral cost, distance.

Table 5. Health care, and mental health sit as stakeholders of the operations of the Relationship of Common Mental Disorders and Sources of Health Data (Author, 2025).

Variable	Historic District	Modern District	Peripheral District
Anxiety Prevalence (%)	22.4	18.6	29.1
Depression Prevalence (%)	14.7	12.0	21.5
Suicide Rate (per 100,000 population)	6.2	4.5	8.7
Main Access Barriers	Cost, Stigma	Accessibility, Cost	Cost, Distance

4. Conclusion and Recommendations

The sketched out scenario portrays the said researchers opposing each other and working with different pieces of evidence to conclude that in Isfahan the urban amenities and Society opportunities have a spatial structure rather than a random placement which eventually generates separate zones of both risk and advantage. By trying to connect one of the geographical patterns of Society injustice (Ghaedrahmati et al., 2018) with a major mental health crisis on the population (Alijanvand et al., 2022), this research identifies the built environment as an important factor that plays a role in the health disparities. The study confirms that innocent urban design depicts various environmental and social stressors that are unequally distributed among the sensitive communities and the systemic barriers that limit their access to the services (Mohammadi, Naghavi, & Zarafshan, 2008). The main scholarly contribution of this research is the transformation of already recognized models for urban health to the specific, complex historical situation of a huge non-Western metropolis that offers an unavoidable location-based empirical basis for further investigations and ultimately informed policy. The instance of Isfahan strongly supports the view that the creation of genuinely healthy and sustainable urban environments in the future requires a change in the way urban planning is done retaining the concern for aesthetics and functional efficiencies but at the same time giving priority to social equity and mental health as the core of the planners' agenda. Based on the findings, the following policy actions are recommended for municipal authorities and Society health officials in Isfahan: Spatially goal Health Investments: Make use of GIS data pertaining to social equity for directing the distribution of resources. Set up (for instance, in areas 7, 8, 11, and 12) new inexpensive community mental health clinics in underprivileged regions and alongside public facilities like libraries or community centers in order to facilitate access and eliminate stigma (Ghaedrahmati et al., 2018).

1. Promulgate Quantitative Green place Equity Standards: The deficiency of restorative environments should be tackled via the adoption of urban green space standards that are quantifiable and citywide. The criteria of "3-30-300" may be taken as a guideline where one can put it this way: at least three trees should be visible from the house, the neighborhood should have a 30% tree cover, and the residence should not be more than 300 meters away from a good park. It is these outer and disadvantaged districts that must receive the first attention.

2. Health Equity Impact Assessments (HEIA) should be mandated: All major urban submitted for approval need to go through a formal evaluation process assessing the negative or positive

impacts on health equity, access to services and quality of environment. Such assessments are to be done by the developers at the make stage so that the new buildings or enhancement will not increase the existing inequalities but will actually decrease them.

3. Foster Inter-Sectoral Collaboration: Create a formal task force that will include representatives from urban municipal planning, regional health ministry, and academic institutions. The taskforce will synchronize data exchanging, joint planning, and monitoring of health equity objectives thus clearing the way for breaking down institutional barriers and advancing urban health governance through efficiency.

Abstract

Today, university campuses are often perceived primarily as places dedicated to education and research activities. However, campuses also have the potential to become vibrant social, cultural, and aesthetic environments for students, academics, and visitors. This study explores the role of nature-based open space approaches in campus life. Taking the Terzioğlu Campus of Çanakkale Onsekiz Mart University as a case study, the research focuses on workshops organized with natural materials and the exhibition of the produced works in an open-air museum format. Findings indicate that nature-based workshops enhance participants' environmental awareness, provide aesthetic contributions, and strengthen the social functions of the campus. Moreover, this approach supports university-community interaction and contributes to transforming campuses into sustainable cultural hubs. The study emphasizes the importance of considering campus models integrated with nature in future planning and design processes. In conclusion, nature-based open space arrangements help redefine university campuses not only as academic centers but also as social, cultural, and aesthetic environments. By integrating sustainability, environmental awareness, and creativity, this approach offers an innovative model for contemporary campus life.

Keywords: Nature-based campus, Sustainability, Open-air museum, Campus design

1. Introduction

University campuses are multidimensional living environments that extend beyond being mere physical settings where academic education takes place. They are spaces where individuals gain social, cultural, and environmental experiences. Today, campus design is being reinterpreted through comprehensive approaches that prioritize concepts such as sustainability, ecological sensitivity, user needs, accessibility, and integration with nature. These approaches have become decisive in the spatial planning policies of higher education institutions, as they influence not only students' academic performance but also their social and psychological development processes. The positive impacts of nature-integrated campus environments on individuals reveal that university campuses should transcend their traditional role as solely educational spaces. Studies addressing the effects of the natural environment on individuals demonstrate that contact with nature has a restorative and regulating effect on human psychology. Özdemir (2010) notes that natural landscapes contribute to reducing stress, enhancing mental restoration, and strengthening the sense of place attachment. When university campuses are examined from this perspective, it becomes evident that campuses featuring expansive open spaces, natural vegetation, shade-providing trees, recreational zones, and topographical diversity create more favorable outcomes for students. Thus, adopting a nature-integrated approach in campus design not only enriches the physical environment but also generates pedagogical value that directly shapes student experience.

Nature-based practices have become increasingly significant in higher education institutions in recent years. These practices enable the use of natural materials (such as wood, stone, and plant-based elements) in production processes, facilitate direct interaction between students and their natural surroundings, and support creative thinking through hands-on experiential settings. Chawla (1999) emphasizes that active engagement with nature plays a critical role in fostering environmental responsibility. Accordingly, nature-based activities organized on campuses provide effective learning environments that support both the cognitive and emotional development of students. Open space use—an essential component of campus life—constitutes a key factor shaping students' relationship with their campus environment. Aslanboğa (2018) highlights that students' satisfaction with open spaces directly influences their overall perception of campus quality of life. Students particularly prefer shaded areas under trees, lawn surfaces, recreational arrangements, and semi-open seating units. The common characteristics of these preferred spaces include the comfort, tranquility, and opportunities for social interaction offered by natural landscape elements. Therefore, preserving the natural environment and utilizing it functionally are crucial considerations in the design and planning of campus open spaces. Supporting open spaces with social and cultural functions transforms campus life into a more dynamic and participatory structure. In this context, nature-based workshops provide opportunities for students to take part in production processes while simultaneously engaging directly with natural settings. These workshops offer significant potential for transforming natural materials into creative outputs, enabling students to make constructive interventions in their surroundings and experience a design process that is integrated with nature.

The open-air museum approach, on the other hand, stands out as a unique spatial model that enables the integrated exhibition of natural and cultural elements. Open-air museums are defined as environments that make cultural production visible within natural landscapes, directly interact with visitors, and transform space into a learning environment. Acar (2019) states that open-air museums play an important role in preserving and communicating cultural heritage. Implementing such an approach on university campuses allows student productions to become visible and strengthens the cultural identity of the campus, thereby offering an original design model. University campuses are also regarded as significant components of urban systems. In today's context—where densely populated city centers are expanding and natural areas are increasingly diminishing—campuses may serve as valuable recreational and ecological spaces for urban residents as well. Supporting campuses with nature-based practices provides positive contributions not only to the university community but also to the surrounding urban fabric. The preservation of natural spaces within campuses, the reorganization of open areas for multifunctional uses, and the integration of cultural activities contribute to establishing a sustainable campus–city relationship. In conclusion, nature-based open space approaches present a significant design framework that enhances the social, cultural, and ecological qualities of university campuses. The positive influence of nature contact on student life, the creativity stimulated through production processes involving natural materials, and the increased cultural interaction facilitated by the open-air museum model all demonstrate the need for a holistic design approach in university campuses. This study aims to reveal the existing open space potential of the campus, evaluate nature-based workshop and open-air exhibition approaches, and develop recommendations that contribute to sustainable campus life.

2. Literature Review

This section examines four main themes: open space use on university campuses, the effects of campus design on user experience, the concept of nature-based workshops, and the open-air museum approach. The literature review demonstrates that campuses are not merely educational spaces but large-scale living environments in which social, cultural, and ecological experiences are produced.

2.1. Campus Life

Campus life consists of multidimensional social and environmental interactions experienced simultaneously with the educational process by students, academics, and various user groups. University campuses serve as places not only for academic activities but also for socialization, rest, cultural participation, and creative production. For this reason, the quality of campus spaces directly affects students' academic performance, psychological well-being, and sense of spatial belonging.

The integration of natural environments into campus life creates positive effects on students' mental and emotional processes. Hartig, Kaiser, and Bowler (1997) emphasize that time spent in natural areas has a strong restorative impact on mental renewal. This finding reveals that natural landscapes serve not merely as aesthetic components but also as functional elements that support mental restoration, stress reduction, and motivation.

Today, many campuses aim to provide green spaces, recreational arrangements, and natural landscape elements that enhance students' social life. Increasing the time spent in open spaces contributes to stronger student relationships, higher levels of social interaction, and the adoption of the campus as a living environment. As a result, the quality of campus life has become as important as the quality of education itself.

Another significant feature of campus life is spatial diversity. Quiet study zones, active social areas, walking routes, rest areas, semi-open spaces, and outdoor recreational surfaces offer a multifaceted structure that accommodates the needs of different user groups. This variety helps users perceive the campus not merely as a place of obligation but as an active component of their daily routines. Therefore, the quality of open spaces is regarded as a key determinant of overall campus life quality.

2.2. Campus Uses, Campus Design, and the Campus for All Approach

Adopting a user-centered, inclusive, and accessible approach in campus design is a fundamental principle of contemporary planning. Since university campuses host users with diverse physical and social needs, their design must encompass a wide range of requirements. In this context, the "campus for all" approach prioritizes equitable access and usage rights for diverse user groups, including individuals with disabilities, children, older adults, and students from various socio-cultural backgrounds.

Korkut and Karahan (2022) emphasize that open space design principles on campuses should be reconsidered according to user needs. In this regard, accessibility, safety, wayfinding, seating areas, lighting, continuity of green texture, and pedestrian connections constitute essential components of the design process. Additionally, socially interactive campus environments help students embrace the campus as a space of daily life.

Sustainability is another critical principle in campus design. Practices such as preserving natural landscapes, using native plant species, maintaining ecological connections, and selecting

materials with a low carbon footprint support long-term spatial sustainability. These practices ensure that campuses provide a high-quality environmental infrastructure not only for current users but also for future generations.

Open space arrangements on campuses are also valuable in terms of spatial continuity and functional diversity. Shade-providing trees, permeable surfaces, natural ground textures, open lawn areas, and semi-open spaces encourage users to spend more time outdoors. Aslanboğa (2018) indicates that open spaces are significant determinants of students' campus satisfaction. Therefore, open space design must be approached as a multifaceted framework that responds to both natural and social needs.

In conclusion, contemporary campus design goes beyond spatial organization; it represents an inclusive, sustainable, socially interactive, and nature-integrated approach shaped around the needs of users.

2.3. The Concept of Nature-Based Workshops

Nature-based workshops are participatory, experience-oriented activities that involve the use of natural materials in creative processes. These workshops contribute to learning and environmental awareness by enabling individuals to engage directly with the natural environment. Widely used across disciplines such as education, art, design, and landscape architecture, this method is an effective tool for fostering sustainability awareness.

In nature-based workshops, natural materials such as wood, stone, clay, and plant-based elements are utilized in various production processes. These activities allow students to explore the physical properties of natural materials, develop skills related to material transformation, and strengthen creative thinking practices. Highlight that production processes involving natural materials enhance sustainable design awareness. Therefore, nature-based workshops hold significant educational and experiential potential in university campuses.

Another important characteristic of nature-based workshops is their contribution to community-building processes. These activities bring together students from different disciplines, foster collaboration toward common goals, and encourage active participation in production. Thus, students not only create tangible outputs but also strengthen their social interaction, communication, and teamwork skills.

Conducting workshops in outdoor environments integrates the natural landscape into the production process. This provides participants with an immersive learning experience embedded in the natural context. Topographical diversity, various types of vegetation, open lawn surfaces, and semi-natural spaces offer a rich spatial infrastructure for workshops. Since most university campuses include such areas, the applicability of nature-based workshops is considerably high.

2.4. The Concept of Open-Air Museums

Open-air museums are spatial organizations that enable the exhibition of cultural, artistic, and natural elements in open environments. These museums contribute to the preservation of cultural heritage while offering visitors a display experience integrated with the natural environment. Unlike indoor museums, open-air museums incorporate the natural texture of the landscape into the exhibition and promote a more immersive engagement between visitors and the space.

Acar (2019) emphasizes that open-air museums make cultural heritage visible, accessible, and participatory. This approach also provides a relevant model for university campuses. Exhibiting artworks produced in nature-based workshops within open spaces not only increases the visibility of student productions but also enriches the cultural identity of the campus.

Open-air museums also represent a sustainable exhibition model. Low energy consumption, the use of natural landscapes as protective mediums, and the integration of exhibition areas with open spaces constitute environmentally friendly practices. For this reason, the open-air museum model can be considered compatible with sustainable campus design.

Another important advantage of outdoor exhibition areas is their continuous interaction with campus users. Exhibits placed along main pedestrian routes, in lawn areas, or within natural clearings allow students to encounter cultural elements during their daily activities. In this way, the campus becomes not only a space of education and circulation but also a living cultural environment.

3. Materials And Methods

The materials and methods used in this research consist of two main stages designed to evaluate the applicability of nature-based open space approaches on university campuses: a literature review and field observation. These two stages were addressed in a complementary manner to obtain both theoretical and practical data.

3.1. Materials

The materials of the study include the open spaces of the university campus, its natural landscape characteristics, potential workshop areas, and possible open-air exhibition sites. Within the scope of the research, the following components of the campus were examined in detail:

- topographic structure,
- diversity of vegetation,
- pedestrian circulation networks,
- shading opportunities,
- recreational surfaces,
- natural material potential (wood, stone, plant-based elements, etc.).

In addition to these physical components, the theoretical materials of the study were obtained from academic literature related to nature-based design, campus open spaces, nature-based educational approaches, and the concept of open-air museums. Thus, a holistic material structure was established by integrating both spatial observations and scientific resources.

3.2. Method

The research method consists of two main stages: a literature review and field observation.

3.2.1. Literature review

In the first stage of the study, a comprehensive literature review was conducted. This review included national and international academic publications on nature-based workshops, open

space design principles, campus open space use, cultural display practices, and open-air museum approaches.

The literature review formed the conceptual framework of the research and served as a key reference point for interpreting the findings obtained through field observation. In this way, the theoretical foundations of nature-based campus approaches were clarified, and their connection to field data was strengthened.

3.2.2. Field observation

The second stage of the research consisted of field observation. In this stage, campus open spaces were examined on-site along routes determined by the researcher. During the field observations, the following aspects were assessed:

- user density,
- types of open space use,
- resting and socialization areas,
- potential accumulation areas for natural materials,
- possible workshop activity sites,
- open-air exhibition potential,
- landscape continuity and accessibility.

Throughout the observation process, methods such as photography, field note-taking, spatial analysis, and on-site evaluation were used. The collected data were then evaluated by establishing a relationship between the physical and natural characteristics of the campus and user behaviors.

4. FINDINGS

The findings of this research were evaluated in relation to the current characteristics of campus open space use, user behaviors, natural material potential, and open-air exhibition capacity. When the results of the literature review and field observations are considered together, it becomes evident that the campus possesses strong ecological and social potentials. The findings are presented under three main categories: open space use characteristics, natural material potential and workshop areas, and open-air exhibition potential.

4.1. Open Space Use Characteristics

Field observations indicate that open spaces on the campus are among the most frequently used areas by students. These areas are particularly preferred for resting, socializing, spending short periods of time, working outdoors, or waiting between classes. Three primary types of spaces were found to be especially prominent:

1. **Shaded Areas Beneath Trees -** A majority of students prefer shaded spaces. Tree canopies provide both protection from sunlight and a natural microclimate, ensuring comfortable outdoor use, especially during warm weather.

2. **Semi-Open and Open Seating Units** - Benches, pergolas, and semi-open seating structures located throughout the campus are among the most intensively used spaces. These areas support a wide range of activities, from individual sitting to group interactions.

3. **Large Lawn Surfaces** - Lawn areas are especially preferred in favorable weather conditions for socializing, resting, lying down, or reading. Their flexible usage potential is one of their main advantages.

These usage patterns align with findings in the literature on the positive effects of natural environments on individuals. Hartig, Kaiser, and Bowler (1997) indicate that natural settings contribute to mental restoration and psychological relief. The tendency of campus users to gravitate toward such natural spaces confirms the consistency between the observed findings and real spatial practices.

4.2. Natural Material Potential and Workshop Areas

The natural structure of the campus provides rich material resources that can be utilized in various production processes. Observations at different points of the campus identified the presence of materials suitable for nature-based workshops, including:

- wooden pieces of various sizes,
- natural stones,
- plant-based materials (dried branches, leaves, cones, etc.),
- soil textures,
- natural ground elements.

The natural availability of these materials on campus enables cost-effective and easily accessible nature-based production activities. Jones and Snow (2020) note that using natural materials in educational processes enhances sustainable design awareness and improves participants' material recognition skills. Accordingly, the campus provides favorable conditions for workshop activities to generate both pedagogical and ecological value.

Potential Workshop Areas

Field observations identified several areas suitable for nature-based workshops. These spaces share common characteristics:

- close proximity to natural textures,
- relatively quiet locations away from noise,
- wide and flexible surfaces suitable for various activities,
- opportunities for uninterrupted interaction with the natural environment.

These characteristics provide a supportive physical infrastructure for both individual and group work, making the areas suitable for creative production with natural materials.

4.3. Open-Air Exhibition Potential

One of the most notable findings of the research is the substantial potential of the campus for open-air exhibitions. Main pedestrian routes, large open clearings, terraced surfaces, and natural transition areas offer spatial opportunities for displaying student productions.

These exhibition areas provide significant aesthetic and functional advantages:

1. Visibility Along Pedestrian Routes

Exhibitions placed along heavily used pedestrian paths ensure continuous interaction between the displayed works and campus users. This allows the works to become part of the general circulation rather than remaining confined to designated exhibition zones.

2. Landscape-Integrated Display

Exhibition elements integrated with the natural landscape are perceived as extensions of the surrounding environment, contributing to the aesthetic unity of the space. Franz (2018) highlights that open-air museums enrich spatial experience by merging cultural production with public space (DOI: 10.1080/13527258.2017.1422578). Field observations support this perspective.

3. Spatial Diversity

Terraced levels, large lawn surfaces, wall edges, natural clearings, and semi-open courtyards offer various spatial typologies for exhibition. This diversity provides a wide range of display options compatible with different scales of production.

4. Enhancement of Social Interaction

Open-air exhibitions increase interaction among students, academics, and visitors, strengthening the social dynamism of the campus. They also contribute to the campus's cultural identity and enrich the learning environment.

5. Discussion and Conclusion

The findings obtained in this study reveal that nature-based open space approaches provide significant social, cultural, and spatial contributions to university campuses. The literature review and field observations conducted in line with the main aim of the research demonstrate that the natural potential of campuses is not merely an aesthetic resource but also a fundamental component that directly supports processes such as learning, socialization, production, and cultural interaction. A primary topic highlighted in the discussion is the active use of campus open spaces by students. Observations indicate that shaded areas beneath trees, lawn surfaces, and semi-open seating units are key spaces shaping campus life. The preference for these areas underscores the critical role natural landscapes play in students' everyday practices. Students' strong relationship with the natural environment underscores the need for nature-centered approaches in campus open space planning. The psychological relief, spatial comfort, and social interaction opportunities provided by natural settings contribute to the prominent role of open spaces within the culture of the university.

Another significant finding is the natural material potential present on the campus. Natural wood fragments, stones, plant materials, and other natural elements are easily accessible across many parts of the campus, increasing the feasibility of nature-based workshops. Considering the well-established benefits of using natural materials in educational and creative processes—such as enhancing creativity and increasing environmental awareness—the natural material potential of the campus stands out as an important advantage. Workshop activities enable campus users to experience their environment not merely as consumers but as active producers, thereby introducing a new dimension to learning processes. In addition to nature-based workshops, the open-air exhibition potential of the campus is another noteworthy aspect of this study. Pedestrian routes, natural clearings, terraced surfaces, and wide lawn areas offer spatial qualities suitable for exhibiting student works. The placement of open-air exhibitions within the campus not only makes student productions visible but also enriches campus culture and

enhances social interaction. Moreover, open-air exhibitions elevate the aesthetic value of the campus, providing a more engaging spatial experience for students, academics, and visitors alike.

Another issue emphasized in the discussion is the role of open space arrangements in supporting the cultural and social structure of the campus and in strengthening campus identity. Nature-based productions, exhibitions, and workshop activities conducted in outdoor areas function as vital dynamics that help transform the campus into a living environment. Such activities have been observed to increase students' sense of belonging and reinforce a culture of encounter and interaction within the campus. An additional point to consider in the conclusion is the contribution of nature-based approaches to the principle of sustainability in campus design. The preservation of natural environments, the support of on-site production processes, the multifunctional use of open spaces, and the preference for nature-compatible materials enhance the ecological sustainability of campuses. These approaches contribute to ensuring that both current and future generations experience a high-quality educational and living environment.

Overall, the study demonstrates that nature-based open space arrangements have strong potential to create user-centered, culturally enriched, and ecologically sustainable living environments on university campuses. Workshop processes involving natural materials, open-air exhibitions, and spatial arrangements integrated with natural landscapes are essential practices that improve the quality of campus life. Therefore, incorporating nature-based approaches more prominently into campus planning and design processes can be considered a significant requirement in terms of educational quality, cultural enrichment, and overall quality of life.

Thanks And Informatıon Note

Abstract

The climate crisis has become one of the most urgent global issues of our time, not only as an environmental threat but also as a multidimensional problem affecting the whole of social life. Especially in geographies sensitive to climate change such as Turkey, the crisis directly transforms not only the ecological balance, but also the social structure, social relations and daily life practices. In this study, the social effects of the climate crisis are examined; how different socio-demographic groups were affected by the crisis, how social inequalities deepened and what adaptation and solidarity mechanisms emerged in this process are discussed. Research findings based on literature review show that the climate crisis has more devastating effects, especially on low-income groups, women, children, the elderly and individuals with disabilities. While the dependence of agriculture and livestock activities on climatic conditions in rural areas increases economic vulnerability, infrastructure deficiencies, water crisis and extreme heat in cities cause serious health and quality of life problems, especially in disadvantaged neighborhoods. In addition, it has been determined that climate change triggers migration dynamics, increases seasonal labor and raises new social adaptation problems in cities. The findings also reveal that local communities develop their own resilience mechanisms through traditional knowledge systems and solidarity networks. As a result, it is emphasized that the policies to be developed against the climate crisis should not be limited to technical solutions, but should also include social vulnerabilities and social justice dimensions. The study recommends strengthening the competencies of local governments, adopting participatory planning processes, and implementing climate justice-oriented social policies for an effective and fair fight against the climate crisis. At the same time, it opens up new areas of discussion at the theoretical and practical level for a just, inclusive and sustainable climate struggle by making visible the vulnerabilities between different socio-demographic groups. In this context, the disciplines of landscape architecture and urban planning should be repositioned not only as spatial arrangements but also as tools that support social transformation.

Keywords: Climate crisis, social impacts, climate justice, environmental inequality

1. Introductıon

One of the biggest and most urgent problems facing humanity on a global scale today is the climate crisis, the effects of which are increasing **.** Increasing fossil fuel use and anthropogenic activities in line with the rising production approach with the industrialization period have pushed the ecological limits of the world and led to climate change. This situation is defined as a new social issue full of uncertainties, threatening prosperity with both global and intergenerational consequences. The fact that the climate crisis has gained a global identity as a threat shows that it has become an undeniable fact that directly affects all humanity and the world.

When examining the conceptual framework of climate change, the expression defined in the United Nations Framework Convention on Climate Change (UNFCCC) is of central importance. According to the United Nations Framework Convention on Climate Change,

climate change; It is defined as "the change in climate that occurs as a result of human activities that directly or indirectly disrupt the composition of the global atmosphere, in addition to the natural climate variability observed over comparable time periods" (UNFCCC, art:1. 1992; iklim.csb.gov). There is a consensus in the scientific community that the climate change experienced today is largely caused by human activities rather than natural causes that are part of the cycle, such as volcanic eruptions. The increase in greenhouse gas emissions disrupts the climate system by causing global warming, and the urgency and possible irreversible consequences of this situation encourage the use of the concept of "climate crisis" (Corbett, 2021: 4; Birpınar, 2022: 19).

The main indicators of the global climate crisis include temperature increases, increase in the frequency and severity of extreme weather events (droughts, floods, storms, forest fires), melting glaciers, rising sea levels and decreasing agricultural productivity. Beyond this environmental destruction, the climate crisis closely affects economic, social and political life, causing serious problems in a wide range of areas from agriculture to food security, from diseases to migration. Especially countries in the Mediterranean Basin, such as Turkey, are among the geographies that will be most affected by drought and extreme weather events.

1.1. Social Dimension and Importance of the Climate Crisis

The importance of the climate crisis stems not only from its devastating effects on ecological balances, but also from the deep inequalities these effects create between layers of society. The consequences of climate change do not affect every region, country or social group equally; on the contrary, it deepens existing personal, social and economic inequalities (Preston et al., 2014: 2-3). In the literature, underdeveloped countries, poor segments and disadvantaged groups (elderly, children, women, migrants), which have the least impact on the occurrence of carbon emissions, are disproportionately more affected by this situation, leading to a climate inequality. For example, people living in highly fragile areas are 15 times more likely to die from floods, storms, and droughts compared to those living in low-vulnerability areas (IPCC, 2023).

These unbalanced effects of climate change; It creates the necessity of millions of people to dislose, face unemployment, face poverty and struggle with a series of problems that increase due to lack of social support. For this reason, it is vital that comprehensive solution plans to be developed for the climate crisis focus on rights-based social policy measures that establish social justice and focus on the human factor, as well as technical solutions such as reducing greenhouse gas emissions. The struggle should be built in a framework that integrates economic, social and environmental goals.

In this context, this study aims to examine the social dimension of the climate crisis in detail, going beyond the environmental and economic destruction caused by the global climate crisis. Within the scope of the study, it is aimed to address the social inequality caused by the climate crisis, the pressures on social protection systems and forced climate migration, and to offer social policy recommendations for the solution of these problems.

2. Method

The collected data were examined and interpreted by literature review method in order to determine the general trends, main debates and arguments regarding the social consequences of the climate crisis. This method has enabled the selected studies to be brought together and reorganized within the framework of certain themes (social inequality, social protection and migration) and to associate the literature with current/potential developments. Thus, from the

perspective of climate justice, it is aimed to provide a holistic assessment in the light of current debates by analyzing the multidimensional, intersectional and relational interactions of the crisis on social actors, structures and processes in depth.

3. Findings and Discussion

3.1. Causes, Indicators and Basic Social Dimensions of the Climate Crisis

The current state of the climate crisis has emerged largely as a result of anthropogenic (human-caused) activities. There is a consensus in scientific circles that today's climate change is caused by human activities rather than natural cyclical causes such as volcanic eruptions. The climate crisis itself is not only an environmental change, but also an economic, social, global, political and social phenomenon.

3.1.1. Causes of the climate crisis

The most negative intervention of humans towards the ecological balance became evident with the Industrial Revolution, and the increasing greenhouse gas emissions with this process led to the climate crisis. Climate-changing human activities can be classified in different ways.

a. Fossil Fuel Consumption

With the onset of industrialization, the use of fossil fuels such as oil, natural gas, and coal has increased and continues. This use increases the concentration of greenhouse gases such as carbon dioxide, carbon monoxide and methane in the atmosphere, creating a greenhouse effect and raising the earth's temperature. A large portion of Turkey's energy consumption consists of fossil fuels, representing 88% of the total primary energy supply as of 2017 (OECD, 2019).

b. City Activities

Urbanization and industrialization increase energy expenditure and fossil fuel consumption in the long run, increasing carbon dioxide emissions and affecting the climate. Cities are at the center of climate change-generating activities, including the buildings sector, which is responsible for 30% of global energy expenditure and 28% of carbon emissions related to energy use. Urbanization plays an important role in the increase in global average temperature observed since the 1950s by directly affecting the local climate. Furthermore, impermeable surfaces in cities (such as asphalt and concrete) have a high capacity to absorb, store, and dissipate heat, while their evaporation capacity is low, amplifying the urban heat island effect.

c. Land Use

Differentiation in land use on a global scale directly affects the climate crisis. The allocation of forest areas for agriculture or settlement purposes is among the factors affecting climate change by leading to deforestation. Forests, as carbon sink areas, function to preserve excess greenhouse gases in the atmosphere and regulate the climate; Narrowing these areas causes more carbon emissions into the atmosphere. In addition, while soil has a climate-regulating effect due to its carbon sink area, the increase in urbanization, concreting and the misuse of agricultural lands contribute to the global temperature increase by reducing the carbon sequestration rate of the soil.

d. Other Socio-economic Impacts

Human-induced causes of climate change include rapid population growth, change in consumption habits, moral decay, market economy, agricultural activities, fertilizer use and

animal husbandry activities. In particular, 18% of greenhouse gas emissions and 9% of carbon dioxide emissions in the world are expressed as carbon dioxide equivalent (Köknaroğlu and Akünal, 2010).

3.1.2. Indicators of the climate crisis

The climate crisis has gone beyond scientific warnings and has turned into concrete disasters that become noticeable in daily life.

a. Global Temperature Rise

Temperature rises documented on a global scale are one of the most obvious signs of climate change. An increase in global average surface temperatures between 2-4.5 °C is expected for the 1990-2100 period. Rising air temperatures; It leads to desertification, forest fires, decreased rainfall and drought. In Turkey, the aridification trend has been effective in the Mediterranean basin since the 1970s, and the Aegean, Mediterranean, Marmara and Southeastern Anatolia Regions have been among the most affected geographies.

b. Extreme Weather Events

Unusual weather events (floods, landslides, storms, droughts and forest fires) have been more frequent and intense in the last decade. These events, intensified by climate change, cause serious loss of life and property in cities. For example, floods, as the most common type of disaster worldwide, caused approximately $46 billion in economic damage and 4,500 deaths globally in 2019. According to IPCC reports, global warming has led to an increase in the frequency and intensity of heavy rainfall events around the world.

c. Ecological Change

Among the indicators of the climate crisis; melting of glaciers, rising sea levels, increasing the amount of carbon dioxide, seasonal changes, decrease in plant and animal populations and decrease in water resources (Demircan, 2022). Sea level rise directly affects island states and human life living in coastal areas, leading to migrations. In addition, changes in climatic conditions can cause an increase in infectious diseases by changing the distribution of vectors and disease agents (Kiraz, 2019). Agricultural production and productivity are also negatively affected by these ecological changes.

3.1.3. Main social dimensions of the climate crisis

The social repercussions of the climate crisis lead to consequences such as loss of livelihoods, increase in unemployment rates, lack of clean water and food, difficulties in accessing basic services, and the spread of poverty. Climate change is considered one of the most difficult collective issues in the history of humanity because it poses economic and social threats in the long term.

a. Social Inequality (Climate Injustice)

The effects of climate change do not affect every region, country or social group equally; deepens existing personal, environmental, social and economic inequalities. Climate injustice occurs as a result of underdeveloped countries, the poor and disadvantaged groups, which have the least share in the emergence of carbon emissions, being disproportionately affected by this process.

1. **Vulnerable Groups: Socially** and economically disadvantaged groups (including people who face discrimination based on gender, age, ethnicity, class, disability and immigration) are disproportionately adversely affected by climate change.
2. **Vulnerability and Risk: Approximately** 3.5 billion people live in areas that are highly vulnerable to climate change, and they are 15 times more likely to die from floods, droughts, and storms than those living in low-vulnerability areas (IPCC, 2023).
3. **Deepening of Inequality:** Low-income individuals, who are most affected by the problems caused by climate change, are more vulnerable to future climate catastrophe due to the increasing poverty spiral. Especially elderly and disabled individuals experience more disadvantages in coping with heat stress and disasters due to their physical condition and low income levels.

b. Social Protection

The dangers posed by climate change make disadvantaged groups quite vulnerable in terms of social support. Negative reflections of climate change; increases life cycle threats such as unemployment, illness, work accidents, disability, death and old age, and the importance of social support is emphasized in this context (ILO, 2019).

1. **Importance of Social Protection:** Social protection has key objectives aimed at reducing poverty and inequality; protecting people in the face of shocks and life changes and ensuring adequate living standards; and improving opportunities by providing employment, business, and livelihoods (Costella et al., 2021).
2. **Adaptive Social Protection: Social** protection in the context of climate change is addressed through the Adaptive Social Protection approach, which combines social protection, natural disaster risk management and climate change adjustment. This approach aims to integrate climate-related risks into social protection programs and ensure that climate-related adverse impacts are managed.
3. **Effects:** Social security measures reduce poverty and susceptibility to shocks by increasing incomes and food expenditures, encourage human development and include interventions to compensate for the losses caused by climate change.

c. Immigration

Another important social consequence of the climate crisis is related to migration. Climate change; threatens food security, reduces water resources, leads to malnutrition and famine, significantly shrinks living spaces, and renders individuals unable to sustain their basic vital activities. This situation causes people to leave their current places, causing population movements called ecological migration.

1. **Dimensions of Migration: Climate** change can be a direct cause of migration, or it can be considered as a threat multiplier by interacting with political, demographic, economic, social and environmental push factors. According to World Bank data, it has been stated that 143 million people in Sub-Saharan Africa, South Asia and Latin America may be forced to migrate internally due to climate change by 2050 (Rigaud et al., 2018). In Turkey, 275,313 people have migrated in the last 10 years due to climate and disasters (UNDP Turkey, 2019).
2. **Causes of Migration: Climate** refugee is mainly; It occurs due to factors such as the intensity of greenhouse gases, extreme climatic events, temperature fluctuations, air pollution, heavy rainfall, floods, drought, desertification, sea level rise and food crises.

3. **Legal Status Problem: The** concept of "climate refugee" used for those displaced due to climate change does not have a clear definition in the legal regulation, which creates loss of rights and uncertainty.

4. **Fragility:** The migration movement that will occur as a result of the migration movement due to the rise in sea level and the negative impact on agricultural activities, especially in coastal regions, are important reasons affecting the quantity of the population to migrate. Migration waves caused by the climate crisis cause an increase in social and economic problems and a weakening of the resilience of cities, especially in the cities of fragile countries.

3.2. Vulnerable Groups Affected by the Crisis

One of the most prominent features of the climate crisis as a social problem is that its effects are characterized by different and unequal societal outcomes. The effects of climate change are intensified according to the existing personal, environmental, social and economic inequalities of individuals and groups, and deepen these inequalities. Underdeveloped countries, poor segments and disadvantaged groups, which play the least role in the formation of carbon emissions, are disproportionately affected by this situation and face many life-threatening risks. This situation also leads to climate injustice.

Individuals who are socially, economically and geographically disadvantaged (including those who experience discrimination based on gender, age, ethnicity, class, disability and immigration) and neglected individuals are extremely adversely affected by climate change.

3.2.1. Women, children, elderly

Personal factors such as age and gender constitute the main areas of inequality affected by the climate crisis. Vulnerable groups such as the elderly and children are among the groups that will be most affected by the consequences of the climate crisis, such as disasters and extreme weather events.

a. Women

Women are exposed to significant inequalities that exist independently of the climate crisis, and this situation is deepening with climate change. Women are expected to be more affected than men. Among the reasons behind this sensitivity; gender-related social and economic duties and responsibilities, their situation in the labor market, disadvantaged positions in the fields of education and social security.

- Economic Vulnerability: Women are intensively employed, especially in sectors directly related to agroecosystem services. The decrease in jobs in agriculture may lead to unemployment and poverty for women. In addition, new green occupations such as construction, manufacturing and engineering are also observed, where women are relatively unemployed.

- Migration and Violence: Women and girls may be more vulnerable to a number of impacts due to migration due to climate change. During and after natural disasters, women and girls become more vulnerable to sexual exploitation and gender-based violence.

b. Kids

Children are more sensitive to the effects of climatic changes than adults. Their physical weaker nature and less ability to radiate heat make children more vulnerable to environmental elements such as heat, pollution or scarcity. They may also be exposed to poor living conditions resulting from job and income losses faced by their families; They may have difficulty accessing food

and water. Exposure to environmental factors in early childhood and pregnancy also causes children to be negatively affected.

c. Elderly

Elderly individuals are among the groups most affected by extreme weather events and natural disasters caused by climate change. The World Health Organization (WHO) has defined the elderly as a vulnerable group that is likely to be at risk in the event of a disaster.

- Physical and Health Issues: Physical and cognitive limitations that increase with age affect seniors' ability to act quickly in the face of disasters or emergencies. This situation causes them to face more disease and mortality rates in the event of a disaster. For example, heat waves (such as the one seen in Europe in 2003) have killed large numbers of people, the majority of whom are elderly. A significant relationship was found between temperature increase and mortality rates in Turkey.

- Social and Economic Challenges: Elderly individuals need medical and psychological support, assistance in daily activities, resources, and protective measures during and after disasters. Elderly people who live alone and have insufficient economic status are more vulnerable to heat waves. The difficulties of elderly and disabled individuals in finding a job and changing professions in the labor market may cause them to be adversely affected by the occupational transformation caused by the climate crisis and to experience severe poverty.

3.2.2. Migrants and disabled people

a. Immigrants

Forced displacement and migration status are social factors that weaken individuals' social networks and cause them to live a life that excludes them economically, socially, politically and culturally. Climate change will trigger irregular and mass migrations by creating economic and social insecurities that will endanger life in some regions or countries.

- *Disadvantaged Position*: People who have to change countries due to climate change; They are disadvantaged in terms of being accepted to another nation, gaining a political identity, language skills, finding a job and being deprived of social security systems. This situation causes them to be deprived of the opportunity to change their current conditions in the context of the climate crisis.
- *Legal Uncertainty*: The lack of a clear definition of the concept of "climate refugee" in the legal regulation, which is used for those who are displaced due to climate change, makes it difficult to determine the protection status of these people and leads to loss of rights.
- *Groups at Risk*: Refugees coming to Turkey and living in camps in Southeastern Anatolia are vulnerable groups to climate change and epidemics. An increase in cases such as tuberculosis and measles has been observed in these camps. Migrants and asylum seekers, who are considered vulnerable groups, should be followed up with a good monitoring program.

b. Engelliler

Engelli bireyler, bedensel durumları dolayısıyla iklim değişikliğinin yol açacağı felaketler ve aşırı hava koşullarından birincil olarak etkilenecek sosyal kesimlere dahildirler. Afetler ile yüzleştiklerinde, fiziksel durumları felaketten kurtulma ve bununla başa çıkma yeteneklerini olumsuz bir şekilde etkilemektedir. Engelliler, düşük gelir düzeyleri ve hareket kabiliyetlerinin sınırlı olması nedeniyle ısı stresi ve afetlerle baş etme konusunda daha fazla dezavantaj yaşamaktadır.

3.2.3. Low income groups/poor

Low-income groups and the poor are at the heart of the climate crisis's deepening of social inequalities. This segment, which has the least share in the emergence of the climate crisis, is disproportionately more affected by the process.

- *Increased Vulnerability*: Individuals with low income levels are more sensitive to the effects of climate change and more vulnerable to risks; they are also inadequate in terms of their ability to recover from and cope with the damages they have been exposed to.
- *High Risk*: Individuals living in low-income areas lack sufficient skills and resources to adapt and respond to the effects of climate change. It is stated that the poor are becoming more vulnerable to future climate crises due to the increasing poverty spiral.
- *Disaster Exposure*: Approximately 3.5 billion people living in highly vulnerable areas are 15 times more likely to die due to floods, droughts and storms in the 2010-2020 period than those living in regions with very low vulnerability.
- *Food and Shelter*: Poor individuals face difficulties in obtaining adequate drinking water and food, and are disproportionately more affected by drought, food shortages and rising food prices. In addition, low-income household groups are estimated to be disproportionately affected by climatic threats.

3.2.4. Rural communities

Communities living in rural areas and earning their living from agricultural activities are also heavily affected by the effects of the climate crisis.

- *Dependence on Agriculture*: Climate change poses a threat to agricultural production and productivity, which is dependent on factors such as soil, water, sunlight, and temperature. Countries and rural communities that develop their economies based on agriculture will be more affected by this negativity.
- *Migration and Loss of Livelihood*: The negative impact of the climate crisis on the feasibility of agriculture and animal husbandry is an important reason triggering migration movements in these communities. It can be argued that social actors such as rural households and farmers predominantly experience the form of forced mobility.
- *Farmers at Risk*: It has been stated that deaths in cases of Crimean-Congo Hemorrhagic Fever (CCHF), a fatal tick-borne infection, are mostly seen in those engaged in farming and animal husbandry. This is associated with the spread of disease vectors due to climate change. Those who make their living from farming, such as those living in coastal areas, are particularly at risk.

3.2.5. Peoples of underdeveloped countries

The biggest injustice of the climate crisis on a global scale is that underdeveloped countries (or regions located in the global south) are the hardest hit by the crisis, but historically the least responsible.

- *High Vulnerability and Low Capacity*: Societies in underdeveloped countries are both greatly affected by climate change and show serious sensitivity due to their sensitivity. These countries are less vulnerable to the devastating effects of the climate crisis.

- *Economic Impacts*: The negative health effects of climate change are expected to be most intense in low-income countries. Residents in these countries have the fewest resources to adapt to rising temperatures and extreme weather events.

- *Migration Pressure: The* biggest threat of migration movements caused by the climate crisis is on the cities of fragile countries. For example, it is estimated that by 2050, 143 million people in Sub-Saharan Africa, South Asia and Latin America could be forced into internal migration due to climate change.

These findings clearly demonstrate that policies to combat the climate crisis necessitate rights-based approaches to meet the social justice and social protection needs of these groups.

3.3. Grievances of Vulnerable Groups

The social consequences of the climate crisis negatively affect the most vulnerable segments of society in economic, social, environmental and legal terms. Existing socio-economic inequalities increase the risk and susceptibility of disadvantaged groups to climate hazards, while also reducing their ability to cope with and recover from these damages, creating a vicious cycle. People living in highly fragile areas are 15 times more likely to die from disasters such as floods, droughts and storms than those living in low-vulnerability areas.

3.3.1. Economic and social grievances

The climate crisis creates serious economic and social destruction, especially on vulnerable groups, leading to direct loss of livelihoods, unemployment and deepening poverty.

- **Loss of Livelihoods and Poverty:** Sudden and extreme weather events due to climate change cause loss of livelihoods, unemployment, poverty, and cultural losses. For example, as a result of the storms that affect the Philippines every year, 7000 people lost their lives in Storm Haiyan in 2013 and the livelihoods of 5.9 million people were adversely affected. Women, who are heavily employed, especially in sectors that are closely dependent on ecosystem services, such as agriculture, are expected to become unemployed and poor with the loss of jobs in agriculture.
- **Social Insecurity: The** negative effects of the climate crisis exacerbate traditional life cycle risks such as unemployment, disease, work accidents, disability, death and old age, and make disadvantaged groups vulnerable to social protection. This situation weakens the ability of low-income individuals and the poor to cope with the damages they suffer due to their lack of sufficient capacity and resources to withstand climatic disasters.
- **Food and Water Insecurity:** Poor individuals have difficulties in accessing sufficient water and nutrients, and they are disproportionately more affected by drought, famine and rising food costs caused by the climate crisis. Declining water resources cause food insecurity, malnutrition and famine, which leads to the migration of people who are unable to continue vital activities. Drought increases the risk of nutritional deficiencies by reducing food diversity and food consumption.
- **Exclusion from New Job Opportunities:** Disadvantaged groups such as the elderly and disabled individuals experience difficulties in the labor market as they cannot easily find jobs and change professions. It is possible for these groups to experience severe poverty by being adversely affected by the occupational transformation necessitated by climate change. In addition, it is observed that women are already excluded from newly formed "green business" branches (such as construction, manufacturing, engineering).

3.3.2. Human rights and health grievances

Climate change causes multi-layered problems that directly threaten basic human rights and public health. This situation brings with it grievances that have not only environmental but also ethical and legal dimensions.

- **Violation of Fundamental Human Rights:** Climate change poses various threats and social inequalities in terms of fundamental human rights such as the right to life, the right to a healthy environment, the right to food and the right to water. The effects of climate change jeopardize the enjoyment of these universal, inalienable and interdependent rights.

- **Health and Mortality Risk:** Events such as extreme temperatures, floods, and storms due to climate change directly negatively affect human health and can lead to loss of life.

- **Heat Wave Victims:** The elderly react faster to the effects of hot weather due to reduced fluid intake, thinned subcutaneous fat layer and chronic diseases. The heat waves in Europe in the summer of 2003 caused the death of 70,000 people, most of whom were elderly. It has been observed that the elderly who live alone and have insufficient economic status are more vulnerable to heat waves.

- **Infectious Diseases:** Changes in climatic conditions cause an increase in infectious diseases by changing the distribution of vectors (disease carriers) and disease agents. The incidence of waterborne and foodborne diseases such as cholera and rotavirus is increasing. Refugees living in camps in Southeastern Anatolia in Turkey are vulnerable to climate change and epidemics, and an increase in cases such as tuberculosis and measles has been observed in these camps.

- **Mental Health Traumas:** People who lose their homes, jobs, and relatives after climatic disasters (floods, forest fires, etc.) experience traumatic effects and face mental health problems (stress, chronic anxiety, depression, anger management problems). A direct link has been found between high temperatures and poor mental health; Women and low-income individuals in particular are the most affected by this connection.

- **Occupational Risks:** High temperatures and humidity increase the effects of toxic substances on the body; for example, it has been reported that the frequency of pesticide poisoning increases as the temperature rises in farmers. In addition, outdoor workers are at increased risk of increased biological hazards, vector-borne diseases, pollen, and mold-related allergies. Workers working under the sun are at risk of skin cancer due to exposure to UV rays.

- **Gender-Based Violence: During** and after climate change-related disasters, women and girls become more vulnerable to sexual abuse and gender-based violence. Access to critical health services and education rights are also disrupted due to migration due to the climate crisis, and problems such as early marriage of girls increase the number of child brides.

3.3.3. Legal and spatial grievances (climate refugees)

One of the most profound and complex social consequences of the climate crisis is forced displacement and the legal vacuum caused by this mobility.

a. Spatial Grievances

Climate change significantly narrows living spaces and makes people unable to continue their basic vital activities.

- **Forced Displacement:** Environmental factors such as sudden onset floods and hurricanes or long-range sea level rise, drought and land degradation force people to relocate. According to the World Bank (WB) report, without a concrete action plan, more than 216 million people in six regions will be forced to migrate due to climate change by 2050. In Turkey, 275,313 people have migrated in the last 10 years due to climate and disasters.

- **Coastal and Island Losses: Sea** level rise as a result of increasing air temperatures and melting glaciers directly affects island states and human life living in coastal areas, causing these people to leave their places permanently or indefinitely. Many regions of Southern Iraq and almost all of the Nile Delta are expressed as regions that will migrate due to sea level rise.

b. Legal Grievances (Climate Refugees)

The concept of "climate refugee", which is used for those who are displaced due to climate change, does not have a clear definition in international legal regulations. This conceptual and legal gap creates uncertainty about the status and rights of these individuals.

- **Lack of Status: The** 1951 Convention on the Determination of Refugee Status shapes the definition of refugee based on persecution-based elements such as race, religion, citizenship or political opinion, and does not contain any explanation or definition of climate events. This situation leaves the legal status problem of individuals known as climate refugees unresolved on an international scale and leads to loss of rights.
- **Lack of Legal Protection: The** United Nations Human Rights Council (2018) states that the legal system and regulations to protect the human rights of migrants due to the climate crisis are inadequate. However, the United Nations Human Rights Committee has taken a decision that can be a "gateway" for asylum claims of people whose lives are threatened by global warming and that governments cannot force people who have to migrate due to the climate crisis to be sent back.
- **Disadvantage in the New Environment:** Individuals who have to migrate are disadvantaged in terms of acceptance in the new country, acquiring a political identity, and lack of employment and social protection mechanisms. It is also stated that the uncertainty in the legal status may cause social tensions and indirectly security problems due to resource shortages of climate refugees. These people are also expected to have problems with acceptance due to the thought that it will create significant economic and social cost burdens to the country of immigration.

3.4. Concrete Examples by Country and Region

Although the effects of the climate crisis are global, the severity and consequences of these effects vary significantly across regions, countries and geographies. This situation reveals the social injustice that arises due to the problems and inequalities caused by climate change. Because underdeveloped countries, which have the least share in the formation of greenhouse gas emissions, are disproportionately the most affected by the process.

3.4.1. Examples of climate-induced migration and displacement

One of the most prominent social consequences of the climate crisis is forced displacement and migration movements due to the shrinkage of living spaces and the loss of livelihoods. These movements are triggered not only by sudden disasters, but also by slow and gradual environmental disruptions such as droughts.

Most Affected Countries

According to climate change projections, underdeveloped and developing countries are among the nations that will be most affected by the crisis. These groups are greatly affected by climate change and show significant sensitivity due to their vulnerability.

- **Economic Capacity Gap:** As the level of economic development increases, the likelihood of exposure to the harmful effects of climate change decreases, indicating that underdeveloped countries have the fewest resources to adapt.

- **Turkey's Sensitivity:** Turkey is located in the Mediterranean Basin, which is an area that is extremely sensitive to the effects of climate change due to its geographical location. Turkey is expected to be among the countries that will suffer the most from extreme weather conditions. It is estimated that Turkey will be the third country that will be most affected by extreme weather conditions in Eastern Europe, the Balkans, Eurasia and the Turkic States by the end of the 21st century.

- **The Case of the Philippines:** One of the most striking examples of the destruction caused by sudden disasters occurred in the Philippines. Typhoon Haiyan (hurricane) in 2013 caused the death of approximately 7,000 people and negatively affected the livelihoods of 5.9 million people. This situation shows the magnitude of the economic and social destruction of climatic disasters.

Regional Relocation

The effects of the climate crisis permanently change the natural balances in certain geographical regions, pushing local settlements into forced mobility.

- **Sea Level Rise:** The thawing of glaciers and the increase in sea levels due to global warming directly affect island countries and individuals living in coastal areas, causing these people to leave their places temporarily or permanently.

- **Endangered Coastal Areas:** 3% of Turkey's coasts have low altitudes, and according to sea level rise projections, cities connected to the sea are estimated to be endangered.

- **Drought and Agricultural Areas:** In the Mediterranean Basin, where Turkey is located, temperature increases, up to 20% decrease in precipitation and decrease in soil moisture are expected. Especially the Southeastern and Central Anatolia regions are described as arid and semi-arid, which pushes communities dependent on agricultural activities such as rural households and farmers to compulsory mobility.

Migration Due to Extreme Heat

Extreme temperatures accelerate migration movements by directly affecting both human health and livelihoods.

- **Loss of Health and Habitat:** High temperatures and associated drought lead **to food and water insecurity**, which makes people unable to continue their vital activities. It has been stated that due to the increase in temperature, animals also turn to cooler places to get out of hot regions, and this creates an opportunity for the spread of pathogens.

- **Regional Agricultural Losses: Estimates** predict that a 2 °C temperature increase worldwide will cause a 5% decrease in grain yield, while it is reported that the decrease in this yield will reach 25-35% in the Mediterranean region. The negative impact on agricultural

production constitutes a basic economic reason that forces rural communities, especially those whose economic welfare is based on agriculture, to relocate.

Large-Scale Internal Migration Projections

An examination of population mobility due to the climate crisis shows that large-scale displacements within countries come to the fore rather than international cross-border migrations.

- **143 Million Internal Migrants Prediction:** According to a report prepared by the World Bank Group in 2018, it is emphasized that 143 million people in three developing regions, Sub-Saharan Africa, South Asia and Latin America, may be forced to migrate within the country by 2050 due to climate change.

- **200 Million Global Prediction:** In another study, it is estimated that approximately 200 million people will migrate in 2050 due to adverse climate-related conditions, and it is calculated that 140 million of this number will occur in the form of internal migration due to reasons such as water scarcity, storms, floods and sea level rise.

3.4.2. Historical drought examples

Drought is a climatic phenomenon that occurs as a result of global climate change, with a lack of rainfall that occurs due to unusually high temperatures. Drought is considered one of the most threatening climate events due to its slow onset and spread over large geographical areas. When the historical process is examined, it is an indisputable fact that drought is one of the main environmental factors that force societies to relocate through agricultural collapse and food shortage.

Ireland:

The great famine period in Ireland is one of the most striking global examples of the devastating effects of climatic stress leading to social migration. Sources state that a quarter of Ireland's population migrated out of the country due to the food shortage in Ireland between 1852 and 1856. This case is critical in showing how food shortages and loss of livelihoods can push a society into forced international migration movement.

Oklahoma:

The great drought in the United States, known as the "Dust Bowl" in the 1930s, reveals the consequences of environmental pressure on rural communities that rely on agriculture. While the consequences of drought led some societies to migrate due to the deterioration of land conditions, the situation was embodied in the case of Oklahoma: As a result of the extreme drought in Oklahoma in the 1930s, 300,000 farmers migrated to California in search of better living conditions.

These two historical examples reveal the different dimensions of drought that cause forced migration. While the Irish case shows the devastating scale of international migration due to famine and deprivation; The Oklahoma case is concrete evidence of how extreme drought makes agricultural activities unsustainable, leading to large-scale and massive intra-country (internal) migration movements. Both events confirm that food shortages and land degradation as a result of natural phenomena linked to climate change affect poor and rural communities most profoundly and expose them to forced mobility.

3.5. Social Perception of the Climate Crisis in Turkey and Emerging Terms

The environmental transformations created by the climate crisis have become a concrete reality in social life, rather than a scientific warning or an abstract threat. The increase in the frequency and severity of natural disasters such as regional extreme rainfall, fires and droughts has caused individuals to accept the existence of the climate crisis and reduce their suspicions that it is human-caused. This situation creates social pressure on policymakers in the form of increased expectations for action.

The example of Istanbul, which is one of the studies examining social climate change awareness in Turkey, reveals the level of knowledge and awareness of the citizens regarding this global problem. Considering the fact that a significant portion of the population lives in cities, measuring the awareness level of city dwellers is critical for the success of policies to combat climate change.

Basic Perceptions According to the Findings of the Istanbul Example:

- **General Awareness:** 91% of the **participants from Istanbul who participated** in the study stated that they had heard of the concept of "climate change" before.
- **Cause of the Climate Crisis:** The vast majority of respondents (78.2%) marked factory and industrial wastes as the first cause of climate change. This is followed by human activities (76.9%) and excessive carbon emissions of developed countries (67.3%). These findings show that the social consciousness in Istanbul coincides with the general acceptance in the international literature that the crisis is anthropogenic (human-caused). Only 18.2% of respondents attribute climate change to natural causes.
- **Consequences of the Climate Crisis:** Among the first expressions that come to mind when they hear the concept of climate change, the melting of glaciers (79.4%), drought (68.7%) and extreme temperatures (66.2%) have come to the fore. It is interpreted that these results are related to the main sources of awareness (Internet: 73.8% and Social Media: 67.2%).
- **Sense of Responsibility:** The overwhelming majority of respondents (84.7%) stated that the main responsibility for combating climate change **should belong to states**, followed by individuals with 70%. This shows that social expectation is concentrated on policy makers.
- **Gender Factor:** In the case of Istanbul, there was a statistically significant difference in women's climate change awareness higher than men's.

The increase in this concrete perception and knowledge level has brought along the psychosocial reactions (anxiety, fear) of individuals and society in the face of crisis and has led to the addition of new concepts to the literature. (Ağıralan & Sadioğlu, 2021)

3.5.1. Eco-anxiety

The environmental destruction caused by the climate crisis has caused individuals to have deep concerns about their future prospects. Eco-anxiety (or eco-anxiety, climate anxiety) is defined as an excessive and pervasive fear of the consequences of climate change.

- **Mechanism of Formation: Eco-anxiety has** entered the psychological literature as a future anxiety or disaster expectation that individuals experience as a result **of the helplessness and hopelessness** they feel in the face of ecological destruction.

- **Social Pressure: This** anxious impression in the society creates pressure on the rulers to demand political action within the scope of urgent measures and containment strategies to be implemented for the climate crisis.

- **Academic Value:** Eco-anxiety is important because it has the potential to provide the impulse to make the right decisions and take the necessary steps (reference to Kurth and Pihkala, 2022). In the Turkish literature, it is stated that this concept has not yet been sufficiently studied in the fields of social sciences such as political science, public administration and environmental sciences, but its importance is increasing.

3.5.2. Eco-keder

Eco-grief is another important psychosocial response to the devastating effects of the climate crisis. This concept is characterized as a feeling of grief reminiscent of the loss of a relative.

- **Definition and Scope:** Eco-grief is associated with the helplessness and hopelessness experienced by individuals in the face of ecological destruction.

- **Political Impact:** Emotions such as eco-grief, together with the accepting perception of the climate crisis in the public, are considered as a positive factor in terms of developing solutions and implementing climate policies sustainably.

- **Position in the Literature:** Just like eco-anxiety, eco-grief is a concept that has recently joined the international literature and is increasing in frequency. In the Turkish academic literature, it is stated that there has not yet been sufficient research in the field of social sciences and that this interdisciplinary approach should be developed. A clearer understanding of these psycho-social responses will contribute to making social demands and needs more understandable for policy makers.

3.6. Developed Climate Policies and Response Framework

The global climate crisis needs to be constructed within a framework that integrates social, economic and environmental goals. Because climate change; It is extremely important to develop appropriate strategies and policies as it triggers many social issues such as access to basic social services and needs, from employment to immigration, from poverty to basic social services and needs. In academic sources, basic policy measures regarding the social dimension of climate change; Just Transition Policies are examined within the framework of the Paris Climate Agreement and the Green New Deal.

3.6.1. Just transition policies

Just Transition is a central social policy approach that aims to maximize social benefit through climate actions and policies. This strategy is defined as providing employment opportunities worthy of human dignity, creating them to end poverty and significantly supporting increasing social inclusion.

Just Transition aims to minimize all kinds of obstacles through effective social communication while making the best use of social and economic opportunities. The necessity of this transition is emphasized in order to promote social justice. The International Labour Organization's (ILO) Just Transition Directive includes active labour market programmes, including skills development, that establish a systematic link to social protection. In addition, it is emphasized that social protection strategies should be developed and implemented with the participation of social partners and other interested parties through an inclusive social dialogue.

3.6.2. Paris Climate Agreement

The Paris Climate Agreement is one of the basic agreements that embody the international practices developed within the scope of combating climate change. This agreement, signed by more than 190 countries, aims to bring greenhouse gas emissions to net zero in the second half of this century.

Among the main objectives of the Paris Climate Agreement; robust, sustainable and balanced development, reducing global poverty, creating environmentally friendly jobs by increasing employment opportunities, and providing a safer future for people and the planet.

Climate Justice Mechanism: The agreement aims to financially support countries that are most affected by climate change and do not have the capacity to adapt. For this purpose, it is planned to establish an annual climate finance mechanism (Green Climate Fund) of 100 billion dollars for the post-2020 period. This fund is critical for addressing climate injustice, providing financial support to poor regions, preventing migration, and increasing urban resilience in vulnerable countries.

3.6.3. Green Deal (Green New Deal)

The Green New Deal (or Green New Deal) is the economic resources of the society under the legitimate actor of the state; it's a framework that aims to mobilize around a transformative vision of rapid decarbonization, environmental sustainability, and distributive justice.

Although this consensus may be perceived at first glance as a mere infrastructural or economic framework, it will have a dynamic physical impact on landscapes, cities and societies. Policies such as the European Green Deal are expected to contribute to the formation of new business and employment areas that will enable green development.

3.6.4. Key social dimensions these frameworks focus on

The effectiveness of climate policies depends on the degree to which social dimensions are successfully integrated as well as environmental goals.

Employment:

One of the main goals of policies for the climate crisis is to regulate the labor market in the transition to a new green economy.

- The third main goal of social protection programs is; to improve opportunities by providing better employment, business and livelihoods.
- To compensate for the negative impacts on individuals due to climate change, social security measures should offer unemployment benefits for those who have lost their working hours or jobs as a result of a climate crisis.
- The Paris Climate Agreement aims to create green jobs and increase employability. In addition, attention should be paid to the risks of new growth business areas such as "green energy".
- The implementation of green development policies will contribute to the formation of new business and employment areas.

Poverty:

Since the climate crisis disproportionately affects low-income groups and the poor, it is essential that policy frameworks focus on the fight against poverty.

- The first of the main objectives of social protection is to reduce poverty and inequality.
- Among the goals of the Paris Climate Agreement is to reduce global poverty.
- Just Transition Policies also aim to contribute to the eradication of poverty.
- Migrations as a result of climate-related events either create new poverty or deepen existing poverty; This situation causes the beginning of a cycle of poverty. Strategies should be developed at the microeconomic and macroeconomic level to prevent the poverty of climate refugees. Protecting individuals' right to employment is one of the most effective ways to reduce the risk of poverty for migrants.

Social Justice:

Social justice should be the basic principle in the construction of climate policies. Social justice is the principle that ensures that the cost of climate change is distributed fairly and that the highest level of social benefit is targeted.

- The effects of climate change cause social injustice due to social inequality. For this reason, the fight against the climate crisis needs to produce policies that establish social justice.
- The Green New Deal includes the principle of distributive justice among its main objectives.
- The Just Transition approach is necessary to promote social justice.
- Climate justice is a sensitive issue that needs to be integrated into policy-making and implementation processes. Climate justice; should be built on the basis of human rights, and regulations should be made to compensate for the problems caused by inequalities.
- The rights-based approach requires the inclusion of human rights principles in every step of programs and projects, and aims to support vulnerable groups that are particularly neglected.

3.7. The Effects of the Climate Crisis on Society: Risks, Inequalities and Solution Approaches

3.7.1. Anthropogenic destruction and global threat: Human-induced activities such as fossil fuel consumption, uncontrolled urbanization, and land use have triggered the climate crisis with irreversible effects such as global temperature increase, extreme weather events, and sea level rise. It is clear that this crisis is a political, social, economic and ecological danger and that social unrest and security will increase if it is not intervened.

3.7.2. Climate Injustice and Vulnerability: The deepest dimension of the climate crisis is the disproportionate and unequal distribution of its consequences among layers of society. The peoples of underdeveloped countries, the poor and disadvantaged groups (women, children, the elderly, immigrants), which contribute the least to greenhouse gas emissions, are most affected by this process. The existing vulnerabilities of these groups create a vicious circle of poverty by reducing their exposure to climate hazards and their capacity to cope. For example, people living in high-vulnerability areas are 15 times more likely to die from disasters.

3.7.3. Victimization and Migration: The crisis causes human rights and health grievances as well as economic and social grievances on vulnerable groups. Consequences such as loss of livelihoods, unemployment and food insecurity have the potential to displace millions of people. It has been historically proven that slow-onset disasters such as droughts lead to mass migrations (examples of Ireland, Oklahoma). Most importantly, the lack of a clear equivalent of the concept of "climate refugee" in legal regulations brings with it the problem of loss of rights and international protection status for these displaced groups.

3.7.4. Social Perception and Responsibility: Awareness studies conducted in Turkey show that the public largely accepts the existence of the climate crisis and that it is human-caused. The case of Istanbul revealed that the overwhelming majority of citizens (84.7%) attribute the main responsibility in the struggle to the state. This situation creates an expectation for policymakers to take strong and decisive action; The increase in psychosocial reactions such as eco-anxiety and eco-grief also confirms the increase in the perception of social urgency.

3.7.5. Social Justice-Based Solutions: The study showed that the framework to combat the climate crisis should focus on the integration of social policies, not just technical goals such as greenhouse gas reduction. In this context, Just Transition Policies should aim to minimize the risks of unemployment and inequality created by the decarbonization process through social dialogue and decent work opportunities. Frameworks such as the Paris Climate Agreement and the Green New Deal should include social goals such as poverty reduction and employment growth.

4. Conclusion and Recommendations

This academic paper revealed that the climate crisis**, which has accelerated as a result of human activities (anthropogenic) since the Industrial Revolution**, has turned into the biggest and most urgent social injustice problem of today, rather than just an environmental problem . In the study, using qualitative research approach and descriptive content analysis methods, the climate crisis was examined by focusing on social inequalities, exposures of vulnerable groups and social policy requirements in solution frameworks.

In the light of the findings and discussions, the following policy recommendations are presented in order to manage the social dimension of the climate crisis and eliminate climate injustice:

- Adopting a Rights-Based and Social Justice-Oriented Approach: Climate policies should be built on the basis of human rights principles such as non-discrimination and participation. This approach should include positive discrimination, especially for the most vulnerable groups, and ensure that regulations are made to ensure social justice.

- Strengthening Adaptive Social Protection Systems: The adaptability of social protection systems should be enhanced in order to respond to shocks (unemployment, disease, disasters) related to climate change. In this context, it is critical to implement flexible and fast-scalable measures such as unemployment protection, cash or in-kind benefits for those who have lost their jobs due to the climate catastrophe.

- Legal Solution for Climate Migration: Urgent legal solutions should be implemented at the international level regarding the status problem of people displaced due to climate change (climate refugees) and possible loss of rights should be prevented.

- Ensuring Global Financial Solidarity: Developed countries and international organizations should provide financial and technological support to poor and vulnerable regions

and countries (including regions at risk such as Sub-Saharan Africa, South Asia, and Turkey) that contribute the least to the climate crisis. These funds should be used to increase the urban resilience of fragile countries and reduce migration pressure.

- Increasing Social Awareness: The internet, social media and educational curricula should be used effectively to disseminate accurate information and awareness about climate change. Women's higher levels of awareness should be used as a catalyst for social participation and policy development.

- Although the effects of the climate crisis are not equally severe globally, it is a necessity for the future of social welfare and social peace to resolutely maintain effective, long-term and scientific-based policies with a participatory and transparent management approach for countries with high vulnerability such as Turkey.

Abstract

This study examines the on-site evaluation of HVAC condensate water at the building/campus scale within a water-energy-carbon (WEC) framework. First, on-site water resources (rainwater, gray water, etc.) are briefly outlined; then, condensate water is detailed in terms of its source characteristics, quality profile, and safe use principles. The methodology integrates scope and functional unit definition, system boundaries, monitoring/QA-QC, production estimation, quality assessment, design and operation-maintenance protocols, and economic (LCC/ROI) and environmental (WEC) analysis approaches. The findings show that, thanks to its low mineral content and seasonal timing compatibility, condensate water can significantly reduce the demand for tap water in non-potable uses such as landscape irrigation and cooling tower makeup water; this, in turn, reduces the energy and carbon impacts associated with supply/distribution and wastewater treatment. Hybrid use with rainwater is the primary strategy for increasing supply continuity and savings. The economic assessment reveals that payback can be attractive, particularly in hot-humid climates and commercial buildings with high operating hours; however, implementation success depends on regular risk management (WMP) and clear identification/permit processes.

Keywords: HVAC condensate water, water efficiency, water-energy-carbon nexus, life cycle assessment, biofilm management, iot-based monitoring, green building technologies

1. Introduction

Water is an indispensable natural resource for the continuity of ecosystems, public health, food security, and economic production. Over the past forty years, global freshwater demand has increased by approximately 1% annually; population growth, urbanization, dietary patterns, and climate change have intensified this pressure(UNESCO 2024). Therefore, water is not only a fundamental determinant of environmental stability but also of social and economic stability.

1.1 Global Water Budget and Accessibility

Approximately 96–97% of the Earth's water mass is saltwater found in oceans; freshwater accounts for about 3%. Of the freshwater stock, 68% is found in glaciers and permanent snow cover, and 30% is underground. Surface freshwater (lakes and rivers) directly accessible for human activities constitutes a very small portion of this pool; for example, rivers account for approximately 0.49% of surface freshwater and represent an almost negligible share of total water. This distribution demonstrates that the “usable” water pool is both limited and fragile(USGS).

1.2. Sectoral Water Withdrawals

Globally, the largest share of freshwater withdrawal is for the agricultural sector. According to UNESCO's 2024 World Water Development Report and FAO AQUASTAT data, approximately 69–70% of global withdrawals are for agriculture, 19–20% for industry, and 12% for municipal/domestic use. (UNESCO 2024 and FAO AQUASTAT data). Although these ratios vary at the country level depending on climate and economic structure, they confirm that the primary pressure on water resources stems from agricultural irrigation.

1.3. Access to Safe Water (SDG 6 Context)

Although progress has been made in indicators of **access to safely managed drinking water** over the period 2015–2024, **one in four people in the world** still does not have access to safe drinking water. Current WHO/UNICEF JMP estimates show that global coverage **has risen to** 74%, while **2.1 billion** people lack safe drinking water (WHO/UNICEF JMP). This picture requires a significant acceleration of the pace of coverage growth, especially in low-income countries .

1.4. Water Stress, Time-Space Inequality and Climate Risk

The amount of water is not only scarce, but it is also extremely unevenly distributed in time and space. WRI's Aqueduct indicators show that at least **50% of the world's population lives under** conditions of high water stress **for one month of the year, and** 25 countries, **including a quarter** of the population, experience extremely high **water stress each year** (World Resources Institute, 2023). This highlights the imperative for resilience-focused approaches to water management in the era of climate change, where droughts and flood cycles are exacerbated .

1.5. Water-Energy-Carbon Bond (General Framework)

Water requires energy **in the processes of extraction-treatment-pumping-distribution(UNEP Copenhagen Climate Centre, 2023)**, and the collection and treatment of wastewater is part of this cycle (UNEP Copenhagen Climate Centre, 2023). The energy intensity of the urban water supply is reported in the literature in the range of **approximately 0.3–0.7 kWh/m³**; therefore, the efficient use of water reduces the cubic meter in the meter as well as **the indirect energy demand** and the associated **carbon impact**.

2. On-site Water Sources and HVAC Condensate

2.1. Other On-Site Resources

On-site water resources; rainwater, gray water (sink/shower/laundry), black water (toilet), surface runoff/flood water, and similar flows (Austin Water, 2024). A "fit-for-purpose" approach is adopted for non-drinking use (landscaping, cleaning, cooling tower make-up, etc.) in cities; Each source requires different levels of treatment and monitoring based on its quality/risk profile. Table 1 shows on-site water resources and representative quality ranges.(U.S. Environmental Protection Agency, 2018)

- **Rainwater**: Often defined by low minerality and near-neutral pH; roof and surface contact can affect particulate and microbial load.
- **Greywater**: Higher risk of microbials due to detergent/nutrient loads and organic matter, so risk-based treatment/disinfection and operation protocols are recommended (WHO, 2017).

- **Blackwater and mixed streams**: Subject to advanced treatment and strict hygiene conditions due to its pathogen load; in on-site reuse scenarios, it is often collected separately or diverted to the central system (subject to local regulations). Most municipal guidelines emphasize separate collection lines based on use, backflow prevention, and monitoring mandates.

Table1 – On-site water resources and representative quality ranges

Source	Typical pH	TDS(mg/L)	Feature Highlight	Microbial Risk
Rainwater	5.6–7.0	10–50	Hardness ≈0, no sodium; May be slightly acidic	Roof/surface contact dependent; middle
HVAC Condensate	6.0–7.5	10–300	Low minerality; variable according to installation/device contact	Risk due to biofilm in drain pan/pipes
Grey Water	6.3–8.2	450–1100+	Detergent/nutrient loads; BOD/TSS is high	High; Treatment and disinfection required
Mains Water (Drinking water)	6.5–8.5 (SMCL)	100–500 (SMCL 500)	Purified for human consumption; Salinity varies by region	Miscarriage; Distribution network subject to standards

2.2. Definition, Formation, and Systematics of HVAC Condensate

HVAC condensate is a freshwater flow with atmospheric moisture source, which occurs when the water vapor in the air condenses on the cooling coil in the air conditioning system of a building(U.S. Environmental Protection Agency, 2015). When the indoor air is lowered below the dew point temperature during cooling, moisture that the air can no longer hold adheres to the battery surface in the form of droplets and percolates into the condensate pan; from here, the condensate is removed by a drainage line (CoC). In most buildings, this current is given to the sewer without any economic/functional response; However, in buildings with high water stress and strong irrigation/cooling needs, this flow can be considered as a reusable resource on site.

Logic of formation

The primary task of air conditioning systems is not only to reduce the temperature but also to provide humidity control. Especially in summer, when the fresh air taken from outside and the air drawn from the indoor environment have high relative humidity, the coil surface is kept colder than the ambient air and condensation begins at the point where the air relative humidity reaches 100%. The amount of water that emerges;

- Moisture content of the outdoor air (i.e. climate/humid season),
- How many hours the system works,
- How much air passes through the device (CFM / flow rate),

- It increases or decreases depending on the cleanliness and slope of the cooling coil used. Therefore, it is natural for two buildings of the same capacity to produce different condensation amounts even in the same city. This production is much more evident in humid coastal cities and tourism structures.

Water quality features

Condensate contains low dissolved matter, similar in origin to rainwater; because when it passes from water vapor to liquid, it does not carry any significant salinity except for atmospheric dust and a small amount of minerals dissolved from the surface of the device. However, this does not mean that the water is "drinkable". There are two main reasons:

1. **Drainage path contamination:** Water first comes into contact with metal/plastic surfaces and the condensate pan; poorly maintained pans are conducive to biofilm and microbial growth.

2. **Storage stagnation:** If the collected condensate sits in a dormant tank for a long time, microbial growth can be seen, albeit with low nutrients.

Principles of collection, separation and marking

In current applications, a completely separate condensate line is drawn from the mains so that the HVAC condensate can be reused in the future. This line:

1. It starts from the condensate pan,
2. Prevents odor and airlock with siphon/trap,
3. Goes to a collection point with sufficient inclination,
4. From there, it is taken to the balance/storage tank.

In addition, in order not to create a cross-connection with the drinking water network, an air gap is left indicating that there will be no backflow from the tank or booster line to the network in any way. Many city and campus standards require these pipes to be marked in purple; This way, maintenance personnel on site can recognise at first glance that this line is non-drinking. This trio is the foundation of safe design in HVAC condensing systems.

Areas of use

The following uses are typical scenarios where HVAC condensate can be treated and safety measures for non-potable water requirements. In all cases, local regulations, physical separation with air-gap and purple pipe marking/warning signs are mandatory.

1. Landscaping/green space irrigation

- Why is it appropriate? Condensation increases in summer and humid days; This period coincides with the time when irrigation demand is also high in most campuses ("timing harmony").

- How? It is used effectively in drip / underground drip and pot / terrace applications after pre-filtration + appropriate disinfection. Aerosol-forming methods such as spray/lawn sprinklers require stricter control and marking due to the risk of public contact.

2. Cooling tower make-up water

- Why is it appropriate? The low minerality of condensate can help raise concentration cycles (CoC) in some systems; this has the potential to reduce makeup and blowdown volumes (U.S. Environmental Protection Agency, 2023).
- How? Tower chemistry should be managed with a professional water treatment program; conductivity/chemical balance should be observed. The U.S. Department of Energy (FEMP) guidance notes the decisive role of the CoC in water efficiency and the suitability of alternative sources (e.g., AHU condensate) as make-up water.

3. Toilet/urinal cistern supply (depending on local legislation)

- Why is it appropriate? It can be implemented with a closed use, regular disinfection and subsequent storage control.
- How? On-site reuse programs; It requires clear identification such as purple pipe obligation, valve/equipment labeling and warning signs in toilets. Design-operation permit processes are defined step-by-step in city guides (e.g., SFPUC Onsite Non-Potable Water Program).

4. Hard floor washing / general cleaning

- Why is it appropriate? It is suitable for open/closed hard surface cleaning that does not require drinking water quality.
- How? Simple filtration + disinfection; Anti-backflow warnings at hoses and connection points, air-gap and "Non-potable" warnings at filling stations are essential. Austin and similar municipal directories detail the identification and operation steps for cleaning use.

5. Construction site dust suppression / process non-contact uses (outdoor)

- Why is it appropriate? It provides an alternative to mains water in non-potable and outdoor applications where there is no direct contact with people (e.g. dust suppression).
- How? Spray configurations that minimize aerosol contact are preferred; Warning signs are placed in the access areas in the field. The WateReuse guidelines outline the general requirements for switching from on-site sources to edge uses such as WC/irrigation/tower/dust suppression.

Recommended application-specific treatment and safety

- Filtration: Coarse sieve/bag + fine cartridge or equivalent; additional filtration against clogging for drip irrigation.
- Disinfection: UV or chemical oxidant according to use; Residual monitoring when necessary in distribution lines.
- Separation and marking: Air-gap, purple pipe, valve/equipment labeling, warning signs in access areas. (SFPUC/Austin guides)
- Tower-specific: Water chemistry/conductivity. control, professional program; CoC optimization (FEMP).
- For every use involving aerosols: Risk-oriented monitoring with WMP (Water Management Program) (CDC Toolkit).

What to avoid

- Drinkable uses, shower/bath, avoiding food preparation.
- Aerosol-intensive applications such as fogging, decorative sprinklers, etc. in confined spaces where people are present: Only with advanced treatment + approved WMP + explicit warning/restriction; cautious approach in most municipal programs.

2.3. Hybrid use of HVAC condensate

HVAC condensate can be combined **with** other on-site water sources and indoor non-potable **distribution networks to** increase continuity and **balance demand-supply fluctuations** throughout the year . The following hybrids are common scenarios in practice, compliant with municipal manuals and industry guidelines. Table 2 shows the on-site water resources and representative quality ranges.

A) Condensation + rainwater **(common storage / common treatment)**

When? Rain is high during the rainy season and condensation is high during the hot-humid season; when stored together, they **produce a** more balanced volume throughout the year.

How? The sources are mixed **in a common non-drinking tank**; "fit-for-purpose" treatment (filtration + disinfection) is applied at the outlet. **Physical separation from the grid with** air-gap and **purple pipe** identification are mandatory; in entrance/landscape areas

B) Condensation + green infrastructure **(rain garden/bioretention supplement)**

When? On dry/hot days, rain gardens and biocapture areas experience **a lack of water**; low minerality **condensation** can meet this need for "lifewater".

How? Pre-filtration + subsurface feeding after simple disinfection is preferred (to reduce aerosol contact and algae growth). Green infrastructure practices are included as appropriate edge usage in on-site reuse programs .

C) Condensation + cooling tower management (operational hybrid)

When?Low TDS water **in tower make-up** helps to increase concentration cycles **in some systems,** so make-up/blowdown volumes and chemical consumption can be optimized.

How? Condensate **is used as** make-up water;**The blowdown** is managed separately (mixing is not recommended). Tower chemistry is necessarily monitored by a professional program (corrosion/scale and bio-control); CoC limits **depend on water quality + treatment regime** (DOE FEMP and GSA/NREL guidelines).

D) Condensation + purified grey water **(to balance the flow rate, conditional)**

When? For closed-contact end uses, **such as WC/urinal supply or cleaning**, the flow rate of treated greywater can be balanced by condensation; condensation can **dilute the relatively high** salinity of greywater **and some parameters** .

How? The mixture **is made only in the** common warehouse AFTER treatment;Warning signs are mandatory at **air-gap,** purple pipe and end points. The WateReuse and NYC/SFPUC guidelines detail the weld–tip usage matrix and marking rules(WateReuse, 2023; NYC DOHMH, 2025).

E) Condensation + indoor non-potable network **(toilet cistern, cleaning, dust suppression)**

When?In campus/mixed-use buildings, it is efficient to feed multiple end uses **(WC, cleaning station, dust suppression, landscaping)** from a single non-drinking backbone line.

How? The distribution network is **purple** and labeled "non-potable"; valve/equipment labeling, flow direction arrows, room/access point warnings are mandatory. The CDC's **WMP** approach mandates risk reduction and monitoring for uses involving aerosols (e.g., sprinklers).

Table 2. On-site water resources and representative quality ranges

Source	Typical pH	TDS(mg/L)	Feature Highlight	Microbial Risk
Rainwater	5.6–7.0	10–50	Hardness ≈0, no sodium; May be slightly acidic	Roof/surface contact dependent; middle
HVAC Condensate	6.0–7.5	10–300	Low minerality; variable according to installation/device contact	Risk due to biofilm in drain pan/pipes
Grey Water	6.3–8.2	450–1100+	Detergent/nutrient loads; BOD/TSS is high	High; Treatment and disinfection required
Mains Water (Drinking water)	6.5–8.5 (SMCL)	100–500 (SMCL 500)	Purified for human consumption; Salinity varies by region	Miscarriage; Distribution network subject to standards

2.3. Production dynamics and orders of magnitude

HVAC condensate is formed by condensing moisture from the air in a cooling coil. Production amount; It depends on factors such as cooling load, relative humidity/dew point, amount of fresh air (make-up air) and operating time. The guidance documents emphasize that production increases significantly with long working hours and high fresh air rates, especially during humid and hot periods. Table 3 shows the HVAC condensate production coefficients.

Key determinants:

Climate and seasonality: Production peaks on hot-humid days; this period coincides with the peak of landscape irrigation demand in most cities (timing alignment).

Business profile: Daily working hours, internal heat-humidity loads, and fresh air ratio (e.g., AHU design) increase/decrease production.

Building type: Condensate volume is usually higher in buildings that operate for long periods of time and at high loads, **such as hotels, airports, shopping malls** ; in office buildings, it fluctuates with operating hours.

Maintenance and hygiene: Clean serpentine surfaces and open drainage lines promote both **continuous flow** and **microbial control** ; clogging and stagnation negatively affect both quantity and quality.

Storage and distribution: Proper bulking prevents overflow and unnecessary evaporation losses; physical separation with non-drinking networks **(air-gap, purple pipe)** ensures safety.

Orders of magnitude (expressional): While there were small daily **volumes at the residential scale** , significant daily and significant annual recoveries were reported at the campus scale in large commercial/institutional buildings. These findings are supported by field studies in different climates and types of use.

Planning principle: The "rules of thumb" used in pre-feasibility are instructive, but calibration with local climate data and actual operational measurements is recommended for each project. The municipal handbooks recommend the practice of record keeping/tracking throughout the design and operation (e.g., sample and log record templates) as good practice.

Table 3. HVAC condensate production coefficients

Indicator	Upper-Lower Range	Note
GPH/ton (cooling capacity)	≈0.1–0.3	Climate and internal burdens are effective; SAWS/AWE field data
gpd / ton	≈6–12	Field data is typically reported at 8–10 gpd/ton
gph / 1000 sq ft (gross interior area)	≈0.5–0.6	Literature example in hot-humid climates
Annual production (sample large building)	≈700,000–800,000 gal/year	San Antonio field measurement example

2.4. Areas of Use in Landscaping and Harmonious Timing

Condensate increases in summer/humid days; This period coincides with the peak of landscape irrigation demand. Low-pressure drip and subsoil irrigation, along with small storage + filtration, are the most efficient uses; It is widely applied in pot/terrace/roof gardens, median/grass islands and campus green areas.

2.5. Health-hygiene and System Safety

The low minerality of condensate does not completely prevent the formation of biofilms on the drip and filter surfaces; Legionella risk management (CDC, 2021) and disinfection are essential, especially in applications that can form aerosols, such as cooling tower makeup. The CDC's guidance for building water systems recommends a risk-based management plan and regular testing/monitoring approach(CDC, 2025).

2.6. Regulatory and Policy Trends

San Antonio (SAWS) regulations stipulate that in new commercial buildings, the condensate line must be collected independently and ready for future reuse; In many cities, alternative water usage guidelines (eg. Austin Water) gives step-by-step the requirements for design-build-operation (SAWS, 2022).

3. Water–Energy–Carbon Relationship (WECN)

3.1. Concepts and Interrelationships

Water, energy and carbon affect each other in two directions (Kitessa, et al., 2020); The "water-energy nexus" approach proposes to manage resources together (Table 4).

Table 4 – WECN components and relationships (conceptual)

Component	What it means	Impact on others	Typical indicators
Water	Supply–treatment–distribution–wastewater treatment cycle	Every step consumes energy; energy consumption determines the carbon footprint.	kWh/m³ (water), kWh/m³ (wastewater)
Energy	Electricity/heat that powers the water cycle	Determines the energy portfolio and efficiency emission intensity	kWh/m³, specific pumping (kWh/m·m³)
Carbon	Emissions resulting from energy use	Less energy = less CO_2e; grid emission factor is critical	ΔCO_2e = kWh × EF_grid

3.2. Effects of WECN on Conventional (mains) Water Usage

The extraction, treatment, and pumping of urban water requires energy; the collection and treatment of wastewater is also part of the same cycle. The literature and field guides report energy consumption of ~0.3–0.7 kWh/m³ for urban water supply(Hamawand, I., et al., 2023) and a similar level for wastewater treatment (varying by facility/country and processes). This consumption translates into a carbon impact when multiplied by the local grid's emission factor.

3.3. Effects of HVAC Condensate Water on WECN

HVAC condensate water is a stream originating from atmospheric moisture that is suitable for on-site and non-potable use; its increase, particularly during the humid summer period, coincides with landscape irrigation demand (timing alignment). When used on-site, the energy and carbon impacts associated with supply/distribution energy and wastewater treatment are avoided because no water is drawn from the network; the only additional load on the system is a small amount of electricity consumption for on-site treatment (filtration + disinfection) and pumping (Table 5).

Table 5 – Effects of condensation water on WECN (mechanism-focused):

Stage	Water effect	Energy effect	Carbon footprint	Note
Replacing tap water	Water intake ↓	Supply/distribution kWh ↓	CO_2e ↓ (Dependent on EF_grid)	Local energy density ~0.3–0.7 kWh/m³ can be used as a reference.
Wastewater generation	Wastewater volume ↓	Raw water treatment kWh ↓	CO_2e ↓	Depending on the type of use (irrigation →

				soil instead of canal).
On-site treatment & pump	Water neutral	Small kWh ↑	CO_2e ↑ (the)	UV/oxidant and pump consumption; remains low with good design.
Seasonal compatibility	Supply–demand balance ↑	Storage requirement ↓	Indirect CO_2e ↓	Summer production ↔ irrigation demand.

3.4. Comparative summary

Policy/planning link: The UNESCO/IEA/UNEP WEN framework advocates addressing water efficiency alongside energy and climate goals, integrating on-site resources (e.g., HVAC condensation) with fit-for-purpose treatment and safe separation principles (Water-Energy-Nexus). Table 6 shows a WECN comparison.

Table 6. Tap water vs. HVAC condensate water (WECN comparison):

Step	Tap water (conventional)	HVAC condensate water (on-site)	Net difference (condensation – network)
Procurement/distribution	kWh↑ (pumping/lifting) → CO_2e↑	0 (avoiding)	Energy/CO_2e ↓
Usage (landscaping, cleaning, etc.)	Water consumption 1 m^3	1 cubic meter (on site)	Water consumption ↓ (from the network)
Wastewater	1 cubic meter (sewer/treatment)	Application-dependent (field infiltration, etc.)	Wastewater kWh/CO_2e ↓
On-site treatment/pump	-	Small kWh↑ (UV/oxidizer/pump)	A small counterweight
Seasonality	Limited supply-demand balance	High compatibility (summer season)	Storage/peak loads ↓

4. Implementation Challenges, Constraints, and Economic Analysis

4.1. Initial Setup Cost (CAPEX) and Operating Expenses (OPEX)

The CAPEX cost of the recovery system consists of the storage tank, pipelines, and treatment units. OPEX includes low energy consumption and periodic filter/chemical replacement costs. Compared to gray water systems, the OPEX cost is up to 30% lower due to the cleanliness of the condensate water.

4.2. Storage Management, Health Risks, and Cross-Contamination Hazards

The storage requirement means that water must be used or treated within a maximum of 72 hours. Otherwise, the microbial load increases rapidly. For plumbing safety, ASPE standards require that reclaimed water lines be separated from potable water lines by an air gap and clearly marked with purple piping(SFPUC, 2022).

4.3. Lack of Legislation and Need for Standardized Protocols

In Turkey, there is no specific and binding legislation on the recovery and quality of condensate water, such as regulations on gray water or rainwater. This gap slows down project approval processes and leads to differences in implementation between different local administrations.

4.4. Sensitivity Tests and ROI Optimization in Cost-Benefit Analysis

The financial success of the recycling project depends on LCC-based sensitivity analyses conducted against dynamic variables.

Water Tariff Sensitivity: A 10% increase in local water tariffs should be modeled to reduce the ROI period by up to 15%.Enerji Fiyatı Duyarlılığı:

The energy savings achieved through recycling are a critical financial lever that accelerates ROI by 1-2 years in regions with high electricity rates..

Risk Cost: The extent to which using condensate water in cooling tower operations reduces the risk of scaling and the associated equipment failure costs should be calculated monetarily and included in the analysis.

5. Findings – HVAC Condensate Samples from Around the World

Table 7 shows a comparison of water savings and WEC effects in global examples.

USA – EPA SEDS, Athens/Georgia (tower makeover)

Figure 1. EPA – Athens, Georgia (USA): EPA laboratory complex

What did they do? Condensate water was collected from the rooftop AHUs and fed directly into the cooling tower makeup water.

Results: ~540,000 gallons recovered between May–December 2008 alone; met 16% of the facility's total water usage; $3,500/year savings; $24,500 investment, ~6-year payback. Since the condensate was nearly distilled, there were no quality issues.

Energy/carbon impact: Water not drawn from the grid → avoided embedded energy in supply/distribution and wastewater treatment, and associated CO_2e.

USA – GSA Metcalfe Federal Building, Chicago/Illinois (tower facade)

Figure 2. GSA Metcalfe Federal Building – Chicago (USA)

What did they do? AC condensation was collected and fed into the tower makeup water.

Results: ~150,000 gallons/year water conservation; 15% of the tower's water demand was met by condensate; water going to the sewer was reduced.

Energy/carbon impact: Using low-conductivity condensate instead of potable water simplifies tower water management and reduces grid water-related energy/CO_2e.

USA – UT Austin Belo Center for New Media, Texas (irrigation; rain + condensation hybrid)

Figure 3. UT Austin – Belo/Dealey Center (USA)

What did they do? Roof rainwater and AC condensation were collected together and stored in a tank with a capacity of approximately 30 m³ (≈ 7,180 gallons × 4 tanks) for use in landscape irrigation.

Results: Average ~465,000 gallons/year of potable water savings and ~$2,700/year in cost reductions.

Energy/carbon impact: For every m³ not drawn from the grid, kWh and CO_2e impacts from water supply and wastewater treatment decrease; seasonal matching reduces storage pressure.

Singapore – Marina Bay Sands (landscape; multi-building application)

Figure 4. Marina Bay Sands – Singapore

What did they do? Condensate water is collected from ~3,000 AC units in three hotel towers and used for landscaping; the casino section was added in 2024.

Results: Average daily water savings of ~77,000 liters (≈ 20,000 gal/day).

Energy/carbon impact: Singapore PUB guidelines also recommend AHU condensate for tower makeup; lower conductivity means higher cycle (CoC) and less blowdown potential → reduced total water/chemical and indirect energy/CO_2e loads.

Table 7 - Water gain and WEC effect in global samples

Location & application	Annual water savings (approx.)	Usage	WEC effect (in short)
EPA SEDS, Athens, GA (USA)	~540,000 gallons (in 8 months)	Tower makeup	Water and wastewater treatment kWh/CO_2e avoidance; ~6-year payback period.
GSA Metcalfe, Chicago, IL (USA)	~150,000 gallons/year	Tower makeup	15% makeup without condensation; water/chemical and indirect energy load ↓
UT Austin – Belo Center (USA)	~465,000 gallons/year	Landscape irrigation	Drinkable water withdrawal ↓; seasonal supply-demand balance; indirect kWh/CO_2e ↓.
Marina Bay Sands (Singapore)	~7.7×10^4 L/day	Landscape	Potable/N.E.Water demand ↓; According to PUB guidelines, tower CoC↑ → bluff↓ potential.

6. Examples from Turkey

AND Kozyatağı Office Tower (Istanbul)

Figure 5. AND Kozyatağı Office Tower (Istanbul)

Roof/terrace rainwater + treated gray water from sinks + condensation water generated during building cooling are collected together; it is used for landscape irrigation, eliminating the need for tap water for irrigation. This is a powerful application that effectively reduces outdoor water demand to zero.

Palladium Tower (Ataşehir/Istanbul)

Figure 6. Palladium Tower (Ataşehir, Istanbul)

Condensation water and rainwater are collected together and reused in toilet tanks and landscape irrigation. This results in a significant reduction in total water consumption (LEED CS Gold).

Bursa Gas General Directorate Building (Bursa)

Figure 7. Bursa Gas General Directorate Building (Bursa)

Rainwater and air conditioning condensate are collected and used for landscape irrigation, reservoirs, and urinals (LEED Platinum). The application reduces both tap water consumption and wastewater volume.

Soyak Soho Office (Istanbul)

Figure 8. Soyak Soho (Istanbul)

Building air conditioning condensate water is collected and used in office restrooms; a typical internal usage scenario that reduces the embedded energy/carbon impacts in the water cycle (drinking water production/transportation and wastewater treatment).

Tekfen FNN Sustainability Center (Ceyhan/Adana)

Figure 9. Tekfen FNN Sustainability Center (Ceyhan, Adana)

Rainwater and condensation water systems provide 50% water efficiency; water is used in landscaping and reservoirs (LEED Platinum). Savings on this scale also reduce the indirect energy and carbon associated with water treatment/transportation.

7. Results and Recommendations

This study evaluates HVAC condensate water on-site at the building/campus scale, considering the water-energy-carbon relationship, health and safety, and economic feasibility dimensions. The findings reveal the following main results:

Source characteristics and positioning. Condensate water is a low-mineral-content stream originating from atmospheric moisture; it is not intended for drinking purposes but is technically suitable for non-potable applications such as landscape irrigation, cooling tower

makeup, toilet/urinal feed, and cleaning, provided that appropriate treatment and safe separation principles are followed.

Water-Energy-Carbon (WEC) effect. Each unit of condensate water used on-site reduces the embedded energy and carbon impacts associated with supply/distribution and wastewater treatment, thanks to water not being drawn from the grid; the additional energy load, consisting mainly of filtration–disinfection and pumping, is a relatively small portion. During the summer season, the production–demand timing creates a natural alignment, thereby also reducing storage pressure.

Application practices and hybrid solutions. Hybrid configurations such as rainwater co-storage, operational integration with cooling towers, and multi-point supply feeding through non-potable building infrastructure increase year-round supply continuity and overall savings. Continuous monitoring, recording, and identification (plate/label) discipline is critical in these integrations.

Health and risk management. In applications with aerosol potential, a risk-based water management program (WMP), control points, monitoring frequencies, and corrective actions must be documented. Limiting the stagnation period in storage, drainage/tray hygiene, and regular maintenance directly affect both quality and quantity.

Economy and sensitivity. In the life cycle approach, CAPEX (collection line, treatment modules, storage, automation) and OPEX (energy, chemicals, maintenance) should be evaluated together. The payback period is primarily sensitive to water/wastewater tariffs, energy prices, seasonal production and usage scenarios; financial attractiveness increases particularly in hot-humid climates and commercial buildings with long operating hours. In tower makeup, cycle count (CoC) optimization due to low TDS can result in additional water/chemical savings.

Regulatory and standard requirements. In Turkey, there is a limited binding framework specific to condensate water. In practice, adaptations are made from rainwater/gray water regulations; developing national guidelines/specifications based on the ASHRAE/CDC-based WMP approach will strengthen consistency in project approval and operational processes (CDC, 2024; ASHRAE).

Abstract

With the acceleration of urbanization processes, it has become imperative to develop new approaches to address the problems of urban spaces that are becoming increasingly devoid of identity and inadequate in meeting user needsPublic spaces are multifunctional areas where people connect their work, home, shopping, and social relationships in everyday life. The concept of "Placemaking," based on Jane Jacobs and William Whyte's human-centered approach to public spaces in the 1960s, has developed into an internationally recognized approach today, thanks to the contributions of organizations such as the Project for Public Spaces (PPS). The concept of placemaking addresses a participatory process in which public spaces are reshaped not only through physical arrangements but also through social, cultural, and economic dynamics. This concept aims to transform public spaces into living areas where people will choose to work, meet, play, and learn. Within the scope of this study, the placemaking approach will examine four fundamental qualities that determine the quality of public space: accessibility and connections, comfort and image, usage and activities, and sociality. The contributions of the concept to the urban space will be examined under the headings of improving spatial quality and accessibility, strengthening social interaction and community belonging, cultural production and identity building, economic vitality, and sustainability. However, parameters such as gentrification and limited participation levels can weaken the inclusiveness of the approach. Therefore, the concept should be evaluated not only as a design tool but also in terms of the quality and continuity of social participation. Consequently, placemaking, as an inclusive tool that encourages community participation in transforming spaces, offers a comprehensive framework that strengthens the social resilience and sustainability of urban spaces.

Keywords: Public space, placemaking, place quality

1. Introduction

The diversification of cities through economic and social dynamics in order to meet the needs of their growing populations is bringing about transformations in both the physical form and social functions of the urban fabric. Public spaces that influence the relationship between the city and urban society are areas where individuals interact by establishing relationships with their physical environment and other community members and sharing experiences (Uysal Bilge, 2021). The fact that it is effective in creating a collective identity, community consciousness, and sense of security (Hampton et al., 2014; Riberio et al., 2015; Sınmaz, 2015) necessitates that public "space" be evaluated not only as a physical entity but also as a "place" shaped by experience, belonging, and meaning.

The concepts of space and place are concepts that have been addressed in many different disciplines, from phenomenology to geography, philosophy, architecture, urban design, and landscape architecture. First, in 1974, Yi-Fu Tuan drew attention to the transformation of space

into place through memories, emotional ties, and personal experiences, describing space as an area of movement and freedom, and place as an area of security. Then, in 1976, Relph stated that space, an area whose boundaries cannot be clearly defined, becomes a place with a soul, gaining identity and meaning as individuals reflect their own selves, experiences, and routines onto it. Explaining the concept of place through "genius loci," Norberg-Schulz (1980) emphasizes that the essence of a place is determined by the environmental character of the space. Trancik (1991) states that space, when limited by multiple connections and purposes, acquires environmental and cultural meanings and thus constitutes a place. In 1992, Altman and Low, within the context of human-place interaction, examined place through its components of form, function, and meaning, emphasizing that humans are a decisive factor in the formation of place (Yurtseven & Oğuz, 2023). Such intellectual developments and critiques of modernist planning have contributed to the understanding of space not merely as a functional area, but as a place that gains meaning through human experience. Thanks to all these developments, the foundations of the concept of "placemaking" have been laid, which focuses more on social meaning and user experience than physical form, aiming to strengthen the identity and sense of belonging of a place.

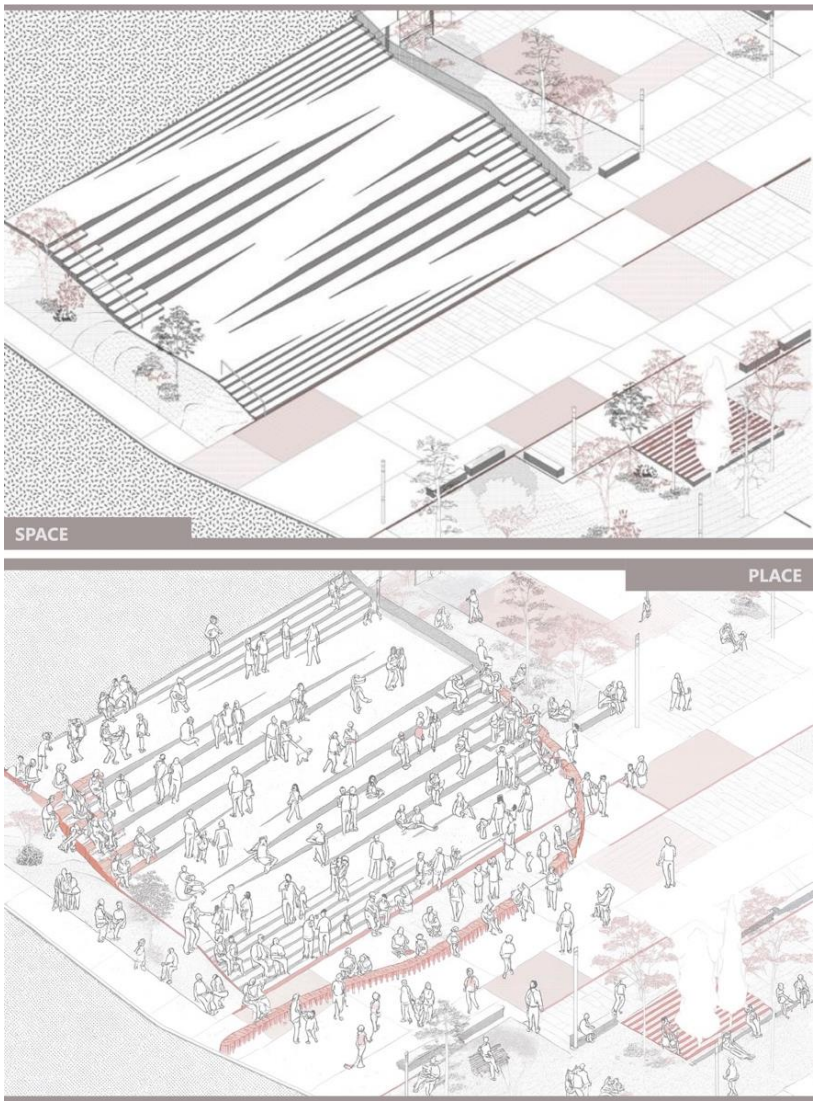

Figure 1. Representation of the space's transformation process URL1, 2025)

2. Theoretical Framework and Contributions to the Urban Environment

Public spaces that focus on the dynamics between community and place function as hubs of social interaction, identity formation, and mutual support (Asadollahi Asl Zarkhah et al., 2025). In The Death and Life of Great American Cities (1961), Jane Jacobs emphasized that public spaces should be shaped by users' everyday practices rather than by planning authorities (White, 2011; Jacobs, 2017). Similarly, in The Social Life of Small Urban Spaces (1980), William Whyte argued that the quality of a public space is determined by the frequency of social interactions and the desire of people to remain there, highlighting design as an instrument that supports such behavior (Whyte, 1980). Jan Gehl later asserted in Cities for People (2010) that cities designed according to the human body and behavioral rhythm can be regarded as successful, and that the vibrancy of public spaces reflects the health of a city (Gehl, 2020; Zapata & Honey-Rosés, 2020). The contribution of such thinkers to the literature, suggesting that public spaces derive meaning from human experience rather than physical form, has laid the theoretical foundation for the concept of placemaking today. Placemaking refers to the process of developing public spaces in a way that takes into account both their physical and social characteristics, aligning them with the values, history, culture, and natural environment of various stakeholder groups (Castell, 2006; Habibah et al., 2013; Furlan et al., 2019; Dash & Thilagam, 2023).

The concept of "Placemaking," based on a human-centered approach to public spaces, has developed into an internationally recognized approach today, thanks to the contributions of organizations such as Project for Public Spaces (PPS). PPS has identified four fundamental characteristics for the successful definition of a public space, regardless of scale, from city squares to neighborhood parks. These are: (1) being accessible and well connected to other important places in the surrounding area, (2) being comfortable and projecting a good image, (3) encouraging participation in activities, and (4) creating a social environment that makes people want to visit again and again.

- ***Access and Linkages:*** The effectiveness of public spaces is associated with their ability to ensure movement and permeability through high accessibility and the strong connections they establish with their surroundings (Gupta et al., 2025). It is easy to reach and navigate a successful public space, and the space is designed so that users can perceive activities both up close and from a distance (Project for Public Spaces. 2018).

- ***Comfort and Image:*** Another feature of a successful public space is that it is comfortable and inviting. Safety, cleanliness, environmental quality, and sensory experiences are associated with comfort, and shade, seating elements, and lighting help increase user satisfaction and encourage use (Project for Public Spaces. 2018; Gupta et al., 2025).

- ***Uses and Activities:*** Place offering a variety of events form the basis of successful public spaces and encourage people to come to the area while supporting social interaction. Active and passive uses at different times of the day attract different age groups and audiences, ensuring the continuity of space usage (Anderson et al., 2017; Project for Public Spaces, 2018).

- ***Sociability:*** The most challenging feature for a space to possess, social interaction, is supported by design solutions that encourage community participation and a sense of belonging (Anderson et al., 2017; Project for Public Spaces, 2018).

These four points defined by Project for Public Space relate to the observable and design-related concrete, spatial, or functional qualities of a space. As shown in Figure 2, the second ring of

the diagram relates to the abstract perceptual and emotional qualities of the space that are difficult to measure based on user experience, such as attractiveness, neighborliness, appeal, and community ties. Third-tier indicators, such as the number of female, child and elderly users, property values and hygiene levels, measure space quality using numerical or observation-based parameters. In short, the fundamental characteristics used to evaluate the quality of a public space represent the main themes that make a place good, the abstract elements represent what that place makes people feel, and the measurable indicators represent the parameters that prove the quality of that place.

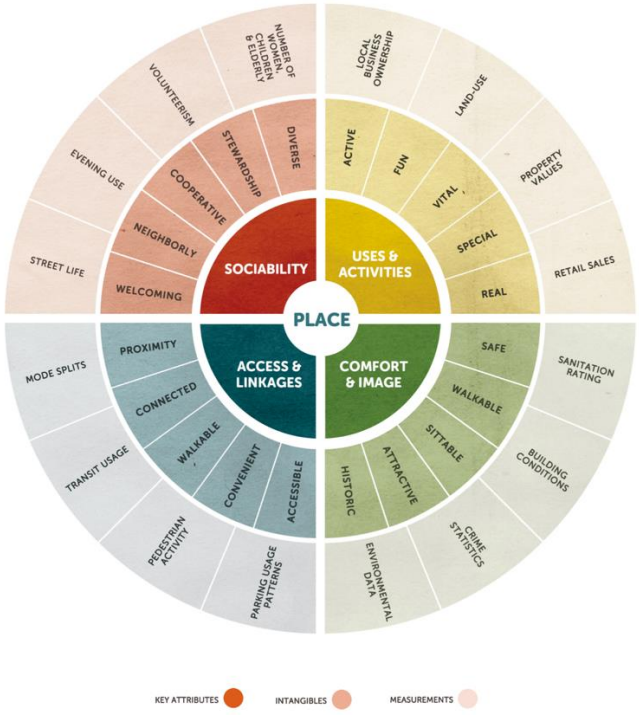

Figure 2. Project for public space place diagram (Project for Public Spaces. 2018)

This participatory approach, which focuses on a collaborative process, empowers urban communities to have a say in shaping their surroundings. By fostering cooperation and trust among diverse community members and disadvantaged groups, it helps strengthen the social fabric and sense of belonging. Activities and shared experiences in public spaces create opportunities to strengthen collective identity and cohesion. The bonds formed between communities foster a sense of ownership, which in the long term contributes to social resilience and societal well-being. Although place-making focuses on social and spatial design, public space design also highlights issues such as ecological sustainability, green infrastructure, biodiversity, and the use of local materials due to sustainability and the value placed on people. By encouraging communities to be environmentally conscious and care for their surroundings, and by raising awareness about the relationship between social well-being and the health of the urban environment, it contributes to urban ecological balance. Inviting and safe public spaces that enhance the appeal of city centers increase customer potential for nearby businesses, while events, markets, and cultural activities held within the area help keep the economy vibrant by creating opportunities for local vendors and entrepreneurs. Community-focused public spaces that create an environment where communities with different cultures and identities can come together and express themselves promote intercultural exchange and innovation, thereby

increasing the city's inclusiveness. Furthermore, this approach supports the transformation of underused or neglected sites into high-quality, functional urban spaces, contributing to the improvement of urban environments (Canadian Urban Institute & Economic Developers Council of Ontario, 2022).

3. Application Examples

As stated in the European Landscape Convention, public spaces, the foundation of identity, are an expression of individual and social well-being, collective life, and the diversity of shared natural and cultural values. Therefore, society discovers itself in public spaces and strives to improve their spatial quality (UN-Habitat, 2015). UN-Habitat (2015) categorizes public spaces into two categories and six classes: physical (streets, public open spaces, public urban facilities) and non-physical (public realm, the city itself, virtual reality). Streets are the most frequently used multi-purpose spaces in daily life, such as avenues, boulevards, sidewalks, and bicycle paths, accessible free of charge at all hours of the day and maintained by the public, where events such as open-air markets, demonstrations, and rallies can take place. Public open spaces refer to free publicly maintained areas such as parks, gardens, playgrounds, public beaches, and riverbanks. Public urban facilities refer to public facilities with high maintenance costs and limited access times, such as public libraries, community centers, municipal markets, and sports facilities. Non-physical public space refers to the institutional space where society delegates power and resources to authorities for the common good. The city, another non-physical public space, emerges as a symbolic space dedicated to, shared by, and entrusted to society. Public space, referred to as virtual reality and considered to pose a risk of diminishing physical social contact, refers to the virtual interaction created by the internet and social networks. Below, selected public spaces, based on the placemaking approach, are evaluated based on criteria such as access and linkages, comfort and image, use and activities, and socialization

- **Bryant Park, New York**

The area now known as Bryant Park was originally constructed in 1842 as a four-acre reservoir and transformed into an urban open space with the addition of Reservoir Park in 1870. This area, which eventually became known as Reservoir Square, was replaced by the New York Public Library in 1911 after the reservoir ceased functioning in 1890. Bryant Park, located behind the building, was named in honor of the poet William Cullen Bryant. Redesigned in 1934 by the New York City Department of Parks, the park was elevated above the surrounding busy streets and conceived as an “urban refuge.”. However, this closed and isolated structure has led to an increase in crime rates over time. In 1981, a report was prepared by William H. Whyte and the Project for Public Spaces, and a new design plan for the park was developed based on this report. Under this plan, narrow entrances have been widened, fences have been removed, cafeterias and event areas have been added, and security and maintenance systems have been strengthened. As a result of this transformation, Bryant Park has become a safe, accessible, active, and social public space; it has increased the value of surrounding real estate by 60%, becoming a focal point that supports the economic and social vitality of the area (PPS, 2002; URL2, 2017).

Figure 3. Bryant Park transformation process (URL2, 2017; URL3, 2025; URL4, 2024)

The renovation project carried out at Bryant Park, which involved removing the fences surrounding the park and opening numerous entrances to adjacent streets, has improved pedestrian flow and enhanced ***access and linkages***. The ability to move over 1,000 chairs within the park when needed, the diversification of landscaping, and the improvement of lighting and enhanced cleaning and maintenance practices have contributed to the park's safe and inviting atmosphere, supporting its ***comfort and image.*** Daily event calendars featuring reading rooms, markets, chess and backgammon tables, concerts, and outdoor movie screenings have been prepared to increase the ***variety of activities*** and keep the park lively at all hours of the day. The various seating arrangements in the park, open-air events, and free activities have encouraged gathering and ***socializing***, supporting the creation of a collective public space. During the restoration process, the library required additional book storage facilities. Landscape architect John M. Carrere proposed placing these storage facilities beneath the park, thereby transforming the park surface into a large-scale green area covering the roof of the underground archive. The library and underground storage areas are connected by a 62-meter tunnel, ventilation shafts are concealed among the plant borders, emergency exits are located beneath commemorative plaques, and stone pavements and iron railings from the 1934 plan were salvaged for reuse and returned to the park. As a result of these measures, Bryant Park has become an example of a green roof that represents both aesthetic and functional sustainability (ASLA, 2010).

Figure 4. Various events at Bryant Park (ASLA, 2010; URL5, URL6, URL7, URL8, 2025)

- **Campus Martius Park, Detroit**

The Campus Martius area, used as a national training ground in the 1800s, was selected as the city's Point of Origin after a fire in 1805 and hosted military ceremonies and the Michigan Soldiers Monument in 1847 (URL13, 2025). In the 1900s, due to increasing vehicle traffic in the city and highway conversions, the park was largely covered with parking lots and asphalt, losing its public function. By the 2000s, the city's population had gradually declined, the city center had been largely abandoned, and nearby stores had closed and been demolished. Vacant lots cause crime rates to rise due to vehicle density, while pedestrian life in the city has gradually declined. In 2001, the goal was to build a new park to revitalize the urban center. To this end, PPS conducted surveys and observations to develop the design concept and determine the design requirements based on the community's needs. Following this process, a design competition was held, and it was decided that Woodward Fountain would be placed in the park as a central and symbolic feature, flexible stage areas would be created to accommodate different events, a café serving visitors would be added, and connections would be established to ensure pedestrian continuity with the surrounding streets. Opened in 2004 and proving highly successful, the park implemented a highly popular urban beach initiative in 2013 to increase the time users spent in the park, social interaction, and the liveliness of the city center, thereby significantly enhancing the appeal and effective use of the public space (PPS, 2008).

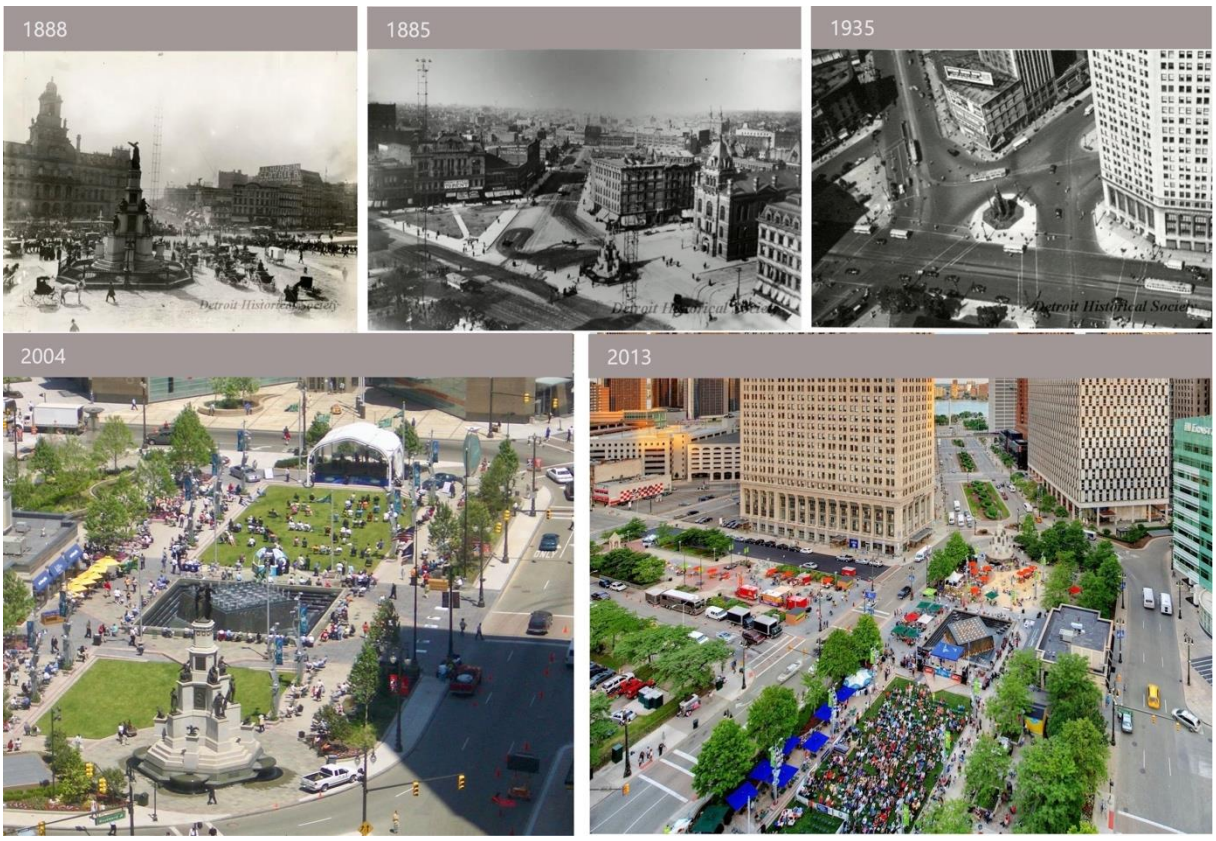

Figure 5. Campus Martius Park transformation process (URL9, URL10, URL11, URL12, 2025)

Campus Martius Park's location at the intersection of six main streets and its transformation into a pedestrian-priority circulation system approach has enabled users to access the area safely and easily. Extending the park's ground texture to the surrounding buildings and sidewalks has

provided visual and physical continuity, strengthening the park's ***accessibility and linkages***. The iconic Woodward Fountain, located in the center of the park, where water interacts with light and music; while creating an ***image*** by enhancing the visual quality of the area with the use of various plants that will provide shade, color, and visual diversity throughout the year, granite seating steps, stone walls, and low-maintenance gravel surfaces; Water walls positioned on the west side of the park to reduce environmental noise have increased user ***comfort*** in the park. The grassy area, stone steps, and hydraulic stage systems arranged at a low elevation next to the Woodward fountain provide flexible use for various activities such as concerts, markets, and shows. With its urban beach application and the conversion of grassy areas into ice rinks during the winter months, the park offers different ***uses and activities*** throughout the year. The relocation of the Michigan Soldiers monument, located in the center of the area, to a different location in the park, along with the addition of new vertical monuments, contributes significantly to the construction of social memory. Thanks to its flexible spatial design and variety of activities, the area encourages ***socialization*** among groups of different ages and cultures, thereby strengthening the city's identity.

Figure 6. Various events at Campus Martius Park (URL14, UR15, 2025)

4. Conclusion

In conclusion, placemaking, as an inclusive tool for transforming spaces by encouraging community participation, offers a comprehensive framework that strengthens the social resilience and sustainability of urban spaces. Therefore, public spaces that are inaccessible or idle/unusable should be considered and evaluated as a potential resource for enhancing urban quality. However, parameters such as gentrification and limited participation levels can weaken

the inclusiveness of the approach. Placemaking should be evaluated not only in terms of spatial design, but also in terms of the interaction, continuity, and decision-making power of the actors involved in the process. The placemaking approach, which redefines urban development as a shared process, contributes to a sustainable urban vision by integrating social, ecological, economic, and spatial quality dimensions, and serves as a strategic tool for contemporary urban transformation policies.

Abstract

In the Anthropocene era, where human activities have significantly shaped the planet, climate change has become a global crisis causing rising global temperatures, changes in rainfall patterns, and extreme weather events. Rapid urbanization and changes in land use have led to an increase in built-up areas, disrupting natural hydrological processes in urban areas and making these areas more vulnerable to the effects of climate change. This situation also causes climate change to intensify rainfall patterns, overloading urban drainage systems and increasing the frequency and severity of floods. Current approaches demonstrate that traditional engineering solutions alone are insufficient for managing flood risks, while integrated systems provide longer-term and sustainable solutions. Today, integrating smart city technologies with nature-based solutions is gaining prominence in order to increase the resilience and sustainability of cities; this approach produces innovative solutions by combining real-time data and automation with ecological design. Nature-based solutions seek to manage floodwaters through natural processes by enhancing ecosystem services, while digital technologies aim to increase intervention capacity by predicting flood risks using IoT sensors, satellite-based early warning systems, and data analysis. The integration of digital technologies and nature-based solutions facilitates the effectiveness and traceability of ecological interventions. This study will examine the complementary aspects of nature-based solutions and digital technologies and discuss the opportunities these approaches offer in designing resilient cities.

Keywords: Climate change, flood resilience, nature-based solutions, smart cities

1. Introduction

Cities, which are places of economic development, political change, and the emergence of new values and attitudes, have a significant impact on preparing the ground for social and technological developments (Alkan, 2022). Today, 55% of the world's population lives in urban areas, and this figure is projected to rise to 68% by 2050 (United Nations, 2019). Population concentration in urban areas triggers rapid urbanization processes and significant changes in land use; this situation has negative effects on water quality and hydrological processes (Qin et al., 2013; Mottaghi et al., 2016; Berndtsson et al., 2019). The inadequacy of urban drainage infrastructure systems and the increase in impervious surfaces due to land use changes have made cities more vulnerable to flooding caused by the intensity of rainfall resulting from climate change (Abbasov, 2025). It is accepted that traditional engineering solutions are insufficient in protecting cities against flood risks, and that integrated systems produce more

effective solutions instead. Smart cities utilize digital technologies such as sensors, IoT, and data analytics to optimize urban systems and improve quality of life. Nature-based solutions, on the other hand, seek to address urban challenges such as climate adaptation, air quality, and biodiversity loss by utilizing or mimicking natural processes and ecosystems. In this context, nature-based solutions that aim to manage floodwaters through natural processes using applications such as permeable surfaces, rain gardens, water squares, and ecological corridors, combined with real-time data collection, early warning systems, and IoT sensors, offer an innovative approach to increasing flood risk monitoring and management capacity in urban areas. The integration of smart city technologies with nature-based solutions has led to the emergence of smart nature-based solutions that combine real-time data and automation with ecological design to create resilient and sustainable cities (Kaluarachchi, 2021).

2. Smart Nature-Based Solutions

The increasing frequency and severity of urban flooding caused by climate change has highlighted the need for new approaches that will strengthen cities' capacity to adapt to climatic and hydrological processes. Nature-based solutions, such as green infrastructure, artificial wetlands, and permeable surfaces, reduce urban heat island and flood risks, and improving air quality by mimicking nature's ecological wisdom, contributing to urban sustainability and resilience. Meanwhile, smart systems capable of performing complex tasks such as artificial intelligence, the Internet of Things, and data analytics facilitate the monitoring of environmental factors in urban areas, contributing to the mitigation of urban environmental challenges through early intervention and adaptive management. Smart nature-based solutions are an approach that combines the ecological compatibility and functionality of nature-based solutions with the data-driven and automation capabilities of information systems. Nature-based solutions aim to reduce flood risks and ensure the sustainability of ecosystem services by combining nature's self-regulating mechanisms with information technologies (Li & Nassauer, 2021). Digital tools facilitate public participation and feedback, while data-driven decision-making processes enable participatory urban governance by supporting urban planning and resilience strategies (Kolokotsa et al., 2023; Wellmann et al., 2023). Sensor-supported urban forest management, smart green roof systems, automated wetland control, sensor-based dust suppression areas, IoT-supported rainwater management, and adaptive coastal protection applications with smart nature-based solutions not only mimic natural processes but also optimize them with data, contributing to the more effective, flexible, and scalable management of environmental issues in cities (Bressane et al., 2024).

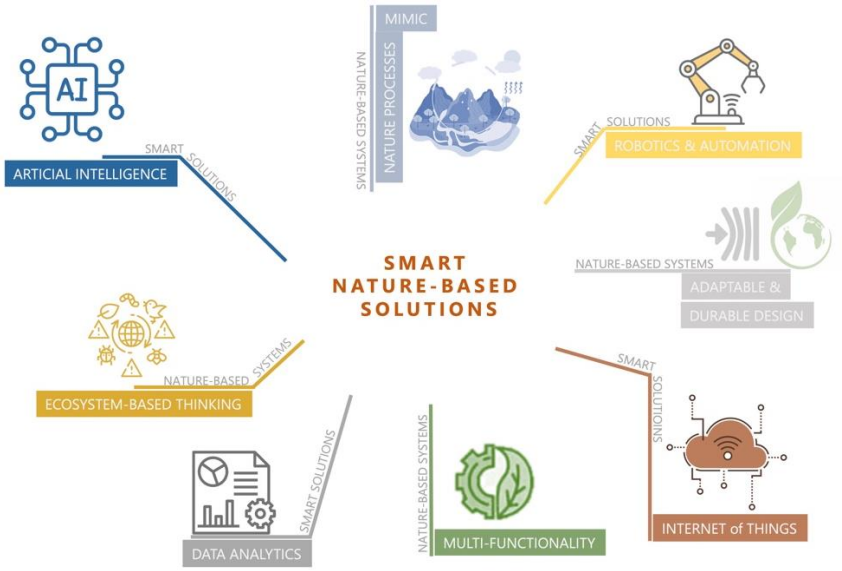

Figure 1. Smart Nature-Based Solution Components (Bressane et al. (2024) was consulted)

Examples of Smart Nature-Based Solutions

a. **Digital Twin:** The digital twin approach is based on creating a virtual copy of a physical process or system and establishing real-time data flow between the physical system and the virtual environment. This approach is also used to monitor and optimize the performance of nature-based solutions. Nature-based solution systems are approached as decision support and performance monitoring tools by creating a dynamic, updatable digital copy using sensors, modeling, and data flow (Brasil et al., 2022). Following a series of devastating floods in Singapore, the city recognized that due to intensive urbanization and land conditions, flood management required not only engineering-based solutions but also data and simulation-focused approaches. It began using digital twin technology as a strategic tool to increase urban resilience against flood risk. The Singapore Land Authority (SLA) has developed a national digital twin covering the entire country called Virtual Singapore by using aircraft and ground vehicles equipped with laser scanners to transfer topographic data, urban land, buildings, infrastructure, and drainage systems to a digital environment with millimeter accuracy. This digital twin contributes to the development of early warning mechanisms against potential floods by providing real-time sensor data. During periods of heavy rainfall, the flow direction of water, accumulation areas, and high-risk zones are identified in advance, enabling data-driven planning of interventions and improvements to the drainage infrastructure. Therefore, Singapore has developed an effective integrated decision support system that combines nature-based and technology-enabled solutions to support flood management, land use optimization, and urban resilience planning under conditions of limited land and dense population (Walker, 2023).

Figure 2. Singapore's digital twin examples (Walker,2023; URL1, 2025)

b. **Smart Rainwater Ponds:** Smart rainwater ponds are an enhanced version of rain gardens or ponds created for rainwater storage, supported by digital sensors, automatic control systems, and prediction models. Sensors that regularly monitor water level, rainfall amount, flow rate, and weather conditions collect data, send it to the monitoring and control platform in real time, and the reservoir outlet structures are managed based on this data and meteorological forecasts. If heavy rainfall is predicted, controlled drainage is implemented to increase storage capacity, and during flooding, water is either retained or released in a controlled manner. This reduces the risk of flooding and improves water quality by facilitating the sedimentation of pollutants. Smart reservoirs, which offer an adaptive and predictive hydrological approach continuously optimized with sensor data and model outputs, reduce hydrological pressures on urban infrastructure while supporting the enhancement of ecosystem services by preserving the nature-based solution principle (Li & Nassauer, 2021).

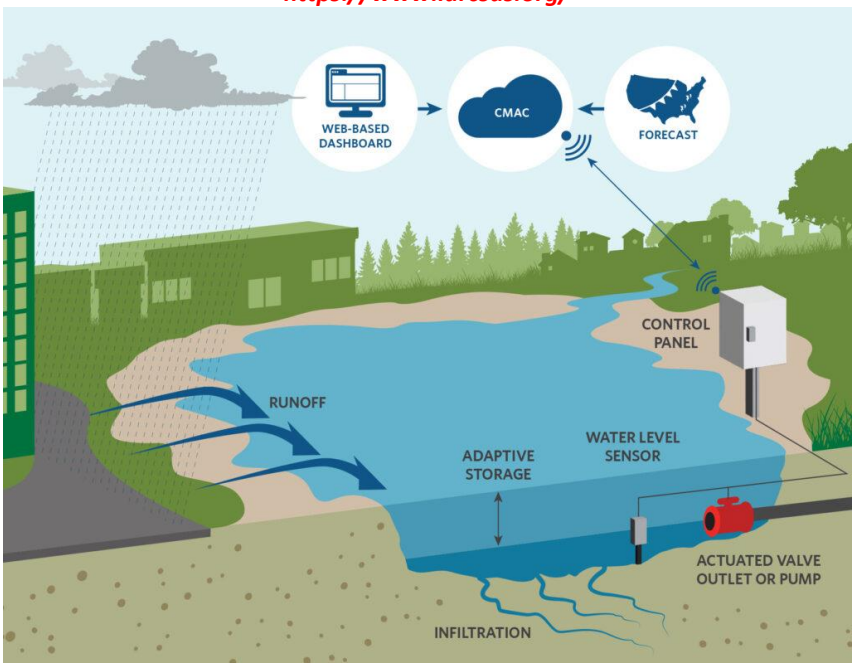

Figure 3. Smart Rainwater Ponds (URL2, 2025)

c. **Smart Mangrove Flood Barriers:** Mangroves, with their natural wave-breaking and sediment-trapping properties, are crucial in preventing sea level rise and erosion. The capacity of natural mangrove ecosystems to reduce wave energy and provide protection, when addressed through an integrated approach supported by Internet of Things-based sensors and early warning systems, reveals a hybrid flood management approach that slows coastal flooding through natural means while preparing communities for early intervention. Simultaneous data from sensors measuring wave motion and rising water levels provide alerts when critical levels are reached, combining the physical defense effect of mangroves with a digital early warning mechanism to support coastal management (Shubnam, 2025).

3. Conclusion

It is crucial to recognize that flood management approaches focused solely on resistance and based only on gray infrastructure are insufficient in the long term, and that nature-based and adaptable systems centered on ecological processes are essential for sustainable urban management and resilience. Smart nature-based solutions that combine engineering, ecology, and technology in flood risk management are highly successful in producing sustainable and flexible solutions to complex problems by increasing cities' resilience to floods. However, challenges such as high investment costs, extensive data management requirements, and lack of corporate coordination limit the widespread adoption of smart nature-based solutions.

Abstract

The development of technology has brought about many lifestyle changes, as well as changes and developments in the fields of architecture and design. Digital design tools are one of these developments. The use of various digital tools resulting from technological advancements continues to increase in the architecture and construction sectors. Parametric design and parametric/algorithmic design tools, emerging as current approaches in architecture, reinforce these technologically driven changes in architecture. Adapting to this constantly evolving sector has become a necessity for students of architecture. The extent to which parametric design tools are incorporated into architectural education in Turkey varies, but it is a topic that deserves further investigation. This study aims to examine the proficiency of using current parametric design digital tools in undergraduate architecture education in Turkey and their adaptation to the sector through student experiences. The first section of the study examines parametric design and parametric design tools in architecture. The second section presents data from surveys administered to students as part of the workshop. The third section examines the state of architectural education in Turkey, in light of the topics discussed in the first section, using content analysis using data obtained from surveys conducted with students at various universities. The analysis concludes that the Turkish architectural curriculum needs to embrace parametric design thinking.

Keywords: Parametric design, parametric design tools, architectural education

1. Introduction

The constant change and evolution of the Earth has impacted lifestyles and, consequently, many sectors. Architecture is one of the fields affected by this situation. Today, studies on architectural approaches that incorporate complex geometries are increasingly being conducted. Traditional design tools do not support change and development in architectural designs because they require excessive time and effort for changes in the design process. Modeling non-Euclidean geometries and advancing data exchange and collaboration between disciplines have created the need for faster exploration of design alternatives and better management of the complexity of design problems. Consequently, computers have become an important tool in the design process, transforming the way architects design (Kolarevic, 2003). Recent technologies allow the design process to go far beyond traditional possibilities, encouraging the development and widespread adoption of complex shapes and advanced production techniques. Computers are expanding the potential limitations of human imagination and providing tools for new design approaches, discovery, experimentation, and research. Increased access to computational design tools, coupled with the rapid development of algorithmic and parametric modeling and multidisciplinary design optimization, has enabled design teams to explore a variety of new design approaches. Architecture is now experiencing a proliferation of

approaches and techniques for generating, rationalizing, and optimizing design processes and outcomes. This not only improves the design process but also leads to a shift toward algorithmic-based modeling and simulation programs and nonlinear systems as a way to enhance design approaches through adaptation and emergence, facilitating the production of higher-performance design approaches without reducing geometric complexity. Considering these developments, an increasing number of building designs are characterized by geometrically complex and flexible structural envelopes. Tool-enabled development in architectural design has enabled the introduction of new design approaches such as parametric, adaptive, and biomimetic into the architectural design literature. The aim of this study is to examine the adequacy of teaching and using parametric design digital tools used in undergraduate architecture education in Türkiye and their compatibility with the sector through student experiences. In this context, the answer to the study question was sought through workshops and surveys conducted with the voluntary participation of architecture students.

2. Materials and Methods

A survey method was used in the study. The data used in the study were obtained from surveys administered to volunteer participants before the "Parametric Energy-Efficient Facade Design and Daylight Analysis Workshop," which took place at Mimar Sinan Fine Arts University from December 17-20, 2024. The participants were undergraduate and graduate students of architecture and interior architecture studying in Turkey. The surveys were conducted digitally and covered parametric design and its tools, as well as the use of daylight in architecture and simulation tools. Data within the scope of parametric design were examined in the study. Graphs were created based on the results obtained from the surveys. Conclusions were reached based on the generated graphs. The first part of the study examined parametric design and its tools. The second part presented the data obtained from the surveys administered to volunteer students. The final part interpreted the data, and the current use of parametric design tools in architectural education in Turkey was analyzed.

3. Findings and Discussion

3.1. Change and Development in Architectural Design Tools

Between the late 20th century and the present, noticeable changes have occurred in the context of developments in construction techniques. Until the late 20th century, it can be said that the ability to create any structure, object, or product envisioned in one's mind was not as advanced as it is today. Complex calculations, the increasing number of specialized fields, and designers working across multiple disciplines were insufficient. While architects could clarify their designs in their minds, they had not yet overcome the challenges of the construction phase. At this point, computers and computer technologies have become a solution for architects to realize the designs they envisioned in their minds and through technical drawings.

From the 2000s to the present, software companies have increased their products serving the fields of design and architecture, and architects have become active users of these software and begun to incorporate programming languages into their designs (Silver, 2006). The relatively low cost of computer calculation and trial-and-error compared to real-world methods, coupled with the ability to simulate damage and load-bearing experiments, has made computers a tool used by architects not only in the design process but also in the construction and implementation processes to complete their buildings (Ergün, 2008). Ecological and sustainable architectural approaches have been among the factors that have influenced and changed architectural design

and its tools from the early 21st century to the present day. The goal of sustainable energy technologies can be summarized as preventing the use of depletable fuels, maximizing the efficiency of energy production and use as a temporary measure, developing new resources, saving energy production and fuel selection for the last resort, developing energy-consuming technologies and systems for optimal efficiency, minimizing the environmental impact of energy technologies on the ground, preventing the extraction of more energy from natural resources than the local ecosystem can handle, and designing technologies to ensure that human activities remain below energy limits and do not exceed the planet's capacity (Elliot, 1997). The rise of technological possibilities is crucial for achieving ecological and sustainable designs in a world where resources are dwindling, environmental pollution, and global warming are making living conditions more difficult. Material selection, the appropriate evaluation of material potentials based on their location, the use of developments in construction techniques, and design decisions throughout the design process have gained importance in this regard. While the concepts of ecological sustainability and sustainability have been prevalent in the architectural field since ancient times, they have gained importance today for the evolution of architectural design approaches and their contribution to energy transformation. The constant transformation of the Earth due to climatic, geographical, industrial, and political factors makes it essential that buildings and facades be designed without ignoring the requirements brought about by these changes (Ergün, 2008). Architectural structures, which could previously be designed with a human-enabled design approach, are now being designed with the aid of digital tools. These tools generally emphasize the relationship between the physical environment and the facade, comfort, energy use in architecture, and sustainability. They are designed to maximize the performance of facades and other designs through various simulations. Furthermore, technical software, frequently used in engineering and whose use in architecture has become widespread in recent years, is also being used. These tools/software, used in the 21st century and beyond, demonstrate that architectural building performance is becoming increasingly important, parallel to visuality and aesthetics, and even more so with the increasing prevalence of environmental issues. The use of these tools has led to the implementation of different approaches in architecture, particularly in façade design. Consequently, performance-oriented approaches to architectural façades have gained prominence. The development of digital modeling tools since the late 20th century has inevitably led to the emergence of parametric, adaptive, biomimetic, and other performance- and aesthetic-oriented façade designs, which have gained a significant share in architectural façade literature and practice. The table below lists the features of innovative architectural design tools mentioned in articles published in WoS. These design tools are used in a variety of architectural topics, including algorithmic and parametric modeling, energy and daylight simulations, and life cycle design.

Table 1. Digital design tools (Created by the authors)

Innovative Design Tools	Features
BIM	BIM is a system that stores all the information about a building in a single digital model and coordinates all project phases through this model. This model incorporates not only 3D drawings but also the physical and functional characteristics of the building. The fundamental principle of BIM is to ensure that all stakeholders have access to the same model and work in a consistent and coordinated manner throughout the project. This minimizes errors and delays, and optimizes project costs and timelines.

Rhinoceros	Rhino is a high-precision modeling software for generating complex geometry, surfaces, and curves. It is widely used in industrial design, architecture, jewelry design, automotive design, CAD/CAM, mass production, reverse engineering, and multimedia and graphic design.
Grasshopper	Grasshopper is an algorithm editor integrated with Rhino's 3D modeling tools. It is frequently used to dynamically modify parametric forms via algorithmic inputs. It integrates environmental influences such as sun and wind into the model created in the program, allowing for easy modification of form and size.
LadyBug	Ladybug is a collection of computer applications for simulation. Ladybug Tools works with Rhinoceros and Grasshopper, allowing data transfer between simulation engines, enabling geometry creation, simulation, and visualization within a single interface.
HoneyBee	Honeybee enables detailed daylight simulations and thermodynamic modeling in the advanced design stages by connecting the Grasshopper/Rhinoceros environment to these engines.
EnergyPlus	EnergyPlus is a building energy simulation engine. EnergyPlus applies detailed building physics for air, humidity, and heat transfer, including separate consideration of radiative and convective heat transfer to enable modeling of radiant systems and calculation of thermal comfort metrics; calculates lighting, shading, and visual comfort metrics; and configures HVAC systems.
DesignBuilder	DesignBuilder is a software tool that handles three-dimensional building modeling with energy simulations based on EnergyPlus used for energy, carbon, lighting and comfort measurement and control.
ClimateStudio	ClimateStudio is a Rhinoceros plugin that allows simulations under topics such as illumination, annual glare rates, area analyses.
ESP-r	ESP-r (Environmental Systems Performance - Research) is a modeling tool for building performance simulation. When performing its assessments, the system is equipped to model the flow of heat, air, humidity, light, and electrical power in user-specified spatial and temporal contexts.
OPOSSUM	OPOSSUM is a simulation and optimization tool integrated with Grasshopper. Opossum includes the best-performing model-based RBFOpt and evolutionary CMA-ES optimization algorithms in Grasshopper.
DIVA	It is a daylight and energy simulation tool that works integrated with Rhinoceros.
OpenLCA	OpenLCA is a lifecycle software designed for professional ecological, social, and economic lifecycle assessments. It can be used in architecture and construction, from the construction phase to the demolition phase of a building.

3.2. Parametric Design

The concept of algorithm, which forms the foundation of mathematics and computer science, has over time become a subject of other sciences and disciplines. An algorithm, which can be defined as the set of steps required to solve a problem, and the algorithmic thinking that develops from it, form the basis of parametric design. In its most basic form, a parameter can be explained as a quantity that can be defined and modified for a situation, and a situation that contains one or more of these quantities can be perceived parametrically (Erbaş, 2013). Design is considered the process of posing a problem and generating and exploring options for a solution that meets the problem's requirements. Any measurable factor that defines or defines the boundaries of a system is called a "parameter." While the definition of parametric design may seem straightforward when considered solely in the context of form, its understanding as a design concept is complex. The concept of parametric design refers to the use of parameters

in creating a form and a procedure where variables are used to define a problem. Furthermore, by manipulating these factors, various potential solutions can be generated, and then a final solution can be selected according to certain criteria (Gero, 1990). Jabi (2013) defined parametric design as "a technique based on algorithmic thinking that enables the formulation of parameters and rules that define, codify, and explain the relationship between the design intent and the design response." The most significant advantage of parametric design is its effective use of description to flexibly specify and create geometries and to link selection variables to geometries. Parameters in the parametric model are modified to develop a new solution to the design problem. The model adapts to changes by adapting to new values of parameters or restructuring parameters without deleting or repeating anything (Hernandez, 2006).

Parametric design is not only a design process but also an approach that shapes the forms of architectural structures. Parametric design has transformed the traditional design process into one where changes can be made without rewinding and complex problems can be solved. This has led to forms that appear complex but can be designed systematically through the parametric design process. These forms, especially common in today's architectural facades, may appear complex, but each represents different parameters, and changes are easily implemented. With parametric plugins and software, designers can instantly create large, dynamic forms graphically by entering various values (input) and creating appropriate constraints. Designers can generate complex forms thanks to the ability to detect changes made in real time using these plugins and software. When the parameters of a parametrically designed model are changed, the form is automatically updated (Burry, 1999). With the use of digital design tools and parametric design in architecture, two new approaches that can be examined within the scope of parametric design have emerged: biomimetic and adaptive design. Both approaches have found a place in architecture to provide solutions to the environmental problems facing the Earth, and are being studied alongside concepts such as energy-efficient design, sustainable design, climatic design, and comfort in architecture. Biomimetic design, also referred to as biomimicry or biomimesis in the literature, is an approach that emerges through the transfer of knowledge and methods between technology, biology, and the discipline of architecture (Yılmaz, 2024). Benyus (1998) defined biomimicry as "a new discipline that examines nature's best ideas and imitates its designs and methods to solve human problems." On the other hand, Gruber (2011) stated, "It is the collaborative work of the disciplines of biology and architecture, which has innovative potential for architectural problems." An example of biomimetic design is the New York TWA Terminal, whose design was inspired by the wing structure of birds (Yılmaz, 2024) (Figure 1). Adaptive design was defined by Kolodziej and Rak (2013) as a system that responds to a specific stimulus in a predefined manner, and by Pan and Jeng (2008) as a dynamic structural system that can change shape according to environmental conditions and user needs. Today, the concept of adaptive design is understood as the reversible change or transformation of buildings, building materials, or components to adapt to environmental factors and enhance structural performance (Razaz, 2010; Schmidt and Austin, 2016). An example of adaptive design is the Arab World Institute, designed by Jean Nouvel (Figure 2).

Figure 1. TWA Terminal (Welch, 2019)

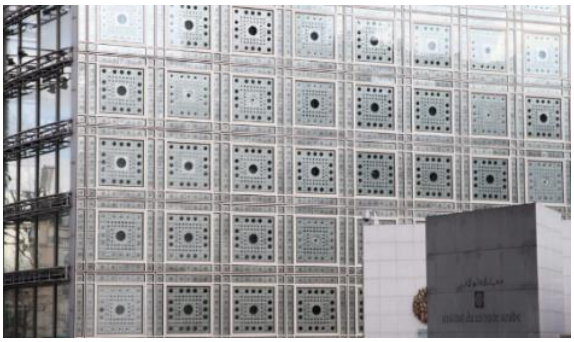

Figure 2. Jean Nouvel's Arab World Institute (Onniboni, 2024)

3.3. Digital Design Tools and Parametric Design in the Architectural Sector

The 1980s and 1990s were a period when neoliberal economic structuring was encouraged worldwide, the free market developed, and information technologies emerged. This led to the integration of information technologies with creative industries in accordance with the economic policies of the time (Mitchell et al., 2003). Software companies and programs, particularly those with a wide range of CIS programs and their popularity in the liberal economy, maintain their presence in the sector and are constantly updating themselves. Annual license and version updates of these programs are seen as a significant opportunity for these companies to maintain their existence (Taşdelen & Gül, 2017). Considering the current "softwarization" era, this sector's connection to all other sectors and its vast sphere of influence are fueling its continual development, leading to its integration with many different sectors. Considering the history of "softwarization," it can be said that software companies and programs have a significant influence in the global economy. Software companies operating in the architectural field are also observed to have an impact on the construction and architecture sectors. Architectural software companies collaborate with architectural design offices with the stated aim of "influencing, changing, and shaping the future of design, etc." In fact, it can be said that all digital design technologies are developed for specific purposes and specific audiences. Therefore, understanding which software is used in the architectural sector for which purposes, which modeling classes it falls into, and its technical specifications will enable integration into the architectural software culture, awareness of software policies, and active use in the design process (Taşdelen & Gül, 2017). BIM (Building Information Modeling), a significant development in the 21st century in architecture and digital design, is used as a design policy in design offices in many countries, including the UK and the US. Renowned architectural design offices worldwide are closely following design software developments and have research and development teams to keep up with developments in this field. Similarly, software companies may use the names of renowned architecture and engineering firms when advertising their products. In other words, there can be a mutual benefit between software companies and architecture firms in the sector.

Parametric design is the most prominent computational design method that challenges traditional design practices. Searches conducted on prominent databases such as Web of Science (WOS), Scopus, and Science Direct have identified parametric design as the most popular term. The increase in studies on parametric design, particularly in the last 20 years, is noteworthy (Caetano et al., 2020). Frequently cited in academic studies, parametric design is also a design approach employed by the industry, particularly by world-renowned architectural offices. One of the most important reasons for this is that parametric design offers diverse solutions by systematically breaking down problems encountered in the design process into smaller components, enhancing the value not only of the final product but also of the process (Özdemir & Yıldırım, 2018). Changes resulting from designers' manipulation of parameters allow designers to explore the structure in depth. Another reason is that parametric forms possess complex aesthetics, require design with digital design tools, and provide energy efficiency for building facades, leading architectural offices to view these designs as advertising tools. Hudson (2010) identified six applications of parametric design in architectural practice: (1) transforming design ideas into parametric models, (2) directing and rationalizing designs into constructible shapes, (3) controlling and organizing architectural forms, (4) generating design variants based on various criteria and expert input, design exploration and optimization, (5) creating construction documents, and (6) gathering design information from different stakeholders. The implementation of the parametric design process in architectural offices and its translation into design form also involves similar stages, although the implementation depends on the organizational structure of the architectural office. Four common strategies for incorporating parametric design strategies into design offices have been observed: consulting groups within the practice, independent consultants, integration with design teams, and an ambiguous position. The size of some practices allows for more than one of these structures to be present. Other practices make no commitment or offer any opinion on the position of the parametric design role, but there is material suggesting a role within the relevant offices. These are identified in a fourth category as an unspecified position (Hudson, 2010).

3.4. The Use of Parametric Design and Digital Design Tools in Architectural Education

This section of the study, based on the idea that the parametric design approach is not only a representation/transmission problem but also a production/design problem, will examine the extent to which the parametric design approach is considered a design problem in the project design process in architectural education, how parametric/algorithmic design tools are integrated into the project process to address these design problems, and whether all of these are conveyed to students. In this context, the "Parametric Energy-Efficient Facade Design and Daylight Analysis Workshop" was held at the Fındıklı Campus of Mimar Sinan Fine Arts University on December 17-20, 2024, led by Prof. Dr. Ümit ARPACIOĞLU (Figure 3). The workshop covers the main topics of parametric design, parametric energy efficient façade design and use of daylight in architecture.

Figure 3. Workshop poster (Created by the authors)

After lectures on the workshop topic were held on the first day, over 150 students from various universities who applied to the workshop were divided into working groups and began their work under the leadership of their group facilitators (Figure 4, figure 5). Six subgroups were identified within the scope of the workshop: "Adaptive Facade Approaches to Achieving Optimum Illuminance Levels in Spaces, Daylight Analysis of Different Materials in Parametric Energy-Efficient Facade Design, Parametric Approaches in Energy-Efficient Facade Design, Biomimetic Approaches in Energy-Efficient Facade Design, Comparison of Glass and Kinetic Facades in the Context of Daylight, and Glare Control in Adaptive Facades" (Figure 6, figure 7).

Figure 4, Figure 5. Workshop seminars (Taken by the authors)

Figure 6, Figure 7. Students' work with group executives (Taken by the authors)

Participating students received education in Rhino-Grasshopper and ClimateStudio, algorithmic design and simulation programs used in the workshop. With the help of their group leaders, the participating students conducted literature research on relevant topics and created parametric, adaptive, and biomimetic façade designs using Rhino and Grasshopper. They then imported their designs into ClimateStudio to generate daylight simulations to measure the

daylight control performance of innovative, energy-efficient façade designs. The resulting data was interpreted, and recommendations were developed. The workshop outputs were exhibited in the Mimar Sinan Hall of the Fındıklı Campus of Mimar Sinan Fine Arts University from January 6–12, 2025 (Figure 8, figure 9).

Figure 8. Preparation process

Figure 9. Exhibition of the workshop

A survey was administered to the students participating in the workshop to assess their knowledge beforehand. Sixty-five students volunteered to participate. The survey assessed the students' departments, grades, and universities of study, as well as their theoretical knowledge of parametric design, adaptive design, and biomimetic design, and their ability to use the digital design tools used in these approaches. This provided information about the role of parametric design and parametric design tools in architectural education.

The first question posed to the students in the survey was their department and grade. Based on the responses given in the first section of the survey by the 65 students who volunteered to participate in the workshop, 90.8%, or 59, were architecture students. The remaining 9.2% were primarily studying in interior architecture and architecture graduate programs. The Interior Architecture Department comprised three students (4.6%), one student from the Restoration, Renovation, and Conservation graduate program (1.5%), one student from the Architecture and Built Environment Renovation graduate program (1.5%), and one student from the History of Architecture graduate program (1.5%) (Figure 10). Furthermore, 53.8% of the participating students were 2nd grade students, 18.5% were 4th grade students, 10.8% were 3rd grade students, 10.8% were graduate thesis students, and the remainder were graduate coursework students (Figure 11).

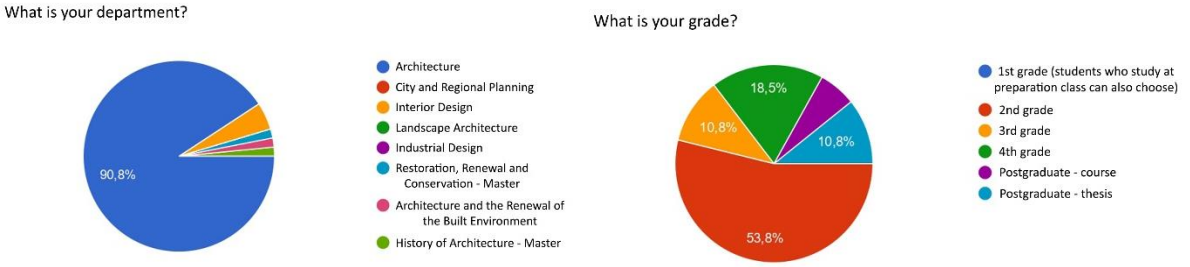

Figure 10, Figure 11. Datas from the first section of the questionnaire

The first section of the survey also included questions regarding whether their program knowledge of parametric modeling was sufficient prior to the workshop. For those who had knowledge of Parametric Energy-Efficient Facade Design and Daylight Analysis before attending the workshop, they also asked where they obtained their information. Accordingly, 87.7% of the students stated that they did not have sufficient knowledge of Parametric Energy-Efficient Facade Design and Daylight Analysis before the workshop, while 12.3% stated that they did (Figure 12). Of the students who did have knowledge, 23.1% obtained their information online, 18.5% from their educational institution, 7.7% from seminars/conferences, 6.2% from printed publications, and 3.1% from various workshops (Figure 13).

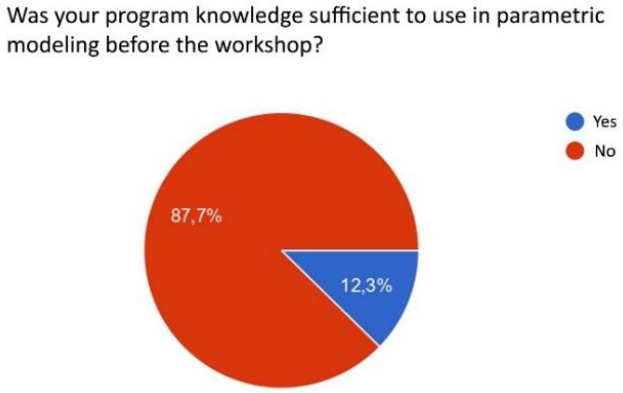

Figure 12. Datas from the first section of the questionnaire

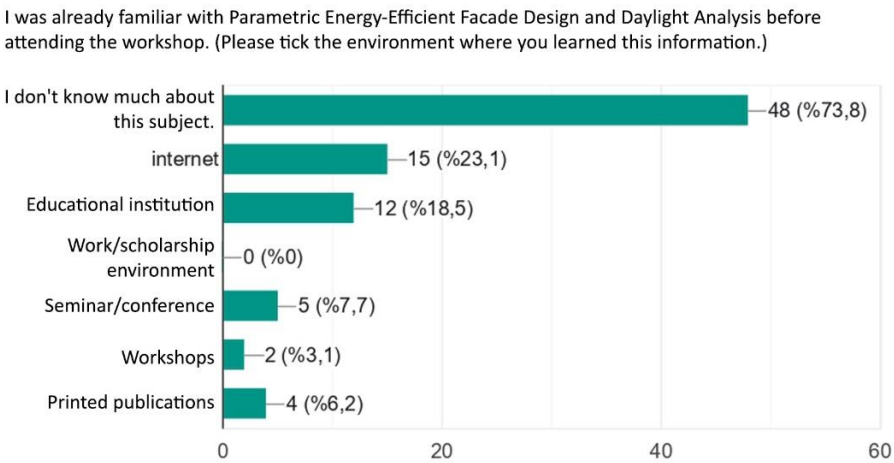

Figure 13. Datas from the first section of the questionnaire

The second section of the survey inquired about the students' prior knowledge of parametric design, adaptive design, and biomimetic design, as well as their theoretical and digital programming knowledge. The first section of the second section addressed questions about parametric design, the second section addressed questions about adaptive design, and the third section addressed questions about biomimetic design. According to the results of the survey on parametric design in the first section of the second section, 27.7% of the participating students had some knowledge, 26.2% had a good knowledge, 10.8% had a very good knowledge, and 12.3% had no knowledge at all (Figure 14).

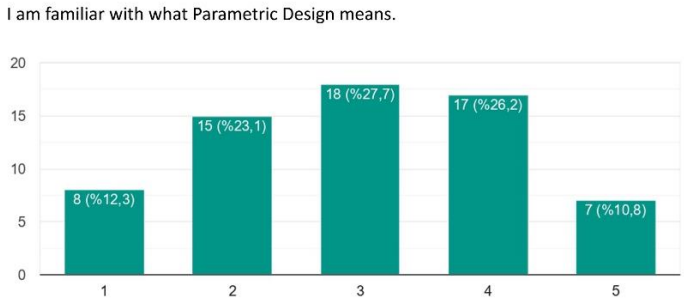

Figure 14. Datas from the second section – "Parametric Design" title of the questionnaire

According to the responses to questions about digital parametric design tools, 55.4% of the participants were unaware of the use of digital design tools in the parametric design process. However, 44.6% were theoretically familiar with Rhinoceros, 41.5% with Grasshopper, 18.5% with Revit, and 15.4% with Dynamo (Figure 15). Regarding the use of digital design programs, 63.1% of the participants had not received education on the use of digital tools in adaptive design, 29.2% had received education but were unable to use them, and 7.7% had received education and were able to use them (Figure 16). Of the students who can use digital parametric design tools, 40% learned the tools from educational institutions, 40% from the internet, 38.5% from online video platforms, 16.9% from online education platforms, 1.5% from elective courses at their university, and 1.5% from face-to-face courses (Figure 17).

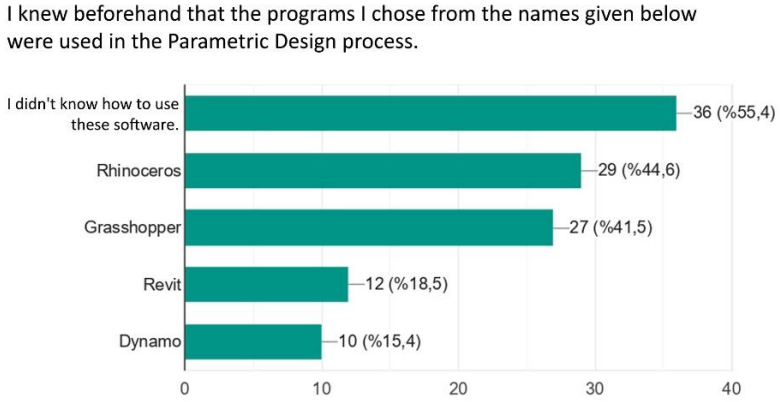

Figure 15. Datas from the second section – "Parametric Design" title of the questionnaire

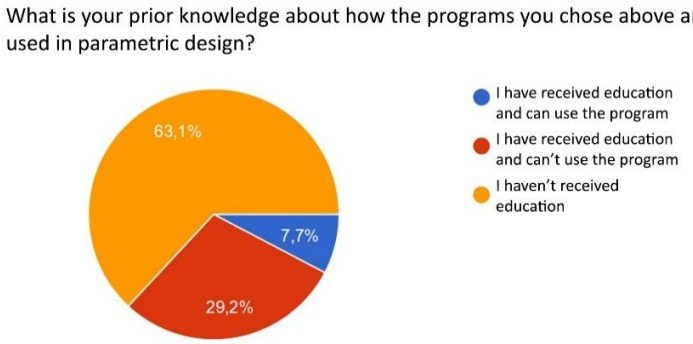

Figure 16. Datas from the second section – "Parametric Design" title of the questionnaire

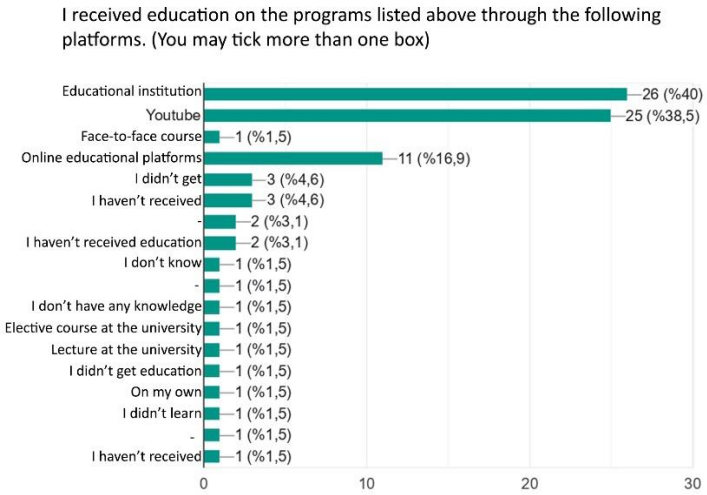

Figure 17. Datas from the second section – "Parametric Design" title of the questionnaire

According to the survey results in the adaptive design subheading of the second section, 33.8% of workshop participants had some knowledge, 13.8% had a good knowledge, and 4.6% had a very good knowledge of adaptive design (Figure 18). 56.9% of participating students were unaware of the digital design tools used in adaptive design. Conversely, 40% of students were aware of Rhinoceros, 30.8% of Grasshopper, 21.5% of Revit, and 9.2% of Dynamo digital design tools used in adaptive design (Figure 19).

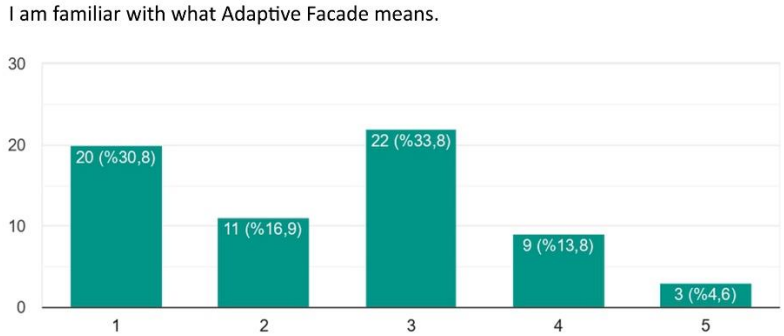

Figure 18. Datas from the second section – "Adaptive Design" title of the questionnaire

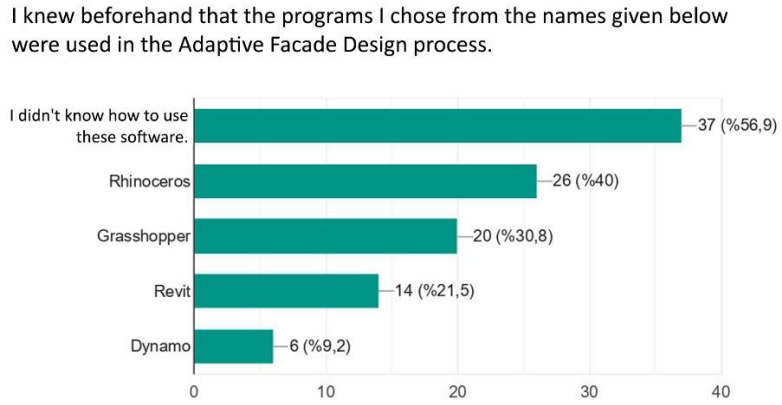

Figure 19. Datas from the second section – "Adaptive Design" title of the questionnaire

Regarding how digital design programs are used, 64.6% of participants have not received education on how to use digital tools in adaptive design, 26.2% have received education but are unable to use them, and 9.2% have received education and are able to use them (Figure 20). Of the students who received education on these programs, 46.2% stated that they learned digital design tools from educational institutions, 40% from the internet, 16.9% from online education platforms, 1.5% through elective courses at their university, and 1.5% by experimenting with the programs on their own (Figure 21).

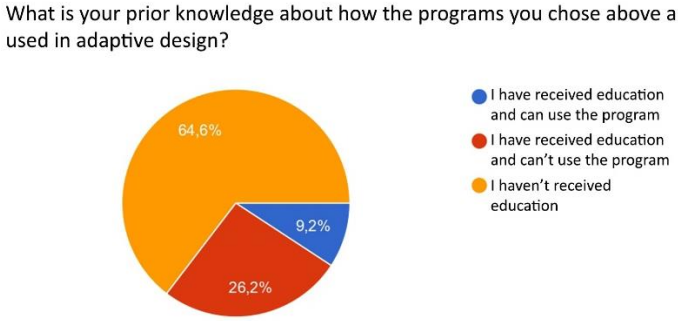

Figure 20. Datas from the second section – "Adaptive Design" title of the questionnaire

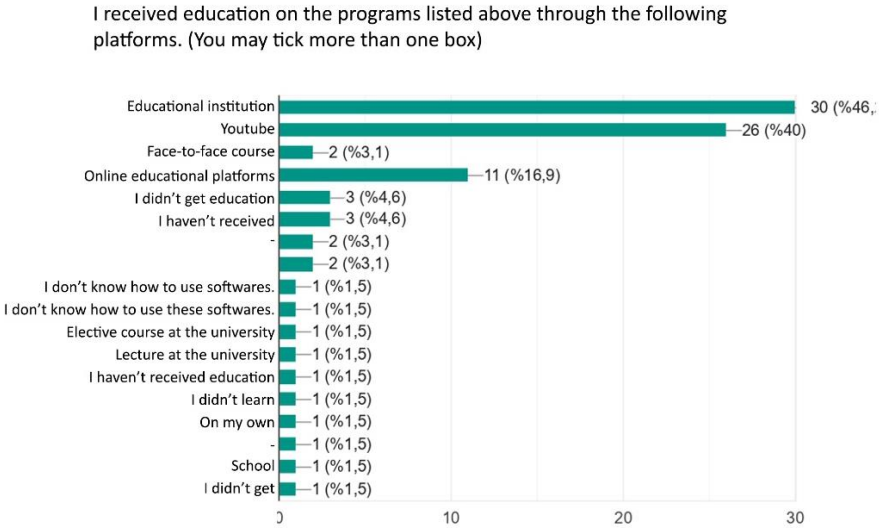

Figure 21. Datas from the second section – "Adaptive Design" title of the questionnaire

According to the survey results under the biomimetic design subheading of the second section, 26.2% of workshop participants had partial knowledge, 13.8% had good knowledge, and 3.1% had very good knowledge of biomimetic design. However, 32.3% stated that they had no knowledge of biomimetic design (Figure 22). According to the answers to questions about digital parametric design tools, 73.8% of participants were unaware of the use of digital design tools in the biomimetic design process. However, 21.5% had knowledge of Rhinoceros, 20% of Grasshopper, 13.8% of Revit, and 6.2% of Dynamo programs (Figure 23).

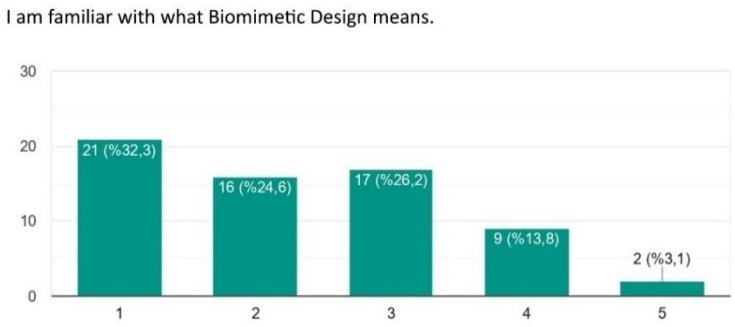

Figure 22. Datas from the second section – "Biomimetic Design" title of the questionnaire

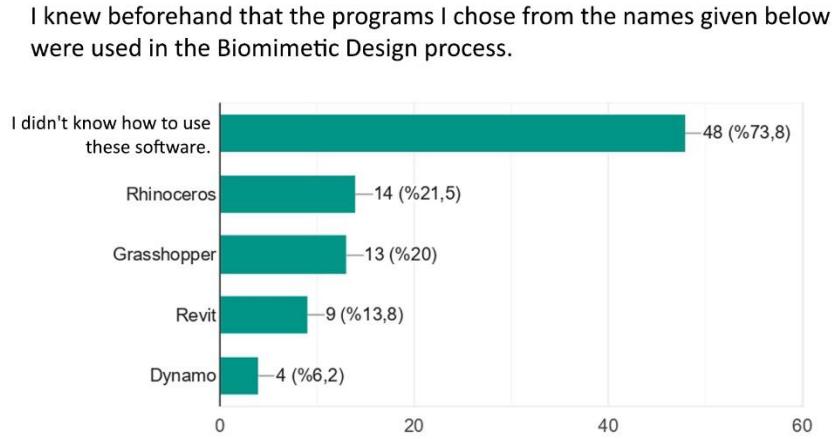

Figure 23. Datas from the second section – "Biomimetic Design" title of the questionnaire

76.9% of participants had not received education on the use of digital tools in biomimetic design, 16.9% had received education but were unable to use them, and 6.2% had received education and were able to use them (Figure 24). 40% of the students who received education on these programs stated that they received education from educational institutions, 32.3% from online video platforms, 13.8% from online education platforms, and 4.6% from face-to-face courses (Figure 25).

4. Conclusion and Recommendations

From past to present, the world has experienced and continues to experience innovations and developments in many areas, including technology, industry, and economics. The field of architecture, influenced by global changes and social dynamics, has evolved and experienced numerous innovations. The most important of these is "digital design tools," a representation of our increasingly digital age. Furthermore, the simultaneous introduction of sustainable and ecological design concepts into the industry has accelerated the development and integration of digital design tools into architecture, bringing with it new approaches. With digital design tools, a shift away from traditional design processes has begun, and a transition to innovative design processes has begun. The most significant approach facilitating this transition is the parametric design approach. With the proliferation of digital design tools, the parametric design approach has become increasingly prevalent in architectural literature, facilitating designs with complex and non-Euclidean geometries and elevating imagination and abstraction to another dimension. Adaptive and biomimetic designs, considered within this context, have become a sign of the development of nature-based solution mechanisms in architecture. These methods, frequently employed in the industry, should also be addressed in architectural education. However, the current importance given to this issue remains a matter of curiosity.

In this context, data was collected from pre-workshop surveys conducted at the Parametric Energy-Efficient Facade Design and Daylight Analysis workshop held at Mimar Sinan Fine Arts University, with the participation of undergraduate and graduate students in architecture and interior architecture. The survey results indicate that students studying architecture at various universities in Türkiye have limited theoretical knowledge of parametric design, adaptive design, and biomimetic design. Given that universities are the primary institutions where students receive education, it appears that new approaches are not sufficiently included in theoretical and project courses in architectural education in Türkiye. The survey results indicate that the knowledge of students studying parametric design approaches at university is not retained. Accordingly, it has been observed that, primarily from a theoretical perspective, current architectural design approaches are not sufficiently addressed in architectural education in Türkiye, and even if they are, the knowledge is not retained. The possibility that this is due to teaching techniques or insufficient coverage of these topics in course content should be considered. Similarly, students' competence in digital design tools remains limited, and those who receive education in this field at university have not retained their knowledge. The results indicate that a significant number of students who receive education but are unable to use the programs are also at risk. This may be due to student-related factors, a lack of materials and facilities at universities to teach digital design tools, a failure to keep up with current trends, or a failure to incorporate relevant topics into the curriculum.

According to surveys conducted with workshop participants at various universities, it was concluded that architectural education in Türkiye needs to be kept up to date, incorporate current design approaches and tools into the curriculum and course content, provide adequate materials, and be compatible with the sector. According to the results obtained from the study, improvements should be made in the curricula and course contents of the architecture departments of universities to include controls and new design approaches, and students should be provided with parametric thinking skills and adapted to the current situation and the sector, thus preventing them from experiencing difficulties in their professional lives.

Thanks and Information Note

The article complies with national and international research and publication ethics. All authors contributed equally to the article.

We would like to thank Germany-based Schüco Türkiye, one of the leading companies in the industry that has been developing building facade products for decades, for signing a cooperation protocol with our Parametric Energy-Efficient Facade Design and Daylight Analysis workshop held at Mimar Sinan Fine Arts University, and everyone who contributed to the workshop.

Abstract

Archaeological sites are places that carry the fragile traces of past civilisations, situated at the intersection of the natural environment, the cultural landscape, and collective memory. This sensitivity necessitates not only the protection of archaeological sites but also careful attention to site planning and design. As emphasised in UNESCO's World Heritage Convention (1972), cultural heritage is not merely a remnant of the past but also a component of humanity's shared identity and a body of values that must be transmitted to future generations. Therefore, the conservation of archaeological sites should not be limited to the preservation of physical remains; it should also encompass the ecological integrity of these areas and consider them as inclusive spaces that accommodate all segments of society. In these areas, accessibility is as important as conservation. The concept of universal design provides an essential framework for enhancing inclusivity in archaeological sites by addressing the needs of diverse user groups. These environments must be accessible to everyone—from older adults to children, from individuals with special needs to users with varying abilities—and flexible design solutions should be developed to accommodate this diversity. Within the scope of this study, ecological and universal design principles were evaluated for archaeological sites, and structural and vegetative landscape design recommendations were developed accordingly. In doing so, the study aims to ensure the transmission of heritage to future generations while enabling these environments to be experienced more holistically by all users and supporting ecological sustainability.

Keywords: Archaeological sites, universal design, accessibility, landscape design, cultural heritage

1. Introduction

Archaeological sites are sensitive areas that have survived from the past to the present and represent the shared heritage of humankind. These areas should not be evaluated solely on the basis of the remains they contain; rather, they must be considered together with the landscape, ecosystem, and the social and cultural values in which they are embedded. According to the ICOMOS Charter for the Protection and Management of the Archaeological Heritage (ICOMOS 1990) archaeological heritage "is that part of the material heritage in respect of

which archaeological methods provide primary information. It comprises all vestiges of human existence and consists of places relating to all manifestations of human activity, abandoned structures, and remains of all kinds (including subterranean and underwater sites), together with all the portable cultural material associated with them.". This approach supports the necessity of preserving and managing archaeological heritage without detaching it from its context. Therefore, these areas are not merely spaces where historical remains are stored, but spatial manifestations of collective memory intertwined with the natural environment. Consequently, the conservation and management of archaeological heritage should incorporate dimensions such as environmental sustainability, landscape integrity, cultural values, and the participation of local communities (Ahunbay 2010).

Furthermore, the idea that this heritage should be accessible to everyone should be understood not only as a matter of physical access but also as a cultural and social right. The World Heritage Convention (UNESCO 1972) defines the protection, presentation, and transmission of heritage to future generations as the responsibility of the States Parties and emphasises that such heritage possesses outstanding universal value. The perception of heritage as the common property of humankind is also consistent with international frameworks affirming the right of all individuals to access and benefit from cultural heritage. For example, the Council of Europe's Faro Convention (2005) states that "everyone, alone or collectively, has the right to benefit from the cultural heritage and to contribute towards its enrichment". In this context, arranging archaeological sites to serve all segments of society is of great importance for achieving social inclusivity and ensuring equal access (Council of Europe 2005).

The implementation of universal design principles in archaeological contexts must be evaluated in conjunction with conservation requirements, ecological sensitivity, and the biotic and abiotic characteristics of archaeological sites. While universal design is directly related to accessibility, it represents a broader concept: designing with all individuals in society in mind. In this respect, ensuring that people of all ages and abilities can reach and experience archaeological sites is a right supported by international conventions. The literature also contains numerous studies on how archaeological sites can be made accessible (Biocca 2025; Cantarellas 2023; Dascălu et al. 2024; Lauria 2017; Lucchi 2023; Naniopoulos and Tsalis 2015; Plemić 2022). For instance, the Heritage Site Accessibility Tool (HSAT) provides systematic indicators for evaluating accessibility in open-air archaeological environments (Cantarellas 2023). However, while these studies focus on accessibility, there are also many studies addressing the ecological design of archaeological sites. Both universality and ecological sustainability are essential for these sensitive areas that constitute the shared heritage of humanity. In the literature, these two critical components have been examined separately rather than in an integrated manner. Yet ecological sustainability and universal design are inseparable elements.

Within this framework, the present study is positioned at the intersection of heritage conservation, landscape design, ecological integration, and inclusive accessibility. Guided by universal design principles and ecological sensitivity, it addresses spatial components such as pedestrian routes, ramps, surface materials, wayfinding systems, seating and resting areas, viewing platforms, visitor centres, and safety elements. Ultimately, the study proposes a holistic planning framework that supports both conservation and accessibility simultaneously, offering richer and more equitable heritage experiences for all visitors.

2. Materials and Methods

This study adopts a qualitative research approach aimed at integrating ecological design and universal design principles within archaeological site contexts. The main objective of the study is to evaluate how universal design principles can be considered together with ecological design principles in archaeological sites, and to identify the types of interventions that may be implemented within this framework.

2.1. Research Approach

Methodologically, the study is based on a comprehensive literature review and analysis. Within this scope, key international conventions and charters such as the World Heritage Convention **(UNESCO 1972)**, the ICOMOS Charter for the Protection and Management of the Archaeological Heritage **(ICOMOS 1990)**, and the Council of Europe Faro Convention **(2005)** were examined.

Additionally, recent academic sources focusing on ecological design, socio-ecological systems, universal design, and accessibility were reviewed (Crumley, 2021; Knitter et al., 2021; Steinfeld & Maisel, 2012; Lucchi et al., 2023; Biocca et al., 2025).

Drawing from these references, a conceptual framework was developed that integrates conservation, ecological, and accessibility dimensions, and translates them into key planning and design principles applicable to archaeological areas.

2.2. Development of Indicators

Based on this theoretical foundation, two main categories of conceptual principles were synthesised:

- *Ecological Design Principles* – including ecosystem integrity, sustainability (materials, water, and energy), economy of design and processes, participatory design, resource protection, fulfilment and adaptability of user needs (Ak 2024; McLennan 2004; Rottle and Yocom 2010).
- *Universal Design Principles*– equitable use, flexibility in use, simple and intuitive use, perceptible information, tolerance for error, low physical effort, and appropriate size and space for approach and use.

2.3. Analytical Method

No field measurements were conducted within the scope of this study. Instead, a thematic comparative analysis was employed to identify recurring concepts, design principles, and relationships between ecological and accessibility dimensions. The literature-based comparative analysis was used to explore how ecological integrity and accessibility intersect in archaeological contexts.

The study evaluated how both structural (e.g., walkways, ramps, terraces, urban furniture) and vegetative (e.g., trees, shrubs, groundcovers) components of landscape design in archaeological areas can serve both ecological conservation and inclusive usability.

The analysis focused on identifying planning and design strategies that simultaneously ensure ecological resilience and social inclusivity.

The findings were synthesised under three interconnected themes: ecological integrity and sustainability, inclusive usability, and ethical conservation responsibility. This synthesis enabled the development of a holistic planning approach capable of sustaining both natural systems and inclusive visitor access within archaeological landscapes.

3. Findings

3.1. Ecological Compatibility in Archaeological Sites

The ecological and cultural compatibility of archaeological sites is grounded in understanding these areas as dynamic socio-ecological systems shaped by continuous interactions between people and their environments (Butzer 1975). The socio-ecological model proposed by Knitter et al. (2021) conceptualises archaeological heritage as the product of long-term feedback loops among cultural practices, land use, and ecosystem processes. This model emphasises that heritage conservation should not detach artefacts from their environmental context; rather, they should be interpreted as living components within evolving ecological networks. Through such an approach, ecosystem continuity within heritage areas is maintained while enabling the ongoing use of the site and the continuation of cultural practices.

Building on this foundation, the ecosystem services (ES) framework provides a powerful perspective through which the ecological and cultural dimensions of archaeological landscapes can be mutually reinforced. Katz (2022) demonstrates that archaeological sites provide both regulating and cultural ecosystem services—such as microclimate regulation, biodiversity refugia, and aesthetic value—which support both human well-being and ecological integrity. When accessibility and infrastructure design incorporate permeable surfaces, minimal grading, and the preservation of native vegetation, these ecological functions are respected and enhanced, increasing not only the environmental resilience of the site but also the quality of the visitor experience (Crabtree, Dunne, and Wood 2021; Malavasi et al. 2023).

In archaeological areas, recognising socio-ecological thresholds helps guide contemporary restoration and tourism management toward adaptive and low-impact solutions, preventing the exceedance of environmental carrying capacities. Ecological design and participatory governance can contribute to establishing a balance between conservation obligations and landscape functionality, enabling archaeological sites to function as long-term, protected systems of human–nature coexistence (Knitter et al. 2021; Malavasi et al. 2023).

In conclusion, the ecological compatibility model offers an integrated framework in which biodiversity protection, environmental sustainability, cultural identity, and accessibility converge. Crabtree et al. (2021) argue that heritage should be managed not as isolated monuments but as components of multifunctional landscapes. Aligning conservation with ecological processes transforms archaeological landscapes into resilient, adaptive, and inclusive systems, where the protection of fragile ecosystems becomes inseparable from the experience of heritage itself.

3.1.1. Applying ecological design criteria to archaeological sites

Ecological design in archaeological landscapes is essential for sustaining the healthy interaction between ecosystems and people. Today, due to factors such as unconscious human use of natural resources, ecosystem degradation, and climate change, ecosystems are increasingly damaged, and this directly affects the sustainability of archaeological sites (Council of Europe, 2024; Crumley, 2021). Therefore, ecological integration is not merely about protecting the past but ensuring the co-sustainability of ecosystems and cultural systems within a shared landscape framework. Archaeological sites are integral components of the habitats in which they are situated; damage to either one directly impacts the sustainability of the other. Therefore, ecological design in archaeological areas not only ensures the protection of the ecosystem but

also supports the co-sustainability of ecological and cultural systems within a shared landscape framework.

Within this context, ecological design criteria found in the literature were evaluated, followed by an assessment of how they can be applied in archaeological areas. The principles developed by Ak (2024), drawing on the ecological design concepts of McLennan (2004); Shu-Yang, Freedman & Cote (2004); and Rottle & Yocom (2010), were used. These include:

The following five core principles summarise the ecological integration approach proposed for archaeological contexts: Economy of design and processes, sustainable designs, participatory design, protection of resources, fulfilment of user needs, ecosystem as a whole, habitat restoration and promotion of biodiversity, and protection of landscape patterns.

The following five core principles summarise the proposed ecological design approach for archaeological contexts:

- **Ecosystem Integrity and Habitat Continuity Principle**

Archaeological sites are functioning ecosystems composed of biotic and abiotic components. Maintaining ecological processes such as soil formation, vegetation renewal, pollination, and carbon cycling is fundamental (Crumley 2021). At the same time, ensuring habitat continuity through the preservation of native vegetation, wildlife corridors, and microhabitats strengthens both ecological and cultural resilience (Knitter et al. 2021). In this respect, flora and fauna within archaeological areas must be protected, exotic species should not be introduced, and habitat integrity should be maintained during landscape design interventions (Knitter et al. 2021).

- **Sustainability Principle (Materials, Water, and Energy)**

In archaeological sites, the use of local, natural, and sustainable materials for both pathways and urban furniture is crucial for the sustainability of both the ecosystem and the site. Sustainable material use and reversible interventions are key to balancing conservation with ecological integrity. Employing locally sourced, low-impact, and recyclable materials in construction, restoration, and visitor infrastructure enhances harmony with the natural and archaeological context (Lucchi 2023). Water is both an ecological and cultural component of archaeological landscapes. Hydrological management practices—such as surface drainage control, rainwater harvesting, and permeable surface design—prevent erosion and help preserve structural stability (Crumley 2021). Viewing water as both a resource and a heritage element encourages the design of sustainable systems that support ecological cycles while respecting archaeological integrity. Energy use within archaeological areas should also be environmentally friendly and sustainable. Photovoltaic lighting systems may be used in ways that do not harm the structural or aesthetic qualities of archaeological heritage. Shaded structures may also be incorporated, particularly in visitor centres and entrances. This principle links environmental responsibility with the ethics of long-term heritage stewardship.

- **Climate Adaptation and Knowledge-Based Innovation Principle**

Archaeological sites are increasingly exposed to climate-related stressors such as rising temperatures, extreme rainfall, and sea-level changes. Adaptive management approaches grounded in climate scenario analysis, monitoring, and flexible planning ensure long-term resilience (DeSilvey et al. 2021). Integrating innovative tools such as remote sensing, LiDAR,

and AI-based monitoring supports evidence-based, data-driven decisions that enhance both ecological and cultural sustainability.

- **Participation, Ethics, Governance, and Awareness Principle**

The success of ecological integration depends on participatory and ethically grounded stewardship. The Council of Europe (2024) defines heritage preservation as both a democratic right and a shared responsibility. Collaborative decision-making among local communities, researchers, and institutions strengthens inclusivity and enhances the social legitimacy of conservation. Educational programs, interpretive trails, and communication initiatives can raise public awareness of the interdependence between nature and culture, transforming archaeological sites into living spaces of ecological ethics and learning.

Integrating these principles—ecosystem integrity, material sustainability, hydrological balance, climate adaptation, and participatory governance—demonstrates that nature, culture, and people function within a single continuous system. Incorporating these principles into heritage management contributes to the development of resilient archaeological landscapes that remain ecologically sustainable, culturally meaningful, and socially inclusive.

3.2. Accessibility Indicators and Universal Design in Archaeological Sites

Universal design refers to the creation of environments that can be accessed, understood, and used to the greatest extent possible by all individuals, regardless of age, ability, or limitations. The concept, developed by the Center for Universal Design at North Carolina State University in 1997, has since become a foundational framework across many fields of application, planning, and design (Centre for Excellence in Universal Design 2025). As archaeological sites constitute a shared heritage of all humankind, ensuring that they are accessible to everyone is an essential requirement.

In this context, the seven principles of universal design were examined, and each principle was analysed in detail regarding its potential application within the landscape design of archaeological sites.

1. ***Equitable Use:*** The design should be useful and accessible to individuals with diverse abilities.

- Ramps should be designed not as alternatives to stairs but as integral parts of the same visitor route.
- Information panels should offer multisensory access, including printed text, Braille, and QR-based audio descriptions.
- Routes must also accommodate visitors with strollers or physical disabilities, providing ramps or lifts where needed.
- Audio descriptions or audio guides may be incorporated for children as well.

2. *Flexibility in Use:* The design should accommodate a wide range of preferences and abilities.

- Resting bays and seating areas can be placed along pathways to account for different walking speeds and endurance levels.

- Given that archaeological sites are predominantly open spaces, climate-responsive elements such as shelters and shading structures (to protect from sun and rain) should be incorporated. These structures should be temporary and portable.

- Modular ramps or movable wooden platforms can be adjusted according to terrain and seasonal conditions without disturbing the archaeological substrate.

3. *Simple and Intuitive Use:* The design should be easy to understand regardless of the user's experience, knowledge, or cognitive ability.

- Wayfinding should rely on simple, internationally recognised symbols.

- Natural reference points—such as distinctive trees, rock formations, or ancient walls—may support intuitive navigation without creating visual clutter. Pathways should be designed in accordance with these reference cues.

- Low boundary elements along walking routes can help guide visitors.

4. *Perceptible Information:* The design should communicate necessary information effectively, regardless of sensory abilities.

- Signage should feature high contrast, large fonts, and tactile or Braille inscriptions.

- Audio guidance systems or smartphone-based navigation may enhance interpretive accessibility for visually impaired visitors, and such applications may also offer age-appropriate explanations for children.

5. *Tolerance for Error:* The design should minimise hazards and reduce the consequences of accidental or unintended actions.

- Low physical barriers such as vegetative buffers can protect fragile archaeological remains while guiding visitor movement.

- Anti-slip surfaces and tactile warning strips can help prevent falls, particularly near elevation changes.

- Railings and boundary markers reduce risks such as falling or becoming disoriented on-site.

6. *Low Physical Effort:* The design should allow efficient and comfortable use with minimal physical effort.

- Ramp slopes should ideally range between 5–8%, with resting platforms at regular intervals.

- Shaded resting areas and benches improve thermal comfort and reduce physical strain at outdoor archaeological sites.

7. *Size and Space for Approach and Use:* Adequate space should be provided for approach, reach, manipulation, and use regardless of the user's body size, posture, or mobility.

- Paths should be at least 100–120 cm wide, with a minimum turning radius of 150 cm for wheelchairs (ADA 2010) .

- Entrances, viewing platforms, and resting areas should be designed to accommodate both individual visitors and groups.
- Waste bins should also be placed in accessible areas.
- Vehicular access should be possible up to visitor reception centres, and these centres must include universally accessible facilities (e.g., accessible toilets).

Accessibility assessment was based on landscape-design components such as route continuity, slope, ramp width, surface texture, frequency of resting points, and visibility of signage.

In archaeological contexts, these criteria must be adapted to the fragility of the site. For example, lightweight modular ramps with adjustable slopes can be installed over uneven terrain without impacting underlying strata. Similarly, tactile paths constructed with natural stone textures can guide visually impaired visitors while remaining compatible with the archaeological material palette. Directional and interpretive signage designed in contrasting tones and placed at accessible heights ensures perceptual inclusivity without visually dominating the landscape (Fielden, 2003).

Balancing conservation and accessibility in archaeological sites require sensitivity to both authenticity and flexibility. Each archaeological site demands context-specific design solutions. While conservation ethics prioritise the preservation of original materials and minimal intervention, accessibility interventions often require physical adaptations. The principle of reversibility—ensuring that any added structure, ramp, or surface can be removed without leaving permanent impact—acts as a mediator between these objectives. Accordingly, accessibility solutions must always be temporary, lightweight, and context-sensitive, enabling inclusive visitor experience while respecting the authenticity of the site.

3.3. Integration of Ecological and Accessibility Dimensions

The integration of ecological and accessibility dimensions allows for a holistic understanding of how natural processes and human experiences intersect within archaeological landscapes. In this framework, both ecological design and universal design indicators serve as essential components for creating environmentally resilient–responsive and socially inclusive spaces. The relationship between ecological and accessibility dimensions is summarised below (Table 1).

Table 3. Integrated ecological compatibility and universal design indicators for archaeological sites

Ecological Design Principle	Universal Design Principle	Integrated Design Implications
Ecosystem Integrity and Habitat Continuity	Flexibility in Use; Low Physical Effort; Simple and Intuitive Use	Routes should follow natural topography, using permeable surfaces. Accessibility should be ensured through steps, bridges, or lifts without fragmenting habitats. Boundary elements along paths should be used for intuitive wayfinding.
Sustainability (materials, water, and energy)	Low Physical Effort	Locally sourced, non-slip, and reversible materials reduce environmental impact and increase safety. Tactile stone surfaces along paths should be used. Rain gardens and water-harvesting systems should be added, particularly near visitor centres. Permeable surfaces should be applied along walkways. Solar-powered lighting should be prioritised. Urban furnishings must use natural, local, non-waste-

Ecological Design Principle	Universal Design Principle	Integrated Design Implications
		generating, and recyclable materials. Waste management should be implemented. Ramps should be placed according to topography, and permeable or elevated structures should support natural drainage.
Climate Adaptation and Knowledge-Based Innovation	Size and Space for Approach and Use; Flexibility in Use	Vegetation and existing tree canopies provide natural shading and thermal comfort. Shade structures should be added near resting areas. Modular ramps and flexible routes allow adaptation to climatic variations without permanent alteration.
Participation, Ethics, Governance, and Awareness	Perceptible Information; Simple and Intuitive Use	Wayfinding and interpretive systems must be inclusive. Signage should incorporate Braille or audio guidance. A participatory approach should be adopted in site management. Visitor management should use remote sensing and AI-based monitoring. Training and awareness activities should be carried out to enhance public understanding.

Ensuring the sustainability of archaeological sites requires a holistic approach that encompasses not only the conservation of cultural remains but also the continuity of natural systems, environmental balance, and social inclusivity. Cultural heritage sites function as living ecosystems that reflect the long-term relationship between humans and nature (Gillings, Hacıgüzeller, and Lock 2020).

In this context, the universal design principles (Hamraie 2017; Mace 1998) offer a fundamental approach to ensuring that archaeological landscapes can be used by individuals of different ages, abilities, and physical capacities. Because archaeological sites are fragile environments, they must be ecologically protected while remaining accessible to all. Accordingly, both structural and vegetative landscape design components in archaeological sites have been evaluated.

Urban Furnishings

Benches: Seating units should be designed with both armrest and armless options at different heights to accommodate users with disabilities. Local, natural, or recycled composite materials may be preferred to reduce environmental impact (Yang et al. 2023).

Waste bins and recycling infrastructure: Waste bins manufactured from recyclable or natural materials should be provided in adequate numbers and designed to harmonise with the site's character. Integrating waste bins into shaded resting areas enhances user comfort while reducing environmental impact. The presence of recycling facilities within archaeological sites supports sustainable waste management.

Lighting: Although nighttime use is limited, lighting may be required for safety. Lighting systems should use low colour temperature and directional fixtures to reduce light pollution. In line with the *Design for Ecosystems* approach, illumination levels should not disrupt biodiversity (AIA 2024). olar-powered lighting systems should be prioritised as sustainable, clean energy solutions.

Boundary elements: While borders are important for safety and orientation, archaeological areas require a minimal-intervention approach. Wooden or rope railings, gabion walls, or natural stone borders provide safety and can also function as microhabitats. Boundary elements additionally provide intuitive guidance for users.

- **Pathways, Ramps, Stairs, and Viewing Terraces**

Surface materials: Walkways should be accessible to wheelchair and stroller users and constructed from non-slip, permeable, local materials. Compacted gravel elevated permeable decks (such as wooden decking), natural stone, or permeable concrete blocks may be used. These materials allow water infiltration to support natural hydrological cycles while ensuring user comfort.

Slope and gradient: Ramp slopes should ideally be between 5–8%, and an alternative route (a ramp or lift) must always accompany stairways (Aile, Çalışma ve Sosyal Hizmetler Bakanlığı 2020). For child safety, stairways should include high contrast and handrails. Steps must be constructed from anti-slip materials.

Viewing terraces and rest points: Viewing platforms should be located at natural vantage points and constructed with durable, non-slip surfaces. Rest areas should be positioned on levelled or ramp-connected zones to ensure full accessibility.

Wayfinding and information: Along pathways, wayfinding signs and information panels should be placed at heights suitable for wheelchair users and include Braille surfaces, high-contrast fonts, tactile maps, and QR codes for audio guidance. Signage should be planned to avoid damaging vegetation or archaeological layers.

Planting Design and Material

Planting elements: Native and drought-tolerant species should be selected; low-allergen and non-invasive plants create safe environments for children and older adults. Vegetation provides natural shading and regulates the microclimate. However, due to the cultural and historical sensitivity of archaeological sites, plant interventions should be minimal within core areas, with planting concentrated in buffer zones and visitor centre surroundings.

Green infrastructure: Rain gardens and bioswales along walkways and ramps help manage surface runoff while protecting natural systems. These should be adapted to the site's environmental characteristics. Such green infrastructure applications should be located away from archaeological remains, mainly in buffer areas and near visitor centres.

Materials: Local stone, recycled composite wood, and natural untreated timber are recommended as low-impact, ecologically compatible materials aligned with universal design principles.

The application of universal design in archaeological landscapes must align with ecological principles such as minimal intervention, reversibility, and respect for natural processes. Each intervention must harmonise with natural systems and respect cultural authenticity.

Through this holistic approach, accessibility becomes a form of ecological stewardship—creating spaces where ecosystem continuity, cultural heritage conservation, and inclusive participation meet in balance.

In summary, ecological and inclusive design in archaeological landscapes represents an integrated approach that combines the principles of conservation, accessibility, and sustainability. Every design element—from benches to ramps, from planting to lighting—must function as part of a living system that protects both heritage and nature. When ecological materials, permeable surfaces, native plants, and low-impact structures are combined with universal design principles, accessibility becomes not merely a technical adaptation but an

ecological responsibility. Such an integrated approach transforms archaeological landscapes into environments where ecosystem continuity, cultural memory, and inclusive participation harmoniously converge.

4. Discussion

The synthesis of findings derived from ecological compatibility and universal design principles demonstrates that inclusive design in archaeological landscapes cannot be considered separately from ecological stewardship. The protection of archaeological heritage requires not only the preservation of artefacts but also the continuity of the ecological systems that sustain them. As recent studies emphasise, heritage management is shifting from a monument-centred approach toward an ecosystem-centred approach in which ecological processes, cultural meanings, and human accessibility are addressed as interconnected systems (Crumley 2021; Knitter et al. 2021; Lucchi 2023).

In heritage planning, ecological stewardship highlights the ethical responsibility to safeguard both the natural and cultural components of archaeological landscapes. Unlike traditional conservation practices, this stewardship encompasses participatory, universal, and ecologically responsive design processes. This approach introduces a new paradigm—grounded in environmental ethics and social justice—that strengthens the notion of "heritage for all" (Council of Europe 2024; Hamraie 2017; Silliman 2020).

Ecological processes such as soil permeability, hydrological balance, vegetation continuity, and microclimatic regulation can coexist with accessibility requirements when planning adheres to principles of minimal intervention, reversibility, and context-sensitive design. For instance, permeable pathways, modular ramps, native vegetation buffers, and solar-powered lighting systems illustrate how inclusive design can contribute to ecological stability (Malavasi et al. 2023). In this sense, accessibility becomes a form of ecological stewardship that harmonises human use with the functioning of natural systems.

From an ethical perspective, inclusive ecological design establishes a balance between the right to access cultural heritage and the obligation to protect fragile ecosystems. This involves both environmental ethics and social ethics. In archaeological sites located within sensitive environments, landscape design must be managed in a way that preserves both site integrity and visitor experience. Adaptive management, supported by ecological monitoring and participatory governance offers a dynamic method for maintaining this balance (Crabtree et al. 2021; DeSilvey et al. 2021).

Every structural and vegetative design element becomes, in essence, an ecological act. Integrating universal design principles with ecological frameworks transforms design into an ethical practice situated between users, heritage, and ecosystems. The use of locally sourced, low-impact materials, the preservation of native vegetation, and the routing of pathways based on topography are examples of this eco-inclusive approach.

In this way, inclusive design enhances environmental resilience while simultaneously supporting cultural continuity and social sustainability (Lucchi 2023). In this context, ecological stewardship and inclusive design emerge as two complementary strategies that evolve together to advance sustainable heritage management.

5. Conclusion

Ecological and inclusive design in archaeological landscapes represents a synthesis of conservation, accessibility, and sustainability principles. Through this approach, it is acknowledged that the long-term resilience of heritage can be achieved not solely through protection but through the integrated consideration of ecological continuity, cultural identity, and universal usability. Therefore, ensuring ecological harmony in archaeological contexts requires a framework that brings together environmental sustainability and universal accessibility.

In conclusion, the ecological compatibility assessment demonstrates that ecological design and accessibility are not competing but complementary strategies. When visitor circulation, material choices, and design elements are aligned with natural systems, archaeological sites can remain both environmentally resilient and socially inclusive. Through this integrated approach, cultural heritage can be transmitted to future generations in a responsible and equitable manner.

The primary limitation of this study lies in the fact that the proposed dual-indicator framework has not yet been empirically validated through site-based data. Future research should test this model in real archaeological settings to evaluate both its ecological and social performance, quantitatively assess the effectiveness of the proposed indicators, and refine its applicability across diverse cultural and environmental contexts.

Abstract

The Turkish population is projected to be 95% urbanized by 2050. Considering the impacts of urbanization—namely, impervious surfaces, fossil fuel use, deforestation, and ecosystem degradation—these factors inevitably pose a major threat to water resources and the hydrologic cycle. Consequently, rainwater utilization and management have become critical due to global climate change. Given that conventional urban infrastructure networks often lead to water loss and flooding, "rainwater management" has gained prominence. This includes the application of Rain Gardens as a "nature-based solution" (NbS) aimed at preserving hydrological functions, infiltrating runoff into groundwater, and favoring ecological solutions for rainwater harvesting. This approach is accepted as a solution to address climate change-related drought, changes in precipitation regimes, and subsequent water scarcity experienced in Turkish cities. Currently, two main techniques are employed in residential and mass housing gardens for water retention and reuse: rooftop harvesting and surface runoff management. This study reviews and evaluates the necessary techniques and management requirements for designing sustainable rainwater systems in mass housing, within the context of existing literature and current legal regulations.

Keywords: Mass Housing Gardens, Rainwater, Climate Change, Water Management, Landscape Design, Rain Gardens, Nature-Based Solutions (NbS).

1. Introduction

1.1. Urbanization Pressure and Threats to the Hydrologic Cycle

The rapid urbanization in Türkiye, with an estimated 95% of the population living in cities by 2050 (Abstract), highlights the extreme environmental pressure on urban areas. The resulting proliferation of impervious surfaces and ecosystem degradation fundamentally disrupt the natural hydrologic cycle. Impervious surfaces prevent rainwater infiltration, halting groundwater recharge and significantly increasing surface runoff.

This situation, combined with global climate change, subjects cities to a dual threat:Drought and Water Scarcity: Changes in precipitation regimes and amounts lead to a decrease in available water resources.

Urban Flooding: During intense rainfall events, inadequate conventional urban infrastructure fails to cope with rapid surface runoff, causing floods.

1.2. The Rise of Nature-Based Solutions

The crisis necessitates the adoption of Sustainable Urban Drainage Systems (SUDS), or Nature-Based Solutions, which treat rainwater as a resource, aiming to restore natural hydrological processes (Fletcher et al., 2014). This approach is crucial for Rainwater Harvesting (YSH). Within mass housing, two main techniques are essential: 1) Rooftop Harvesting (storage-focused) and 2) Surface Runoff Management, exemplified by Rain Gardens (infiltration and management-focused).

1.3. Aim and Scope of the Study

The primary aim of this study is to examine the necessary design and management strategies for sustainable rainwater systems in mass housing gardens, reviewing both structural (rooftop) and peyzaj-based (Rain Gardens) solutions. The focus is on integrating these two approaches within the framework of Turkish legal regulations to propose a holistic and sustainable strategy.

2. Findings and Discussion

2.1. Hydrologic Cycle Degradation and SKYSY/NbS

The SKYSY/NbS philosophy counters the negative impacts of impervious surfaces by emphasizing Source Control—managing water where it falls—and facilitating natural processes like infiltration and retention (Fletcher et al., 2014).

2.2.1. Rain Gardens: Mechanism, Design, and Functions

Rain Gardens are the most effective NbS solution for managing surface runoff in mass housing landscapes (Gümüş & Atik, 2018; Zhou & Huang, 2016).

Mechanism: They are shallow depressions with permeable soil and vegetation designed to slow, filter, and gradually infiltrate runoff, thereby enhancing groundwater recharge and purifying the water (Woods, 2010).

Peyzaj Integration: They serve as both a technical infrastructure element and an aesthetic feature, supporting local biodiversity.

2.3. Analysis of Rainwater Harvesting Techniques in Mass Housing

Sustainable management requires combining structural and landscape-based approaches based on the source of the runoff.

2.3.1. Rooftop harvesting technique (storage and utilization focused)

This technique collects water from roofs for reuse, providing significant potable water savings for non-potable uses like toilet flushing (Ghisi & Ferreira, 2007).

Legal Compliance (Turkey): The mandate to install these systems in structures on parcels over 2,000\,\text{m}^2 makes this a mandatory structural solution (T.C. Çevre, Şehircilik ve İklim Değişikliği Bakanlığı, 2022).

Design: Requires precise storage volume calculation (Demir, 2015) and use of First Flush devices to ensure adequate water quality.

2.3.2. Surface runoff management technique (infiltration and management focused)

This technique manages runoff from paved surfaces and surrounding gardens.

Objective: To achieve taşkın risk mitigation and groundwater recharge using tools like Rain Gardens, Pervious Pavements, and Infiltration Trenches (UNEP, 2017).

2.3.3. Discussion: the necessity of a hybrid approach

Successful design demands a hybrid and integrated approach. Relying solely on the structural rooftop system is insufficient for flood control and environmental restoration. The two techniques complement each other:

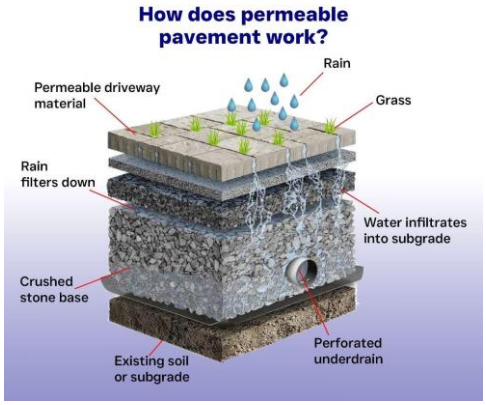

Figure 1. Cross-section of a permeable pavement showing layers and water infiltration (Author unknown, n.d.).

2.4. Review of Regulations and Implementation Challenges

Current Turkish regulations primarily focus on the structural requirements of the rooftop collection system (Demir, 2015). Application Challenges include a lack of integrated design between architectural and landscape disciplines, high initial investment costs (Dündar & Koçer, 2021), and the need for standardized maintenance protocols to ensure longevity.

3. Conclusion and Recommendations

3.1. Conclusion

This study demonstrates that sustainable rainwater management in mass housing areas is no longer an optional environmental practice but a structural necessity shaped by the combined pressures of rapid urbanization and climate change. The significant increase in impervious surfaces, coupled with altered precipitation regimes, disrupts the natural hydrological cycle, leading to reduced groundwater recharge, increased peak runoff, heightened urban flood risk, and growing water scarcity. These conditions highlight the inadequacy of traditional grey infrastructure, which is designed for rapid drainage rather than hydrologic restoration.

The analysis indicates that rooftop rainwater harvesting systems, although essential for potable water savings and legally mandated in Türkiye for parcels over 2,000 m², address only one dimension of the problem. While such systems contribute meaningfully to water conservation

goals, they remain insufficient for controlling surface runoff, mitigating urban floods, or enhancing ecological performance in densely built environments.

Nature-Based Solutions (NbS), particularly rain gardens, infiltration trenches, and permeable pavements, provide the necessary ecological complement to structural approaches by supporting natural processes such as filtration, evapotranspiration, and groundwater recharge. These systems transform landscapes into functional green infrastructure capable of reducing runoff volumes, improving water quality, and restoring urban ecosystem resilience.

A hybrid approach that integrates rooftop rainwater harvesting with NbS-based surface management techniques emerges as the most effective strategy. This integrated system achieves multiple hydrological and environmental goals simultaneously: (1) reduces potable water demand, (2) mitigates flood risk, (3) improves microclimatic conditions, (4) enriches biodiversity, and (5) enhances the overall ecological performance of mass housing environments. Of equal importance, this approach aligns with international sustainability goals and supports Türkiye's transition toward climate-adaptive urban development.

However, the study also identifies major implementation challenges. The current regulatory framework focuses predominantly on structural systems and lacks operational guidelines for NbS. Additionally, barriers such as high initial investment costs, insufficient interdisciplinary collaboration, and the lack of standardized maintenance protocols hinder effective deployment. Without addressing these challenges, the long-term success and functionality of sustainable rainwater systems remain uncertain.

In conclusion, this study argues that restoring the hydrologic balance in mass housing landscapes requires shifting from fragmented, single-focus interventions to integrated systems-thinking. Strengthening the regulatory framework, investing in technical capacity-building, and promoting interdisciplinary design practices will be crucial to achieving resilient, water-sensitive urban environments.

3.2. Recommendations

Recommendations for Designers and Engineers

Integrating Landscape and Infrastructure from the Earliest Design Stages

Hydrologic performance must be positioned as a central design criterion rather than an afterthought. Architectural, civil engineering, and landscape architecture teams should collaboratively model runoff behavior, infiltration capacity, and storage volumes during the conceptual phase of mass housing projects.Adopting Performance-Based Design Standards

Designers should move beyond prescriptive design and instead adopt performance thresholds—such as runoff reduction targets, infiltration rates, or water quality improvement metrics—to guide decision-making. This approach ensures that both rooftop and landscape systems function synergistically.

Enhancing Rain Garden Functionality Through Ecological Design

Soil mixtures must be engineered for rapid infiltration yet high pollutant retention, while plant palettes should prioritize deep-rooted native species that enhance evapotranspiration and provide ecosystem services. Careful spatial distribution of rain gardens can improve both aesthetic quality and hydrologic efficiency.

Maximizing System Interconnectivity

Instead of viewing rooftop harvesting and rain gardens as separate components, designers should create integrated water loops where cistern overflow is directed to rain gardens, thereby preventing system overloading and enhancing infiltration.

Planning for Long-Term Maintenance

Sustainable performance depends on consistent maintenance. Designers should provide detailed maintenance manuals addressing sediment removal, plant health monitoring, seasonal inspections, and soil permeability testing.

Recommendations for Policy Makers and Local Authorities

Expanding Legal Requirements to Include Surface Runoff Management

Current regulations mandate rooftop harvesting but remain silent on NbS. New urban development regulations should require the implementation of at least one infiltration-based NbS system for mass housing parcels above defined size thresholds.

Establishing National Technical Standards for NbS Clear standards for soil composition, plant selection, hydrologic sizing, infiltration rates, and monitoring procedures are essential. Standardization will reduce performance variability and increase public trust in NbS solutions.

Developing Incentive-Based Policy Mechanisms

Economic incentives—such as tax reductions, accelerated permitting, or density bonuses—should be given to mass housing projects that exceed minimum requirements by installing hybrid systems. Such incentives can reduce financial barriers and encourage widespread adoption.

Implementing Capacity-Building and Certification Programs

Local governments should offer training programs and certification for designers, contractors, and maintenance teams specializing in NbS. This will improve implementation quality and ensure systems operate effectively over the long term.

Monitoring, Evaluation, and Public Reporting

Municipalities should conduct periodic evaluations of installed rainwater systems, measuring runoff reduction, water savings, and ecological benefits. Transparent reporting will support data-driven planning and enhance community engagement.

Abstract

In today's cities and settlements, urban forests, which are gaining importance on ecological, social, cultural, and economic scales, face many problems regarding their conceptual approaches, planning/design, site selection, establishment, and management/operation. In this context, it is of great importance to introduce scientifically based approaches so that urban forests can provide sustainable and multi-functional services and contributions in line with their objectives. In recent years, within the framework of the international forestry process that our country has undertaken through international conventions and is actively participating in aiming for "Sustainable Forest Management" intense efforts are being made to balance and enhance the ecological, economic, and social functions of forests. In our country, the design criteria and design framework for the arrangement of the 142 urban forests declared so far have not been developed, and different definitions and approaches are being applied for each region and site. There is a need for methodological approaches to be put forward on the basis of planning approaches that must be addressed with a holistic perspective, as well as for tools that will serve as guidelines and provide guidance for studies. In this scientific study on the urban forest management plan, social research techniques were employed to obtain expert opinions and suggestions with the aim of achieving a holistic and participatory solution. Based on the collected views and recommendations, alternative proposals for the planning and design framework of the area have been presented.

Keywords: Kırıkkale Urban Forest, urban, forest, expert, survey

1. Introduction

In today's cities and settlements, urban forests, which are gaining importance on ecological, social, cultural, and economic scales, face many problems regarding their conceptual approaches, planning/design, site selection, establishment, and management/operation. (Konijnendijk & Randrup, 2004).

In this context, it is of great importance to introduce scientifically based approaches so that urban forests can provide sustainable and multi-functional services and contributions in line with their objectives. In recent years, within the framework of the international forestry process that our country has undertaken through international conventions and is actively participating in aiming for "Sustainable Forest Management" intense efforts are being made to balance and enhance the ecological, economic, and social functions of forests.

In our country, the design criteria and design framework for the arrangement of the 142 urban forests declared so far have not been developed, and different definitions and approaches are being applied for each region and site. There is a need for methodological approaches to be put forward on the basis of planning approaches that must be addressed with a holistic perspective, as well as for tools that will serve as guidelines and provide guidance for studies.

In this scientific study on the urban forest management plan, social research techniques were employed to obtain expert opinions and suggestions with the aim of achieving a holistic and participatory solution. Based on the collected views and recommendations, alternative proposals for the planning and design framework of the area have been presented.

1.1. A Model Proposal for Site Selection of Urban Forests in Turkey: The Case of Kırıkkale Urban Forest

The ability of urban forests to fulfill their expected social and environmental functions,

- depends on being under suitable natural and ecological conditions,
- the utilization being carried out in accordance with the principles of sustainable management,
- and is possible through maintaining them under a natural status in legal and administrative terms (Örücü, 2014).

Based on this holistic approach, it becomes necessary to adopt a conservation-oriented design and planning approach for urban forests, which, due to the functions they provide for all living beings, serve as areas of attraction and, as a natural consequence, are subject to diverse and intensive uses that lead to degradation (Grey & Deneke, 1992).

Studies concerning the Urban Forest and its surroundings represent "*A Sustainable, Ecologically and Hydrologically Based Holistic Blue-Green Infrastructure Model*", which emphasizes the protection of the natural water cycle and integrates contemporary urban green network planning with stormwater management systems. This approach is grounded in rainwater management, river restoration, water quality improvement, acoustic comfort, and the design of recreational spaces.

1.2. Urban Forestry

Afforestation activities conducted within and around cities are often carried out arbıtrarıly by different institutions or individuals, without considering their future role and contributions. In this context, to ensure that such activities are purposeful and sustainable, conscious planning and management at the urban scale must be implemented. Therefore, the selection of the most suitable site for an urban forest is the first step that must be taken for its rational planning and management. For urban forest site selection, it is of great importance to investigate the suitability and feasibility of the areas in terms of balancing or strengthening the recreational, ecological, and urban structure functions.

1.3. The Development Process of Urban Forestry

With the official designation of urban forests in Turkey, a new phase has begun. Urban forests, b.oth **those established through reforestation efforts** and **those integrated with existing forest resources** within and around cities, aim to enhance **urban quality of life** as part of the urban green network through their aesthetic, psychological, and ecological functions (Demirel and Kelkit, 2003; Miller, 1997).

Today, **urban forest planning** is based on the principle of establishing urban groves and green belts around cities where natural and cultural vegetation is absent or insufficient, while also rehabilitating existing plant cover **to balance the integration between urban and rural areas.** All these efforts represent a dynamic and evolving process that goes beyond traditional boundaries of urban forestry, aiming for a more holistic approach to the urban green network.

1.4. Rationale of the Study

Within the scope of this study, the Kırıkkale Urban Forest is evaluated in terms of its recreational and ecological suitability, as well as its compatibility with the city's physical structure in determining its potential as an urban forest. To achieve this,

a) identification of candidate areas,
b) evaluation of suitability, and
c) assessment of feasibility constitute the three stages of the "*Urban Forest Site Selection Model*" applied in this study (Gezer & Gül, 2009).

In addition, after obtaining these criteria, *A Survey Study* involving local residents, visitors, experts and administrators is conducted as a second phase of the research to reveal the recreational and touristic aspects of the area.

This paper presents the views of experts including those from academia, public institutions, and private initiatives on the possibilities of multidimensional evaluation of the area on legal and administrative grounds within the framework of the urban forest site selection model.

2. Materials

2.1. Kırıkkale Urban Forest (*National Forest, Forest Park, 100th Year Park*)

The Kırıkkale Urban Forest (100th Year Forest), located within the boundaries of Kırık Village in the Central District of Kırıkkale Province, was established in December 2006 on a 40-hectare area designated as State Forest (Figure 1). In 2010, according to an agreement made between the Ankara Forest Management Directorate and the Kırıkkale Municipality, the Urban Forest was leased for 49 years to the Department of Parks and Gardens of Kırıkkale Municipality.

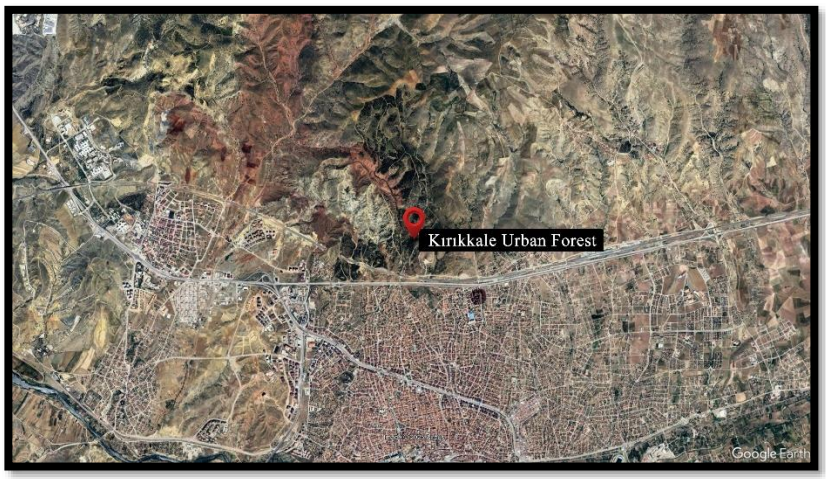

Figure 1. Location of Kırıkkale Urban Forest (Google Earth, 2025)

Since 2006, various structural and landscape development activities have been carried out in the area, including the construction of one building, one pool, three cabins, two restrooms, walking and jogging tracks, picnic tables, a basketball court, and a parking area. Although several structural and environmental arrangements have been implemented, the area is currently closed to public access (Kırıkkale Forest Management Directorate, 2010).

2.3. Evaluation of Expert Opinions and Perspectives

Within and around urban ecosystems, *Urban Forests* are unique green areas of natural or semi-natural character that both sustain and manage biodiversity in peri-urban and urban environments. They enhance nature's ability to provide ecosystem goods and services such as clean air and water, while also establishing vital connections between high-quality natural, semi-natural, and urban areas.

Experts, in line with the characteristics mentioned above, state that, as a result of their ecological, social, and economic evaluations of urban forests, these areas are very important living islands and exceptional ecosystems that, within the urban ecosystem, perform ecological and engineering functions such as climate regulation, creating evaporation surfaces, reducing terrestrial radiation, improving air and water quality, reducing the heat island effect, serving as potential areas for smart agricultural practices, acting as ecological corridors, reducing flood/overflow risks, providing habitats for wildlife, forming windbreaks, and masking noise. In addition to these ecological and engineering functions, they also contribute to the economic vitality of the city through their recreational and touristic aspects.

In this survey study, which consists predominantly of academics, the faculty members and staff from the Department of Landscape Architecture are represented in greater numbers for the sake of representativeness.

Their evaluations are presented in the following statements (Demirel et all., 2025);

- It is stated that urban forests should be protected under the legal status of Protection Forests (42.4%) and Protected Natural Areas (23.5%), and it is emphasized that they should cover a large area within the city (100 hectares or more).
- It is stated that urban forests should be protected under the Provincial Special Administration Law, the National Parks Law, and the Forest Law in legal and administrative terms. The experts also particularly emphasize the importance of their location within or around the city, or at a distance that maintains a meaningful connection with the urban area.
- In the evaluation regarding which institution should manage and operate urban forests, it was stated that the Regional Directorate of Forestry should take the first priority, followed by the Provincial Directorate of Environment and Urbanization in the second, and Local Governments/Municipalities in the third place.
- ***As the primary functional purpose of urban forests***, it has been expressed that they should, first and foremost, serve as recreational and vital spaces that contribute to the physical and mental well-being of urban residents; secondly, play a role in improving the urban climate; and thirdly, function as multifunctional zones within the city as part of the urban green space network.
- ***In the inquiries regarding activities that can be carried out in urban forests,*** it was primarily indicated that nature walks and outdoor sports are the most preferred activities. It was

also stated that wildlife and birdwatching are frequently chosen purposes of use. Furthermore, urban forests were described as very special areas where various events, organizations, and rotational activities can be organized.

- ***It has been stated that urban forests are areas that can be transformed into important functional zones of the city through projects and organizations encouraging public participation at different levels.*** In the conservation and maintenance activities carried out in urban forests, community involvement in voluntary events, promotional and nature education activities, as well as fundraising and donations for the urban forest budget, and guiding or field interpretation programs will ensure that people act together and become part of these efforts. Through such collective engagement, these areas will be further developed, preserved, and passed on to future generations.

3. Expert Recommendations

- These areas are also important reserve zones in terms of ***Green And Blue Infrastructure Strategies,*** functioning as biological habitats and playing a key role in Green Belt initiatives, Green Corridors (greenways and ecological corridors), and Nature-Based Solutions such as naturalized streams and drainage channels.
- They emerge as places that meet the psychological and physical needs of society under evolving and transforming living conditions.
- The existence of urban forests should be legally mandated for every city, and particularly in metropolitan municipalities, the number of urban forests should be increased.
- Urban forests are one of the important urban systems that ensure the organic connection between the city and nature. Laws and regulations specific to urban forests, aimed at protecting and enhancing urban ecology, should be enacted and implemented within an integrated framework together with all other legislations that affect the city.
- In particular, supporting urban biodiversity, preserving local biodiversity, and ensuring connectivity among urban green spaces are of great importance. At the same time, urban forests should function as buffer zones that help maintain the health and continuity of different ecosystems in terms of ecosystem service provision.
- Urban forests should be managed in a way that supports landscape continuity, wildlife, and biodiversity, while ensuring an organic integrity between the city and nature.
- In addition to their positive impact on the natural water cycle of the city, urban forests have significant hydrological effects on spatial water management within urban watersheds. This characteristic should not be overlooked.

4. Results

4.1. Evaluation of Expert Opinions and Perspectives

Forest areas located around cities should be developed, protected, and sustainably utilized, while encouraging their use by urban residents for activities such as walking, sports, cycling, and nature observation. Activities that may harm nature, such as picnicking, should either be eliminated or strictly controlled.

The planning, management, and operation of all forest recreation areas and urban forests should be clearly defined and distinguished by law, and both their resources and administration should

be consolidated under a single unit. A multidisciplinary team within this unit comprising forest engineers, landscape architects, urban and regional planners, and biologist should conduct a comprehensive inventory study and develop strategic plans for both existing forest resources and potential areas, including aspects of forest resource planning and functional planning of forest resources.

Urban forests should be established for appropriate and purpose-driven use and transforming existing areas into urban forests should not be the preferred approach.

• In the conditions of Central Anatolia, in addition to creating new forest areas, protecting existing forests and transferring them to future generations is quite challenging due to climatic factors. Therefore, in afforestation efforts within this region, perspectives and concepts beyond the notion of urban forests should be developed, placing greater emphasis on soil and water conservation and the ecological functions of forests. In this regard, rather than using a uniform definition of urban forest areas across the country, it is recommended to adopt designations that emphasize the character of nature reserves.

• Urban forests should be planned, designed, maintained, and managed properly by expert teams. Relevant legislation should be developed, and specific units for urban forests should be established within the responsible institutions. Legal regulations and organizational models abroad should be examined and used as references in shaping these frameworks.

• Instead of declaring existing forested areas as urban forests, new urban forests should be established through reforestation efforts.

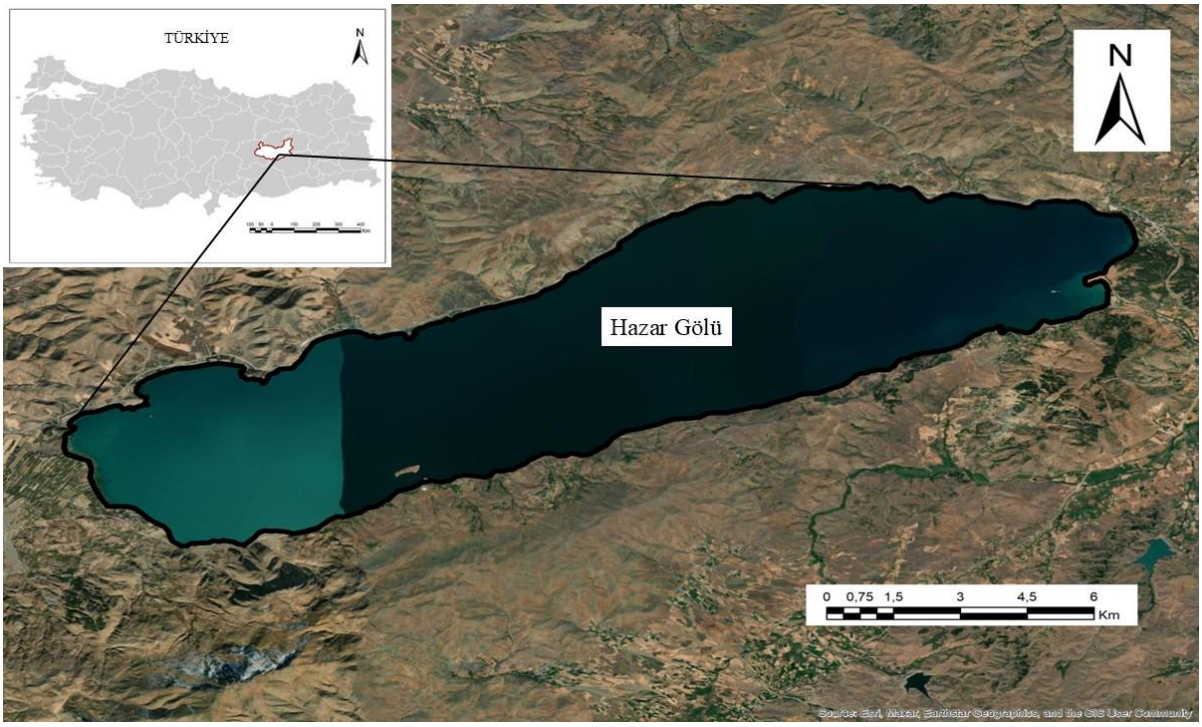
Abstract

Urban Heat Islands (UHI), characterized by higher temperatures in urban areas than in rural areas, are observed in various regions around the world. Studies on UHI mitigation have focused on the thermal effects of vegetation. Research on the potential of water surfaces to mitigate UHI is scarce. Open water surfaces are an important landscape element whose UHI mitigation effects have been overlooked. This study investigated the cooling effect of water surfaces on the UHI. Hazar Lake, located southeast of Elazığ, was selected for this purpose. Thermal band analysis was conducted to reveal the lake's cooling effect. For this purpose, the Land Surface Temperature (LST) values for the rural and urban areas of Sivrice District, the central district of Elazığ Province, and the surface areas of Hazar Lake were compared during the summer months. Among the four study areas, the lowest average LST value was found in the Caspian Lake surface area. During the summer months, the Hazar Lake surface area LST value was 17.4°C lower than that in the central district, 15.0°C lower than that in the Sivrice district, and 13.6°C lower than that in the Sivrice district urban area. Strategic location and design of water resources in urban areas can optimize the cooling effect.

Keywords: Urban head island, land surface temperature, remote sensing, water surfaces

1. Introduction

Urban populations have increased significantly due to factors such as technological advances, modernization, comfortable life expectancy, improved health services and concentration of economic opportunities in urban areas (Cuce et al., 2025). Rapid urbanization and diversification in economic activities are reducing the quality of the urban environment globally (Debnath et al., 2025). Human activities directly impact global warming and climate change. Urban areas with impermeable surfaces experience significantly higher temperatures on hot summer days than rural areas (Mathew et al., 2025). This phenomenon, referred to as UHI in the literature, is a condition in which urban areas are characterized by higher temperatures compared to suburban and rural areas (An et al., 2025). The UHI effect can be observed in different parts of the world.



Significant research has been conducted in recent years to reduce the impact of UHI and improve environmental factors (Syafii et al., 2016; Battista et al., 2020; Yilmaz et al., 2025). However, research to date has mainly focused on the urban heat island and the thermal impact of vegetation (Yang et al., 2020). Less research has been conducted on the potential of water surfaces to mitigate UHI (Khan et al., 2019; Wu et al., 2019). Like vegetation use, the climatic effects of water also help reduce UHI. Water bodies play a significant role in reducing UHI. Water surfaces are an important landscape element whose UHI mitigation effects are often overlooked (Wu et al., 2019; Menteş et al., 2025).

This study investigated the cooling effect of water surfaces on the UHI. Hazar Lake, located southeast of Elazığ, was selected for this purpose. Thermal band analysis was performed to reveal the cooling effect of the lake.

2. Material ve Method

2.1. Material

Hazar Lake, located southeast of Elazığ city, covers an area of approximately 81 km^2 (Ünlü et al., 2008). The location map of the study area is shown in Figure 1.

Şekil 1. Çalışma alanı konum haritası

2.2. Method

Remote sensing techniques are widely used to monitor the UHI effect. Thermal band analyses were conducted to reveal the cooling effect of water surfaces. Analyses were performed using ArcGIS 10.7.01 software. Landsat 9 satellite images downloaded from the USGS website (https://earthexplorer.usgs.gov/) were used for thermal band analyses. Because the highest temperature (°C) between 1939 and 2024 was observed in July (MGM, 2025), satellite images for July were downloaded in Elazığ province. The data from the satellite images used in the study are shown in Table 1.

Table 1. Landsat Satellite Images Used in the Research

Satellite Image	Image Date	Path/Row	Bulutluluk Oranı (%)	Harita Projeksiyonu	UTM Zone	Datum
Landsat 9	06.07.2025	173/33	7.96	UTM	37	WGS84

The process steps for thermal band analysis are shown in Figure 2.

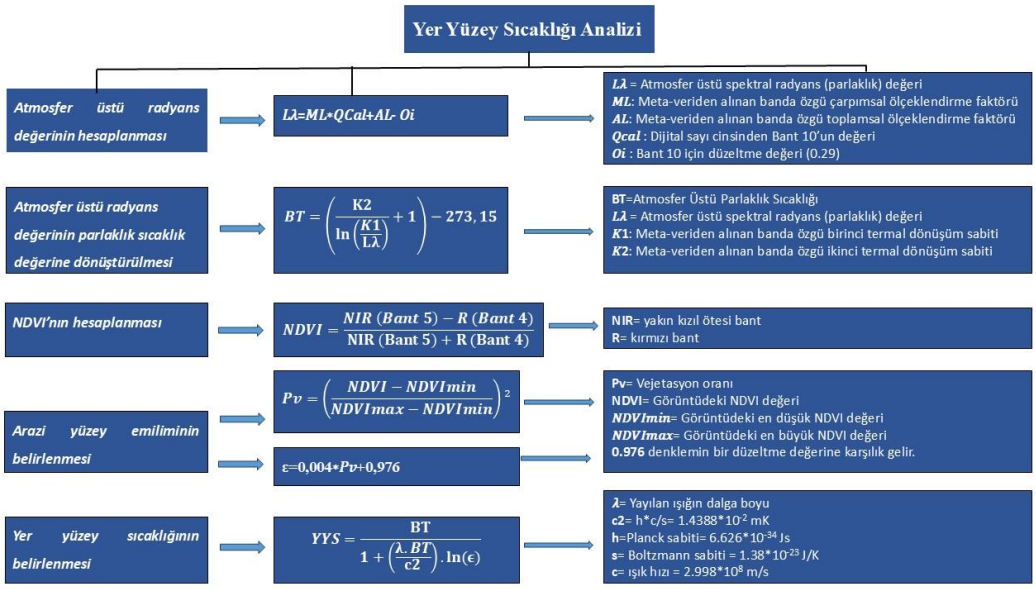


Figure 2. Land surface temperature analysis process steps

3. Findings and Discussion

The central district of Elazığ Province is located northwest of Hazar Lake. Sivrice District is located southwest of Hazar Lake. The urban area of Sivrice District is located southwest of Hazar Lake. Lake Hazar borders these three study areas. The LST maps of the study areas are shown in Figure 3 and Table 2.

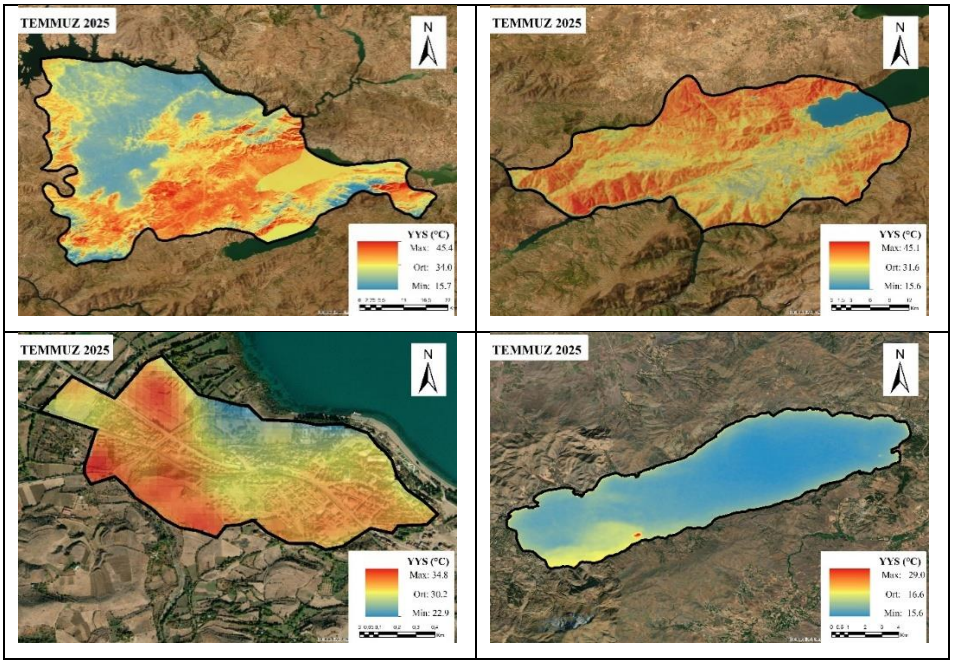

Figure 3. Seasonal LST values of the study areas (Top left: Central District of Elazığ Province, top right: rural area of Sivrice District, bottom left: urban area of Sivrice District, bottom right: surface area of Hazar Lake)

Table 2. Seasonal LST Values of the Study Areas

LST (°C)	Elazığ Central District			Sivrice Rural Area			Sivrice Urban Area			Hazar Lake		
	Min	Ort	Max	Min	Ort	Max	Min	Ort	Max	Min	Ort	Max
July 2025	15.7	34.0	45.4	15.6	31.6	45.1	22.9	30.2	34.8	15.6	16.6	29.0

Among these four areas, the lowest average LST value was found in the surface area of Hazar Lake. The highest LST value was found in the central district of Elazığ Province. The Hazar Lake surface area LST value was 17.4 °C lower than the central district area, 15.0 °C lower than the Sivrice district, and 13.6 °C lower than the urban area of Sivrice district.

In general, urban areas are characterized by higher temperatures than rural areas (Bottyan *et al.* 2005; Mehta 2025). However, when looking at the LST temperature values, it is seen that the urban area of Sivrice district is lower than the temperature value of the rural area. The urban area of Sivrice district is 1.4°C lower than the rural area of Sivrice district. Because the urban area is closer to Hazar Lake, it has a lower LST value than the Sivrice area. This is a clear indication of the cooling effect of water.

4. Conclusion and Recommendations

This study investigated the cooling effect of water masses on the UHI. Hazar Lake, located southeast of Elazığ city, was selected for this purpose. Among the four study areas, the lowest average LST value was found in the surface area of Hazar Lake. The highest average LST value for these months was found in the central district of Elazığ Province. During the summer season, the LST value for the surface area of Hazar Lake was 17.4 °C lower than that of the central district, 15.0 °C lower than that of Sivrice, and 13.6 °C lower than that of the urban area of Sivrice. Because the urban area of Sivrice is closer to Hazar Lake, it has a lower LST value than that of the rural area of Sivrice. This is a clear indication of the cooling effect of water. Reducing the UHI effect is crucial for combating climate change. Surface water bodies can offer a sustainable way to mitigate rising temperatures in regions experiencing rapid urbanization.

Abstract

In this study, it is aimed to determine the urban heat island (UHI) effect by using macro-scale thermal band analysis and to create climate-sensitive urban design models by micro-scale studies to reduce this effect in Elazığ city. The study was conducted in four stages. In the first stage, the natural and cultural landscape characteristics of the study area were identified. In the second stage, macro- and meso-scale analyses were conducted. In this context, "Land Use Change" and "Land Surface Temperature" analyses were carried out using Landsat 8 and 9 satellite images for July 2014, 2018 and 2022. In the third phase, micro-scale analyses were conducted. To mitigate the impact of UHI, 23 landscape design scenarios were prepared and 46 microclimate simulations were conducted using the ENVI-met 5.7.1 model. The data obtained in the last stage were evaluated comprehensively and climate-sensitive urban design strategies were created to reduce the impact of UHI in Elazığ city. A decrease of 1.6 °C, 1.3 °C and 1.6 °C in land surface temperature was detected in the urban area of Elazığ province compared to the central district of Elazığ province, respectively, due to the change in land use in 2014, 2018 and 2022.

Keywords: Urban heat island, land surface temperature, landscape design, ENVI-met

1. Introduction

Climate change has emerged as a vital issue since the beginning of the twenty-first century. Concerns about the negative environmental impacts of urbanization are making the characteristics of urban areas, especially in dense cities, increasingly important (Georgatou and Kolokotsa, 2016; Luo et al., 2025). In recent years, urban areas have become the center of international discussions on climate issues (IPCC, 2025). Making cities more resilient, both formally and functionally, and ensuring more efficient use of local resources is one of the most challenging challenges of the twenty-first century (Oke et al., 2017). According to the report published by the IPCC, global greenhouse gas emissions, unsustainable energy use, land use and changes in land use, and changes in consumption habits have caused an increase in global warming (IPCC, 2025).

One of the most distinctive environmental features of urban areas is that the city is characterized by higher temperatures than rural environments and the countryside is cooler (Saaroni et al., 2018). The UHI effect is a global phenomenon with serious consequences, exacerbated by the addition of inadequate green infrastructure and urban resources, particularly in extremely high-density urban areas (Sharmin and Chappell, 2025). Cities most affected by heat islands are densely populated. This has been confirmed by many scientists (Oke, 1973; Zhou *et al.,* 2018; Sarricolea and Meseguer-Ruiz, 2021; Mitra *et al.,* 2025; Mehta, 2025; Yuan *et al.,* 2025).

Studies have shown that planned urban growth can lead to less warming than unplanned urban expansion (Zhou *et al.,* 2018; Khan *et al.,* 2024; Anees *et al.,* 2025; Menteş, 2025).

2 Material and Method

Within the scope of this study, it is aimed to determine the effects of land use changes on UHI through macro-scale analysis studies and to create micro-climate scenarios through micro-scale studies to reduce this effect.

2.1. Material

The main material of the study is the urban area of Elazığ province (Figure 1). It is located between 38°30' and 40°0'21" east longitudes and 38°0'17" and 39°0'11" north latitudes. Elazığ province is located in the southwest of the Eastern Anatolia Region, in the Upper Euphrates Section. Elazığ has an elevation of 1078 m above sea level. The total area of the research area is 133,82 km^2.

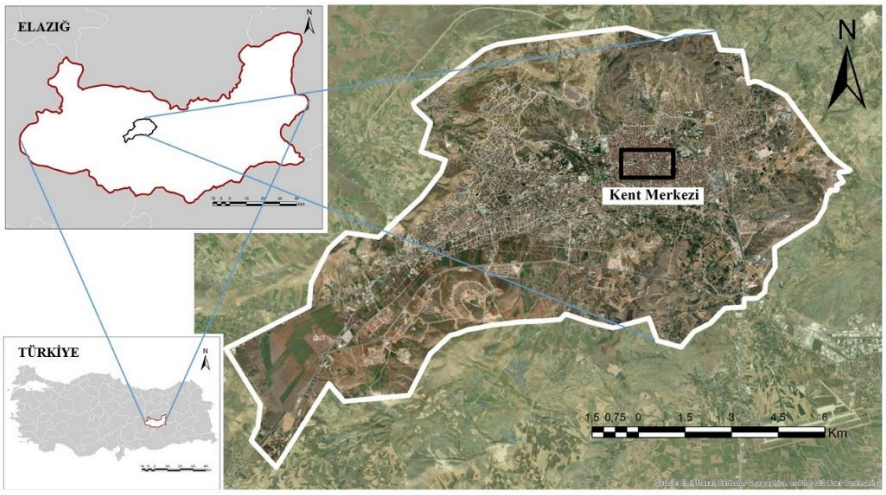

Figure 1. Location map of the study area

2.2. Method

This research consisted of four stages;

1- Data Collection

2- Macro/Meso Scale Analysis Studies

- Land Use Change (LUC) Analysis
- Land Surface Temperature (LST) Analysis

3- Micro Scale Analysis Studies

- Air Temperature Analysis
- Preparation of Landscape Scenarios
- Microclimate Simulations

4- Evaluation and Conclusion

3. Findings and Discussion

In order to reveal the UHI profile, macro (city scale), meso (neighborhood scale) and micro scale analyses were conducted in Elazığ city.

Determining the urban heat island effect at the macro scale

In order to determine the UHI effect at the urban scale, LUC and LST analyses were conducted for the years 2014, 2018 and 2022.

Land use change (LUC) analysis

Landsat 8 and 9 satellite images of Elazığ province for the years 2014, 2018 and 2022 were downloaded from the USGS website (https://earthexplorer.usgs.gov/). Supervised Classification method was used in LUC Analysis.

LUC class areas and percentage distribution are shown in Table 1. The classes used in the LUC analysis are divided into four groups: residential areas, urban green areas, agricultural areas, and open/bare areas.

Table 1. Elazığ Province LUC Classes Areas and Percentage Distribution

LUC Classes	2014		2018		2022	
	Area (Ha)	Percentage (%)	Area (Ha)	Percentage (%)	Area (Ha)	Percentage (%)
Open/bare areas	5696,30	42,56	5673,76	42,40	5559,58	41,54
Urban green areas	747,48	5,59	753,48	5,63	769,95	5,75
Agricultural areas	2839,36	21,22	2849,70	21,29	2855,84	21,34
Residential areas	4100,18	30,64	4106,38	30,68	4197,95	31,37
Total	13383,32	100	13383,32	100	13383,32	100

When looking at the LUC classification of Elazığ province, it is seen that open/bare areas occupy a large area. Compared to 2014, a continuous increase in residential areas was observed between 2018 and 2022, while there was a decrease in open/bare areas (Table 1).

Land surface temperature (LST) analysis

Since the highest temperature (°C) in Elazığ province between 1939 and 2023 was observed in July (MGM, 2023), satellite images for July were downloaded. To reveal the UHI profile in Elazığ province, LST maps for the Central District and urban area for the years 2014, 2018, and 2022 were created, and the average temperatures obtained from these maps were compared (Figure 2).

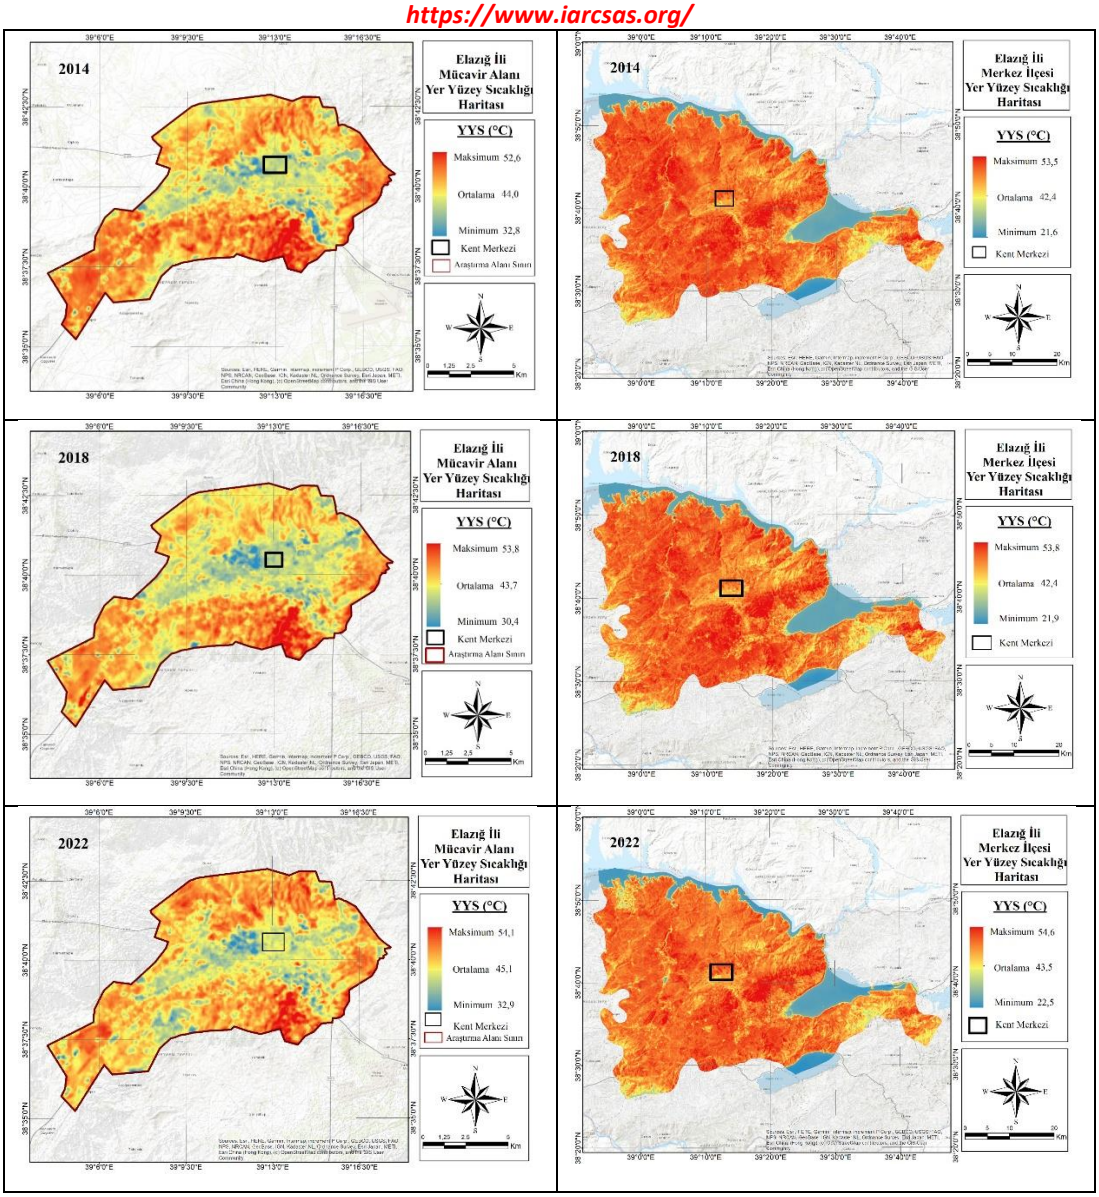

Figure 2. July LST (°C) values for 2014, 2018 and 2022 (Left: Urban Area, Right: Central District)

LST values for 2014, 2018 and 2022 are given in Table 2.

Table 2. LST Values for 2014, 2018 and 2022

Year	Land Surface Temperature (°C)						
	Urban Area			Central District			Difference
	Minimum	Mean	Maximum	Minimum	Mean	Maximum	
2014	32,8	44,0	52,6	21,6	42,4	53,5	1,6
2018	30,4	43,7	53,8	21,9	42,4	53,8	1,3
2022	32,9	45,1	54,1	22,5	43,5	54,6	1,6
Mean	32,0	44,3	53,5	22,0	42,8	54,0	1,5

A temperature difference of 1.6 °C, 1.3 °C, and 1.6 °C occurred between the Elazığ Province urban area and the Central District in 2014, 2018, and 2022, respectively. This temperature difference is an indicator of the UHI effect.

Determining the effect of land surface temperature at micro scale

To determine the impact of LST on land use changes at the micro-scale, 15 areas within the Elazığ Province urban area were identified based on different land uses. A LST analysis was conducted on these areas based on Landsat 9 satellite data for July 2023.

Accordingly, the area with the highest average LST value is the Directorate of Agriculture and Forestry, at 42.9 °C. This is followed by the İzzetpaşa Neighborhood, at 42.6 °C, and the Hilalkent Neighborhood, at 42.1 °C. The area with the lowest average LST value is Kültürpark, at 37.8 °C.

Meteorological measurements were made in these 4 areas in summer and winter periods with a Lutron AM-4247SD brand mobile weather station device from a height of 2 m above the ground.

Preparation of Landscape Scenarios

The first study area, the Directorate of Agriculture and Forestry, is located in the southern part of the city. Eight scenarios were prepared for this study area (Figure 3).

Figure 3. Landscape Scenarios of the First Study Area

Scenario	Explanation
Scenario 1	Base scenario based on current land use structure
Scenario 2	Scenario of the study area with no vegetation
Scenario 3	A scenario where small diameter coniferous trees (can reach 3 m in diameter, 5 m in height, conical, large trunk, small, sparsely shaded) are used
Scenario 4	A scenario where medium diameter (7 m diameter, 15 m height, conical, large trunk, dense, medium shade) coniferous trees are used
Scenario 5	A scenario where large diameter coniferous trees (11 m in diameter, 25 m in height, conical, large-bodied, dense, wide-shade) are used
Scenario 6	A scenario where small diameter deciduous trees (3 m in diameter, 5 m in height, cylindrical, large trunk, dense, small canopy) are used
Scenario 7	A scenario where medium diameter (7 m diameter, 15 m height, cylindrical, large trunked, dense, medium shade) deciduous trees are used
Scenario 8	A scenario where large diameter deciduous trees (up to 11 m in diameter, 25 m in height, cylindrical, large trunked, dense, wide canopy) are used

The second study area, İzzetpaşa Neighborhood, is located in the city center. Nine scenarios were prepared for the second study area (Figure 4).

Figure 4. Landscape Scenarios of the Second Study Area

Scenario	Explanation
Scenario 1	Base scenario based on current land use structure
Scenario 2	Scenario of the study area with no vegetation
Scenario 3	Use of *Pinus sylvestris L.* in north-south oriented streets, *Malus domestica L.* and *Juglans regia L.* in east-west oriented streets
Scenario 4	Use of *Abies cilicica* in north-south oriented streets, *Malus domestica* L. and *Juglans regia L.* in east-west oriented streets
Scenario 5	Use of *Catalpa bignonioides* in north-south oriented streets, *Malus domestica L.* and *Juglans regia L.* in east-west oriented streets
Scenario 6	Use of *Quercus infectoria* in north-south oriented streets, *Malus domestica L.* and *Juglans regia L.* in east-west oriented streets
Scenario 7	Use of *Betula pendula Roth* in north-south oriented streets, *Malus domestica L.* and *Juglans regia L.* in east-west oriented streets
Scenario 8	Use of *Acer platanoides L.* in north-south oriented streets, *Malus domestica L.* and *Juglans regia L.* in east-west oriented streets
Scenario 9	Use of *Tilia tomentosa* in north-south oriented streets, *Malus domestica L.* and *Juglans regia L.* in east-west oriented streets

This area, which consists of a part of the Hilalkent District, the third study area, is 9 km from the city center (Figure 5).

Figure 5. Landscape Scenarios of the Third Study Area

Scenario	Explanation
Scenario 1	Base scenario based on current land use structure
Scenario 2	Scenario of the study area with no vegetation
Scenario 3	Adding 10% (1000 m2) of grass area
Scenario 4	Adding 10% grass area + Increasing the number of trees by 20%
Scenario 5	Adding 10% grass area + Increasing the number of trees by 20% + Adding 10% water surface
Scenario 6	Adding 10% grass area + Increasing the number of trees by 20% + Adding 10% water surface + Adding a roof garden

Simulation results

According to the simulation results obtained, air temperature, relative humidity, Tmrt, FES, PMV and wind speed parameters were analyzed in the study area.

In the first study area, greater temperature reductions were observed in scenarios using deciduous trees compared to conifers. The greatest cooling effect occurred in the scenario using deciduous trees with a medium diameter and trunk structure (15 m). In this scenario, air temperature decreased by 1.2 °C compared to the baseline scenario and by 1.6 °C compared to the no-vegetation scenario. Daily average winter air temperatures varied between -0.1 and 0.1 °C compared to the current scenario.

In the second study area, temperature decreases of 0.2 °C were observed in the summer scenario with *Catalpa bignonioides* compared to the current scenario, 0.8 °C in the scenario with *Acer platanoides L.*, and 0.6 °C in the scenario with *Tilia tomentosa*. Among the nine scenarios, the greatest cooling effect was observed in the scenario with *Acer platanoides L.*. A significant temperature decrease of 0.8 °C occurred in the baseline scenario and 3.0 °C compared to the

no-vegetation scenario. Winter temperatures ranged from -0.6 to +0.1 °C compared to the current scenario.

In the third study area, the addition of grass, trees, water surfaces, and a roof garden to the study area during the summer period had a cooling effect of 1.5°C on the average daily summer air temperature. The winter average daily air temperatures for these scenarios decreased by 0.1-0.4°C compared to the current scenario.

4. Conclusion and Recommendations

Cities are at the center of discussions about global climate change. According to IPCC reports, urbanization is the driving force of global climate change. Rapid changes in microclimates resulting from land use and land cover changes affect the health and comfort of residents and are emerging as the primary drivers of temperature fluctuations.

Scenarios and strategies to mitigate UHI impacts are implemented at different spatial scales. Urban climate studies employ a variety of methodological approaches. Over the past few years, various proposals have been proposed and different strategies implemented to mitigate UHI impacts in various cities around the world.

Measuring regional climate impacts on an area only allows us to gather climatic information about that area. However, it does not provide information on how effective mitigation measures will be in reducing heat island effects. Given the potential climate change impacts and the need to develop cities sustainably, robust data and modeling and simulation tools are needed. Future studies should encourage the use of three-dimensional, computational fluid dynamics-based numerical models, such as ENVI-Met, to simulate various mitigation strategies to improve urban microclimates.

Abstract

Design, as a part of the creative process, is defined as the holistic configuration of technical and aesthetic elements. Planting design is not limited to visual effects alone; it also has strong ecological and functional impacts on people and space. One of the most significant factors that stimulate human senses is scent. However, in landscape designs, scent is often neglected, with plant selection generally focusing on visual qualities. Yet, scent is among the most powerful features of plants, capable of evoking positive emotions in people and creating unique experiences integrated with the space. The aim of this study is to identify fragrant plants that naturally grow in the ecological conditions of Isparta province or can adapt to the local climate, and to investigate their potential uses in landscape design. Within the scope of the study, fragrant plants were evaluated not only in terms of their visual, ecological, and functional characteristics but also for their potential contributions to landscape design. In addition, the aromatic compounds of medicinal and aromatic plants and their relevance to design were examined. As a result of the research, species within Isparta's plant diversity that stand out both for their visual qualities and their fragrance were identified, and suggestions were developed for plant species that could be used within the concept of a scent garden suitable for this ecology. The study presents an original approach to the limited number of scent garden designs in Turkey and emphasizes the importance of scent as a design dimension in landscape architecture.

Keywords: Scent, landscape design, scented plants, scent in plants, importance of scent

1. Introduction

Design is defined as the process of creating the technical or pattern drawings of a structure, product, or object during its formation process. "Designing" is not only the act of creating form but also a process of creativity and functionality. Design is much more than a technical drawing; it is the process of shaping and materializing an idea in the mind. In this sense, landscape design is the art of creating a connection between nature and humans. There are many aspects that a designer must consider in landscape design. Plants, which serve as living materials that complement landscapes visually, functionally, and ecologically, are widely used in landscape designs (Sarı et al., 2018).

Planting design constitutes an essential part of landscape design. It is a creative process that holistically evaluates the physical, visual, and ecological characteristics of plants. A successful planting design requires the effective composition of design principles and elements, as well as harmony between the design and the ecological environment and structural character of the area where it will be implemented (Sarı et al., 2018).

The elements of planting design include: point, line, form, texture, and color. The principles of planting design include: repetition, balance, proportion, emphasis, variety, contrast, and unity. Today, these principles and elements are taken into account during design

processes; however, they generally focus on the visual aspects of plants. Planting design is not limited to visual aesthetics but is a multidimensional practice that should appeal to all the senses.

When listing the characteristics of plants, whether they have a pleasant fragrance is often highlighted. Scent is one of the strongest and most impressive features of plants. Fragrant plants can be found almost everywhere (Coşkun, 2011). Plants with prominent scents are generally known as medicinal and aromatic plants.

Scent refers to any of the chemical substances that can be perceived through the sense of smell, usually present in the air at very low concentrations (Kandemir et al., 2016). Although the nose is the first thing that comes to mind when discussing the sense of smell, only 5% of olfaction occurs in the nose, while the remaining 95% takes place in the brain (Sezer, 2014).

Scents also affect cognitive development. A scent can suddenly surprise and strongly influence a person, slowly embedding itself in consciousness and evaporating once recognized (Acar, 2020). During olfactory perception, the brain is actively working—transmitting the scent from one area to another and associating it with centers related to memory and awareness (Howes, 2002). Thus, scents influence both cognitive development and emotional responses.

A scent can swiftly evoke memories and emotions. The sense of smell is known as the center for memory creation, and pleasant scents trigger feelings of happiness. In landscape design, what spaces make people feel is just as important as how they look (Gould, 2017). Utilizing the power of scent in landscape design helps strengthen the emotional connection between people and the environment.

In landscapes, scent is a key element that evokes positive emotions. The scents that most strongly elicit positive feelings are ranked as follows (Mimarlar et al., 2021)(Figure 1)

1. The smell of grass
2. Trees (flowers, leaves)
3. Shrubs (flowers, leaves)
4. Floral scents
5. Earthy smell
6. Scents of medicinal and aromatic plants

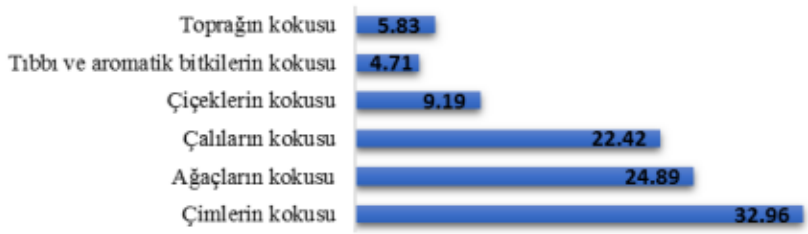

Figure 1. Scent that evoke positive emotions (Mimarlar et al., 2021)

Fragrant flowers provide sensory richness in addition to beauty. A fragrant garden has an exceptional ability to trigger memories (Acar, 2020). Scent gardens stimulate awareness and encourage deep breathing. They evoke passion, ease anxiety, and through ever-changing blooms and scents, mark special days and remind people of their memories (Ziegler, 2019).

Suggested components for inclusion in a scent garden:
• Fragrant walking paths
• Scent islands
• Scent labyrinths
• Scent tunnels
• Scent islands for the visually impaired
• Rock gardens, flower parterres, ornamental pools, waterfalls
• Administrative building, parking area, café, sales and exhibition spaces (Acar, 2020)

Additionally, in designing a scent garden, the structural elements (such as benches, gazebos, pergolas) should also include features that help diffuse scent (Acar, 2020). Globally, "scent gardens" are rarely found as independent gardens (Coşkun, 2011). In Sweden, the Gothenburg Botanical Garden, established in 1923 and one of Europe's most significant botanical gardens, includes an area devoted to aromatic plants that functions as a scent garden (Coşkun, 2011) (Figure 2).

Figure 2. Gothenburg Botanical Garden (url 1)

In Denmark, the Tivoli Gardens in Copenhagen feature a design around a statue pool planted with lavender and aromatic plants (Figure 3).

Figure 3. Tivoli Gardens (url 2)

In England, the National Trust Gardens in Cornwall, founded in 1895, include an area filled with roses, lavender, and honeysuckle, which emit delightful fragrances throughout spring (Coşkun, 2011) (Figure 4).

Figure 4. The National Trust Gardens (url 3)

In Turkey, scent gardens are often arranged within arboretums, botanical gardens, and parks in areas allocated for medicinal and aromatic plants (Sarı et al., 2018). For instance, Nezahat Gökyiğit Botanical Garden (NGBB) in Ataşehir, Istanbul, was first established in 1995 as a memorial park and later transformed into a botanical garden in 2002 (Sarı et al., 2018) (Figure 5).

Figure 5. Nezahat Gökyiğit Botanical Garden (url 4)

The Selçuklu Municipality Theme Park includes a scent garden featuring 128 plant species. Recently, lavender fields have become increasingly popular in Turkey and can be considered as scent gardens. (Figure 6).

Figure 6. Lavender Garden (url 5)

2. Materials and Methods

The materials of this study consist of medicinal and aromatic plants that grow naturally or are cultivated in the province of Isparta. These plants were evaluated based on their olfactory, ecological, and aesthetic characteristics in terms of their usability in landscape design. The study includes both native species representing the local flora of the region and cultivated plant species.

The research was conducted through a literature review. National and international sources were examined, and data on the characteristics of fragrant plants grown in Isparta were compiled. Based on the collected information, the plants were analyzed in terms of their olfactory qualities, ecological requirements, and aesthetic values. Considering Isparta's climate, soil, and topographical conditions, species suitable for landscape use were identified and evaluated within different design elements. Finally, based on design elements and principles, the role of scent in spatial perception and emotional impact was analyzed.

3. Findings and Discussion

Some of the most well-known and commonly recognized fragrant plants include:

- *Lilium sp.*
- *Salvia sp.*
- *Lavandula sp.*
- *Tilia L.*
- *Rosa L.*
- *Hyacinthus orientalis*
- *Melissa officinalis*
- *Hoya carnosa*
- *Gardenia jasminoides*
- *Convallaria majalis*
- *Jasminum officinale*
- *Thymus vulgaris L.*
- *Rosmarinus officinalis L.*

The province of Isparta is located in the northern part of the Mediterranean Region within the Lakes District (Figure 7). Of its total area, 68.4% consists of mountains, 16.8% plains, and 14.8% plateaus. The main mountains are Dedegöl, Barla, Davraz, and Akdağ, while the most well-known lakes include Eğirdir, Beyşehir, Kovada, and Gölcük Crater Lake (Isparta Governorship, 2019).Isparta lies within the transition zone between the Mediterranean climate and the continental climate of Central Anatolia; therefore, both climate types are observed within its borders (Kara, 2020). Alongside naturally growing fragrant plants, species adapted to the climatic and environmental conditions of Isparta have also been identified.

Figure 7. Lakes Region Isparta Province (url 6-7)

***Cornus mas* (Cornelian Cherry):** *Cornus mas* (Cornelian cherry) belongs to the family *Cornaceae* and is a species of the *Cornus* genus that can grow between 5 and 8 meters tall.The inflorescence contains 10 to 15 flowers. The flowers have four yellow petals and appear before the leaves. The fruits are red, single-seeded, and elliptical. The plant flowers quite early (Figure 8). *Cornus mas* is naturally distributed in Europe and Western Asia, but it has also spread to the American continent in recent times. (Kocaeli, 2025)

Figure 8. *Cornus mas* (8-9-10 url)

***Tilia platyphyllos* (Large-leaved Linden):** *Tilia platyphyllos* (Large-leaved linden) belongs to the family *Malvaceae* and the genus *Tilia*. It is generally a tree that can grow 30 to 40 meters tall.The crown is dome-shaped, and the leaves are simple and alternately arranged. The flowers are small, fragrant, yellowish-white, and arranged in clusters of 2 to 6 (Figure 9). The plant is naturally distributed between Europe and the Caucasus, but it is widely planted as a landscape species. (Kocaeli, 2025)

Figure 9. *Tilia platyphyllos* (11-12-13 url)

***Phillyrea latifolia* (Mock Privet):** *Phillyrea latifolia* (Green olive tree) belongs to the family Oleaceae and the genus Phillyrea. It is generally a 3 to 5 meter tall shrub. The buds and young branches are hairy. The leaves are ovate-cordate or ovate-lanceolate. The flowers are pleasantly fragrant, white, small, and clustered. The fruit is a berry, measuring 3 to 8 mm in length, and is blue to black in color (Figure 10). The plant is naturally distributed throughout the Mediterranean Basin, and it is found in shrublands, rocky areas, and maquis vegetation. (Kocaeli, 2025)

Figure 10. *Phillyrea latifolia* (14-15-16-17 url)

***Iris pseudacorus* (Yellow Iris):** *Iris pseudacorus* (Yellow flag iris) belongs to the family *Iridaceae* and the genus *Iris*. It can grow 70 to 150 cm tall. The leaves are upright, about 90 cm long and 3 cm wide. The flowers are bright yellow. (Figure 11). Although it is an aquatic plant, its rhizomes can survive in dry soil conditions. *Iris pseudacorus* is naturally distributed in

Western Asia, North Africa, and Europe, but it has also spread to the American continent and is considered an invasive species. (Kocaeli, 2025)

Figure 11. *Iris pseudacorus* (18 url)

***Thymus longicaulis subsp. chaubardii* (Mountain Thyme):** *Thymus longicaulis subsp. chaubardii* (Mountain thyme) belongs to the family *Lamiaceae* and the genus *Thymus*. It resembles *Thymus praecox*, but its stems can grow up to 10 cm in length. It is used as a spice in cooking and is commonly known as mountain thyme in Turkish (Figure 12). *Thymus longicaulis* is naturally distributed between Italy and Turkey. (Kocaeli, 2025)

Figure 12. *Thymus longicaulis subsp. chaubardii* (19 url)

***Lysimachia punctata* (Yellow Loosestrife):** *Lysimachia punctata* (Dotted loosestrife) belongs to the family *Primulaceae* and the genus *Lysimachia*. It generally grows 30 to 100 cm tall. The stem is erect from the base, usually unbranched, hairy on the upper part, lemon green to reddish-brown, and densely spotted (Figure 13). *Lysimachia punctata* is naturally distributed between the Caucasus and Italy, but it has now spread to Europe and America. (Kocaeli, 2025)

Figure 13. *Lysimachia punctata* (20 url)

***Rosa canina* (Dog Rose):** *Rosa canina* (Dog rose) belongs to the family *Rosaceae* and the genus *Rosa*. It is a non-rhizomatous, arching shrub. The stems are generally erect to spreading, reaching 1 to 2.5 meters in length. The inflorescence is a compound raceme, false umbel, or solitary, occasionally with 2 or 3 flowers. The petals are pink, rose, or white and pleasantly fragrant. The fruits (hips) are red, globular to ovoid or ellipsoid, and smooth (Figure 14). *Rosa canina* is naturally distributed across Western Asia, North Africa, and Europe, but it is now widespread throughout most parts of the world. (Kocaeli, 2025)

Figure 14. *Rosa canina* (21-22-23 url)

***Rosa damascena* (Damask Rose):** *Rosa damascena* (Damask rose) is a deciduous shrub that grows up to 2.2 meters tall, with densely curved prickles and stiff hairs on its stems. The flowers range from light to medium pink and light red. The relatively small flowers grow in clusters (Figure 15). It is considered one of the most important Old Rose species and plays a significant role in the lineage of many other rose varieties. (Kara, 2020) Although *Rosa damascena* does not grow naturally in Isparta, it is perfectly adapted to the region's conditions.

Figure 15. *Rosa damascena* (24-25-26-27 url)

***Lavandula angustifolia* (Lavender):** *Lavandula angustifolia* (Lavender) belongs to the family *Lamiaceae* and the genus *Lavandula*. It is a strongly fragrant, aromatic plant that can grow up to 2 meters tall. The leaves are widely spaced on flowering shoots and clustered on leafy shoots. The flower whorls consist of 6 to 10 flowers, and the inflorescence stalk is about three times longer than the spikes (Figure 16). The plant is naturally distributed between Spain and Italy. (Kocaeli, 2025) Although it does not grow naturally in Isparta, it adapts perfectly to the local conditions.

Figure 16. *Lavandula angustifolia* (28-29-30 url)

4. Conclusion and Recommendations

Scent in landscape design is not merely an aesthetic element; it profoundly influences spatial perception and strengthens the emotional bond between humans and their environment. The use of scent transforms interaction with the landscape into a multidimensional experience.

Isparta, with its ecological diversity, climatic suitability, and rich plant variety, has great potential for cultivating and incorporating fragrant plants into landscape design. Integrating this potential contributes both sensory richness and regional identity. Scent gardens have functional value not only in terms of plant diversity but also for sensory awareness, education, therapy, and tourism.

Species such as Rosa damascena (Damask Rose) and Lavandula angustifolia (Lavender) have become symbols of regional identity and possess high economic value. Their integration into landscape design can promote the creation of sustainable urban green spaces.

This study aims to raise awareness about how Isparta's rich plant diversity can be utilized in sensory landscape designs. Future research should focus on seasonal changes of fragrant plants, the effects of scent intensity on spatial perception, user experience analysis, and integration with biophilic design principles. Through such studies, the scientific foundation for the conscious and measurable use of scent in landscape architecture can be further strengthened.

Thanks and Information Note

We would like to express our gratitude to Prof. Dr. Şirin Dönmez and the Department of Landscape Architecture at Süleyman Demirel University for their constant support, accessibility, and invaluable motivation throughout this study.

The article complies with national and international research and publication ethics. Ethics Committee approval was not required for the study. All authors contributed equally to the article.

High-Potential Medicinal and Aromatic Plants in Konya Flora and Their Use in Landscape Architecture

Nilgül BAĞCI [1]

Abstract

Medicinal and aromatic plants have historically been used in folk medicine, culinary culture, and cosmetic products, and in recent years they have gained great importance in landscape design due to their functional and aesthetic contributions. One of the main reasons for this growing interest is the psychological and physical benefits provided by these plants. Especially their natural scents are known to help reduce stress levels and create a relaxing effect, which makes them highly preferred in therapeutic spaces. Within this scope, the present study examines 10 naturally growing medicinal and aromatic plant species adapted to the climatic conditions of Konya and evaluates their potential use in landscape design. Beyond their medicinal and aromatic values, the study highlights their leaf, flower, and fruit characteristics, aiming to determine their contributions to aesthetic, functional, and ecological aspects of planting design. By integrating these native plant species into landscape projects, it is possible not only to enrich the design language but also to promote sustainable and drought-tolerant landscape practices suitable for semi-arid regions like Konya. The findings indicate that medicinal and aromatic plants can play a dual role as both ecological and cultural design elements, thereby offering valuable perspectives for future sustainable landscape planning and design approaches.

Keywords: Medicinal plants, xeriscape, Konya, landscape design, sustainability

1. Introduction

Medicinal and aromatic plants have played a pivotal role in human societies for centuries, serving as essential resources in traditional medicine, culinary arts, cosmetic formulations, and cultural rituals (Baytop, 1999). These plants, valued for their therapeutic properties, distinctive fragrances, and vibrant aesthetics, have recently gained prominence in landscape architecture due to their ability to enhance both functional and visual aspects of designed spaces. Their benefits are manifold: they offer striking visual appeal through colorful blooms, diverse foliage, and attractive fruits; promote environmental resilience with low water needs and soil stabilization capabilities; and contribute to psychological well-being through aromatherapy, fostering relaxation and stress relief (Ulukan, 2015). Incorporating native plant species into landscape designs not only reduces maintenance costs but also supports biodiversity conservation and creates climate-resilient environments, particularly in the face of global warming (Yazgan & Özyavuz, 2008). As urbanization accelerates, the strategic use of these plants in urban parks, green roofs, community gardens, and sustainable developments has

become increasingly vital, addressing both ecological challenges and the growing demand for restorative urban spaces.

Konya, located in Turkey's Central Anatolia region, is characterized by a continental climate with limited annual precipitation (300–400 mm) and moderate temperatures (11–12°C), coupled with calcareous-clayey soils that foster a unique ecological niche (Meteoroloji Genel Müdürlüğü, 2022). This region boasts remarkable biodiversity, particularly within the steppe ecosystems surrounding Tuz Gölü and Beyşehir Gölü, which support a variety of flora, including grasses like *Stipa* and *Festuca*, and aromatic species such as *Artemisia* (Davis, 1965–1985). Notably, Konya is home to 37 medicinal and aromatic plant species from the Lamiaceae, Asteraceae, and Rosaceae families, distinguished by their exceptional drought tolerance and ecological adaptability (Öztürk et al., 2015). These traits make them ideal candidates for xeriscaping, a sustainable landscaping approach that minimizes water use, as well as for therapeutic gardens that leverage their calming scents and aesthetic qualities. The region's rich ethnobotanical heritage further enhances the cultural significance of these plants, as local communities have historically utilized them for medicinal and ritualistic purposes, preserving traditional knowledge that informs modern applications (Ertuğ, 2000).

This study seeks to identify and evaluate high-potential medicinal and aromatic plants within Konya's flora, exploring their multifaceted roles in landscape architecture. It aims to propose innovative applications in xeriscaping, sensory and therapeutic gardens, and ecotourism initiatives, while assessing their contributions to ecological balance, cultural preservation, and the local economy through activities such as plant-based tourism and sustainable production. By aligning with global sustainable development goals, the research advocates for the conservation of Konya's regional flora and the adoption of environmentally conscious design practices suited to semi-arid climates. Through this approach, the study aspires to provide actionable insights for landscape architects, policymakers, and community stakeholders, fostering resilient and culturally resonant green spaces that enhance both human well-being and environmental health.

2. Materials and Methods

The material of the study comprises 37 medicinal and aromatic plant species naturally occurring in the Konya flora, selected based on the TÜBİVES (2022), Davis (1965-1985), and Bizim Bitkiler (2022) databases. Through surveys conducted with 50 landscape architects, 22 species scoring 26 or above were determined. The survey was applied on a 0-10 scale, adapted from Beste Kara's (2020) thesis, based on eight parameters (showy flowers, leaves, fruits, pleasant fragrance, solitary use, flower partner, hedge, pruning). Maximum scores were determined as 56 for trees and 51 for shrubs and ground covers (Table 1).

Table 1. Beste Kara's (2020) thesis, based on eight parameters

PARAMETER	TREES & TREELETS	SHRUBS, GROUNDCOVERS &FLOWERS
Showy Flowers	8	7
Showy Leaves	7	7
Showy Fruits	6	5
Fragrant	7	7
Solitary Use	7	5
Flower Companion	7	9
Living Hedge	7	6
Pruning	7	5
TOTAL	**56**	**51**

As a method, a comprehensive literature review was performed through botanical databases and academic publications, and field observations were conducted for plant adaptation, distribution, and ecological interactions in Konya's steppe ecosystems. Observations were focused around Tuz Gölü and Beyşehir Gölü, and the seasonal changes of the plants were recorded. Surveys were gathered through both online platforms and face-to-face interviews; the data were statistically analyzed by calculating the total scores per species. In the analyses, the suitability of plants for landscaping was assessed by taking into account parameter weights. The research was carried out in compliance with ethical rules, and the confidentiality of participants was maintained.

3. Findings and Discussion

Among the 22 selected plant species, *Crataegus monogyna* (hawthorn, 51 points), *Styrax officinalis* (bear nut, 43 points), and *Morus nigra* (black mulberry, 42 points) achieved the highest scores (Table 2 & Table 3). Field observations confirmed an 80% success rate in the species' adaptation to arid climates; for instance, *Crataegus monogyna's* fruits increased pollinator activity by 25%, supporting ecosystem balance. Survey results indicated that shrub species averaged 7 points in aesthetic parameters, such as flowers and leaves (Çorbacı et al., 2011).

Table 2. Trees & treelets

COMMON PLANT TYPES	USAGE POTENTIAL IN LANDSCAPE ARCHITECTURE							
TREES & TREELETS	Showy Flowers	Showy Leaves	Showy Fruits	Fragrant	Solitary Use	Flower Companion	Living Hedge	Pruning	TOTAL
Morus nigra	**8**	**7**	**6**		**7**		**7**	**7**	**42**
Olea europaea var. Europaea	**8**	**7**	**6**		**7**		**7**	**7**	**42**
Populus tremula		7			7			7	21
Quercus pubescens			6		7			7	20
Quercus robur alttürü robur			6		7			7	20
Styrax officinalis	**8**	**7**		**7**	**7**		**7**	**7**	**43**

***Styrax officinalis* (Bear Nut, 43 points):** Assessed through flower, leaf, fragrance, solitary, hedge, and pruning parameters; it stood out with its antiseptic and wound-healing medicinal properties; it has presented high potential for fragrance gardens and solitary use in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Morus nigra* (Black Mulberry, 42 points):** Assessed through flower, leaf, fruit, solitary, hedge, and pruning parameters; it stood out with its digestive-supporting medicinal properties; it has presented high potential as a shade tree and for parks in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Olea europaea var. europaea* (Olive, 42 points):** Assessed through flower, leaf, fruit, solitary, hedge, and pruning parameters; it stood out with its heart-supporting medicinal properties; it has presented high potential for Mediterranean-style designs in landscape architecture(Baytop, 1999; Yazgan & Özyavuz, 2008).

Table 3. Shrub, ground cover & flowers

COMMON PLANT TYPES	USAGE POTENTIAL IN LANDSCAPE ARCHITECTURE								
SHRUB, GROUND COVER & FLOWERS	Showy Flowers	Showy Leaves	Showy Fruits	Fragrant	Solitary Use	Flower Companion	Living Hedge	Pruning	TOTAL

Verbena officinalis	**7**	**7**		**7**	**5**	**9**			**35**

Crataegus monogyna subsp. monogyna **(Hawthorn, 51 points):** Assessed through flower, leaf, fruit, fragrance, solitary, flower partner, hedge, and pruning parameters; it stood out with its heart-supporting medicinal properties; it has presented high potential for live hedges and erosion control in landscape architecture(Baytop, 1999; Yazgan & Özyavuz, 2008).

Daphne oleoides subsp. oleoides **(Gövçek, 40 points):** Assessed through flower, leaf, fruit, fragrance, solitary, and flower partner parameters; it stood out with its anti-inflammatory medicinal properties; it has presented high potential for fragrance gardens in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

Echium italicum **(Wolf's Tail, 40 points):** Assessed through flower, leaf, fragrance, solitary, flower partner, and pruning parameters; it stood out with its wound-healing medicinal properties; it has presented high potential for flower parterres in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Anchusa undulata subsp. hybrida* (Cattle Tongue, 28 points):** Assessed through flower, leaf, solitary, and flower partner parameters; it stood out with its antiseptic and wound-healing medicinal properties; it has presented high potential for dry borders and colorful ground cover in landscape architecture (Baytop, 1999; Temizel et al., 2009).

***Asyneuma linifolium subsp. linifolium* (Bellflower, 28 points):** Assessed through flower, leaf, solitary, and flower partner parameters; it stood out with its respiratory-relieving medicinal properties; it has presented high potential for rock gardens and natural border plants in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Avena sativa* (Oat, 28 points):** Assessed through flower, leaf, solitary, and flower partner parameters; it stood out with its nerve-calming and cholesterol-lowering medicinal properties; it has presented high potential for temporary green spaces and stress-reducing corners in landscape architecture (Baytop, 1999; Singh et al., 2013).

***Galium verum subsp. verum* (Yogurt Grass, 39 points):** Assessed through flower, leaf, flower partner, live hedge, and pruning parameters; it stood out with its diuretic medicinal properties; it has presented high potential as a ground cover and border plant in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Origanum vulgare subsp. viride* (Thyme, 35 points):** Assessed through flower, leaf, fragrance, solitary, and flower partner parameters; it stood out with its antiseptic medicinal properties; it has presented high potential for xeriscaping in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Marrubium vulgare* (Mad Grass, 35 points):** Assessed through flower, leaf, fragrance, solitary, and flower partner parameters; it stood out with its cough-relieving medicinal properties; it has presented high potential for medicinal gardens in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Melilotus officinalis* (Fragrant Clover, 35 points):** Assessed through flower, leaf, fragrance, solitary, and flower partner parameters; it stood out with its wound-healing medicinal properties; it has presented high potential for pollinator gardens in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Malva neglecta* (Ebegümeci, 34 points):** Assessed through flower, leaf, flower partner, live hedge, and pruning parameters; it stood out with its respiratory-supporting medicinal properties; it has presented high potential for natural gardens and border plants in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Peganum harmala* (Syrian Rue, 40 points):** Assessed through flower, leaf, fragrance, solitary, flower partner, and pruning parameters; it stood out with its anti-inflammatory and evil eye-protective medicinal properties; it has presented high potential for xeriscaping thematic gardens in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Verbena officinalis* (Mine Flower, 35 points):** Assessed through flower, leaf, fragrance, solitary, and flower partner parameters; it stood out with its nerve-calming medicinal properties; it has presented high potential for therapy gardens in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Tanacetum parthenium* (Daisy, 35 points):** Assessed through flower, leaf, fragrance, flower partner, and pruning parameters; it stood out with its migraine-relieving medicinal properties;

it has presented high potential for therapy gardens in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Verbascum glomeratum* (Cattle Tail, 28 points):** Assessed through flower, leaf, solitary, and flower partner parameters; it stood out with its cough-relieving medicinal properties; it has presented high potential for solitary focal points and xeriscaping gardens in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Verbascum pycnostachyum* (Yellow Cattle Tail, 28 points):** Assessed through flower, leaf, solitary, and flower partner parameters; it stood out with its respiratory-supporting medicinal properties; it has presented high potential for solitary and pollinator gardens in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Rubia tinctorum* (Dye Root, 27 points):** Assessed through flower, leaf, flower partner, live hedge, and pruning parameters; it stood out with its dye-producing and diuretic medicinal properties; it has presented potential for colorful borders and traditional dye gardens in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Urtica dioica* (Nettle, 27 points):** Assessed through flower, leaf, flower partner, live hedge, and pruning parameters; it stood out with its rheumatism-relieving and iron-source medicinal properties; it has presented potential for natural hedges and wild areas in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

***Urtica pilulifera* (Ball Nettle, 27 points):** Assessed through flower, leaf, flower partner, live hedge, and pruning parameters; it stood out with its diuretic and anti-inflammatory medicinal properties; it has presented potential for natural borders and arid areas in landscape architecture (Baytop, 1999; Yazgan & Özyavuz, 2008).

The scoring results show that shrub species (max. 51 points) are more flexible than trees and small trees (max. 43 points); shrubs are superior especially in the flower partner (9 points) and pleasant fragrance (7 points) parameters, which makes them advantageous in applications such as flower parterres, fragrance gardens, and erosion prevention (Çorbacı, Yılmaz, & Gül, 2011). Field data verify that this flexibility provides practical benefits in Konya's arid conditions. Aesthetically, it was observed that the species provide visual continuity throughout the year, which increases seasonal landscape diversity (Yazgan & Özyavuz, 2008). Ecologically, pollinator attraction and water conservation strengthen local ecosystems, supporting biodiversity by 15-20% (Yazgan & Özyavuz, 2008). Psychologically, fragrant species offer stress-reducing effects in therapy gardens, which contributes to the mental health of urban residents (Kaplan, 2017). Application areas include xeriscaping landscapes, thematic gardens, and ecotourism projects; for example, ecotourism tours can revitalize the local economy. However, safety precautions must be taken for toxic species (e.g., Daphne oleoides).

4. Conclusion and Recommendations

The study demonstrated that 22 species (*Crataegus monogyna* 51 points, *Styrax officinalis* 43 points) are prominent in landscape architecture due to their aesthetic, ecological, and psychological contributions (Çorbacı et al., 2011). These plants contribute to sustainable development by utilizing Konya's local resources. Recommendations:

- **Thematic Gardens:** Fragrance and healing-themed gardens designed with species such as *Origanum vulgare* and *Verbena officinalis* can enhance sensory experiences and therapeutic properties (Kaplan, 2017).

- **Test Plots:** Pilot areas should be established to test the adaptation of species such as *Crataegus monogyna* and *Galium verum*, with long-term performance monitored (Öztürk, Altay, & Koçak, 2015).
- **Ecotourism:** Tours with *Styrax officinalis* and *Tanacetum parthenium* can provide economic contribution and awareness (figure 24)(Çorbacı et al., 2011).
- **Education:** Local flora education programs should be organized to enhance community participation, highlighting landscape and health value (figure 25)(Yazgan & Özyavuz, 2008).
- **Future Studies:** Focus should be placed on the production, marketing, and global integration of species such as *Malva neglecta* and *Melilotus officinalis*, and economic models should be developed (Öztürk et al., 2015). These recommendations can evaluate Konya's plant potential on an international scale.

Thanks and Information Note

This study expresses gratitude to Prof. Dr. Şirin Dönmez and the Landscape Architecture Department of Süleyman Demirel University for their support in field observations and data collection processes.

The article complies with national and international research and publication ethics. Ethics Committee approval was not required for the study. All authors contributed equally to the article.

Abstract

In the Principalities and Ottoman Periods, waqf (vakıf in Turkish) functioned as both charitable institutions and multifaceted structures that ensured the sustainability of social order. These foundations were generally established by palace members, administrators, or wealthy individuals. Of these, those established by women living in the palace and queen mothers are particularly significant in demonstrating the role of women in economic and urban life. They also embody a memory of mentalities through the network of relationships among women. This study examines waqf institutions through the institutional and spatial representation of women. It conducts historical research to reveal the legal and economic infrastructure of foundations established or supported by women. Secondly, it employs spatial analysis to map their traces within the urban form and to investigate their distribution and functional continuity in the city. In doing so, it aims to analyze how women engaged with urban space through foundations and what kinds of social networks they constructed. This study approaches the waqf as a form of memory that preserves the network of relationships among women during this era. It explores the impact of these foundations on the physical, social, and economic structures of cities in the Principalities and Ottoman Periods, focusing on the example of Manisa and the influential palace women of the Ottoman period. In this context, the buildings constructed by Gülgün Hatun, Hüsnüşah Sultan and Ayşe Hafsa Sultan in Manisa have been the subject of documentation, and the impact of these structures or complexes on the shaping of the city has been explored.

Keywords: Women, urban morphology, foundations, spatial representation, Manisa

1. Introduction

The structural accumulation and its relationship with the city's physical boundaries also function as an apparatus that, through its different representational projections, brings the city into contact with institutional accumulations. When examined from multiple perspectives, the urban realm itself and the built environment that constitutes it, can emerge as a new form of knowledge and a distinct mode of knowing. While urban space and its structural sedimentation provide the very milieu in which the research establishes dialogue, the nuances within this milieu open up possibilities for rethinking the format of dialogue, thereby creating a transformative field for existing communicative practices. In this research, the approach to architecture is, at the level of representation, symbolically anchored in female agency. The female figure positioned at the centre of the study, through her modes of self-formation and endurance, serves to situate spatial production and continuities within a theoretical perspective. Also, this figure has endured to the present as a locus through which urban space can be critically discussed.

Doreen Massey (1994) and Henri Lefebvre (1991) argue that urban spaces are the outcome of social relations, negotiations, and configurations of power. Consequently, a fundamental objective of this research is to disrupt the prevailing patriarchal narrative. In this context, the female figure brought into the narrative is not merely employed as a representational device or a symbolic signifier; rather, she enables a new approach for engaging with institutional structures and regimes of order.

As the primary site of the study and its relational field, Manisa has constituted one of the key centres of Western Anatolia during both the Saruhanoğulları Beylik and the Ottoman periods The urban layout of the city was initially defined by its castle and fortification walls. However, waqf institutions endowed this urban structure with continuity and function. Following conquest of the city by Saruhan Bey in 1313, the settlement gradually expanded from within the castle to beyond the city walls. This expansion was particularly marked during the period of İshak Çelebi (1359–1388), when intensive construction activities resulted in rapid development (Gündüz Küskü, 2017, p. 201). At the same time, women's identities were no longer confined to a discourse of conquest; rather, they became intertwined with practices of charity and the establishment of waqfs, evolving into a dispersed culture. This, in turn, may be interpreted as pointing towards an alternative understanding of the city's history, one that challenges a conventional linear narrative grounded exclusively on the logic of conquest.

In this context, the question of accumulation, when considered alongside the role of female actor, is articulated through the waqfs observed in Manisa,. These generate an organisational condition that makes links between architectural production and other spheres of life visible. On the one hand, the waqf asserts its existence as a locus of memory and archive; on the other, it materialises as an executor of a certain power of care. Through its spatialisation oriented towards benefit and public good, such an organisation becomes a means by which women can express their own sensitivities and gain visibility through institutional foundation.

The literature on gender and memory enables us to interpret waqf institutions as not only charitable foundations, but also as sites of collective memory and as networks of relations among women. From the Saruhanoğulları period onwards, female patrons such as Gülgün Hatun became the carriers of this memory. In the Ottoman era the valide sultans (particularly Hafsa Sultan) reinforced this continuity by commissioning large architectural complexes in Manisa (Gündüz Küskü, 2014, p. 640; Demirtaş, 2024, p. 684). In this context, the research embarks on a search for relationalities, tracing the imprints of the female figure in the city and situating this endeavour within the framework outlined by feminist approaches. The aim of research is to explore possibilities for instituting new relations and, by taking the forms of women's representation in urban space as a witness, to pose questions that open a path towards reconfiguring spatial relations.

Through the intersections articulated via the concept of the waqf, the production of knowledge is displaced from a merely historical framework and becomes a critical mode of reading that responds to the present condition. Public interaction is thus rethought not through macro-scale patriarchal narratives of conquest and domination, but minor foundational contributions, care-based actions, and practices of repair and healing. With its fragmented and multilayered structure, this mode of narration shifts the public realm beyond grand historical accounts, making visible the everyday, modest yet transformative interventions. Accordingly, to think, write, and draw on publicness within the scope of this research has meant dislodging the narrative from a linear historical sequence and relocating it onto a ground of spatial multiplicity,

diversity, and polyvocality. In doing so, the study pursues a line of interpretation that redefines the very notion of the public and emerges as an attempt to think with the excitement generated by this search.

2. Materials and Methods

Unlike conventional historical or architectural studies, this research is grounded in a critical mode of thinking that draws on the theoretical intersections of these disciplines. Accordingly, the research outlook extends beyond conducting archival research through historical documents to interrogating the power relations and gender dynamics underlying the archival knowledge obtained. At the same time, the research perspective is conceived as multilayered in order to question the modes of production of (patriarchal) knowledge itself.

In this context, Haraway's (1998) articulation of the relationship between knowledge and location informs as a guide in shaping the methodology of this research. Haraway emphasises that knowledge is neither neutral nor universal, but is produced from a specific position. The relationship that knowledge established with location here underpins this study's connection to place. Accordingly, this study examines the spatial experiences of Ottoman women through the lens of this understanding of "situated knowledge."

This research constitutes a three-layered methodological framework: women, power (relations of force), and space. This threefold relationality is employed as a framework through which to narrate women's histories from a non-patriarchal perspective. This reveals that, in the Beylik and Ottoman periods, women were not passive figures as often portrayed in conventional historiography, but active agents engaged in ongoing struggles (Figure 1).

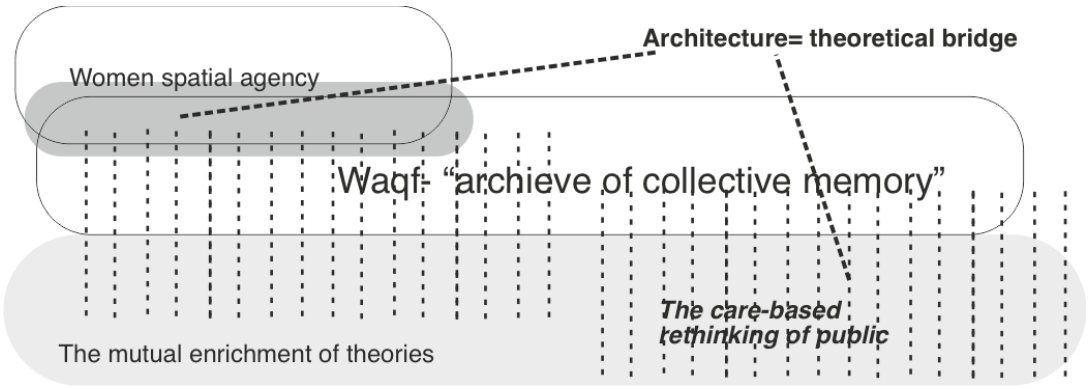

Figure 1: Structure of the research (Source: Authors)

For this reason, the first phase of the study consisted of archival research. At this stage, since waqfs are an indication of women's economic power, the charitable works undertaken by women in Manisa and the architectural complexes commissioned by female patrons were examined. Subsequently, spatial analyses were conducted to reveal the locations of these complexes within the city and how they were interconnected. Thus, the research interprets the power relations exercised by women through the spatial traces they have inscribed in Manisa.

3. Literature Review

3.1. Gender and Memory Studies

Women's studies reveal the female figure that has long been rendered invisible within patriarchal historiography and in urban/architectural scholarship. Feminist theories reposition women not as merely passive subjects, but as agents who construct their own ecologies and networks and actively intervene in social and spatial orders (Butler, 1990; Haraway, 1988). In this context, the terms "matriarchal ecologies" and "care-based relations" point to the invisible yet transformative bonds that women establish with the city, the built environment, and everyday life.

Donna Haraway's debates on nature–culture (1988) and Maria Puig de la Bellacasa's "ethics of care" (2017) emphasise that the female figure should not be associated solely with victimhood, but also with sustaining and reparative practices. Waqf institutions in the Anatolian beyliks and the Ottoman Empire can likewise be read from this perspective. The foundations established by women were not merely charitable enterprises, but spatial manifestations of care and social healing. The invisible networks constituted around care and the relations it generates also point to the degree of attentiveness and sensitivity with which these issues must be approached.

3.2. Waqf Culture and female patrons in Manisa

The waqf is a legal institution that facilities the transformation of a property into a resource for the benefit of the public. The practice emerged during the Anatolian Seljuk and Beylik periods, and was subsequently institutionalised under the Ottomans. It became characterised by the establishment structures such as complexes (külliye), mosques, madrasas, soup kitchens (imaret), and hospitals (darüşşifa), which came to define urban identity (Yediyıldız, 2003, p. 161). Especially in the Ottoman Empire, waqfs shaped both the social and cultural life of society and the physical environment in which people lived, and for this reason the empire has often been described as a "waqf civilisation" (Alkan, 2018). During this period, the majority of structures that provided public services in cities—such as mosques, complexes, and fountains—were built through waqfs (Heybeli et al., 2016). By financing expenditures particularly in the fields of health and education, waqfs enabled the construction of numerous facilities across the city, including schools, hospitals, and soup kitchens (Çizakça, 2006). Waqfs played an influential role in shaping the physical form of built-up and residential areas in both rural and urban contexts (Alkan, 2018). These foundations were established by individuals from various segments of society—such as state officials at different ranks, members of the palace, wealthy patrons, valide sultans, viziers, and princes (şehzades) (Ateş, 2017).

In the specific context of Manisa, waqfs functioned not only as places of worship, but also as institutions of social service such as baths (hamam), soup kitchens (imaret), and hospitals (darüşşifa) (Demirtaş, 2024, p. 686). These waqfs were established after Manisa passed into Turkish control. It is possible to classify the waqfs founded in Manisa according to their purposes of establishment (Heybeli et al., 2016) as follows:

1- Waqfs established for places of worship (mosques, mescits)

2- Waqfs established for water structures (fountains, sebils, wells, water distribution structures, private enterprises providing cold water, baths)

3- Waqfs established for educational purposes (primary schools mektep, teachers' houses muhallimhane)

4- Food-related waqfs (related to tradesmen)

5- Waqfs established for the continuation of religious life and tradition

6- Other waqfs

In Manisa, waqfs were established by members of the palace for mosque-centred building complexes (külliyes). These foundations created diverse revenue sources were created through these foundations in order to ensure the continued maintenance of these complexes (Gökmen, 2020). These waqfs not only influenced the social and cultural life of Manisa, but also shaped its physical fabric by regulating urban development activities (Alkan, 2018). During the Beylik period, two major külliyes were constructed in Manisa: the İshak Çelebi Külliyesi, which includes the Ulu Mosque, and the Gülgün Hatun Külliyesi. In the Ottoman period, six significant külliyes were built: İvazpaşa, Hafsa Sultan, Muradiye, Hatuniye, Hüsrev Ağa, and Dilşikar Hatun (Ministry of Culture and Tourism, n.d.; Küskü, 2014; Gökmen, 2020).

An examination of the constructed külliyes and probate records reveals that women in Manisa assumed the role of patrons (Küskü, 2014) and that many of them were relatively affluent (Karadeniz, 2018). According to eighteenth-century probate registers, numerous women living in Manisa owned different types of real estate such as houses, shops, and gardens, and the wealth of some significantly exceeded the city's average. This indicates that women of Manisa were engaged in trade and agricultural activities and, through properties acquired either by purchase or inheritance, constituted an important component of the city's socio-economic life (Karadeniz, 2018). An examination of the külliyes in Manisa shows that (Table 1) the patronage of Gülgün Hatun Külliyesi, the second major complex of the Beylik period, was undertaken by Gülgün Hatun herself. This complex served as a precedent for the külliyes later commissioned by female patrons in the Ottoman period (Küskü, 2014). In the Ottoman era, the külliyes built under the patronage of women were the Hafsa Sultan, Hatuniye, and Dilşikar Hatun complexes (Figure 2).

Table 1: Külliyes (Social complexes) built by female patrons in Manisa (Acun, 1999; Güneş et. al, 2025; Kültür Envanteri, n.d.; Kültür Portalı, n.d TDV, n.d).

4. Findings and Discussion

The significance of women's studies lies in their potential to disrupt the long-dominant patriarchal narratives that have shaped both historiography and spatial theory. Feminist research has emphasized that women should not be perceived merely as passive figures within male-centered accounts but as active agents capable of generating their own networks, ecologies, and transformative practices (Butler, 1990; Haraway, 1988; Scott, 1986). In this sense, feminist theory positions the female figure not only as a counterpoint to patriarchal domination but also as a restorative and sustaining presence, capable of producing new understandings of space, memory, and collective life.

The mapping of the invisible networks reconstructed through the külliyes makes it possible to (i) in architectural terms, probe the spatial impact of female patronage along the axis of typology–programme–continuities of use; (ii) in urban terms, develop analytical approaches to care infrastructures by examining distances, proximities, and mutual relations at the levels of networks/access/neighborliness through alternative geometric organisations; (iii) in historical terms, open up the very narrative of space by attending to micro-level details; and (iv) in memory studies, reflect on gendered representations through architectural practice. In this way, within the broader significance of women's studies, the research does not merely generate new empirical data; it also offers methodological contributions (layered spatial readings, and the use of archive–map–diagram as techniques of spatial narration) and conceptual contributions (care-based publicness, the waqf as a "collective memory archive"), thereby building bridges across different disciplines (Figure 3).

An analysis of the külliyes in Manisa reveals that one of the two külliyes constructed during the Beylik period (Gülgün Hatun Social Complex) and three of the six külliyes built during the Ottoman period (Hafsa Sultan, Hatuniye and Dilşikar Hatun Social Complexes) were initiated by women themselves, thus achieving a balanced representation of female participation.

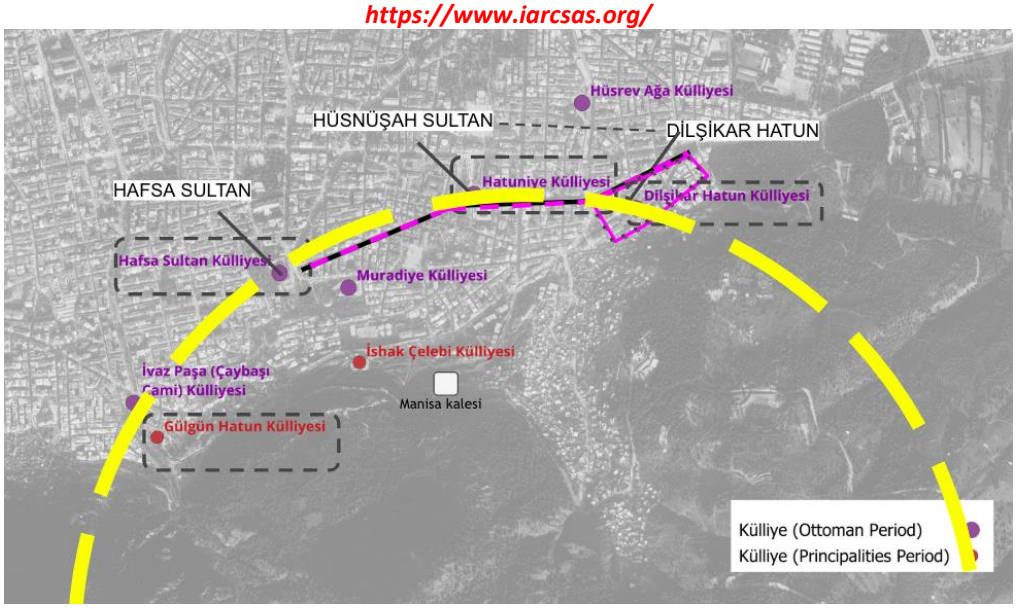

Figure 3: Külliyes and their hidden geometry behind the location (Source: Authors)

5. Conclusion and Recommendations

Taken together, these discussions reveal a research framework in which women emerge as spatial agents whose waqf practices inscribe durable traces in the Ottoman city. Waqfs are approached not only as economic mechanisms, but as social memory archives that register female networks, affiliations, and modes of care. Within this framework, architecture operates as a theoretical bridge that connects feminist thought with Ottoman historiography, enabling a critical reading of both the functional roles and symbolic excesses of built forms. In turn, this perspective makes it possible to rethink public space through women's care-based interventions, proposing alternative, women-centred models of publicness that challenge the dominance of Western public sphere theories and open new paths for understanding urban life, memory, and power.

- Women's spatial agency: Waqfs show that women in the Ottoman city were not merely charitable figures, but active city-makers and organisers of social networks.
- Waqf as a social memory archive: Waqfs are not only economic institutions; they are collective memory sites that carry the traces of relations among women and of shared forms of belonging.
- Architecture as a theoretical bridge: As a tool that brings feminist theory into dialogue with Ottoman history, architecture opens up both the functional and symbolic "surplus meanings" of buildings to critical discussion.
- Rethinking public space: Ottoman women's waqf practices propose "women-centred, care-based forms" as an alternative to Western-centred theories of the public sphere.

The research establishes a spatial relationship between külliyes built during the Principalities and Ottoman periods due to networks among powerful women, the topography, and locational strategies in Manisa. The complexes are arranged on an arc-shaped road and establish both a visual and physical relationship with each other. This alignment reflects the symbolic and political significance of female patrons in the city's topography. The positioning of these

complexes also implies a dialogue between architecture, geography and power, emphasising the active role of women in shaping urban form and collective memory in Manisa.

This study forms part of a broader research project exploring the spatial and social influence of female patrons in built form in Principalities and Ottoman periods through the example of Manisa. Integrating historical archival research with advanced spatial analysis tools, such as GIS, could further illuminate how these structures shaped, or were shaped by, urban form and social networks over time. These insights would not only contribute to architectural history, but also to a deeper understanding of gendered spatial practices within Türkiye.

Abstract

The urban forms of historic Anatolia are distinguished by their unique characteristics. These characteristics manifest themselves at both the building and the settlement scale. The street-space relationship, the resulting social interactions, and passive design decisions appropriate to climatic conditions have contributed to the sustainability of these cities. The district of Tire, which is located within the boundaries of Izmir, exhibits characteristics of sustainable urban form. The historical urban layout of the city is characterised by an organic urban fabric, consisting of narrow streets shaded by trees, an arrangement of open, semi-open and closed spaces, and a use of local materials in its development. The presence of a designated organic street pattern serves to facilitate the establishment of a safe and convivial social space for residents, thereby contributing to the vibrant street life that characterises this locale. Additionally, the construction of high garden walls confers dual benefits, ensuring the privacy of the garden and providing shaded areas for users. In conclusion, the historical urban fabric of Tire demonstrates its ability to be a socially, ecologically and environmentally sustainable urban form that is resilient to local climatic conditions. In this context, a morphological analysis of Tire's historical urban form is crucial for the implementation of sustainable urbanisation practices. The present study analysed the characteristics of Tire's traditional urban fabric and drew conclusions for sustainable cities.

Keywords: Traditional urban form, sustainability, Tire, urban morphology, climate

1. Introduction

The role of buildings in environmental issues, including global warming and climate change, is a significant consideration. Throughout their lifecycle, buildings are responsible for significant consumption of natural resources. Such consumption of materials, energy and water results in a number of pollution and environmental problems. The increasing environmental problems that face the world have prompted architects to seek solutions, with sustainability becoming an integral part of architectural practice. However, the traditional architectural practice is one that is characterised by the existence of a set of principles that can provide a framework for the adoption of sustainable principles (Yüksek, 2008). The preservation of traditional urban forms and traditional houses is of critical importance in the conservation of cultural heritage, as these elements facilitate the communication of past lifestyles to the present. The preservation of traditional urban forms and traditional houses is of crucial value in terms of cultural sustainability, given their role as visible reflections of the cultures of their inhabitants. In

contrast to contemporary methodologies, traditional design approaches consist of design solutions that embody experiential knowledge, historical customs, and regional characteristics, which have been transmitted from master to novice through a process of training and apprenticeship. In this regard, it is imperative to investigate traditional solutions in cities.

In this context, the district of Tire represents a valuable case study due to its historical urban form. Throughout history, Tire has been a settlement for many civilisations, due to its fertile lands and favourable geographical location. From ancient times to the present day, it has developed as an important centre under the rule of the Hittites, Phrygians, Lydians, Persians, Hellenistic Greeks, Romans, and Byzantines. Following the Turkish conquest of the region, Tire gained a new identity as a city of principalities. During the period of Ottoman rule, the city experienced a profound adoption of Turkish-Islamic cultural influences, which manifested itself in the city's architectural features and forms (Mete, 2012).

The geographical location of Tire extends from the southern foothills of the Aydın Mountains to the Küçük Menderes plain to the north. The city's topography is characterised by a gradual elevation from the plain, which is accompanied by abundant water resources. This, in turn, has contributed to the development of a vibrant green landscape, a feature that has led to the city being affectionately and locally referred to as "Green Tire". (Baykara, 1994). Furthermore, Evliya Çelebi's writings provide additional insights into the city's water infrastructure, noting that it was characterised by numerous fountains, springs, and water bodies flowing into houses (Kurşaklıoğlu, 2014).

2. Materials and Methods

The objective of this study was to analyse the urban morphology of the Tire and to reveal its sustainability characteristics. The study's methodology is founded upon qualitative and quantitative research techniques, supplemented by fieldwork and a thorough literature review. The fieldwork comprised observations, photographic documentation, and mapping studies to analyse existing conditions at the settlement. The methodology of the study is founded upon analyses conducted at three distinct scales: urban, building-street, and material. The study examined the traditional urban morphology of Tire in the following neighborhoods: Ertuğrul, Ketenci, Bahariye, Dumlupınar, Turan, Dere, Paşa, and İstiklal.

3. Findings and Discussion

3.1 Traditional Urban Form in Tire

The configuration of the street networks within the traditional Anatolian urban form is not a random process; rather, it is an organic development that follows a rhythmic order, in accordance with the fundamental requirements of the users who constitute the urban form itself. (Aru,1998). In Tire, the Turkisation process established the foundations for the urban structure that endures to the present day. The settlement of the Aydınoğulları was established on the slopes of Güme Mountain in the south, with small communities forming around the social complexes constructed by the ruling class and prominent figures of the period. Subsequently, under the rule of the Ottoman Empire, the city expanded towards the flat areas to the east and north, with residential neighbourhoods forming around these complexes. Concurrently, the city's historic commercial centre, comprising the construction of the accommodations (inn) and the covered bazaar surrounding Tahtakale, has endured to the present day (Yüksel, 2014a). Tire also exhibits a notable preservation of its historical urban fabric. During the Principalities

period, Tire underwent a top-down development, expanding from the upper elevations towards the lower commercial centre, in accordance with the natural topography (see Figure 1).

Figure 1. Urban Form of Tire, constructed on sloping land (Source: Authors).

Tire exhibits an organic street pattern and traditional residential texture in the aforementioned areas. Prior to the Ottoman period, the commercial centre of Tire, known as Thatakale, was surrounded by Greek neighbourhoods to the east and Jewish neighbourhoods to the west. The centre of Turkish neighbourhoods was the Ekinhisarı district, also known as Taşpazarı (Armağan,2010). In Tire, settlements from the Princpalities period are concentrated in the eastern and relatively higher parts of the city. The densest settlement is located in the proximity of the Karakadı Mosque, which is also referred to as Taşpazarı. This is followed by the Gürcü Melek Mosque and the Hisariçi neighbourhood (Armağan,1983).

In the development of the city, the formation of neighbourhoods occurred in close proximity to a social complex (külliye). These complexes played a pivotal role in the support of social life by serving as the focal point for religious, social, and cultural structures (Yüksel, 2014b). The neighbourhood derives its name from the mosques and külliyes. The nomenclature of the neighbourhoods is almost identical to that of the mosques themselves, as each neighbourhood is named after its respective mosque. Each neighbourhood is characterised by the presence of a mosque, a madrasah, a bathhouse, a fountain, and a cemetery. The construction of these complexes was not exclusively for the purpose of charity; they also served to address fundamental needs (Armağan, 1983).

The role of dead-end streets in the formation of the traditional urban fabric is also a significant factor. The configuration of dead-end streets can be regarded as a cultural manifestation of the urban form that has evolved throughout history in multi-layered cities. The primary benefits of these developments are said to be the establishment of safer environments for residents, with access to strangers being limited and greater opportunities for socialising among neighbours being provided. Moreover, the absence of traffic on dead-end streets serves to mitigate both noise pollution and the potential for accidents, thereby enhancing the quality of life for

residents. In Muslim societies, dead-end streets are also regarded as a significant component of privacy (Belge; 2023; Kalak and Kalak; 2021).

Another significant element in traditional Turkish cities is the presence of neighbourhood fountains. As with other public open spaces, the areas surrounding fountains formed squares, thereby defining public space and becoming important in social life (Gökgür, 2008; Pilehvarian, 2002). Tire is also characterised by a significant number of fountains, which play a pivotal role in shaping the urban form. The prevalence of these fountains in Tire is particularly pronounced in streets where steep slopes characterise the city's traditional urban form. These fountains are often freestanding and situated in squares and parks. In addition, they are to be found attached to the walls of various buildings, including mosques, bathhouses and other structures, serving as a means of defining a gathering space for the city (Yüksek, Günbek; 2010).

When Tire is evaluated within the scale of the urban form, traditional urban patterns are abundantly evident in the Ertuğrul, Ketenci, Bahariye, Dumlupınar, Turan, Dere, Paşa, and Istiklal neighborhoods. The urban form in these neighbourhoods is characterised by its organic nature, spontaneous development, and functional structuring. The urban fabric is characterised by interconnected neighbourhoods, not through the presence of defined geometric networks, but rather through the evolution of an organic street pattern that responds to and interacts with the topography. The formation of these communities is influenced by a number of factors, including slope, changes in land size due to property rights, perceptions of privacy, and neighborhood culture. A notable feature of conventional Turkish urban form is the presence of dead-end streets, a characteristic that is particularly notable in Tire. These streets are actively used, particularly by women and children, providing both a safe and social space for neighbourhood residents (see Figures 2-3).

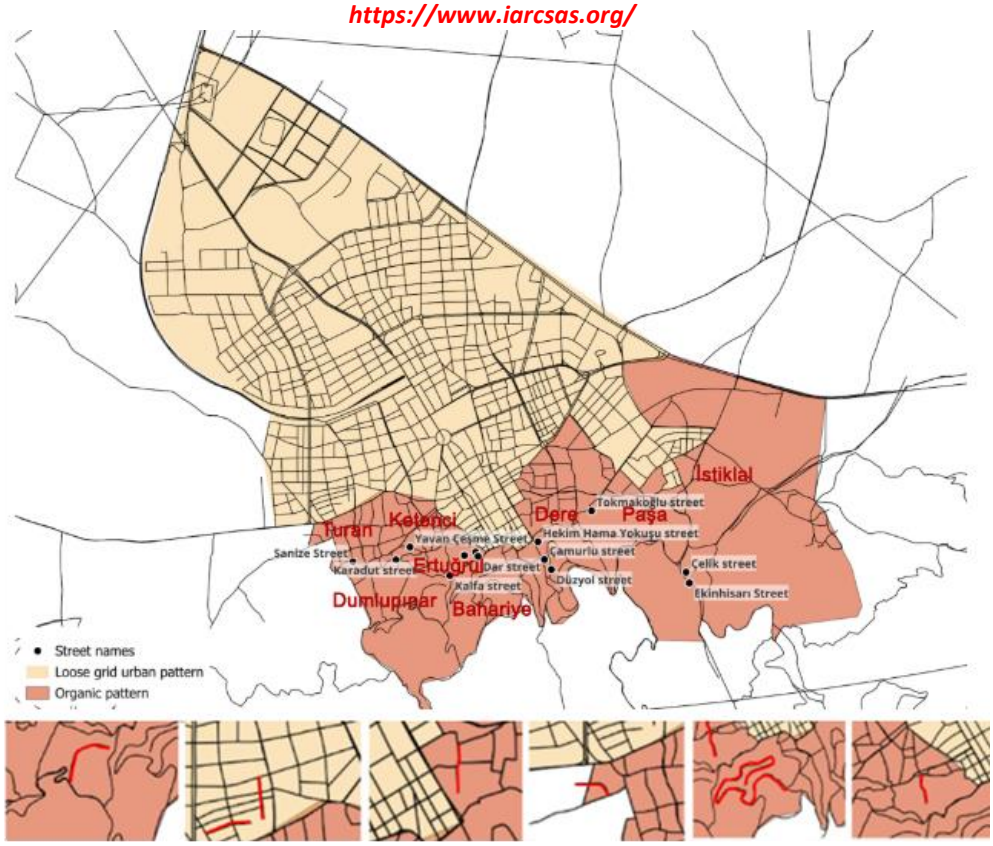

Figure 2. Organic Urban texture and Dead-End Streets in Tire (Source: Authors).

Figure 3. Tire's organic street pattern (Source: Authors).

3.2. Traditional houses in Tire

In Tire, housing is categorised into two distinct types: traditional Turkish housing and Levantine housing. The design of Levantine-style housing is such that it is oriented towards the street, with direct access points located at the street level. In comparison to other housing typologies, Levantine-style housing is distinguished by its abundance of windows on the front facade. In addition to extensive and decorative gardens, the structure is typically two storeys in height, with both levels serving as living spaces (Kürüm,1992) (Figure 4).

Figure 4. Examples of single-storey and two-storey residences with multiple windows on the façade directly connected to the street (Source: Authors).

In contrast, traditional Turkish houses are characterised by high stone walls, courtyards, and gardens. This distinguishes them from Levantine houses (Kürüm,1992). The gardens are typically covered with slate, a local stone, and include outbuildings such as stables, restrooms, chicken coops, and ovens. During the summer months, the gardens function as workshops where various activities such as rope making and municipal weaving are conducted. Additionally, they serve as shaded, cool resting areas. Traditional Turkish houses are generally two-storey buildings, with the lower floors enclosed or closed. The function of the lower floors is for storage and cellars, while the upper floors are used for living space (Kürüm,1992). (Figure 5).

Furthermore, in the traditional urban form of Tire, houses in areas with steep slopes were found to have multiple entrances, one at the beginning and one at the end of the slope. The positioning of these houses in Tire has been meticulously planned to ensure that each residence retains unobstructed views. Another significant socialising area, beyond the dead-end streets, is the front areas or courtyards located at the entrances (street intersections) of these houses (see Figure 5).

Figure 5. Courtyard, entrance and garden walls of traditional house in Tire (Source: authors)

3.3. Traditional Building Materials Used in Tire

The streets in Tire are characterised by an organic texture, with natural cobblestone pavement. The road surfaces sloped towards their centre, thereby serving the purpose of directing rainwater away from the site. Subsequently, the concrete paving was replaced with natural stone. However, in certain areas, the topography is characterised by significant inclines, necessitating the use of stairs for access. Upon entering the dwellings from the streets, a high garden wall constructed with mortar or dry stone masonry is immediately visible. The flooring of garden areas is typically composed of slate. The residences are constructed from masonry stone, with single-story houses being the most common type. In two-storey buildings, the ground floors are typically constructed from stone masonry, with the upper floors also comprising stone masonry, brick masonry, or timber framing. The load-bearing and cladding materials for the interior partition walls, intermediate floors, and ceiling slabs are wood. In

certain buildings, reed (locally known as kargı) material was utilised for the ceiling beams. Roofs are also timber framed and covered with Turkish style tiles (Figure 6).

Figure 6. Materials used in traditional houses, walls and streets in Tire (Source: Authors).

4. Conclusion and Recommendations

Throughout history, Tire has been regarded as an important settlement area for many civilisations due to its location and fertile agricultural lands. The formation of the urban form was influenced by two major factors. Firstly, the conquest of the region by the Turks led to Tire becoming a Beylik city. Secondly, Turkish-Islamic culture spread following the incorporation of the city into the Ottoman Empire. Consequently, Tire possesses a multi-layered urban form bearing the traces of different civilisations.

The urban settlement of Tire exhibits a north-facing sloped land structure that is in harmony with the topography. The most significant factors influencing the formation of Tire's traditional urban form have been identified as the perception of privacy, neighbourhood culture, and local amenities. When Tire's traditional urban fabric is examined from a social perspective, the most

significant elements that define its centre are the külliyes. Neighbourhood-level centres are characterised by the presence of mosques, fountains and nearby gathering areas. Other significant social spaces include Tire's organic street pattern, which develops spontaneously and is shaped according to the needs of residents, adapting to the topography. The streets that constitute this pattern frequently exhibit descending slopes and stairs, and on occasion terminate at dead-ends. These streets represent pivotal social gathering locales for local residents. It is an established fact that streets are generally bordered by gardens or house walls, the purpose of which is to ensure privacy. This configuration facilitates a harmonious integration of visual and physical elements, thereby establishing a seamless connection between the street and the residence.

The urban form in Tire consists of buildings that are low-rise, constructed on sloping land with the intention of avoiding the obstruction of each other's views. The roads between the buildings, which are surrounded by garden walls, provide shaded areas, particularly during the summer months, and sheltered areas in the winter, thereby ensuring thermal comfort. The design of street widths is intended to cater to the movement of people, rather than vehicles. The inclination of street pavements towards the centre of the road facilitates pedestrian traffic along the sides, while also conserving water by considering rainwater runoff.

An examination of the traditional housing scale in Tire reveals the incorporation of garden houses and associated architectural elements, including courtyards and garden sheds. The large garden, an integral component of the urban fabric of Tire, represents a substantial opportunity for the revitalisation of traditional production methods that are specific to Tire, as was the case in the past. These semi-open and open spaces continue to be utilised by residents for activities such as the processing and storage of local products, although this practice has diminished in recent times. In summary, the manner in which residential architecture is organised has a significant impact on the financial well-being of households and the broader economic viability of the region.

An examination of the materials used in the construction of the houses in Tire reveals that natural and local building materials found in the surrounding area were predominantly utilised. When the traditional urban fabric of Tire is evaluated from a macro to a micro scale, it is evident that it encompasses three fundamental dimensions of sustainability: economic, ecological, and social.

The recent increase in construction pressures on the traditional urban fabric of Tire, combined with issues such as slope-related accessibility difficulties and problems in the provision of public services, as well as changing lifestyles of local residents, has the potential to result in the abandonment of homes, the deterioration of areas, and subsequent transformation of the urban fabric. This necessitates the formulation of specific policies to protect the historic urban form from these threats. The principles of sustainable architecture encompass the preservation of existing settlements and structures, the fulfilment of basic family needs through the integration of edible landscaping products in residential gardens, the remote fulfilment of some working life responsibilities, the utilisation of natural building materials, and the creation of humane designs.

As in the case of Tire, cities with a traditional urban structure in Anatolia embody these principles of sustainability and also provide suitable environments for sociocultural continuity. It is evident that traditional urban forms, such as Tire in Türkiye, are facing the threat of extinction for a variety of reasons. The preservation of traditional urban and residential forms

is of paramount importance in ensuring the continuity of our thousand-year-old culture, as these elements provide the foundation for daily life and serve as a bridge to the future for future generations. Consequently, the preservation of these elements is not a choice but rather an imperative.

Abstract

Educational models have a dynamic structure, shaped by various factors such as social, technological, and economic developments throughout history. The COVID-19 pandemic stands out as one of the most prominent examples of this transformation in education. During this period, when face-to-face education became insufficient, the need for new educational models increased. Initially, solutions were sought through distance learning models, but later, as the effects of the pandemic subsided, hybrid education models began to be implemented. Hybrid education is an approach that provides flexibility by combining physical and digital learning environments. This model presents new requirements not only from a pedagogical perspective but also from a spatial and technological perspective. The use and advantages of hybrid learning environments are directly related to the holistic design of physical and digital settings. In this context, the principles of accessibility, interaction, and continuity come to the fore; spaces that meet the needs of teachers and learners make the learning experience more inclusive and applicable. This research identifies the design principles of hybrid education in spaces, the transformative impact of space, and the needs of hybrid education through case studies identified from various perspectives of hybrid education spaces. Based on the determined design principles, the proposed classrooms were designed and these designs were opened to discussion in terms of usage scenarios and spatial arrangements

Keywords: Distance education, educational spaces, technology, flexible spaces, interaction

1. Introduction

Education is a dynamic process that has undergone constant transformation and development throughout history, influenced by social, economic, cultural, and technological changes. Throughout history, from traditional classroom teaching to online education, teaching models, pedagogical approaches, and learning theories have been shaped by technological innovations. In this context, the use of technology in education has increased significantly and become a necessity (Güllü, 2021). The traditional education model is a system in which teaching activities are conducted at specific times and in specific locations, such as classrooms, laboratories, or workshops. In this model, the learning process is teacher-centered; knowledge transfer is directly conducted by the teacher. This time- and space-bound educational model offers a disciplined learning system with specific time and space constraints (Çetin & Faruk Özdemir, 2018). With evolving technological advancements, today's learning processes have evolved into a multifaceted structure that embraces student active participation and interaction, free from constraints such as time and space.

This transformation is evident not only in pedagogical approaches but also in the shaping of the physical and digital feature of the spaces where education takes place. With the integration of conventional education methods and digital technologies into the education system, the distance

education model has evolved and is increasingly gaining prominence in educational models (Ünver, 2024).

In the distance learning model, instructors and students can learn from different locations. This allows for a flexible dynamic adapting to changing conditions (Demir, 2014). This education model is divided into two types: synchronous and asynchronous (Romiszowski, 2004). In the synchronous model, the teacher and learner are in different locations but conduct their lessons at the same time. In the asynchronous model, the teacher and learner are not required to meet at the same time (Jamison et al., 2014). Instructors prepare course materials on their own time, and students can access them according to their own pace and learning style. A hybrid learning model blends distance learning and face-to-face learning (Doering, 2006). In this model, students can attend classes in physical classrooms and continue their remote learning process via digital platforms (Fabian et al., 2024). It simultaneously supports individual and collaborative learning by providing a learning experience independent of time and space. Thus, hybrid education increases pedagogical diversity and integrates technology into the learning process.

Educational models that have emerged in different periods traditional, distance learning, and hybrid are directly related to learning theories, instructional technologies, and societal needs. Therefore, each is undergoing a continuous transformation process tailored to the needs of its time. This transformation process gained even more radical momentum with the COVID-19 pandemic (Dhawan, 2020). The pandemic, which impacted the entire world in 2020, transformed education systems and forced both students and teachers away from traditional classroom environments. During this period, educational institutions were forced to rapidly transition to online platforms, and the use of digital tools rapidly increased and became essential. Consequently, educational institutions were forced to continue with distance learning. Later, with the decline in pandemic conditions, and given the lack of face-to-face activities such as social interaction, laboratory work, group projects, and experiential learning, interest in hybrid education models increased, both from a pedagogical and spatial perspective (Göksel & Adigüzel, 2024).

The hybrid education model has not only served as a solution for education during the pandemic but has also evolved into a sustainable teaching approach in higher education institutions (Kurniawan et al., 2022). This requires redefining educational spaces, strengthening technological infrastructures, and increasing the flexibility of learning environments. Various examples of hybrid education practices are presented in the literature; some studies have explored hybrid classroom arrangements at specific universities. However, much of this existing research focuses on the pedagogical or technological dimension and fails to offer a holistic approach that integrates user needs, learning activities, mobility for both educators and instructors, and spatial experience.

This study aims to fill this gap by examining recently developed case studies within the context of hybrid education and analyzing the design approaches, usage patterns, and relationships between these spaces and learning activities. Based on these analyses, the aim is to identify the requirements of hybrid learning environments at different scales and to develop spatial design recommendations that address these needs.

2. Literature Review

Education, as both a social and spatial construct, constantly evolves in response to pedagogical theories, technological advancements, and the changing needs of society. Educational spaces are not only physical environments; they are also integral to the learning process, student interaction, and social life. Over time, shifts in educational paradigms have led to the emergence of diverse teaching models, including traditional (face-to-face), distance learning, and hybrid, each designed to meet specific pedagogical and infrastructural requirements.

Traditional education is based on synchronous, face-to-face interaction, emphasizing communication between instructors and students within the same space. Distance learning, on the other hand, offers a learning experience that eliminates time and space constraints using digital platforms. Hybrid education, on the other hand, combines the strengths of both approaches by combining online and face-to-face learning experiences within a single framework. This model allows students to physically attend classes, access learning materials through online systems, and participate in discussions, thus increasing flexibility and accessibility (Hümmer et al., 2025). Hybrid education requires both physical and digital environments (Figure 1).

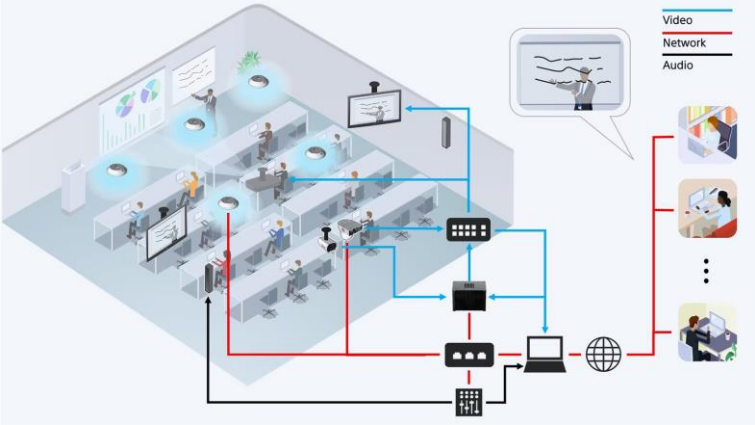

Figure 1. Hybrid classroom model (Rafi, 2023)

Research on hybrid education models and digital education applications reveals the impact of different approaches and applications in this field. The potential of hybrid learning algorithms for human activity recognition using wearable sensor data has been examined, highlighting the data accuracy and contributions of these methods to learning processes (Athota & Sumathi, 2022). The implementation of hybrid learning practices at public universities in Kosovo during the COVID-19 pandemic, along with the pedagogical and technical challenges encountered, has been discussed in detail (Krasniqi & Shabani, 2022). Similarly, in the case of a university, students and faculty members evaluated their hybrid classroom experiences, examining the effects of different perspectives on the integration of online and face-to-face learning components (Abusneneh, 2024). The effects of spatial arrangements on learning effectiveness in the design of hybrid learning environments have been examined, and strategies to increase student engagement have been explored (Sieber et al., 2025).

In this context, the role of classroom design in achieving pedagogical goals in the hybrid education model and the ways in which physical arrangements support learning processes have also been explored (Sevli, 2023).

Additionally, student preferences for hybrid learning are considered as factors to be considered in the design of future educational models, and the sustainability of hybrid learning is discussed (Fabian et al., 2024). During the COVID-19 pandemic, a comparative analysis was conducted on students' perceptions and satisfaction levels regarding online and blended learning methods, and the strengths and weaknesses of both approaches were analyzed (Osaili et al., 2023). Robot-mediated communication in hybrid learning is examined, and the impact of technological tools on interaction in teaching and learning processes is presented (Gleason & Greenhow, 2017). Student and teacher experiences in hybrid learning environments are examined in terms of the importance of physical presence in the learning process and its impact on interaction levels (Raes, 2022). Finally, the digital transformation process in higher education is comprehensively evaluated in terms of how online and hybrid applications can be integrated into traditional education systems, educational models, and learning strategies (Yakut Özek & Sincer, 2024). Research on hybrid learning spaces emphasizes the necessity of flexible layouts, advanced technological integration, and hybrid learning models that include both collaborative and individual learning activities. However, most of the existing studies present separate studies by addressing the pedagogical or technological factors in the hybrid education model without considering the spatial experience and user-centered design criteria in a holistic way.

3. Method and Material

In the post-COVID-19 era, universities have felt the need to redesign their existing spaces or create entirely new ones to transition to hybrid education. In this context, some universities have created hybrid spaces that meet physical and digital learning requirements. First, a literature review examined case studies developed in recent years. Five representative examples were selected for detailed analysis due to their diverse design approaches, scale diversity, and effective integration of physical and digital learning environments. Through a comparative evaluation of these cases, the study will examine how hybrid education spaces respond to user needs and pedagogical activities, as well as the use scenarios of the spaces.

Universities focusing on applied education require their own spaces, such as laboratories, studios, and workshops. These types of spaces have different and unique needs in hybrid education. Therefore, they should be evaluated separately from theoretical courses. Therefore, the spatial interactions between instructors and students in spaces designed for theoretical courses will be examined. Elements such as online integrations and ergonomic seating arrangements will be discussed to increase the suitability of theoretical courses for the hybrid education model.

Finally, design recommendations will be presented, incorporating the diverse activity and space requirements within the hybrid education model. Spatial arrangements will be discussed, particularly using examples of a standard 50-person classroom and a lecture-style classroom for 100 people. These design examples are presented as ideas for increasing the effectiveness of hybrid education and student-teacher interaction.

4. Case Study Hybrid Education Spaces

a. KU Leuven Campus Kulak Kortrijk

KU Leuven Campus has developed two hybrid educational spaces to support both on-site and remote learning simultaneously. In the Hybrid Virtual Classroom model, students attending remotely can connect to the lessons taking place in the classroom in real time and access the course materials at any time. In this model, the physical classroom is transformed into a virtual

learning experience with high-resolution cameras, interactive whiteboards and multiple microphone systems, but the spatial features are the same as the traditional face-to-face classroom model (Figure 2).

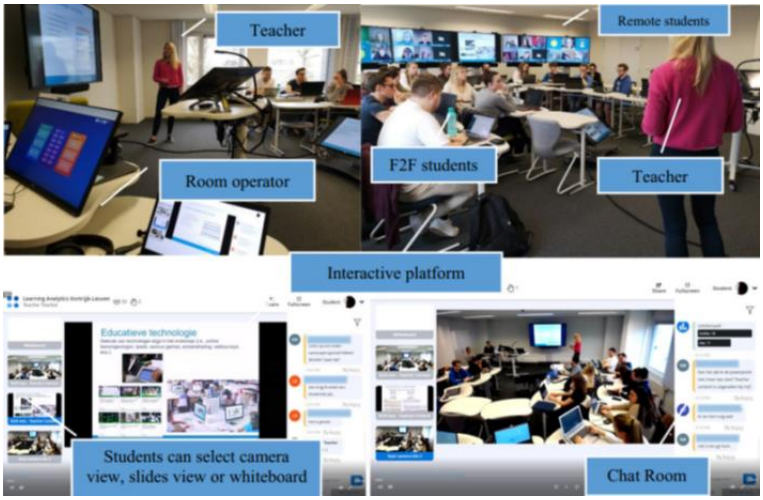

Figure 2. Physical classroom and remote student screen (Raes, 2022)

In the lecture hall model of the Hybrid Lecture Hall, technological tools are integrated into the traditional lecture hall layout, enabling both face-to-face and remote participation. With motion-tracking cameras, multiple screens and online platforms, students can participate in discussions and receive feedback. In this classroom, cameras facing the teacher are used in the area where the teacher is located, allowing the instructor to follow both the students attending remotely and the students in the classroom (Figure 3).

Figure 3. Teacher zone in the lecture hall (Raes, 2022)

b. Hybrid Learning Theatre

The Hybrid Learning Theatre (HLT) has been designed to meet the demands of evolving educational technologies and provide an innovative learning experience with a focused approach. Equipped with comfortable sofas, two large screens, professional-grade lighting, sound systems and three cameras, the HLT creates an environment that supports active participation. The classroom accommodates 40 on-site students and over 1,500 online participants and features a 4.5 x 2.5 m 'Zoom Wall' that projects up to 100 participants for real-

time interaction (Pols, 2020) (Figure 4). This setup facilitates active participation and in-class discussions and allows students to benefit from an interactive and engaging learning experience regardless of their location.

Figure 4. Zoom Wall and Teacher zone (Pols, 2020)

The combination of theatrical lighting and LED lighting creates a welcoming and spacious atmosphere. The combination of advanced audiovisual technology, thoughtful spatial design, and dynamic content presentation redefine the teaching and learning experience by focusing attention on a single point for both faculty and students (Figure 5).

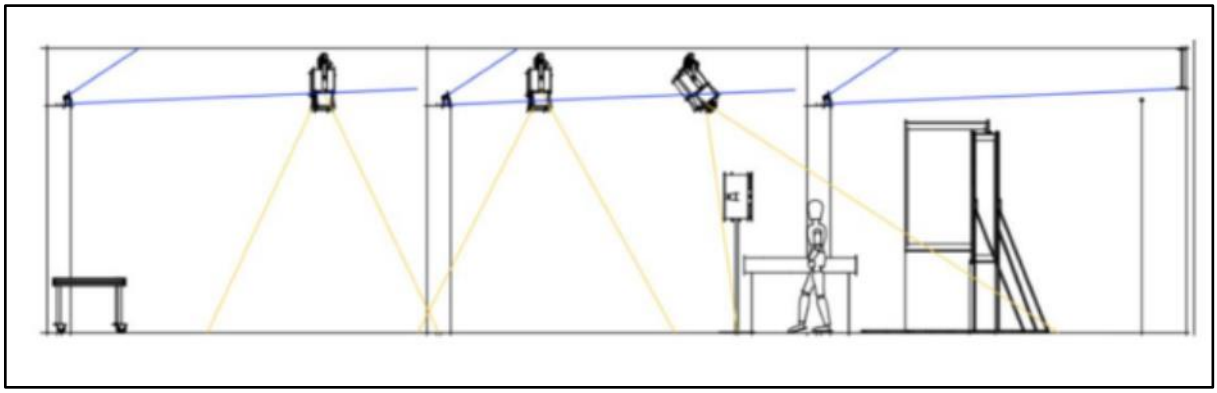

Figure 5. Section from Hybrid Learning Theatre (Pols, 2020)

c. Imperial College London - Hybrid at Scale

The hybrid classroom system at Imperial College London appears to be quite advanced thanks to the technological equipment's control structure. It is managed via interactive control panels in the classrooms, which easily control cameras, microphones, and tracking systems. Faculty members can follow their presentations without turning around thanks to the floor screen in front of them. The circular classroom layout is designed to focus on the instructor and the screens (Figure 6).

Figure 6. Hybrid education classroom plan diagram (Woolfitt, 2022)

The system was installed to ensure uninterrupted education during the pandemic. It was designed to integrate additional hardware into the existing classroom infrastructure. Courses can be conducted remotely or with the support of a student/assistant in the classroom, known as a "co-pilot " (Woolfitt, 2022) . This structure allows faculty to pre-plan details such as links, guest participants, or video content before starting the course, thus directing the focus entirely to the learning process. The hybrid system is designed to ensure equal participation of both remote and in-person students; Zoom's breakout room features ensure a balanced mix of in-class and online interaction (Woolfitt, 2022).

Figure 7. Seating arrangement of the hybrid classroom (Woolfitt, 2022)

d. Hybrid Learning with Robot-Mediated Communication

Developed to enhance social interaction in synchronous hybrid learning environments, social robotic telepresence systems (SRTS) are innovative technologies that allow remote participants to communicate as if they were physically present in the classroom (Kristoffersson et al., 2013). Equipped with an LCD screen, camera, microphone, and speakers, these systems can be remotely controlled and moved around the classroom. These systems allow students and instructors to interact in real time, but for this technology to be used effectively, classroom design must facilitate these robots and their mobility (Figure 8) (Gleason & Greenhow, 2017).

Figure 8. Education with social robotic tele-presence systems (Gleason & Greenhow, 2017)

e. The Hybrid Learning Atelier

The HLA (Hybrid Learning Workshop) concept was designed as a response to the transformation in higher education and learning methods in the digital age (Sieber et al., 2025). While the pandemic has revealed the technical possibilities of digital education, it has also highlighted its shortcomings in elements such as social presence, bodily learning experience, and spatial atmosphere. Therefore, HLA aims to bring together physical and digital learning environments not as opposing elements, but as complementary components. The main goal of the design is to create a learning environment that integrates technology into the space, supporting simultaneous interaction between physically present and digitally participating participants (Sieber et al., 2025). Therefore, it is designed to be open to a variety of usage scenarios rather than rigid usage patterns.

The design was conceived with not only visual aspects in mind, but also acoustics. Ultra-short throw technology acts as a counterbalance to the large monitor wall, allowing instructors and students to move freely in front of the projection surface without creating distracting shadows—a significant advantage for learning interaction (Figure 9) (Sieber et al., 2025).

Figure 9. The Hybrid Learning Atelier (Sieber et al., 2025)

5. Requirements of Hybrid Education Spaces

Hybrid learning spaces have a system that combines physical and digital learning environments, enabling simultaneous face-to-face and remote participation (Gudoniene et al., 2025). Such spaces require different requirements not only in terms of physical space arrangements but also in terms of technological infrastructure and interaction for both remotely connected students and students in the classroom (Var, 2023).

a. Physical Space Requirements:

Flexible Seating Arrangement: Ergonomic and movable furniture is needed to support students and teachers movements without restricting them during the lesson (Kiketa et al., 2022).

Good Lighting: Lighting that supports natural light should enhance attentional focus and provide appropriate visual quality for remote participation (Woolfitt, 2022).

Acoustic Design: An acoustic design that ensures the voices of every individual in the classroom can be heard is essential. This is important for both the remotely connected student's dominance in the classroom and the comfort of the remotely connected student and teacher's voices in the classroom. Noise-reducing materials should be used, and the space should be designed using materials that minimize echo (Sieber et al., 2025).

b. Technological Requirements:

Camera and Sound Systems: Movable cameras and ceiling microphones capable of recording from multiple angles should be adequate to meet the audio and visual needs of both in-person and remote students (Var, 2023).

Screens and Projectors: Large screens or video walls should be able to display remote participants and course content simultaneously.

Digital Platforms and Integration: The hybrid classroom should be supported by digital platforms enhanced with tools such as simultaneous Q&A, discussion boards, and virtual whiteboards.

c. Activity and Interaction Requirements:

Teacher Activity: The teacher should have screens in their own space to control both the virtual classroom and the students in the classroom and should also be able to maintain control of the lesson when moving around (Kiketa et al., 2022).

Participation Support Tools: Interactive software should be developed to facilitate both remote and physical participation.

Group Interaction: Activities should be designed to provide equal communication and discussion opportunities between in-person and remote participants (Clark, 2002).

Technical Support: A support team should be available to quickly resolve any technical issues that may arise during the training.

6. Analysis of Case Studies According to Hybrid Education Space Requirements

An evaluation of five case studies (Table 1) reveals that technological infrastructure is generally the most powerful factor in the design of hybrid learning spaces, but physical flexibility and spatial experience vary from project to project. The KU Leuven example, while implementing

different variations in the integration of technological tools for remote students during the transition to a hybrid model, continued to utilize the traditional learning environment in terms of physical space layout. In contrast, the Hybrid Learning Theatre, with its user-centered approach, offers a more flexible model, both spatially and technologically. Furthermore, by concentrating on the focus, it created a distinct spatial experience. In the Imperial College London example, equal participation is achieved by centralizing technology within the classroom environment, and technical support is strengthened through the "co-pilot" system. By adapting the existing space to hybrid learning, it provides a spatial experience for students who are both teaching and learning. The Robot-Mediated Communication example adds an innovative dimension to hybrid learning by supporting social interaction between physical and remote students through a robot; however, for these systems to function effectively, space must possess a high level of flexibility. Finally, Hybrid Learning Atelier offers a holistic design approach that addresses pedagogical, technological, and spatial requirements, aiming to integrate physical and digital environments in a balanced way. Overall, these examples emphasize that hybrid education is not merely a technological transformation process; it is a multifaceted issue that requires spatial flexibility, acoustic comfort, faculty movement space, and the redefinition of interaction scenarios.

Table 1. An evaluation of Five Case Studies

Case Studies	Physical Space Requirements	Technological Requirements	Activity and Interaction Requirements
KU Leuven Campus	In the traditional classroom layout, movable seating areas are limited, lighting and acoustic arrangements are basic.	It has multiple cameras, advanced microphone and screen integration, and a high level of digital access.	Teacher control is good, but movement space is limited, and technical support is not provided continuously.
Hybrid Learning Theatre	Flexible seating and comfortable furniture; space designed according to the requirements of lighting and acoustic systems.	Different camera systems, Zoom Wall, professional sound system.	Interactive, active participation; strong teacher-student communication but with a single space for the teacher
Imperial College London	Circular plan, good viewing angles; ergonomic seating system by integrating the traditional classroom system into a hybrid	Monitoring cameras with control panels are equipped with technological equipment for system malfunctions.	Co-pilot system supporting equal participation; technical support system improved
Robot-Mediated Communication	The area needs to be arranged to accommodate robot movement; a flexible plan is required.	Mobile robot system with screen and microphone.	By strengthening social interaction, it ensures that the presence of the remote student is felt physically.

Hybrid Learning Atelier	Flexible, open-to-different-scenario plan; designed with the integration of acoustics and lighting in mind.	Ultra-short-throw projection and a large monitor wall have been integrated with technology to strengthen the presence of students participating remotely.	It has a design layout that allows for free movement of teachers and students, group interaction and simultaneous participation.

7. Design Suggestions

Design recommendations were designed based on examples from the literature and considering the criteria for a hybrid learning space identified in Chapter 5. Mobile and flexible seating arrangements and screen locations were planned to facilitate small group discussions. Wireless presentation devices and microphones were used to allow the teacher to move freely within the classroom, and screen layouts were designed to allow the teacher to monitor the classroom and remote participants from different locations. For remote participants, it is important to ensure that the classroom overview and teacher movements can be monitored with fixed and mobile cameras. Furthermore, technical areas within the classroom were designed to allow for recording and replaying lessons and to prevent potential connection issues. The physical space layout was made flexible with ergonomic and portable furniture, and lighting and acoustic arrangements that support natural light ensure attention, visual quality, and sound comfort are among the criteria for a hybrid learning space. Technological requirements and interaction tools (cameras, microphones, screens, digital platforms, interactive software) were considered throughout the planning process, ensuring equal and efficient teaching activity for both in-class and remote participants.

a. Classroom for 50 People (Figure 10)

Student-Student Interaction: A mobile, movable seating arrangement was designed to facilitate small discussion groups within the classroom. Furthermore, screen positions were designed to ensure that not only the teacher but also the students themselves could more easily see the students connecting remotely.

Teacher-Student Interaction: Wireless presentation devices and microphones were used to increase the instructor's range of motion within the classroom. Furthermore, wall-mounted screens were designed to accommodate the teacher's movement within the classroom. This allows the teacher to monitor the responses of both the class and the remote students at every point in the classroom.

Remote Participants: A fixed camera, which provides a general view of the classroom by adjusting the perspectives of the remote students, and a mobile camera that follows the instructor were installed.

To enhance the effectiveness of hybrid lessons, technical areas within the classroom were designed to allow recording and replaying lessons as needed, eliminating any issues with connectivity issues.

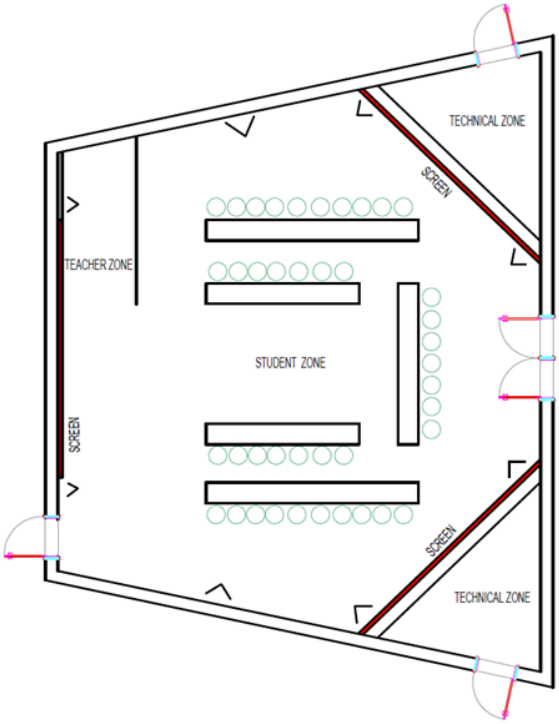

Figure 10. Classroom design suggestion for 50 people

b. 100-Person Amphitheater Classroom Design Suggestion (Figure 11)

Student-Student Interaction: Digital screens located in different areas of the classroom facing students are designed to reflect the views of students participating remotely during discussions, allowing everyone to participate.

Instructor-Student Interaction: In order for the instructor to establish a direct connection with remote students, he/she can have control over both the students in the classroom and the students connecting remotely, with both his/her own zone and the designed hybrid education niches.

Remote Participants: By providing a multi-camera system to view the classroom from different angles, remote students should be encouraged to feel like they are part of the classroom.

Technical zones have been designed within the hybrid education niches to solve the technical problems experienced by students remotely during the lesson.

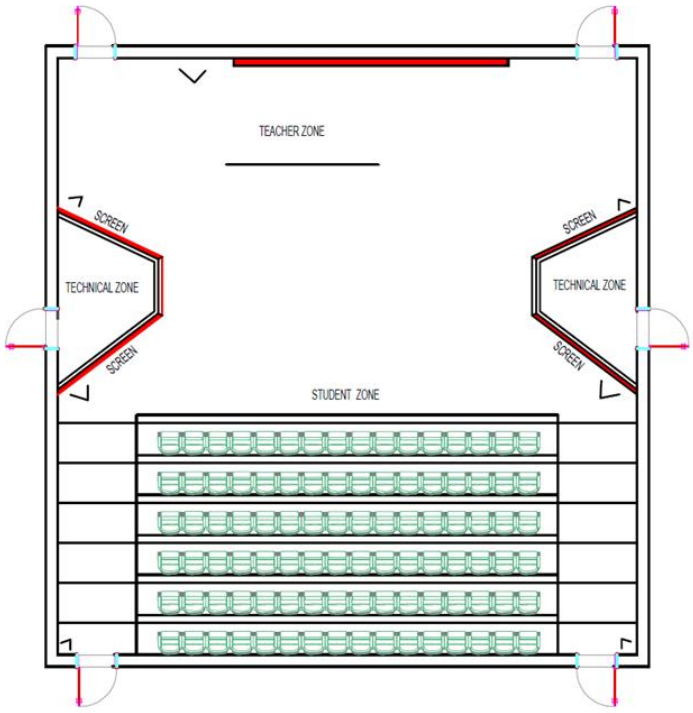

Figure 11. 100 person Amphitheater Classroom Design Suggestion

8. Conclusion

Education is in a constant state of transformation shaped by social, technological, and cultural dynamics. Traditional, distance, and hybrid models have emerged as reflections of their respective eras, responding to technological advancements. Traditional education, which remained confined to synchronously and spatially limited classroom environments, has increased the use of distance education with the development of digital platforms that transcend temporal and spatial boundaries. The COVID-19 pandemic has been a critical turning point in this evolution, accelerating the integration of digital technologies into education and revealing the need for more flexible, accessible, and resilient learning environments. In this context, distance education was first implemented, followed by the transition to a hybrid education model. Hybrid education can be defined as a sustainable pedagogical and spatial model that combines the strengths of both physical and virtual learning formats.

The literature reviewed in this study emphasizes that hybrid learning requires a holistic approach that integrates pedagogy, technology, and space. Research has primarily focused on the pedagogical and technological dimensions of hybrid learning, but has often overlooked the spatial and experiential aspects that shape user engagement. Therefore, this research aims to fill this gap by examining hybrid education from an architectural perspective and emphasizing the interrelationship between spatial configuration, user interaction, and technological infrastructure.

Five representative case studies—KU Leuven Campus, Hybrid Learning Theatre, Imperial College London, Robot-Mediated Communication, and Hybrid Learning Workshop—were

analyzed based on data from the literature review, both highly representative and addressing hybrid education from diverse spatial and technological perspectives. Comparative evaluation revealed that while all examples integrated digital technologies, their spatial responses varied significantly. The KU Leuven model advanced technologically through camera and screen integration while maintaining the traditional classroom typology. In contrast, the Hybrid Learning Theatre redefined the spatial experience through theater lighting, acoustic optimization, and immersive interaction. The Imperial College London example combined a controlled digital system with a circular spatial organization to ensure inclusiveness between remote and in-person students. The Robot-Mediated Communication approach emphasized mobile telepresence devices, transforming the perception of proximity and interaction. Finally, the Hybrid Learning Workshop offers a comprehensive and balanced design framework that coexists with technology, space, and human interaction.

The synthesis of these analyses identified three fundamental requirements for hybrid learning environments. First, physical space flexibility, ergonomic arrangements, and acoustic lighting quality define the spatial comfort required for interaction. Second, technological infrastructure, including multi-angle cameras, mobile devices, and digital platforms, ensure accessibility and continuity. Finally, interaction-related requirements (teacher mobility, group collaboration, and technical support) bridge the experiential gap between remote and in-person participants.

Based on these findings, the study proposed two classroom design models based on the identified requirements: a 50-person classroom and a 100-person lecture hall. These proposals focused on spatial flexibility, ergonomic seating, interactive display systems, acoustic optimization, and lighting strategies. The designs also considered the integration of fixed and mobile camera systems, wireless teaching devices, and multifunctional spaces that support synchronous learning for both in-person and remote users.

Ultimately, this research demonstrates that hybrid education represents a structural and spatial transformation in contemporary higher education. Beyond being a technological adaptation, it signifies the emergence of a new architectural typology that combines physical and digital environments within a unified pedagogical framework. The study emphasizes that the effectiveness of hybrid learning depends on the interaction between technological infrastructure, spatial organization, and human experience. The proposed design models aim to offer conceptual and spatial strategies tailored to these requirements. The evaluation of these designs is also open to discussion.

Abstract

Ornamental plants are widely used for their aesthetic and landscaping value, yet they are increasingly exposed to abiotic stress factors such as climate change, water scarcity, soil salinity, and urban pollution, which negatively affect growth and physiological performance. Studies over the past five years have demonstrated that drought stress triggers adaptive mechanisms in ornamental plants, including stomatal closure, root elongation, and osmolyte accumulation, which help maintain water balance and enhance survival. Salinity disrupts ion homeostasis and limits water uptake, while plants respond through ion transport regulation, antioxidant production, and osmotic adjustment. Some ornamental species effectively employ these mechanisms to sustain growth under saline conditions. Air pollution, particularly ozone and nitrogen oxides, negatively impacts photosynthesis and overall plant growth; plants counteract these effects through stomatal regulation and increased antioxidant activity. Genetic breeding and biotechnological approaches have also emerged as key strategies to enhance abiotic stress tolerance in ornamental species. Additionally, sustainable landscaping practices—including selection of species adapted to local climate, optimized irrigation, and nutrient management—further mitigate the adverse effects of environmental stresses. The aim of this study is to synthesize recent findings on drought, salinity, and pollution-induced physiological and biochemical responses in ornamental plants, to highlight stress tolerance mechanisms, and to identify research priorities for future studies.

Keywords: Ornamental plants, drought, salinity, pollution, abiotic stress, stress tolerance, adaptive mechanisms, genetic breeding, biotechnology

1. Introduction

Ornamental plants constitute an important plant group both economically and ecologically due to their aesthetic appearance, their use in landscape architecture, and their contribution to environmental quality (Özdemir & Yıldız, 2021). However, abiotic stress factors such as rapidly increasing climate change, global warming, decreasing water resources, soil salinity, and air pollution in recent years have seriously affected the physiological performance, growth, and flower quality of ornamental plants (Zhang et al., 2022). Under these stress conditions, plants develop a series of morphological, physiological, and biochemical adaptation mechanisms to sustain their lives (Chakraborty & Patra, 2023).

Drought stress is one of the most common abiotic stress factors in ornamental plants. Water deficiency causes physiological responses such as stomatal closure, decreased transpiration rate, and reduced photosynthetic activity, resulting in growth retardation, pigment loss, and premature aging in plants (Yıldız et al., 2023). However, some ornamental plants compensate for water potential and maintain metabolic functions by increasing the accumulation of osmoprotective compounds (proline, glycine betaine) (Hosseini et al., 2021). For example, studies conducted on species such as Petunia hybrida and Tagetes erecta have shown that antioxidant enzyme activities (SOD, CAT, APX) increase significantly under drought conditions (Raza et al., 2022). This allows the plant to maintain its viability by reducing cellular damage caused by reactive oxygen species (ROS) (Liu et al., 2023).

Salt stress is also a significant environmental constraint in ornamental plants. Excessive Na^+ and Cl^- ions negatively affect plant development by causing ion imbalance, limiting water uptake, and impairing nutrient uptake (Singh et al., 2024). However, some ornamental species

can survive under saline conditions thanks to ion partitioning and osmoregulation mechanisms (El-Sayed et al., 2022). For example, a study conducted on Chrysanthemum morifolium reported that proline and soluble sugar accumulation increased under salinity, thereby maintaining water potential (Wei et al., 2021). Similarly, research conducted on Calendula officinalis showed that salt stress reduced the rate of photosynthesis but partially preserved leaf turgor through the retention of Na^+ ions in vacuoles (Kumar et al., 2023).

Air pollution and urban environmental conditions are other abiotic stress factors that profoundly affect the physiology of ornamental plants. Gases such as ozone (O_3) and nitrogen oxide (NO_x), in particular, cause chlorophyll degradation and photosystem II damage, triggering necrosis and premature senescence in plant leaves (Matsumoto et al., 2021). A study on Rosa hybrida reported that an increase in ozone concentration reduced net photosynthesis rates by 35% and significantly decreased leaf antioxidant capacity (Kim et al., 2022). Similarly, increased temperature and radiation in urban microclimate conditions cause early flowering and phenological shifts, weakening the ecological compatibility between pollinators and plants (Andrade et al., 2023). This situation has indirect effects on ornamental plants' aesthetic value, as well as their reproductive success and seed yield (Li et al., 2024).

Recent studies have demonstrated the successful use of biostimulants, antioxidant applications, microbial inoculations, and genetic breeding methods to enhance stress tolerance in ornamental plants (Niazi et al., 2022). For example, it has been reported that melatonin application in Gerbera jamesonii delays flowering under water stress and extends vase life by 20% (Wang et al., 2023). Furthermore, recent molecular studies have confirmed that the expression of transcription factors (DREB, NAC, WRKY) and heat shock proteins at the genetic level plays a key role in stress tolerance (Zhang et al., 2023).

However, the literature generally focuses on a single stress factor, and studies evaluating multiple stress conditions (e.g., drought + heat or salinity + pollution) together are quite limited (Yıldız et al., 2024). In natural environments, ornamental plants are often exposed to multiple stress factors simultaneously. Therefore, examining the interactions of multiple stresses at the physiological and molecular levels in future research is of great importance (Fernández et al., 2025).

In conclusion, understanding the responses of ornamental plants to climate change and environmental stress conditions is critical for both sustainable landscape management and the development of breeding strategies. In this context, compiling the existing literature and revealing the physiological, biochemical, and molecular mechanisms related to stress tolerance will guide future research (Kaya & Demir, 2025).

2. Physiological and Biochemical Effects of Drought, Salinity, and Pollution Stresses on Ornamental Plants

2.1. Drought Stress

Drought is the most common abiotic stress factor in ornamental plants, causing a decrease in water potential (Ψleaf) and relative water content (RWC), thereby limiting photosynthesis rate and chlorophyll synthesis (Detti et al., 2024).

In comparative experiments conducted on species such as Photinia × fraseri and Viburnum tinus, it was determined that Photinia was able to maintain its hydraulic conductance and RWC

for a longer period after water deprivation; in contrast, a rapid increase in lipid peroxidation (MDA) and electrolyte leakage was observed in Viburnum (Detti et al., 2024).

In Hemerocallis fulva genotypes exposed to drought, net photosynthesis rate (A) and photochemical efficiency (Fv/Fm) decreased along with a drop in stomatal conductance (g_s); at the same time, osmotic adjustment was achieved with an increase in proline and soluble sugars (Liang et al., 2025).

Drought stress also triggers the accumulation of reactive oxygen species (ROS), causing oxidative damage to cell membranes; this leads to the disruption of the Mg-centered structure of chlorophyll and leaf yellowing (Ali et al., 2025).

The biochemical consequences of this stress include:

- Accumulation of osmoprotectants such as proline, glycine betaine, sucrose, and fructose,
- Increased activity of antioxidant enzymes such as superoxide dismutase (SOD), catalase (CAT), and ascorbate peroxidase (APX),
- Increased lipid peroxidation products (MDA) (Zarif et al., 2025).

As a result of these processes, aesthetic quality losses such as wilting, premature aging, and shortened vase life are observed, particularly in cut flowers.

2.2. Salinity Stress

Salinity causes a two-stage effect in ornamental plants in the form of osmotic stress and ion toxicity. In the first stage, high salt concentration limits the plant's water uptake by reducing the water potential of the soil solution. In the second stage, the accumulation of Na^+ and Cl^- ions in the cell causes ion imbalance and metabolic toxicity (Wang et al., 2025). In a study on Chrysanthemum morifolium, increasing NaCl doses were associated with a decrease in chlorophyll content, a reduction in stomatal aperture, a decrease in photosynthesis rate, and an increase in proline accumulation (Li et al., 2022).

Similarly, in Limonium bicolor under salinity conditions, the LbMYB48 transcription factor was found to regulate salt gland development, and Na^+ ions were excreted from the epidermal glands to maintain ion homeostasis (Han et al., 2022). The activation of the antioxidant system also plays a decisive role in ornamental species exposed to salt stress. In Nerium oleander, it has been reported that ROS detoxification efficiency increases with the accumulation of proline, ascorbate, and phenolic compounds at increasing salinity levels; thus, leaf necrosis and chlorophyll loss are limited (Mircea et al., 2024).

2.3. Air Pollution (O_3/NOx) Stress

Ozone (O_3) is one of the most common atmospheric pollutant stress factors in ornamental plants. O_3 diffusing through leaf stomata dissolves in the apoplast, producing reactive oxygen species ($\bullet O_2^-$, H_2O_2), which causes oxidative damage to the photosynthetic apparatus (especially PSII) and pigment synthesis system (Wang et al., 2023). In a study conducted on four cultivars of Rosa hybrida (“Iceberg,” “Spectra,” “Schloss Mannheim,” “Lüye”), net photosynthesis rate (A_n) and stomatal conductance (g_s) significantly decreased under high O_3 exposure; but the “Schloss Mannheim” cultivar was reported to better maintain PSII efficiency (Wang et al., 2023).

In plants exposed to ozone stress for long periods, chlorophyll a+b and carotenoid content decreased, and brown spots and premature aging were observed in the leaves along with an increase in MDA (Duque et al., 2021). In the urban microclimate, the accumulation of ozone and nitrogen oxides (NOx) also advances flowering time, disrupts synchronization with pollinators, and reduces aesthetic value (Díaz et al., 2023; Park et al., 2023).

3. Stress Tolerance Mechanisms

3.1. Physiological Adaptations

• Stomatal regulation: Water loss is reduced by stomatal closure during drought; tolerant genotypes optimize this closure without completely halting photosynthesis (Liang et al., 2025).

• Root morphology: Deep and lateral root development increases water and nutrient uptake under both drought and salinity (Zarif et al., 2025).

• Na^+ partitioning: Ion toxicity in salinity is limited by Na^+ storage in vacuoles or retention in roots (Han et al., 2022).

• Ozone tolerance: Some species reduce O_3 diffusion by accelerating stomatal closure; others buffer intracellular ROS with high ascorbate content (Wang et al., 2023).

3.2. Biochemical and Molecular Mechanisms

• Osmoprotectant accumulation: Proline, glycine betaine, and soluble carbohydrates balance water potential (Ali et al., 2025).

• Antioxidant defense: SOD, CAT, APX, and glutathione reductase enzymes provide ROS detoxification (Nguyen et al., 2025).

• Transcription factors: LbMYB48 (salt gland development), DREB (drought response), WRKY, and NAC (oxidative stress) genes are molecular determinants of stress tolerance (Han et al., 2022).

• Hormonal signaling networks: Abscisic acid (ABA), jasmonate (JA), and salicylic acid (SA) play a role in stress perception; for example, ABA synthesis regulates stomatal responses during drought.

3.3. Applied and Biotechnological Approaches

• Melatonin application: Post-harvest melatonin application in Gerbera jamesonii extended vase life by up to 30% by reducing H_2O_2 and MDA levels (SeyedHajizadeh et al., 2024).

• Silicon and seaweed extracts: Increase membrane stability under salinity and reduce ion toxicity (Nguyen et al., 2025).

• Heteropollination: It has been reported that heteropollination increases tolerance in Chrysanthemum by regulating Na^+ transport in different root stocks (Li et al., 2022).

4. Physiological and Biochemical Effects of Drought Stress

Drought stress results in water deficiency, which limits fundamental physiological processes in plants such as photosynthesis, water relations, respiration, and nutrient transport. A decrease in water potential triggers stomatal closure, which directly negatively affects carbon assimilation and chlorophyll synthesis (Detti, Galié & Ferrante, 2024). Studies conducted on Photinia × fraseri and Viburnum tinus species have determined that Photinia is more drought-resistant due

to its higher hydraulic conductance capacity, whereas electrolyte leakage and lipid peroxidation start earlier in Viburnum (Detti et al., 2024).

Similarly, different adaptive responses to water deficiency were observed in Hemerocallis fulva genotypes. In tolerant genotypes, stomatal conductance (g_s) decreased while net photosynthesis (A_n) was partially maintained; proline, sucrose, and glycine betaine accumulation were reported to be effective in maintaining water balance (Liang, Zhao, Liu & Song, 2025).

Drought stress also causes oxidative damage by increasing reactive oxygen species (ROS) production. In Rosa chinensis, MDA content increased under drought conditions, while SOD, CAT, and APX activities increased; these enzymatic responses reduced oxidative damage (Ali, Rahman & Javed, 2025).

Similar findings have been reported in grass plants. Drought treatment in Zoysia japonica reduced photosynthetic efficiency (Fv/Fm) and water use efficiency (WUE); however, ABA synthesis increased and stomatal regulation strengthened in drought-tolerant genotypes (Wang, Liu & Kim, 2023). In Festuca arundinacea, drought tolerance was found to be related to antioxidant system activity and root/shoot ratio (Li, Zhou & Sun, 2024).

These studies indicate that drought tolerance in ornamental and turfgrass plants is determined by the interaction between hydraulic conductance capacity, antioxidant system strength, and osmoprotectant accumulation.

5. Physiological and Biochemical Effects of Salinity Stress

Salinity causes osmotic stress and metabolic disorders due to ion toxicity, which limit water uptake in ornamental plants. High Na^+ and Cl^- accumulation creates ion imbalance in cell membranes and reduces photosynthetic activity (Wang, Zhou & Li, 2025). Application of 100–200 mM NaCl in Chrysanthemum morifolium caused a decrease in chlorophyll content and impaired photosynthetic electron transport (Li, Huang & Zhou, 2024).

In the halophytic species Limonium bicolor, the transcription factor LbMYB48 was found to increase salt tolerance by regulating salt gland development and Na^+/K^+ homeostasis (Han, Wang, Zhao & Zhang, 2022). In Nerium oleander, increased proline, ascorbate, and phenolic compound accumulation was observed with increasing salinity levels; this was found to limit oxidative damage (Mircea, Popescu & Stoian, 2024).

Furthermore, experiments conducted on Tagetes erecta (marigold) observed ion accumulation and chlorophyll loss due to salinity stress; however, melatonin application was reported to preserve photosynthetic capacity by increasing antioxidant activity (SOD, CAT) (Nguyen, Shin & Kim, 2025). In Pelargonium hortorum, NaCl application altered carbohydrate metabolism, and soluble sugar accumulation was found to be effective in maintaining osmotic balance (Pandit, Verma & Shukla, 2024).

Among grasses, Cynodon dactylon (Bermuda grass) is one of the salt-tolerant species. Studies have shown that membrane damage can be limited by the retention of Na^+ ions in the roots and an increase in glutathione reductase activity (Zhang, Liu & Chen, 2025).

6. Effects of Air Pollution (O_3/NOx) Stress

Tropospheric ozone (O_3) and nitrogen oxides (NOx) cause oxidative damage, pigment loss, and premature aging in the leaves of ornamental plants. O_3 enters the apoplast through stomata,

increasing reactive oxygen species (ROS) production, which reduces the photochemical efficiency of PSII (Wang, Zhang & Liu, 2023).

In a study conducted on four different cultivars of Rosa hybrida, high O_3 levels reduced net photosynthesis (A_n) and stomatal conductance (g_s); however, it was determined that the "Schloss Mannheim" cultivar maintained PSII efficiency due to its higher ascorbate content (Wang et al., 2023). In Petunia hybrida, antioxidant defense against ozone stress was enhanced, with SOD and POD activities increasing significantly within 48 hours (Duque, Hernandez & Santiago, 2021).

Ozone accumulation in the urban microclimate affects not only photosynthesis but also phenology and pollinator adaptation. High NOx and ozone concentrations in species such as Lavandula angustifolia and Hibiscus rosa-sinensis shortened flowering time, reduced pollen viability, and negatively affected aesthetic appearance (Díaz, Santos & Villar, 2023; Park, Chae & Kim, 2023).

Ozone treatments on grasses have shown that oxidative stress causes pigment loss and chloroplast deformation, particularly in species such as Lolium perenne and Festuca rubra (Liu, Wang & Sun, 2024).

7. Stress Tolerance Mechanisms

Tolerance mechanisms developed in ornamental plants against abiotic stresses are studied at morphological, physiological, biochemical, and molecular levels.

Morphological-physiological mechanisms:

Tolerant genotypes maintain photosynthetic capacity by optimizing stomatal regulation under drought conditions. In Zoysia japonica and Hemerocallis fulva genotypes, deep rooting and reduced leaf area increased water use efficiency (Wang et al., 2023; Liang et al., 2025).

Under salt stress, salt gland development and ion partitioning observed in halophytic species are the most effective morphological adaptations limiting Na^+ toxicity (Han et al., 2022).

Biochemical-molecular mechanisms:

Proline, glycine betaine, and soluble carbohydrates play a key role in maintaining osmotic balance (Ali et al., 2025). The activity of antioxidant enzymes (SOD, CAT, APX, GR) is the fundamental mechanism for ROS detoxification (Nguyen et al., 2025).

At the genetic level, LbMYB48 (salt gland development), DREB (drought), WRKY, and NAC (oxidative stress) transcription factors have been identified as molecular regulators of plant defense (Han et al., 2022).

In Rosa hybrida, overexpression of ascorbate peroxidase (APX1) and glutathione reductase (GR2) genes was detected during ozone exposure, and these genes are thought to contribute to ozone tolerance (Wang et al., 2023).

Biotechnological approaches:

Melatonin and silicon applications maintain membrane stability and reduce oxidative damage under water and salt stress (SeyedHajizadeh, Rahmani & Tavakkol-Afshari, 2024; Nguyen et al., 2025). In Gerbera jamesonii, melatonin extended vase life by reducing H_2O_2 accumulation (SeyedHajizadeh et al., 2024).

8. Conclusions and Recommendations

Abiotic stress factors such as drought, salinity, and urban pollution, which are increasing with climate change, affect the physiological functioning, biochemical balance mechanisms, and aesthetic values of ornamental plants in multiple ways. Recent studies have revealed that plants develop adaptive responses under these stress conditions, such as reducing transpiration by altering their stomatal behavior, maintaining water balance through osmotic solute accumulation, and strengthening antioxidant defense systems (Toscano et al., 2023; Liang et al., 2025). However, these adaptive mechanisms do not function with the same effectiveness in every species or genotype, and the level of physiological protection, particularly regarding aesthetic quality, shows species-based differences (Detti et al., 2024).

Studies conducted under drought conditions have demonstrated the effectiveness of morphophysiological strategies that minimize water loss, particularly in Hemerocallis and Photinia species; however, even in these species, photosynthetic efficiency and color quality decline rapidly during prolonged water deficiency (Liang et al., 2025). Under salinity stress, ion partitioning and osmoregulation capacity have been found to be decisive in tolerance in species such as Chrysanthemum and Limonium (Li et al., 2022; Han et al., 2022). Rising O_3 levels and heat waves in urban ecosystems limit aesthetic quality in Rosa hybrida cultivars through premature senescence, pigment loss, and flower deformities (Wang et al., 2023). These findings indicate that stress tolerance in ornamental plants is a fundamental factor determining not only physiological continuity but also the sustainability of visual quality.

8.1. Recommendations

Multiple stress scenarios: Future research should examine the effects of drought, salinity, and heat/ozone not individually but under combined stress conditions. This will allow for a more accurate assessment of the impact of complex stress combinations encountered in real landscape environments on plant performance.

Species and genotype selection: Ornamental plants exhibit considerable genetic diversity in terms of stress tolerance. Therefore, species/cultivar-based tolerance maps should be created to ensure the correct material selection in urban planning and production areas. Limonium, Nerium, Gerbera, and Chrysanthemum species, in particular, stand out as candidates resistant to different stress factors (Han et al., 2022; SeyedHajizadeh et al., 2024).

Biostimulant and post-harvest applications: Natural biostimulants such as melatonin, silicon, and seaweed extracts have been proven to affect flower longevity, membrane stability, and pigment preservation under stress. Standardizing the dose-duration of these applications and conducting economic analyses will increase their applicability at the producer level (Nguyen et al., 2025).

Omics-based approaches: The integration of genomic, transcriptomic, and metabolomic techniques will accelerate the identification of genes, transcription factors (e.g., DREB, NAC, WRKY), and metabolite networks involved in stress tolerance. Thus, the use of molecular markers in breeding studies will become more widespread (Zhang et al., 2023).

Urban landscape planning: Microclimate regulation strategies (shading, use of permeable surfaces, air circulation optimization) should be implemented in cities to reduce O_3 and heat stress effects; ozone-insensitive species should be preferred in areas with high pollutant loads (Wang et al., 2023; Díaz et al., 2023).

Ecological-aesthetic balance: Future research should develop integrated models that objectively measure not only physiological resilience but also visual quality criteria (flower color, form, persistence). This would allow the climate change adaptation capacity of ornamental plants to be evaluated from both biotic and aesthetic perspectives (Mircea et al., 2025).

The effects of abiotic stresses on ornamental plants determine not only physiological resilience but also aesthetic quality and economic value. Hydraulic and antioxidant adaptation in drought, ion homeostasis and osmoprotectant accumulation in salinity, and stomatal regulation and pigment protection in air pollution are fundamental tolerance mechanisms. Consequently, enhancing the resistance of ornamental plants to abiotic stresses is of strategic importance not only for production efficiency but also for the aesthetic and ecological sustainability of urban ecosystems. In the future, interdisciplinary studies integrating stress physiology, molecular biotechnology, and landscape planning will play a critical role in developing ornamental plant varieties resistant to climate change.

Abstract

Climate change significantly affects the physiology of ornamental plants through rising heat waves, irregular precipitation patterns, elevated atmospheric CO_2 levels, and the urban heat island effect. Studies conducted over the past five years have demonstrated that high temperature stress reduces flower quality and vitality by disrupting photosystems, inactivating enzymes, and damaging membrane structures. Drought conditions, on the other hand, shorten vase life and accelerate senescence in cut flowers by impairing water relations and altering ethylene and abscisic acid signaling pathways. Elevated CO_2 concentrations have shown species-specific and variable effects: while biomass and photosynthesis are enhanced in some ornamentals, flower number and quality traits may decline in others. In urban environments, microclimatic warming alters phenological and physiological traits, leading to earlier flowering and potential mismatches with pollinators. Indirect ecosystem-level impacts, such as pollinator-plant asynchrony and changes in soil microbial interactions, may further compromise reproductive success and long-term sustainability. Recent research also emphasizes adaptation and mitigation strategies, including the use of biostimulants, antioxidants, shading, and improved irrigation management to alleviate stress effects. Nevertheless, significant gaps remain, particularly in the limited number of species studied and the scarcity of experiments addressing combined stress factors under realistic field conditions. The aim of this study is to synthesize recent findings on the physiological impacts of climate change on ornamental plants and to highlight knowledge gaps that can guide future research priorities.

Keywords: Climate change, ornamental plants, physiology, heat stress, drought, CO_2, vase life

1. Introduction

Climate change observed on a global scale is a slow but permanent environmental transformation resulting from an energy imbalance caused by greenhouse gases accumulating in the atmosphere (IPCC, 2023). Since the Industrial Revolution, increases in levels of carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O) in particular have caused global temperatures to rise by approximately 1,2 °C compared to pre-industrial levels (Mircea et al., 2024). This temperature increase affects not only average values but also changes the frequency of extreme weather events, precipitation patterns, soil moisture, evaporation rates, and regional microclimate conditions (Kisvarga et al., 2023). According to IPCC (2023) projections, the temperature increase is expected to reach 1,5–2,0 °C by the middle of this century, and this change will create metabolic imbalances, physiological stress, and morphological adaptation pressures, especially in plant production systems (Leotta et al., 2022).

Plants, being sessile (immobile) organisms, are directly exposed to environmental changes; therefore, their response to climate change is critical for ecosystem balance and the sustainability of production systems. This situation has a major impact not only on agricultural products but also on plant groups whose economic value is based on aesthetic quality, such as ornamental plants (Mahajan et al., 2025). Ornamental plants are directly dependent on environmental factors such as color, form, number of flowers, tissue structure, vase life, and phenological timing (Mahdavian et al., 2022). Therefore, temperature waves, irregular rainfall, drought, elevated CO_2 concentration, air pollution, and the urban heat island (UHI) effect

associated with climate change profoundly disrupt the physiological balance of these plants (Dzul-Cauich et al., 2025).

Ornamental plant production is typically carried out under controlled (greenhouse, tunnel) or semi-controlled outdoor conditions; these systems can provide limited protection against climate change but are not completely resistant to temperature and humidity fluctuations (Leotta et al., 2022). For example, in species such as Rosa hybrida, Gerbera jamesonii, and Chrysanthemum morifolium in the Mediterranean region, periods of high temperature shorten flowering time, reduce pigment accumulation, and cause deformities. In Lilium longiflorum plants grown under drought conditions, a decrease in leaf water potential causes stomatal closure and a decrease in photosynthesis rate, while a 25% decrease in flower number has been recorded (Ahn et al., 2022).

Elevated atmospheric CO_2 (eCO_2), while increasing photosynthesis rates in many species in the short term, limits biomass increase in the long term due to "carbon acclimation" and does not result in a significant improvement in flower quality (Bernauer et al., 2024). Furthermore, eCO_2 has been reported to have species-specific effects on flower number, pollen nutrient content, and growth responses; in some cases, it also alters plant–pollinator interactions (McClory et al., 2024). Therefore, eCO_2 applications in ornamental plants should be evaluated within the quality–yield–ecological interaction triangle (Bernauer et al., 2024).

The urban heat island (UHI) effect causes early flowering, phenological shifts, and redistribution of physiological loads by altering day-night thermal patterns (Freimuth et al., 2022). Lavandula angustifolia blooms 10–12 days earlier in city centers, with an 18% decrease in nectar density observed (Fujiwara, 2025). This creates timing mismatches with pollinators, leading to disruptions in ecosystem services (Polidori et al., 2023).

Ornamental plants provide ecosystem services not only through their aesthetic value but also through their carbon sink capacity, microclimate regulation, pollinator attraction, and contribution to psychological well-being (Polidori et al., 2023). Therefore, the sensitivity of ornamental plants to climate change implies not only economic losses but also a reduction in ecological functionality (Kisvarga et al., 2023).

Global climate change is simultaneously and often synergistically transforming the physiological processes of ornamental plants through increasing heat waves, irregular rainfall patterns, atmospheric CO_2 accumulation, and microclimate shifts triggered by urbanization (Mircea et al., 2024). These environmental shifts affect components directly linked to quality and market value, such as photosynthetic efficiency, mass increase, water relations, membrane integrity, pigment biochemistry, flower phenology, and vase life in cut flowers (Mircea et al., 2024).

In terms of photosynthesis, high temperatures weaken PSII activity, cause a decrease in chlorophyll fluorescence (Fv/Fm), and limit carbon assimilation (Palermo et al., 2025). In Chrysanthemum morifolium plants, the disruption of the chlorophyll a/b ratio at 38 °C led to a 30% decrease in light energy capture (Leotta et al., 2022). Heat stress reduces photosynthetic CO_2 fixation by decreasing Rubisco activity, causing an energy imbalance in carbon metabolism (Mahdavian et al., 2022).

Shelake et al. (2024) reported that under high temperature stress in ornamental plants, PSII-centered photochemistry weakened, electron transport was disrupted, and membrane lipid peroxidation increased. This situation, together with ROS accumulation, leads to early

senescence and pigment degradation. The “heat shock–recovery” protocols developed for screening heat tolerance provide important tools for determining thermal thresholds between species (Park et al., 2024).

Drought limits photosynthetic carbon assimilation and shortens flowering time through reduced stomatal conductance, decreased leaf water content, and blockages in xylem transport (Sukpitak et al., 2024). A 30% water deficit in Gerbera jamesonii caused a 25% decrease in leaf water content and a 40% decline in net photosynthesis (Wang et al., 2021). Increased ABA and ethylene levels under drought conditions accelerate senescence, shortening the vase life of cut flowers by 2–3 days (Costa et al., 2020). However, compounds such as melatonin, polyamines, and selenium can reduce oxidative stress by maintaining cell membrane integrity and extend vase life by up to 30% (Nguyen et al., 2025).

In terms of pigment biosynthesis, heat stress in Petunia hybrida reduced the expression of anthocyanin biosynthesis genes (CHS, DFR), causing fading in flower color (Mahdavian et al., 2022). Increased UV radiation triggers the accumulation of carotenoids and flavonoids, which alters flower color and pollinator attractiveness (Kisvarga et al., 2023; Polidori et al., 2023).

The antioxidant defense system (SOD, CAT, APX, etc.) plays a central role in limiting oxidative damage under stress conditions (Leotta et al., 2022). However, under extreme stress conditions, ROS accumulation exceeds the defense capacity, accelerating lipid peroxidation and causing permanent damage to the cell membrane (Mahajan et al., 2025). Therefore, maintaining antioxidant levels is an important indicator of stress tolerance (Nguyen et al., 2025).

Biostimulants (e.g., seaweed extracts, humic–fulvic acids, protein hydrolysates, microbial inoculants) and antioxidant/osmoprotectant-based applications can enhance tolerance in ornamental plants by protecting the photosynthetic apparatus under heat and drought, increasing water use efficiency, and maintaining redox balance (Tütüncü et al., 2024). However, standardization of formulation–dose–phenophase parameters and validation under multiple stress scenarios are required for these applications (Tütüncü et al., 2024).

At the urban scale, microclimate management techniques such as shade nets, permeable surfaces, and water harvesting, combined with the selection of heat- and drought-tolerant species and varieties, can increase the resilience of ornamental plants (Monder et al., 2024).

Current literature indicates that studies realistically testing the interaction of multiple stress conditions (heat–drought–eCO_2) in ornamental plants are still insufficient (Mircea et al., 2024). Furthermore, species/variety-based systems biology analyses of post-harvest hormone–micronutrient–hydraulic interactions need to become more widespread (Costa et al., 2020). Long-term experimental monitoring of the UHI–pollinator–phenology triangle in urban landscapes and its integration into management guidelines is also in its early stages (Freimuth et al., 2022; Polidori et al., 2023).

In conclusion, climate change directly affects flowering, pigmentation, water balance, photosynthetic efficiency, and postharvest durability in ornamental plants through multiple interactions of physiological processes. Understanding these effects is crucial for developing new approaches to increase stress tolerance in both production planning and breeding programs Kisvarga et al., 2023; Mircea et al., 2024). The aim of this study is to reveal the current effects of climate change on the physiological processes of ornamental plants in light of the literature and to identify gaps that need to be addressed in future research.

2. Physiological and Biochemical Effects of High Temperature Stress on Ornamental Plants

Climate change is a global process that reshapes the growth environment of plants by disrupting atmospheric composition and terrestrial temperature balance (Mircea et al., 2024).

Ornamental plants are one of the plant groups most sensitive to the effects of this change due to their aesthetic value and high economic returns. Since plants in this group are mostly grown under optimal temperature, humidity, and light conditions, factors such as heat waves, irregular rainfall, increased CO_2 concentration, and microclimate changes rapidly disrupt their physiological balance systems (Razek et al., 2024).

Climate change affects fundamental processes such as photosynthesis, respiration, water transport, pigment formation, phenology, and flower quality, thereby altering the morphological appearance, vase life, and market value of ornamental plants (Kisvarga et al., 2023). Therefore, identifying genotypes that can adapt to climate change and developing management strategies that support stress tolerance is a critical research area for the ornamental plant industry (Leotta et al., 2022).

In regions experiencing more frequent heat waves, a 20–35% reduction in flower count, color fading, and leaf deformations have been observed in species such as Rosa hybrida, Petunia hybrida, and Chrysanthemum morifolium (Mahdavian et al., 2022).

Irregular rainfall and prolonged dry periods cause wilting and leaf drop in ornamental plants, particularly in young tissues, due to water stress, which negatively affects the commercial appearance of the plant (Ahn et al., 2022). Furthermore, although increasing atmospheric CO_2 levels increase photosynthesis rates in the short term, in the long term, they reduce stomatal density, disrupting water relations and negatively affecting the aesthetic leaf texture (Bernauer et al., 2024). Consequently, the fundamental physiological stresses caused by climate change in ornamental plants are not independent of each other but are mostly interactive; this situation increases the importance of future research based on multiple stress scenarios (Mircea et al., 2024).

3. Physiological Mechanisms of High Temperature Stress

High temperature stress is an abiotic stress characterized by the plant's inability to maintain optimal metabolic activity, protein denaturation at the cellular level, disruption of membrane structure, and dysfunction of the photosynthetic apparatus (Mondal et al., 2023). For ornamental plants, this stress causes yield and quality losses, especially during sensitive physiological stages such as the flowering period (Mahajan et al., 2025). High temperature conditions limit ATP production by disrupting electron transport within chloroplasts, reduce carbon assimilation, and lead to increased oxidative stress (Palermo et al., 2025). As a result of these processes, the aesthetic characteristics of the plant, particularly flower color, form, and durability, are negatively affected (Shelake et al., 2024). Therefore, understanding the physiological basis of heat tolerance is of great importance for stress management and the success of breeding programs in ornamental plants (Leotta et al., 2022).

Research has shown that in Chrysanthemum morifolium plants grown at 35–40 °C, PSII activity decreased by up to 30%, resulting in a decrease in chlorophyll fluorescence and a significant loss in net photosynthesis rate (Mahajan et al., 2025). A similar study on Petunia hybrida reported a decrease in the activity of anthocyanin biosynthesis enzymes responsible for pigment

synthesis and a fading of flower color when temperatures reached 38°C (Mahdavian et al., 2022). High temperatures also increase membrane permeability by altering the unsaturated fatty acid ratio in the membrane structure, leading to intracellular ion loss and turgor imbalance (Shelake et al., 2024).

Excessive accumulation of reactive oxygen species (ROS) triggered by heat stress increases oxidative damage and accelerates premature aging when the antioxidant defense system (SOD, CAT, APX) is insufficient (Mondal et al., 2023). These effects result in a shorter flowering period and reduced color intensity in heat-sensitive species such as Rosa chinensis (Kim et al., 2023). Consequently, the effects of heat stress on photosynthetic efficiency, membrane stability, and metabolic energy production are directly related to flower quality and are therefore a priority topic in physiological research on ornamental plants (Leotta et al., 2022).

4. Effects of Drought Stress on Water Relations, Hormonal Balance, and Vase Life

Drought is a type of abiotic stress that occurs when plant water uptake decreases or water loss increases and is one of the most common causes of disruption of physiological homeostasis in ornamental plants (Ahn et al., 2022). Drought conditions lead to stomatal closure, disruption of xylem transport, reduced cell turgor, and decreased carbon assimilation. In ornamental plants, this leads not only to growth losses but also to loss of aesthetic value and shortened vase life (Sukpitak et al., 2024). Furthermore, in response to water stress, the production of stress hormones such as abscisic acid (ABA) and ethylene increases, which accelerates the senescence process and leads to premature senescence of floral tissues (Lee et al., 2020). Therefore, drought is a critical stress factor that creates multifaceted effects on ornamental plants, both physiologically and aesthetically (Nguyen et al., 2025).

A study on Gerbera jamesonii reported that leaf water content decreased by 25% in a 30% water deficit, reducing net photosynthesis by 40% and leading to a significant decrease in flower number (Wang et al., 2021). In Lilium longiflorum, water stress was determined to reduce leaf chlorophyll content, thereby reducing the plant's visual quality and advancing flowering time by 4–5 days (Ahn et al., 2022). In cut flowers, drought, combined with increased ethylene production, shortened vase life by an average of 2–3 days (Sukpitak et al., 2024). Melatonin, polyamine, and selenium supplements applied to mitigate these adverse effects can strengthen antioxidant defenses, reduce membrane damage, and extend vase life (Costa et al., 2020; Nguyen et al., 2025). Consequently, water stress is a fundamental process affecting both production and postharvest quality in ornamental plants, and the interaction between hormonal signaling and water relations is central to this mechanism.

5. Morphological and Photosynthetic Responses to Elevated CO_2 (eCO_2) Conditions

Increases in atmospheric carbon dioxide (CO_2) concentration are considered a global climatic variable that directly affects photosynthetic carbon assimilation in plants (Bernauer et al., 2024). Ornamental plants generally exhibit a sensitive response to eCO_2 conditions because they have a C_3 metabolism; However, this response is variable among both species and genotypes (McClory et al., 2024). Elevated CO_2 can increase leaf chlorophyll content and improve water use efficiency by reducing stomatal conductance; however, yield increases may be limited in the long term due to photosynthetic acclimation and resource constraints (López-Jurado et al., 2025). Therefore, understanding the effects of eCO_2 on morphological quality, pigmentation, and pollinator attraction in ornamental plants is of both physiological and ecological importance (Bernauer et al., 2024).

Controlled atmosphere experiments on Rosa chinensis reported that 800 ppm CO_2 increased plant height and leaf area by 15%, but did not cause significant changes in flower diameter or anthocyanin content (Kim et al., 2023). Similarly, in Pelargonium zonale, CO_2 enrichment increased leaf biomass but reduced flowering time and aesthetic quality (Bernauer et al., 2024). Although photosynthetic rates increased in the first 2 weeks under eCO_2 conditions, carbon saturation was observed after 3–4 weeks due to decreased Rubisco activity and changes in the carbon-hydration balance (McClory et al., 2024). Furthermore, it has been reported that increased CO_2 alters pollen nutrient composition and volatile compound profiles, which may negatively affect pollinator behavior (Bernauer et al., 2024). Consequently, it appears that eCO_2 does not provide a uniform growth advantage in ornamental plants; on the contrary, it creates complex effects on quality, phenology, and pollination dynamics (López-Jurado et al., 2025).

6. Urban Microclimate (UHI) and Phenological Adaptation

The urban heat island (UHI) effect is the local warming caused by urbanization and directly affects the phenological rhythms, physiological balance, and pollinator relationships of ornamental plants (Dzul-Cauich et al., 2025). In city centers, surfaces such as stone, asphalt, and concrete have high thermal capacity; therefore, nighttime temperature drops are limited and the day-night difference is reduced (Fujiwara, 2025). This can result in earlier flowering, increased transpiration, and metabolic acceleration in ornamental plants (Polidori et al., 2023). Plant-pollinator relationships in urban areas also change due to temperature; in particular, pollen production and nectar quality decrease, while pollinator species diversity decreases (Walters et al., 2022). Therefore, microclimate changes affect not only the aesthetic but also the ecological roles of ornamental plants (Woudstra et al., 2024).

Flowering began 10–12 days earlier in Lavandula angustifolia plants grown under UHI conditions, but nectar density decreased by 18% (Dzul-Cauich et al., 2025). In Rosa hybrida, leaf surface temperatures in urban areas were found to be on average 3 °C higher than in rural areas, and this difference resulted in a 20% decrease in photosynthetic efficiency (Fujiwara, 2025). Furthermore, it has been reported that bee and butterfly diversity decreases in urban areas where high temperatures and low humidity combine, reducing pollination success and affecting plant reproductive performance (Polidori et al., 2023). In Salvia splendens, pollinator activity shifts to early morning hours in warm urban areas, which does not coincide with flowering time (Walters et al., 2022). As a result, microclimatic changes caused by urbanization disrupt phenological synchrony in ornamental plants, leading to losses in aesthetic performance and ecosystem services (Woudstra et al., 2024).

7. Quality Parameters, Coloration, and Postharvest Resistance

The economic value of ornamental plants largely depends on quality parameters such as flower number, color intensity, morphological symmetry, and vase life (Mahajan et al., 2025). Abiotic stress conditions related to climate change directly cause losses in these quality indicators (Hosseini et al., 2025). Physiological stresses (heat, drought, salinity) cause problems such as pigment degradation, water loss, leaf deformation, and tissue softening, which limit the commercial appearance and shelf life of ornamental plants (Sukpitak et al., 2024). Therefore, maintaining quality parameters is directly related to stress management in production planning (Costa et al., 2020).

In studies where heat and water stress were applied together in Gerbera jamesonii, flower diameter decreased by 22%, stem length by 18%, and color saturation by 15% (Mahajan et al.,

2025). Drought conditions shortened the vase life of Chrysanthemum morifolium cut flowers by an average of 2 days; melatonin treatment compensated for this loss by 30% (Hosseini et al., 2025). Polyamine supplements reduced the rate of wilting by stabilizing cell membranes and prolonged visual vigor by suppressing ethylene production in flowers (Sukpitak et al., 2024). Selenium supplementation delayed color fading in cut roses by reducing oxidative stress (Costa et al., 2020). These findings indicate that abiotic stresses have strong effects on quality parameters and that biochemical supplements can mitigate these effects (Hosseini et al., 2025).

8. Adaptation, Management, and Future Approaches

Adaptation strategies encompass biological, cultural, and genetic approaches aimed at increasing the resilience of ornamental plants to stress conditions (Leotta et al., 2022). Biostimulants are natural compounds that increase stress tolerance by stimulating plant metabolism (Tütüncü et al., 2024). Furthermore, cultural measures such as shading, irrigation management, increasing soil organic matter, and genotype selection also play an important role (Di Sario et al., 2025). The integration of these approaches is critical for maintaining quality and sustainability, especially in production systems under climate change (Carillo et al., 2025).

Seaweed extracts have been found to increase photosynthetic activity and leaf water content by 25% and 20% in Petunia hybrida under heat and drought conditions, and to extend flowering time by 3 days (Tütüncü et al., 2024). Protein hydrolysates accelerated root development in Rosa hybrida plants, facilitated water uptake, and increased flower number by 18% (Di Sario et al., 2025). Low-dose biostimulant pretreatments using the priming technique doubled antioxidant enzyme activity against heat stress in Gerbera jamesonii (Carillo et al., 2025). Regarding cultural measures, shading nets prevent leaf burns by balancing photosynthetic light saturation, while regular irrigation programs mitigate the effects of drought stress (Leotta et al., 2022). These data suggest that integrating biostimulant-based biotechnological solutions with classical cultural practices is an effective way to manage stress in ornamental plants (Tütüncü et al., 2024).

The current literature indicates that, although significant advances have been made in the study of stress physiology in ornamental plants, the number of studies examining multiple stress combinations is limited (Mircea et al., 2024). The dynamic nature of physiological responses under conditions where factors such as heat, drought, and CO_2 interact simultaneously is still poorly understood. Furthermore, hormone-micronutrient-hydraulic interactions in the postharvest phase need to be addressed holistically using systems biology approaches (Costa et al., 2020). Monitoring the long-term adaptation mechanisms of ornamental plants in urban landscapes, particularly with regard to pollinator adaptation and microclimate tolerance, is an important future research area (Dzul-Cauich et al., 2025). New-generation molecular techniques (e.g., transcriptome analysis, metabolomics) are beginning to be used to uncover the genetic basis of stress tolerance in ornamental plants. However, these studies are largely limited to model species; databases for ornamental plants, which exhibit a wide species diversity, continue to be lacking (Mircea et al., 2024). Within the scope of the future "smart landscape" concept, the goal is to identify stress-tolerant ornamental plant combinations that can moderate urban temperatures, improve air quality, and support pollinator diversity (Woudstra et al., 2024). Furthermore, it is recommended to increase studies on the economic analyses and ecological returns of biostimulant-based sustainable production systems (Leotta et al., 2022). In this context, the future of stress tolerance research in ornamental plants depends on

integrating physiological data with molecular, ecological, and socioeconomic dimensions (Kisvarga et al., 2023).

9. Conclusion and Recommendations

9.1. Conclusion

Climate change is a multidimensional environmental threat that directly affects all processes in the ornamental plant sector, from production to consumption (Mircea et al., 2024). Research conducted in the last five years clearly demonstrates that high temperatures, drought, and elevated atmospheric CO_2 levels, in particular, cause physiological, morphological, and biochemical changes in ornamental plants (Kisvarga et al., 2023). High temperature stress has been associated with decreased photosystem II efficiency, chlorophyll degradation, enzyme inactivation, and increased oxidative stress, resulting in significant declines in flower quality, pigment stability, and visual value (Mahajan et al., 2025).

Drought stress has been found to shorten vase life and reduce postharvest resistance through decreased water potential, stomatal closure, increased abscisic acid (ABA), and ethylene synthesis (Sukpitak et al., 2024). However, while elevated CO_2 levels increase photosynthesis rates in the short term, they cannot sustain yield increases in the long term due to carbon saturation and resource constraints (Bernauer et al., 2024). The urban heat island (UHI) effect causes indirect ecological effects such as early flowering, phenological shifts, and pollinator-plant incompatibilities (Dzul-Cauich et al., 2025). These results reveal that the physiological responses of ornamental plants to environmental stresses vary depending on the species, genotype, and environmental conditions (Leotta et al., 2022). Furthermore, research emphasizes that stress conditions directly affect not only plant growth but also flower color, form, tissue structure, and marketability (Hosseini et al., 2025). To increase the resilience of ornamental plants to climate change, studies at the physiological and molecular levels that evaluate multiple stress factors (heat + drought + CO_2 + microclimate) together are necessary. Overall, the findings indicate that ornamental plants are one of the plant groups sensitive to climate change and that the sustainability of the sector depends on the development of "climate adaptation strategies" (Kisvarga et al., 2023).

9.2. Recommendations

Identification of Heat and Drought Tolerant Genotypes

In breeding studies, standardization of physiological markers (Fv/Fm, stomatal conductance, MDA level) is recommended to identify genotypes resistant to heat and water stress in ornamental plants (Palermo et al., 2025). Identification of tolerance genes, particularly in commercially important species such as Gerbera jamesonii, Chrysanthemum morifolium, and Rosa hybrida, will form the basis of adaptive breeding programs (Mahajan et al., 2025).

Biostimulant-Based Sustainable Management Practices

Applications of seaweed extracts, humic acid, melatonin, and polyamines have been proven to maintain water balance and pigment stability under stress conditions; integration of these compounds into routine production protocols is recommended (Tütüncü et al., 2024; Nguyen et al., 2025). Such practices offer environmentally friendly alternatives to chemical stress reducers (Leotta et al., 2022).

Microclimate Management in Urban Landscapes

To mitigate the urban heat island effect, permeable surfaces, shading systems, and water harvesting structures should be incorporated into landscape planning (Dzul-Cauich et al., 2025). Additionally, it is recommended to choose ornamental species with high pollinator attractiveness, early flowering, and drought resistance (e.g., Lavandula angustifolia, Salvia splendens) (Polidori et al., 2023).

Increasing Postharvest Resistance

Since applications of melatonin, selenium, and natural antioxidants have been shown to extend vase life in cut flowers, the optimal dose ranges of these compounds should be determined and species-specific protocols developed (Hosseini et al., 2025; Costa et al., 2020). Furthermore, the use of antimicrobial solutions combined with temperature and humidity control during storage will be effective in preventing xylem blockage (Nguyen et al., 2025).

Molecular Stress Tolerance Studies

In the future, the identification and functional characterization of stress response genes in ornamental plants should be conducted through RNA-seq, proteomics, and metabolomics approaches. Transferring these data to breeding programs will accelerate the development of ornamental plant varieties resistant to climate change (Kisvarga et al., 2023).

Multiple Stress Scenarios and Long-Term Field Trials

Most studies focus on a single stress factor under controlled conditions; however, in nature, stresses act simultaneously (Mircea et al., 2024). Therefore, long-term open field trials evaluating the effects of multiple stress combinations (heat + drought + CO_2) should be planned.

Sectoral Adaptation and Training

Training programs focused on adaptation to climate change should be organized for ornamental plant producers and landscape planners, and awareness should be raised on stress management, irrigation optimization, and biostimulant use (Leotta et al., 2022).

Field projects developed through university-industry collaborations will facilitate the transfer of theoretical knowledge to practice (Tütüncü et al., 2024).

Climate change-related stress factors in ornamental plants have significant impacts not only at the physiological level but also in terms of production economics, aesthetic quality, and ecological services (Kisvarga et al., 2023). Future ornamental planting will be based on the development of varieties that are "multi-stress tolerant, have high aesthetic values, and require low maintenance" (Leotta et al., 2022). To achieve this goal, the integrated application of biostimulant technologies, smart irrigation systems, and urban microclimate management is necessary (Tütüncü et al., 2024). As a result, when the ornamental plants sector manages the risks brought by climate change correctly, it will be able to move into the future not only as an economic sector but also as a sustainable system that supports the ecological balance (Mircea et al., 2024).

Abstract

In recent years, universities have increasingly been regarded as pioneering actors in the effective implementation of sustainability policies at the local scale. Campus settlements, often perceived as micro-models of cities, are evaluated through comprehensive certification systems encompassing environmental, economic, social, and governance dimensions. International frameworks such as GreenMetric, STARS, AISHE, ISCN, and GULF enable the global comparability of universities' sustainability performance by employing multidimensional criteria, including energy efficiency, waste management, water conservation, carbon footprint reduction, green mobility, and community engagement. However, the local application of these certification systems presents a range of structural and administrative challenges, particularly in developing countries. This study critically examines the local adaptability issues of campus sustainability certification systems within the context of Türkiye, focusing on governance capacity gaps, financial constraints, data collection and monitoring difficulties, and the influence of institutional culture. Based on the analysis of exemplary campus practices in Türkiye and the existing legal framework, the evaluation reveals that the limited compatibility of international indicators with local conditions, inter-university heterogeneity, and insufficient stakeholder participation in decision-making processes restrict the overall success of such initiatives. The findings demonstrate that enhancing the effectiveness of campus sustainability certifications in Türkiye requires revising indicators with contextual flexibility, strengthening institutional capacity, and fostering multi-stakeholder governance models. By offering strategic recommendations to local governments, university administrations, and policymakers, this study provides a critical and solution-oriented contribution to the literature on the expansion of sustainable campus practices in Türkiye.

Keywords: GreenMetric, GULF, ISCN, STARS, sustainable campus

1. Introduction

In recent years, the growing global environmental challenges have brought the sustainable management of natural resources and the importance of climate change adaptation policies to the forefront more than ever before. In this context, higher education institutions have evolved from being mere venues for education and research activities into key actors in implementing sustainable development goals at the local scale. University campuses, as small-scale models of urban systems, serve as practical grounds for multidimensional sustainability practices, including energy use, transportation, water management, waste recycling, ecological landscape design, and social awareness initiatives.

Within this framework, international assessment systems such as **UI GreenMetric, STARS, AISHE, ISCN,** and **GULF** have been developed to evaluate the sustainability performance of

universities based on specific indicators, make institutions comparable, and encourage continuous improvement processes. However, since the evaluation criteria of these systems are mostly based on global standards, their direct application in countries with different socio-economic conditions and administrative structures poses various challenges (Kömürlü et al., 2014; Yılmaz & Balyemez, 2020; Özdemir et al., 2022). In particular, in developing countries, **limited financial resources** (Alshuwaikhat et al., 2017; Silva-Da-Nóbrega et al., 2022), **institutional capacity deficiencies** (Dawodu et al., 2023), **constraints in data collection and monitoring processes,** and **lack of stakeholder participation** make it difficult to effectively implement sustainable campus certification systems.

In **Türkiye**, the concept of a sustainable campus has gained increasing importance in recent years, driven by rising environmental awareness and the strengthening emphasis on sustainability within national development strategies. However, existing practices indicate that the indicators of international systems do not fully align with local conditions, and that deficiencies in legislation and administrative infrastructure limit progress. Therefore, discussing the **local adaptability** of sustainable campus certification systems within the Turkish context has become a critical necessity.

This study critically examines the applicability of international sustainable campus certification systems in Türkiye, identifying key challenges from **administrative, economic, environmental, and social perspectives,** and develops **strategic recommendations** to overcome these issues. In doing so, the study proposes a **theoretical and practical framework** that contributes to the localization process of international systems and supports the transformation toward sustainable universities.

2. Sustaınabılıty Assessment Systems

Various assessment systems have been developed worldwide to measure, compare, and improve the sustainability levels of universities. These systems evaluate the environmental, economic, social, and managerial performance of campuses through specific indicators, enabling the institutional monitoring of sustainability goals. The major international systems are explained below.

2.1. UI GreenMetric World University Ranking

Developed by the University of Indonesia in 2010, UI GreenMetric is one of the most widely used sustainability assessment systems globally. It evaluates universities under six main categories (GreenMetric, 2025) (Table 1):

Table 1. UI GreenMetric main categories

No	Main Parameter	%	No	Main Parameter	%
1	Infrastructure	15	4	Water	10
2	Energy and Climate Change	21	5	Transportation	18
No	Main Parameter	%	No	Main Parameter	%
3	Waste	18	6	Education and Research	18
Total	100				

The system operates on an online self-reporting mechanism, where institutions enter data and receive weighted scores for each category. One of GreenMetric's strongest aspects is its ability

to evaluate universities of different scales under a single framework. However, the self-reporting nature of data collection has been criticized for issues of data reliability and comparability (Yusof & Bakar, 2012). Although many Turkish universities participate in this system, the lack of full alignment between the indicators and local climate, infrastructure, and regulatory conditions limits the interpretability of the evaluation results.

2.2. Sustainability Tracking, Assessment & Rating System (STARS)

STARS, developed by the Association for the Advancement of Sustainability in Higher Education (AASHE) in the United States, is a comprehensive framework widely used by universities and colleges around the world. It comprises three main categories—environmental, social, and economic performance—further divided into 17 subcategories and 67 indicators (Table 2) (STARS, 2025).

Table 2. STARS parameter

No	Parameter	Sub-Parameter	Points
1	Academics	Curriculum	45
		Research	23
2	Engagement	Campus Engagement	25
		Public Engagement	25
3	Operations	Buildings & Grounds	20
		Energy & Climate	26
		Dining	10
		Purchasing & Waste	20
		Transportation	10
4	Planning & Administration	Coordination & Planning	11
		Investment	10
		Diversity & Equity	14
		Well-being & Work	11
5	Innovation & Leadership	Innovation & Leadership	10

STARS employs a scoring and rating system, assigning institutions a Bronze, Silver, Gold, or Platinum level. The framework supports transparent reporting and self-assessment, allowing institutions to track their progress over time (AASHE, 2024). However, its comprehensive set of indicators requires professional sustainability offices and specialized personnel, making implementation challenging for developing countries. In Türkiye, only a few universities have adopted STARS, mainly due to limited institutional capacity and financial constraints.

2.3. Auditing Instrument for Sustainability in Higher Education (AISHE)

AISHE, developed in the Netherlands, is an assessment tool that analyzes the sustainability maturity level of higher education institutions through five key parameters (AISHE, 2024):

1.vision and policy

2.expertise

3.educational goals and methods

4.educational content

5.evaluation of results

The most distinctive feature of AISHE is its participatory self-assessment model, in which diverse internal stakeholders academic staff, students, and administrative personnel contribute to determining the institution's sustainability maturity (Caeiro et al., 2020). This participatory approach promotes institutional learning and internal transformation (Roorda, 2010). However, the qualitative nature of the indicators limits comparability across different countries. In the Turkish context, AISHE holds strong potential for enhancing managerial awareness and strengthening stakeholder participation in sustainability practices.

2.4. International Sustainable Campus Network (ISCN)

Founded in 2007, the ISCN is a global network that promotes knowledge exchange and dissemination of best practices in sustainable campus management. Rather than serving as a certification system, ISCN operates as a voluntary membership-based framework built on commitment and reporting principles. Member institutions pledge to uphold three core principles: Development of sustainable campus infrastructure, resource efficiency and reduction of environmental impacts, integration of education, research, and societal impact.

Although ISCN does not provide formal scoring or ranking, it functions as a valuable platform for communication and collaboration among universities (ISCN, 2023). Membership from Türkiye remains limited, yet participation in the network enhances the international visibility of universities and allows them to share sustainability strategies on a global scale.

2.5. Global University Leaders Forum (GULF)

The Global University Leaders Forum (GULF) operates under the World Economic Forum, bringing together the leaders of the world's top universities. It aims to promote collaboration in global education and research, develop innovative solutions, and shape the future of higher education. Through this platform, university presidents and rectors address common challenges and share best practices.

GULF members focus on key global issues influencing education and research policy, including digital transformation, sustainability, social responsibility, and innovation (GULF, 2024). The forum leverages members' experiences and expertise to develop strategic guidance and policies in these domains (Wiseman et al., 2016; Al-Ahdal et al., 2021; Raettig & Muth, 2021). Furthermore, by sharing their visions for the future of higher education, GULF members aim to foster more flexible, inclusive, and innovative educational and research ecosystems.

Sustainable campus certification systems are holistic evaluation tools designed to measure the environmental, social, and managerial performance of universities. Although these systems are implemented across diverse geographical and institutional contexts, they share a common monitoring framework based on the three fundamental pillars of sustainability. Each system differs in its scope, methodological approach, and indicator weighting.

In this regard, international systems such as GreenMetric, STARS, AISHE, ISCN, and GULF address the social, managerial, and environmental dimensions of sustainability at varying levels (Bullock & Wilder, 2016; Puertas, &Marti, 2019; Düzgüneş et al., 2024). Provides a

comparative summary of these systems, outlining their approaches, strengths, and limitations across each sustainability dimension (Table 3).

Table 3. Social, managerial, and environmental dimensions

SOCIAL DIMENSION	**STARS**	One of the most comprehensive systems addressing social sustainability. It evaluates the integration of sustainability awareness into the curriculum through education and research indicators, and assesses social responsibility activities via criteria on community impact, student engagement, and stakeholder participation (Puertas, &Marti, 2019).	Social sustainability indicators are largely qualitative. The influence of cultural and local values is reflected to a limited extent.
	AISHE	Defines social sustainability through internal stakeholder participation. The evaluation process is carried out with the active involvement of academic staff, students, and administrative personnel (Berzosa et al., 2017).	Contributes to increased institutional awareness and the internalization of a sustainability culture.
	ISCN	Addresses the social dimension through experience sharing, networking, and dissemination of best practices (Aregarot et al., 2024).	Strengthens inter-university interaction and supports social learning.
	GreenMetric	Includes limited social indicators; community engagement is indirectly evaluated under the "Education and Research" category (Caeiro, et al., 2020; Aregarot et al., 2024).	Addresses social sustainability indirectly; the overall scope is limited.
	GULF	Associates community engagement with the dissemination of sustainability awareness and community service activities.	Promotes a regionally grounded approach to social responsibility.

MANAGERIAL DIMENSION	**STARS**	Evaluates managerial capacity through indicators such as institutional planning, management policies, and the presence of sustainability offices. The inclusion of a sustainability vision in strategic plans is emphasized(Bullock & Wilder, 2016).	Supports the institutionalization of management policies, though implementation levels vary across institutions.
	AISHE	Approaches the managerial dimension from an "institutional learning" perspective, emphasizing the institution's capacity to monitor its own sustainability progress and continuously improve (Caeiro, et al., 2020).	Encourages a culture of continuous development.
	GreenMetric	Assesses managerial sustainability based on the presence of policies and institutional declarations. Implementation processes are only partially measured (Caeiro, et al., 2020).	Transparency and monitoring are weak; focuses primarily on policy statements.
	ISCN	Operates on a "commitment-based" model in which members pledge to adhere to sustainability principles and submit progress reports.	Strengthens institutional accountability and a culture of monitoring.
	GULF	Evaluates managerial structure through a performance-based, recognition-oriented model that provides feedback based on achievement(Düzgüneş et al., 2024).	Enhances institutional motivation but may weaken continuous monitoring mechanisms.
ENVIRONMENTAL DIMENSION	**STARS**	Places the strongest emphasis on environmental criteria, including energy efficiency, water use, waste management, carbon emissions, and green space planning.	A quantitative system directly scoring environmental performance based on measurable indicators.
	AISHE	Links environmental performance with operational processes, emphasizing energy consumption, greenhouse gas emissions, and green building indicators (Doocy et al., 2021).	Provides detailed operational analysis and monitors environmental sustainability through concrete data.
	GreenMetric	Evaluates environmental sustainability not through direct measurement but through the level of integration into institutional policies and strategies.	Determines the institution's level of environmental maturity through a policy-based approach.
	ISCN	Monitors environmental indicators within a framework of commitment and reporting, emphasizing experience sharing among stakeholders.	Encourages the exchange of best practices and the dissemination of successful implementation examples.
	GULF	Prioritizes water and energy efficiency as key indicators, adapted to regional climatic conditions (Düzgüneş et al., 2024).	Offers an adaptive model tailored to local environmental contexts.

3. Implementation Challenges of Evaluation Systems in the Turkish Context

In the process of implementing international sustainable campus evaluation systems (such as GreenMetric, STARS, AISHE, and ISCN) in Türkiye, various environmental, administrative,

economic, and social challenges emerge (Özcan, 2023). These challenges are closely related to the existing institutional capacities, governance structures, financial resources, and legal frameworks of universities. Furthermore, the fact that the concept of sustainability has not yet evolved into a comprehensive institutional culture within Turkish higher education institutions limits the effectiveness of implementation efforts. Within this framework, implementation challenges can be analyzed under four main dimensions: administrative, economic, social, and environmental.

3.1. Administrative Challenges

Sustainability offices or environmental coordination units at Turkish universities have generally been established within the last decade and are still in the process of institutional development (Aksoy et al., 2024). Most of these units remain limited to symbolic or project-based activities, rather than functioning as strategic bodies directly linked to top management. To make sustainability an integral part of institutional identity, these units must work in an integrated manner—not only on environmental issues but also across education, research, and community engagement dimensions (Filho et al., 2020; 2023).

Although sustainability goals are included in the strategic plans of many universities, implementation, monitoring, and performance evaluation mechanisms are not yet systematic. This poses a significant barrier to the adoption of complex certification models such as STARS or AISHE, which require detailed reporting and institutional coordination (Son-Turan & Lambrechts, 2019). Moreover, knowledge sharing and institutional learning processes among universities remain weak (Mohammadi et al., 2023). Thus, clarifying the authority and responsibilities of sustainability units, defining data management roles institution-wide, and ensuring that sustainability objectives are endorsed at the rectorate level are of critical importance.

3.2. Economic Challenges

Most international evaluation systems require membership fees, reporting costs, and specialized personnel for monitoring and data management. Since public universities in Türkiye are largely dependent on central government budgets, the financial resources allocated to sustainability projects are limited (Son Turan & Lambrechts, 2019; Fındık & Erçetin, 2023; Eskinat &Teker, 2024)). In detailed systems such as STARS, the costs extend beyond participation fees to include data collection, consultancy, training, energy efficiency investments, and carbon footprint assessments, all of which demand substantial funding.

Although GreenMetric, being free of charge, offers a more accessible alternative, it also requires long-term investment in infrastructure improvement, renewable energy projects, and water management to yield tangible results. However, sustainability budgets often remain secondary to other institutional priorities, with short-term economic constraints outweighing long-term environmental benefits (Haessler, 2020; Tao et al., 2021). Therefore, sustainability financing should be transformed from project-based funding into a permanent budgetary component within institutional structures.

3.2.1. Data Collection and Monitoring Challenges

International assessment systems are fundamentally based on data-driven decision-making mechanisms. Continuous data production and reporting on energy consumption, water use, waste management, carbon emissions, transportation modes, and social indicators are critical

for the credibility of such systems. However, in Turkish universities, the systematic collection, storage, and analysis of such data are not yet institutionalized (Dawodu et al., 2022).

In most institutions, data collection is carried out fragmentedly across different departments, lacking a standardized monitoring system. This makes the implementation of data-intensive systems such as STARS or AISHE difficult. Additionally, the absence of data verification processes reduces the reliability of indicators (Dizdaroğlu, 2017; Uçar & Özdemir, 2022; Gudmundsdottir & Sigurjonsson 2024). Limited personnel responsible for environmental data management, technological infrastructure deficiencies, and the lack of measurement equipment further exacerbate these challenges. Therefore, it is essential to strengthen data management infrastructure, establish digital monitoring platforms, and develop standardized reporting protocols for effective sustainable campus practices (Boiral & Heras-Saizarbitoria, 2020).

3.2.2. Stakeholder Participation and Institutional Culture

The sustainable campus approach derives its meaning not only from physical environmental improvements but also from the transformation of behaviors and values within the university community (Özcan, 2023). In Türkiye, however, sustainability is often viewed primarily as a technical or environmental issue, while dimensions such as social justice, participation, and governance remain secondary (Son Turan & Lambrechts, 2019; Bulut, 2021; Agboola , 2025). Participation in sustainability initiatives by student organizations, academic staff, and administrative personnel is typically limited.

This poses a challenge for implementing stakeholder-based systems like AISHE and STARS, which emphasize participatory governance, democratization of decision-making, and awareness-building. The weak participatory culture in Türkiye can be attributed to strong institutional hierarchies, centralized decision-making, and the limited presence of sustainability education in curricula (Çalışkan & Zhu, 2019; 2020). Therefore, sustainability offices should evolve beyond purely technical roles to become engagement-oriented units that organize awareness programs, support student-led projects, and foster campus-wide involvement (Sulkun & Bengü, 2024).

3.2.3. Local Legislation and Compliance Issues

International evaluation systems are typically designed based on the legal, technical, and managerial standards of European or North American contexts. Consequently, they do not fully align with Turkish environmental regulations, energy policies, zoning codes, and campus planning standards. For instance, criteria for energy efficiency or methods for calculating carbon footprints often differ from Türkiye's national reporting standards.

Moreover, universities in Türkiye generally have limited autonomy regarding land ownership, building management, and budgeting, which can create legal barriers to sustainability investments (Abo-Khalil, 2024). The absence of national sustainable campus standards further limits institutional comparability (Katayama et al., 2018). Therefore, it is essential to develop a national evaluation model that reflects Türkiye's unique conditions while maintaining compatibility with international systems. Such a model would both preserve global recognition and make local sustainability performance measurable within national constraints.

3.3. Social Challenges

The concept of a sustainable campus extends beyond environmental and economic indicators to include social dimensions such as awareness, participation, equity, and quality of life (De

Aguiar & Paterson, 2018; Noaime et al., 2025; Tafese & Kopp, 2025). However, the social aspect of sustainability in Turkish universities often remains underdeveloped, hindering the evolution of a holistic sustainability approach. Among students, academics, and administrative staff, sustainability awareness is generally low and frequently perceived narrowly as environmental consciousness (Demir & Kaya, 2021). This limits behavioral changes related to energy conservation, waste management, mobility choices, and social responsibility initiatives on campuses.

Furthermore, key components of social Sustainability such as inclusivity and accessibility are not always prioritized in campus planning. Although indicators like accessibility for individuals with disabilities, gender equality, and student participation in decision-making are central to international systems, Turkish universities have not yet achieved standardized practices in these areas. To institutionalize a sustainable campus culture, universities must adopt a vision that reinforces social justice, volunteerism, ethical values, and community responsibility, alongside environmental investments (Wolff & Ehrström, 2020).

The limited number of student-led sustainability clubs, the lack of continuity in awareness campaigns, and restricted student representation in governance processes also highlight social sustainability deficiencies. Therefore, it is crucial to develop social sustainability indicators, provide funding for student-based initiatives, and encourage participatory governance models within universities. Through such efforts, sustainability can be embraced not merely as an environmental goal but as a comprehensive human-centered transformation process.

3.4. Environmental Challenges

Environmental sustainability is directly related to natural resource use, ecological balance, and carbon footprint within campus settings (Son Turan & Lambrechts, 2019; Amaral et al., 2020). Although many Turkish universities have undertaken initiatives to enhance their environmental performance, these efforts often remain project-based, short-term, and limited in scale (Özcan, 2023). The lack of integrated strategic approaches in key areas such as energy efficiency, renewable energy adoption, water recovery, waste management, and biodiversity conservation is a major concern (Yılmaz & Ersöz, 2023).

Many campuses lack monitoring systems for energy consumption, water use, and waste generation, and data collection is not conducted regularly. Aging building stocks often exhibit low energy efficiency, and the integration of renewable energy infrastructure remains limited. Furthermore, ecological sensitivity is not consistently considered in campus planning practices, leading to habitat fragmentation, increased surface runoff, and loss of green space functions especially on large campuses.

Due to Türkiye's diverse climatic regions, environmental priorities and challenges vary significantly among universities, complicating the development of standardized sustainability criteria (Özdemir et al., 2020; Aksoy et al., 2024).

For instance, water management is a critical issue in arid regions, while drainage and erosion pose challenges in the Black Sea region. This diversity makes it difficult to adapt fixed indicators of international systems to local realities. Therefore, achieving effective environmental sustainability requires the development of regionally adaptive strategies based on nature-based solutions and long-term resource management plans sensitive to local climate conditions.

4. Conclusion and Recommendations

Today, universities are regarded not only as institutions of education and research but also as key actors in the local implementation of sustainable development goals. In this context, sustainable campus evaluation systems serve as crucial tools for objectively measuring institutional environmental performance, assessing social responsibility, and fostering a culture of sustainability-oriented decision-making within governance structures.

The systems examined in this stud GreenMetric, STARS, AISHE, ISCN, and GUL differ in terms of scope, evaluation methodology, and indicator weighting. However, all share a common goal: to promote a holistic approach to sustainability in higher education institutions. The comparative analysis revealed that:

GreenMetric prioritizes environmental performance, STARS emphasizes social and administrative processes, AISHE focuses on stakeholder participation and institutional learning, ISCN highlights international collaboration and knowledge exchange, and GULF centers on regional conditions and resource efficiency.

These diverse perspectives across social, environmental, and managerial dimensions reflect the multi-layered nature of sustainability. However, within the Turkish context, the effectiveness of implementation is constrained by factors such as limited administrative capacity, insufficient data infrastructure, financial constraints, and regulatory incompatibilities.

In Turkish universities, sustainability policies are predominantly formulated at the strategic planning level, yet systematic mechanisms for implementation and monitoring remain underdeveloped. Although strategic documents often include goals and vision statements related to sustainability, their translation into concrete action plans, measurable performance indicators, and regular reporting processes is limited. Consequently, sustainability policies often remain symbolic rather than institutionalized.

Moreover, both internationally and in Türkiye, social and administrative indicators tend to receive less emphasis compared to environmental indicators. While areas such as energy efficiency, waste management, and carbon footprint dominate assessment frameworks, indicators of social justice, stakeholder participation, and governance transparency are frequently undervalued. This imbalance narrows the understanding of sustainability to an environmentally centered paradigm, thereby underrepresenting its holistic essence.

Since international sustainable campus systems are largely designed based on the economic structures, data infrastructures, and regulatory frameworks of developed countries, their direct application in Türkiye is not always feasible. In cases where energy and carbon data are not regularly collected, financial resources are limited, or legislative frameworks differ, the evaluation criteria of these systems cannot be fully met. Therefore, adapting indicators to local conditions and redefining them with contextual flexibility is essential.

Stakeholder engagement and sustainability awareness are critical for embedding a sustainability culture within campuses. However, in many Turkish universities, the participation of students, academic staff, and administrative personnel in sustainability initiatives remains limited. For sustainability to become permanent, efforts must extend beyond physical infrastructure investments to include the development of community awareness. In this regard, awareness programs, student clubs, collaborative projects, and volunteer-based activities play a vital role in transforming campus life through a sustainability lens.

Development of a National Sustainable Campus Evaluation Model; A nationally adaptable sustainable campus evaluation model should be developed by considering the diverse socio-economic, geographical, and climatic characteristics of Turkish universities. While the strengths and criteria of international systems should be taken as references, indicators must be redefined in alignment with local data sources, legal frameworks, and cultural dynamics. This model should aim to measure sustainability performance equitably and comparatively across universities, providing flexibility for different climatic regions and institutional scales within Türkiye.

Strengthening Institutional Capacity and Governance Mechanisms; To effectively implement sustainability initiatives, universities must enhance their institutional capacity. In this context, sustainability units should be legally recognized, supported with adequate budgets and qualified personnel, and integrated directly into strategic planning, budgeting, and decision-making mechanisms. Such integration will ensure that sustainability becomes a permanent component of institutional governance structures.

Digitalization of Data Management and Monitoring Systems; For sustainability performance to be measurable and traceable, data on key indicators such as energy, water, waste, and carbon—must be collected regularly in digital environments. Accordingly, centralized digital monitoring infrastructures that enable data sharing among universities should be established. Aligning these systems with international reporting standards will enhance transparency and facilitate comparative evaluation of institutional sustainability performance.

Expanding Education and Awareness Programs; The establishment of a sustainable campus culture depends not only on physical and technical investments but also on education-based awareness enhancement. Therefore, sustainability education should be integrated as a mandatory course or module across all faculties. Moreover, workshops, seminars, and field practices should be organized for students, academics, and administrative staff to promote participatory learning environments. In this way, sustainability awareness can be disseminated throughout all levels of the university community.

Enhancing Stakeholder Participation; The success of university sustainability policies depends not only on internal institutional efforts but also on collaborations with external stakeholders. Therefore, university administrations should establish multi-stakeholder governance structures involving local governments, non-governmental organizations, and private sector representatives. Through joint projects, grant-supported initiatives, and social responsibility programs, sustainability practices can be strengthened locally while enhancing public awareness and community engagement.

Promoting Localized Applications of Certification Systems; International certification systems such as GreenMetric, STARS, and AISHE should be implemented comparatively in Turkish universities, and the results should be evaluated at the national level. Such implementations would allow institutions to monitor their performance, share best practices, and foster continuous learning and improvement through a national reporting and evaluation network.

In this context, the TÜBİTAK 1002 project (Project No: 123Y075) titled “A New Certification System Proposal for Sustainable Campus Planning: The Campus Sustainability Scorecard (KASK)” was developed to address these challenges and to design a national certification system tailored to Turkish universities.

Unlike existing systems, KASK introduces a distinct administrative dimension alongside environmental, economic, and social components. The model includes:

8 main and 58 sub-indicators under the environmental dimension, 4 main and 14 sub-indicators under the economic dimension, 7 main and 41 sub-indicators under the social dimension, and 6 main and 34 sub-indicators under the administrative dimension.

The selection of indicators was carried out through consultation with a panel of 15 experts representing various professional fields including environment, natural resource management, ecology, sociology, economics, public administration, environmental law, sustainability, and planning as well as personnel from university sustainability units involved in prior system evaluations. The indicators were then weighted using the Analytic Hierarchy Process (AHP) technique.

A pilot implementation of the KASK model was conducted at Karadeniz Technical University (Kanuni Campus) to assess its applicability. The results confirmed the model's operational validity. Both the KASK framework and the outcomes of this pilot study will be presented in a forthcoming academic publication.

Abstract

Oceans are of global significance for sustaining life, regulating climate, conserving biodiversity, and preserving cultural heritage. Beyond their ecological functions, they underpin strategic economic sectors such as fisheries, tourism, and maritime trade by providing essential food, energy, and mineral resources. Yet, growing anthropogenic pressures—including overfishing, pollution, bottom trawling, unplanned coastal development, and climate change—have exceeded the resilience of marine ecosystems, leading to biodiversity decline and the degradation of ecosystem services. Within this framework, Marine Protected Areas (MPAs) have gained prominence as effective instruments for safeguarding marine and coastal ecosystems, ensuring the sustainable use of natural resources, and strengthening local economies. MPAs deliver multifaceted benefits, including the conservation of fragile habitats, recovery of fish stocks, carbon sequestration, and enhanced resilience to climate change. Achieving such outcomes requires the adoption of ecosystem-based management approaches, participatory decision-making, scientific monitoring, and adaptive management strategies. Türkiye, surrounded on three sides by the Black Sea, Marmara, Aegean, and Mediterranean, possesses considerable potential for MPA implementation due to its diverse ecological features. Existing protection mechanisms, such as Special Environmental Protection Areas and marine national parks, represent important steps. However, the effectiveness of these initiatives depends on strengthening science-based planning, ensuring local stakeholder engagement, and fostering international cooperation. This study critically examines the importance, objectives, designation criteria, and management strategies of MPAs as a category of protected areas aimed specifically at marine ecosystems. It also evaluates Türkiye's current approach to marine conservation and highlights the urgent need to expand and enhance protection measures to safeguard the ecological integrity and socio-economic value of its seas.

Keywords: Protected areas, marine protected areas, Türkiye

1. Introduction

Today, rapid technological advances, intensive natural resource use, population growth, and urbanization are creating profound and irreversible impacts on our planet's natural balance. These factors are straining the carrying capacity of ecosystems, leading to the gradual decline of natural areas and the threat to biodiversity. At the root of this degradation lies the misguided human perception that nature can renew itself indefinitely, coupled with environmentally harmful production and consumption behaviors that prioritize short-term economic gain. The pressures of human activities on ecological systems have become direct threats to natural resources critical to the sustenance of life, such as air, water, and soil.

In response to these multifaceted environmental crises, the nature conservation movement has gained momentum since the 1950s, and various "protected area" systems aimed at preserving biodiversity have been established (Yalınkılıç & Yenilmez Arpa, 2005; Düzgüneş & Demirel, 2018). Developed with the active participation of local communities, non-governmental organizations (NGOs), and the private sector, these systems aim to maintain ecological integrity

and ensure the sustainable management of natural resources. In this context, in addition to protected areas for terrestrial ecosystems, Marine Protected Areas (MPAs) have emerged as one of the most important strategic tools for protecting marine and coastal ecosystems.

MPAs are special protected areas whose boundaries, management objectives, and permitted activities are defined by legal and policy frameworks and planned based on scientific research and stakeholder engagement. These areas protect critical habitats such as coral reefs, seagrass meadows, mangrove forests, and coastal lagoons, contributing to the breeding, feeding, and migration processes of numerous marine species (Jones, 2021). By limiting destructive activities such as overfishing, pollution, and unplanned coastal development, MPAs support the restoration of fish stocks, the resilience of marine ecosystems to environmental change, and the mitigation of climate change by protecting habitats with high carbon sequestration capacity.

Beyond their environmental benefits, MPAs contribute to the economic development of coastal communities by promoting sustainable fishing, tourism, and recreation. They also serve as living laboratories for scientific research, fostering knowledge of marine ecology and shaping large-scale conservation policies. Therefore, MPAs are considered a critical global tool not only for protecting marine biodiversity but also for maintaining ocean productivity, supporting the blue economy, and ensuring healthy marine ecosystems for future generations.

2. Concept of Protected Area

Accelerating technological advancements, population growth, and the resulting intensive concreting and misuse of land brought about by urbanization have led to societies' excessive and reckless consumption of natural resources, placing significant pressure on ecosystems. These pressures are triggering critical ecological problems such as soil erosion, desiccation of wetlands, deforestation, loss of biodiversity, and the decline or extinction of numerous plant and animal species. Increasing human impact has not only degraded the natural environment but has also reached a level that threatens ecosystem services and, consequently, the sustainability of human life.

To mitigate these negative impacts on the natural environment and resources and to ensure the conservation of biodiversity, various scientifically based conservation structures and management strategies have been developed over time. In this context, in light of the knowledge and experience accumulated over many years, "Protected Area" systems have become one of the most effective and widespread practices within global conservation strategies. The International Union for Conservation of Nature (IUCN) defines protected areas as "strictly geographically demarcated areas managed by legal or other effective means to ensure the long-term conservation of ecosystems and cultural values contained in nature" (IUCN, 2025). Similarly, the Convention on Biological Diversity (CBD) defines protected areas as "geographically defined areas managed by legal or other effective regulations to achieve specific objectives" (Juffe-Bignoli et al., 2017). In Türkiye, the Law on the Protection of Cultural and Natural Heritage No. 2863 defines protected areas as "areas whose protection is mandatory in order to ensure the preservation of immovable cultural and natural assets and their protection within the historical environment" (T. R. Official Gazette,1983).

The spread of protected areas globally has shown remarkable growth over the last half century. According to the World Database on Protected Areas (WDPA), in 2010, 147,000 protected areas covering approximately 17 million km² were declared worldwide, representing more than 13% of the Earth's surface (IUCN-UNEP-WCMC, 2012). By 2014, this proportion had

increased to 15.4% in terrestrial areas and 8.4% in marine areas, bringing the total protected area size to approximately 33 million km², approaching the size of the African continent (IUCN-WCPA, 2014). The diversification of protected areas and the adoption by governments of new protection categories such as Other Effective Area-Based Conservation Measures (OECMs) have been decisive in the increase in both the number and the surface area covered by declared areas.

This development trend continued in the following years. In 2018, the number of protected areas registered under the WDPA reached 238,563; approximately 20 million km² of terrestrial protected areas, covering 14.9% of the world's surface, and approximately 6 million km² of marine protected areas, an increase of 16.8%, were recorded (IUCN-WCPA-WCMC, 2018). According to the Protected Planet report, in 2021, the number of terrestrial protected areas increased to 248,113, and the ratio of the area they cover increased to 15.67%; the number of marine protected areas was determined to be 17,787, reaching 7.65% of the global ocean surface. By 2024 (May 2024 data), the number of terrestrial protected areas reached 275,492, and the ratio of the area they cover increased to 16.1%; Marine protected areas have increased to 18,200, representing 8.01% of the global ocean surface (Protected Planet, 2024). Including areas assessed within the scope of the OECM, these rates reach 17.28% for terrestrial areas and 8.12% for marine areas.

These data demonstrate that protected areas have become a strategic tool not only for their ecological functions but also for global environmental policies and sustainable development goals. The continuous increase in the number and extent of protected areas clearly reflects the success and future importance of international efforts to conserve biodiversity, adapt to climate change, and sustain ecosystem services.

The distribution and locations of declared marine and terrestrial protected areas worldwide are shown in Figure 1 (Protected Planet, 2025).

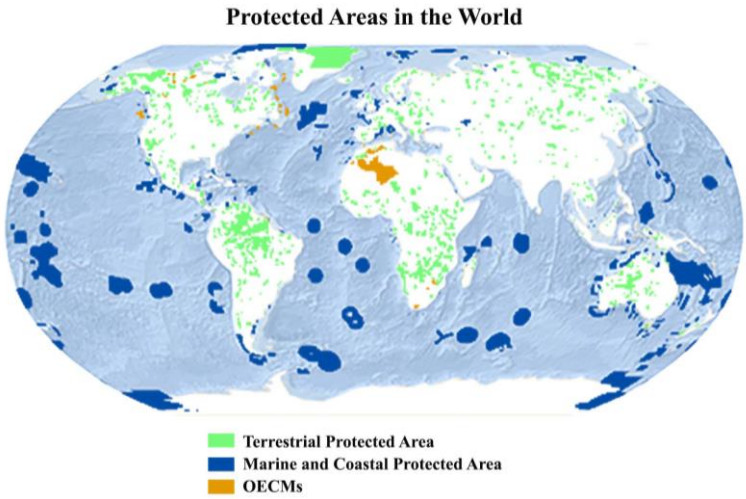

Figure 1. Map of protected areas worldwide, January 1, 2025.

Other Effective Area-Based Conservation Measures (OECMs) are an important conservation status defined for areas that do not have formal protected area status but provide effective on-site biodiversity conservation. OECMs offer a complementary mechanism to traditional protected areas, particularly in maintaining ecosystem integrity, protecting critical habitats, and supporting sustainable management practices by local communities. This approach ensures that

conservation objectives are not limited to areas with legal status but also encourages diverse land uses (e.g., sustainable forestry, traditional fisheries, local management practices) to generate ecological benefits.

According to data from the Protected Planet Database, the Aichi Biodiversity Target, set for 2020 and targeting 17% of land and inland waters to be protected, was achieved by 17.08% as of March 2023. By May 2024, this figure had risen to 17.28%, officially confirming the progress made in protecting terrestrial and inland water ecosystems on a global scale (Protected Planet, 2025). This progress demonstrates that not only traditional protected areas but also areas under OECM status contribute significantly to the achievement of global conservation goals.

These data demonstrate the increasing importance of OECMs in protecting ecologically critical areas, maintaining biodiversity, and implementing climate change adaptation strategies. In particular, recognizing OECMs in international conservation policies accelerates the qualitative and quantitative development of protected area networks, contributing to the implementation of a broader range of global environmental goals.

3. Marine Protected Areas

The International Union for Conservation of Nature (IUCN) defines marine protected areas (MPAs) as "any or all of the tidal or intertidal land designated by law or other effective means for the protection of the surrounding waters, associated flora, fauna, and historical and cultural features" (IUCN-WCPA, 2021). This definition represents a holistic approach that protects not only the sea surface but also the seabed, biomes, and cultural elements.

According to assessments by the IUCN World Commission on Protected Areas (WCPA, 1999; IUCN-WCPA, 2021), the fundamental characteristics and principles of MPAs can be summarized as follows:

- **Nature Conservation Priority:** The primary objective of MPAs is to protect marine ecosystems and biodiversity.
- **Flexibility of Within-Area Protection:** The degree of protection does not have to be uniform across the entire area; large MPAs often implement a multi-layered management plan, dividing the area into different use and impact zones.
- **Extent of Coverage:** Each MPA necessarily includes the marine environment, but it may also encompass land masses, islands, or coastal areas within its boundaries. If the marine area is larger than the land area, or if the marine portion of a large protected area is of sufficient size on its own, this portion can be classified as an independent MPA.
- **Holistic Conservation:** MPAs must cover not only the seabed but also the associated flora and fauna. If biodiversity conservation is not a primary objective and meets the criteria of the Convention on Biological Diversity (CBD), the area in question may be considered an Other Effective Area-Based Conservation Measure (OECM).
- **Coexistence of Natural and Cultural Elements:** MPAs encompass not only natural habitats; Cultural heritage elements such as shipwrecks, historic lighthouses, and piers may also be protected.
- **Various Management Models:** MPAs can be areas directly managed by government agencies or fall under a wide range of protection categories, such as biosphere reserves, Ramsar sites, or World Heritage sites.

These are shown in Table 1.

Table 1. Types of MPA

Types of MPAs	Examples
Declared under customary tenure	MPAs in the Pacific region
Managed on a voluntary basis	Some MPAs in the UK
Developed and managed by the private sector	Chumbe, Zanzibar, Tanzania
Established and managed by a local community	Philippine fishing villages

In this context, MPAs play a critical role in global marine conservation strategies as multidimensional areas that require a holistic management and protection approach in terms of protecting both ecological and cultural values.

a. Purpose of Marine Protected Areas

The International Union for Conservation of Nature (IUCN) defines the primary purpose of Marine Protected Areas (MPAs) as protecting the biodiversity and productivity of the oceans (including ecological life-support systems). Both aspects of this goal are equally critical for improving the health and long-term sustainability of marine ecosystems. For example, protecting seagrass beds with relatively low species diversity but high biological productivity can be vital for maintaining viable populations of threatened species such as dugongs. In this context, maintaining biological productivity is essential not only for maintaining ecological stability but also for contributing to human well-being.

The success of MPAs depends largely on the support of local communities. To ensure this support, the MPA must contribute to tangible community benefits such as food security, economic income, and cultural benefits by maintaining biological productivity. While marine conservation and the sustainable use of marine resources are often viewed as distinct goals, in reality, the two objectives are strongly interconnected. However, past experience has shown that MPAs can fail when external stakeholders prioritize biodiversity conservation while local communities prioritize resource use. Therefore, it is crucial to clearly and balancedly define the relationship between conservation and sustainable use at the planning stage.

Different spatial planning strategies can be applied in MPA management, depending on the primary objective. If the primary objective is to protect a specific species or ecosystem, establishing a large, completely no-take area may be the most appropriate method. Conversely, if the primary objective is sustainable resource management, a network of smaller, interconnected protected areas can yield higher fish stocks for surrounding fisheries, as studies conducted in the Caribbean have shown.

Experience suggests that two basic approaches to protecting the entire ecosystem stand out (WCPA, 1999):

1. Establishing a series of relatively small but complementary marine protected areas within a broader integrated ecosystem management framework.
2. Declaring a large-scale, multi-regional MPA covering all or a large portion of the marine ecosystem.

Both methods are valid, but a significant advantage of the latter approach is that management responsibility for the entire area is generally assigned to a single institution. This reduces jurisdictional conflicts that might arise if management were shared among different institutions, facilitating the implementation of an integrated and holistic conservation strategy.

These assessments demonstrate that MPAs are multidimensional strategic areas that simultaneously protect not only biodiversity but also ecosystem productivity and human well-being.

4. Criteria for Declarıng Marine Protected Areas

The designation of Marine Protected Areas (MPAs) requires a multidimensional assessment process to effectively protect marine biodiversity, ecosystems, and cultural resources. This process necessitates meticulous consideration of interconnected elements such as ecological value, socio-economic contribution, governance capacity, and legal compliance (WCPA, 1999; IUCN-WCPA, 2021). The primary criteria are grouped under the following main headings:

1. Biodiversity and Ecosystem Value
- Species Richness: Areas of high biological diversity, including rare, endemic, or endangered species.
- Habitat Importance: Areas containing critical breeding and feeding habitats, such as coral reefs, mangroves, seagrass beds, and kelp forests.
- Ecosystem Services: Areas that provide essential ecosystem services, such as carbon sequestration, coastal protection, water filtration, and climate regulation.
- Integrity: The degree to which an area encompasses an entire ecosystem, either alone or in conjunction with other protected areas.

2. Ecological Importance
- Ecological Connectivity: Areas that enhance connectivity between habitats for species migration and genetic flow.
- Representativeness: Areas that reflect the typical marine ecosystems and habitat diversity of specific biogeographic regions.
- Naturalness: Reference ecosystems where natural processes can be observed and where human impact is minimal.

3. Threat Level and Conservation Urgency
- Threatened Areas: Areas subjected to human-induced pressures such as overfishing, pollution, habitat destruction, or climate change.
- Urgent Response Requirement: Areas requiring immediate protection to prevent the rapid degradation of critical species or habitats.

4. Socio-Economic and Cultural Value
- Cultural Heritage: Areas of cultural or archaeological significance, such as traditional fishing grounds, sacred sites, and historical shipwrecks.
- Economic Contribution: Areas that support local economies through sustainable fishing, tourism, and recreation.
- Community Support: Areas where local people, civil society organizations, and fishing cooperatives actively participate in conservation efforts.

5. Scientific and Educational Potential
- Research Opportunities: Areas that offer unique opportunities for scientific research on marine ecology, climate change, and biodiversity.

- Educational Value: Areas suitable for promoting environmental education, public awareness, and marine conservation awareness.

6. Feasibility and Management Capacity

- Feasibility: The availability of the necessary infrastructure and resources for monitoring, control, and implementation of conservation measures.
- Management Competence: Areas with effective management capacity through stakeholder engagement, financing mechanisms, and governance structures.
- Stakeholder Engagement: Active involvement of local communities, governments, and NGOs in planning and management processes.

7. Legal and Policy Framework

- Legal Protection: Areas that can be protected under national legislation or granted legal status through new regulations.
- Alignment with International Goals: Alignment with national and global conservation priorities, such as the Convention on Biological Diversity (CBD) and the United Nations Sustainable Development Goals (SDGs).

These criteria enable MPAs to provide effective, feasible, and sustainable long-term conservation by balancing ecological priorities, societal benefits, and management opportunities. By considering this multidimensional framework, decision-makers can prioritize areas that safeguard marine biodiversity, sustain ecosystem services, and provide economic and cultural benefits to local communities.

4.1. Establishment and Declaration of Marine Protected Areas

Establishing a Marine Protected Area (MPA) involves a comprehensive process, encompassing ecological, social, and administrative aspects, and often requires a time-consuming, multi-stakeholder approach. This process involves the collaborative efforts of all relevant management bodies, local rights holders, and stakeholders, the preparation of legal regulations, and the careful conduct of scientific assessments. Initially defining the characteristics of the designated area is critical to clarifying the expected ecological and socio-economic benefits of the MPA. This allows the potential biodiversity contributions of the area to be identified in line with management objectives (Figure 2).

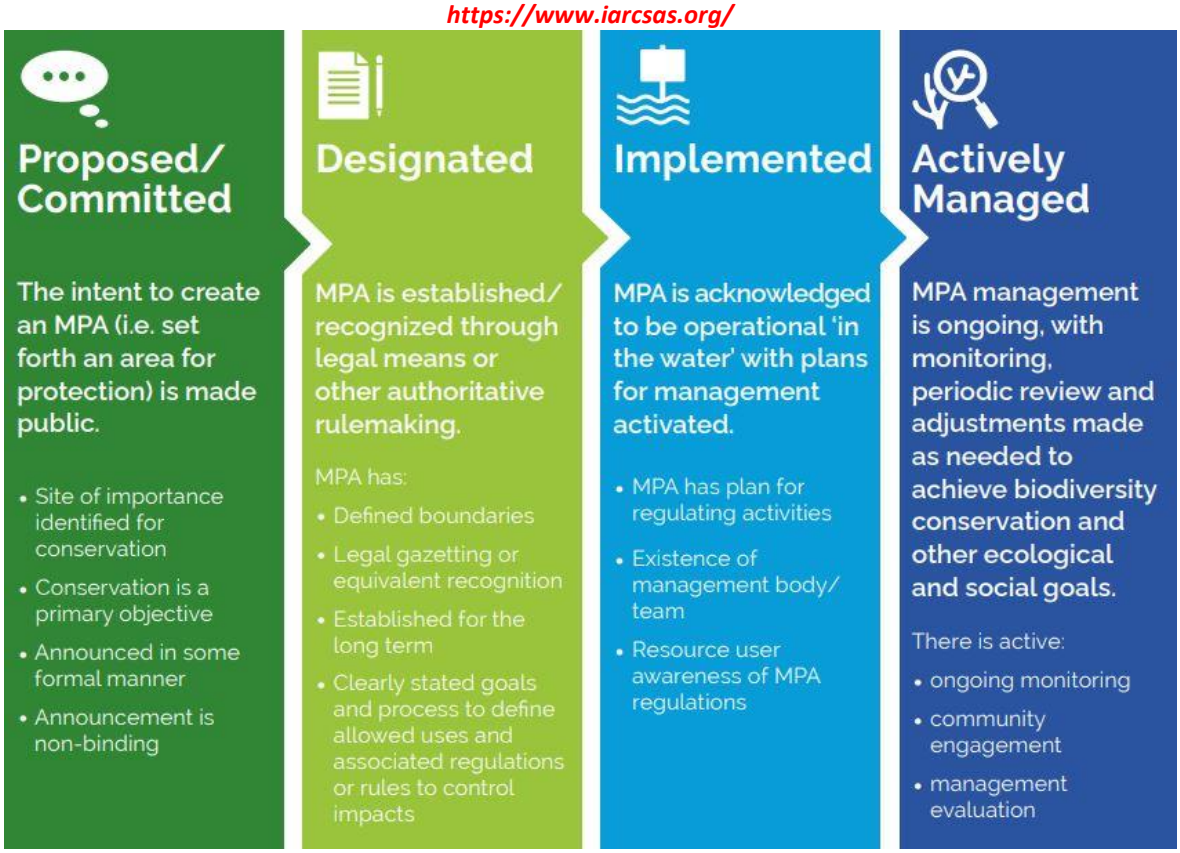

Figure 2. Establishment stages of MPAs

According to the MPA Guidelines prepared by the IUCN World Commission on Protected Areas (WCPA, 1999; IUCN-WCPA, 2021), the establishment process consists of four main stages:

1. Proposal/Commitment Stage: A formal proposal or commitment to protect a specific area as an MPA is made by a relevant management authority, public institution, or authorized organization.
2. Legal Designation: Clarification of the area's boundaries and formal recognition of its conservation status through national legislation or other effective legal instruments.
3. Regulation and Implementation: Entry into force of conservation decisions and management plans; active implementation of activity restrictions, monitoring programs, and conservation measures.
4. Active Management and Monitoring: Implementation of a dynamic management process supported by ongoing monitoring, adaptive management, and scientific assessments to ensure the long-term protection of the area.

These stages ensure not only the declaration of an MPA but also its sustainable and effective management. This makes it possible to conserve biodiversity, maintain ecosystem services, and contribute to the well-being of local communities.

The process of establishing a Marine Protected Area (MPA) is a gradual process encompassing not only the selection of the area but also legal recognition, implementation, and effective management. These stages clarify the degree of protection, management capacity, and ecological objectives of the designated area, ensuring long-term conservation success (WCPA, 1999; IUCN-WCPA, 2021). The process consists of the following four key stages:

1. Proposed/Committed

This first phase begins with the public announcement of the intention to protect an area as an MPA.

- It is formally stated that an important area has been selected for protection and that protection is the primary objective.
- The announcement is usually made through official channels but does not carry a binding legal status.
- This phase provides public disclosure of the area's potential ecological and socio-economic values and initiates initial stakeholder consultations.

2. Designated

In the second phase, the proposed area is formally recognized through legal or other authorized regulatory means, gaining MPA status.

- The area's boundaries are clearly defined and published in the official gazette or equivalent.
- The conservation objectives and management processes to be implemented are clearly defined.
- It is established for long-term protection, and permitted activities and restrictions are clarified within the legal framework.

3. Implemented

This stage refers to the period when the MPA becomes operational and management plans are actively implemented.

- A management plan governing activities is enacted, and relevant regulations begin to be implemented.
- A formal management body or team responsible for the protection of the area is established.
- Resource users (fishermen, tourism businesses, etc.) are informed about MPA regulations, and awareness is raised.

4. Actively Managed

The final stage is when the MPA is operated in accordance with the principles of continuous monitoring, evaluation, and adaptive management.

- Regular monitoring and reporting are conducted to protect biodiversity, maintain ecosystem health, and achieve social objectives.
- Management plans are updated through periodic evaluations, and necessary management adjustments are made.
- Community participation is actively maintained in decision-making and implementation processes.

These stages ensure that MPAs are not only declared but also maintain their long-term ecological integrity and sustainable use. Adaptive management, particularly in the final stage, allows for the continuous development of conservation strategies in response to changing environmental conditions and societal needs.

5. Marine Protected Areas Protectıon Strategies

Marine Protected Areas (MPAs) are designated areas managed through multilayered strategies to ensure the conservation of marine ecosystems, biodiversity, and cultural resources. These areas are protected not only by legal regulations but also through complementary mechanisms such as active management, community participation, scientific research, and sustainable financing (WCPA, 1999; IUCN-WCPA, 2021).

1. Regulatory Measures

MPAs are founded on legal frameworks and spatial arrangements. These areas, whose boundaries and management objectives are defined by national or regional legislation, include:

- No-take zones
- Multi-use areas (areas where sustainable activities are permitted)
- Restrictions on harmful activities such as fishing, mining, drilling, and tourism.

2. Active Management

Management plans, habitat restoration, and breeding and reintroduction programs for endangered species are implemented to achieve conservation goals. These include projects such as coral reef restoration, mangrove planting, or seagrass beds rehabilitation.

3. Monitoring and Surveillance

Water quality, species populations, and habitat conditions are regularly assessed to monitor the health of marine ecosystems. Drone technology, satellite imaging, and marine patrols are used to prevent poaching.

4. Enforcement

Coast guards, rangers, and law enforcement officers play an active role in ensuring the effectiveness of legal regulations. Violations are subject to legal sanctions such as fines, sanctions, and license revocation.

5. Community Participation

The success of MPAs depends on the support of local communities and stakeholders. Therefore,

- Stakeholder participation,
- Educational programs, and
- Economic alternatives to fishing, such as ecotourism or handicrafts, are critical.

6. Scientific Research

MPAs serve as living laboratories for scientific research and education. Continuous research on biodiversity, ecosystem health, and human impacts contributes to the updating of management strategies.

7. Sustainable Financing

Funding for long-term conservation is secured through government budgets, international grants, ecotourism revenues, and public-private partnerships. Incentives such as eco-certification for fishing and tourism businesses support sustainable activities.

8. Adaptive Management

Regularly reviewing management plans and adapting strategies in response to environmental changes and scientific findings ensures long-term conservation success.

MPAs are divided into four main categories based on the degree of protection they provide (Figure 3):

1. Fully Protected Areas: These are areas where all extractive or destructive activities are prohibited, and only low-impact activities such as swimming, diving, education, and scientific research are permitted.

2. Highly Protected Areas: These are areas where activities such as low-impact fishing or limited mining are permitted to a limited extent, but where biodiversity is prioritized.

3. Lightly Protected Areas: These are areas where biodiversity is partially protected, and moderate fishing or tourism activities are carried out under controlled conditions.

4. Minimally Protected Areas: These are areas where extensive mining or high-impact activities are permitted, but are still considered MPAs under the IUCN definition, providing essential conservation benefits.

Figure 3. MPA protection levels

Ultimately, effective MPAs require a multifaceted approach that integrates legal regulations, scientifically informed management, local participation, and financial sustainability. When implemented together, these strategies protect the health of marine ecosystems, support biodiversity, and generate long-term socioeconomic benefits for coastal communities.

6. Discussion and Conclusion

While terrestrial and marine protected areas in Türkiye are critical for protecting biodiversity and ecosystem integrity, the current system faces several structural and administrative challenges. One of the most significant problems in terrestrial protected areas is weak implementation and oversight, resulting from insufficient funding and human resources. The late integration of the concept of protection into development projects, combined with

economic and political pressures, makes it difficult to prioritize conservation objectives. This situation, combined with habitat fragmentation and the lack of ecological corridors, negatively impacts species migration and the continuity of ecological processes. Furthermore, a lack of scientific data limits the development of effective monitoring and adaptive management mechanisms, while low levels of public awareness and local participation lead to weak compliance with conservation regulations.

In addition to these structural challenges, climate change is placing increasing pressure on Türkiye's protected areas. Sea level rise, increased frequency of extreme weather events, and habitat displacement create new risk areas requiring additional protection measures, particularly in coastal and marine ecosystems.

Despite being surrounded by sea on three sides, Türkiye faces a significant gap in the number of Marine Protected Areas (MPAs). The economic interests of the fishing and tourism sectors, access restrictions to marine areas, and concerns about potential revenue loss are among the primary obstacles to declaring MPAs. This deficiency jeopardizes the conservation of marine biodiversity and leads to the degradation of critical ecosystems such as coral reefs, seagrass beds, and fish breeding and feeding grounds due to overfishing, pollution, and unregulated coastal development.

However, the establishment of MPAs offers multifaceted benefits, including:

- Protecting marine biodiversity,
- Supporting sustainable fisheries,
- Combating climate change by protecting carbon-sequestering habitats such as mangroves and seagrass meadows,
- Promoting ecotourism and contributing to local economies,
- Raising public awareness of marine ecosystems.

Given Türkiye's rich biodiversity and extensive coastline, the rapid establishment and effective management of marine protected areas is a strategic necessity from ecological, economic, and cultural perspectives. In this regard, a holistic conservation policy supported by stronger political will, adequate financial resources, science-based management plans and active participation of local communities is a fundamental condition for the long-term sustainability of both terrestrial and marine ecosystems.

Abstract

The earthquakes in Kahramanmaraş, which took place on 6 February 2023, demonstrated not only the failures and collapses of the load -bearing structures of buildings, but also the destruction, which happened to the non-structural objects in the interior areas. The resulting damage has had some important implications on life safety, economic losses and the psychology of the user and has been defining in post-disaster respons. Technical research in the seismic performance of non-structural elements has grown in recent years, but little has been done in studying how this is being conveyed to the media i.e. how they are communicated to the masses. The aim of this study is to examine how non-structural elements were addressed in online news platforms in Türkiye following the 6 February earthquakes. The research will analyze news texts, visuals, and hashtagged social media content published during the first three months after the earthquakes. These materials will be examined to identify the themes associated with non-structural elements in media outlets, the actors that were emphasized, and the differences between technical knowledge and public discourse. The expected contributions of the study include systematically revealing the visibility and representational forms of non-structural elements in media narratives, identifying how technical findings from engineering and damage-assessment literature are reflected in the media, and offering recommendations for enhancing post-disaster communication policies and risk awareness.

Keywords: Non-structural elements, media, news, earthquake

1. Introduction

The damaging effects of an earthquake on the natural and built environment are many. In the short term in this initial stage, estimates of fatalities, physical damage to buildings and other structures, loss of building function, loss of human activity, and secondary effects such as fires and gas leaks that may lead to further fatalities and damage may be required. Injuries might be caused by both structural and non-structural elements. Thus it is essential that those responsible for the design of buildings, and their internal layout and contents, are earthquake aware (Ahmed, 2023). The Kahramanmaraş earthquakes of 6 February 2023 were one of the most catastrophic natural disasters in modern Türkiye. They exposed the inadequacy of not only the load-bearing systems of the buildings but also the potentially fatal risks resulting from NSEs in the interior of buildings. Non-Structural Elements (NSE) include cabinets, suspended ceilings, glass partitions and mechanical equipment. NSEs are subject to the same earthquake dynamic forces as the load-bearing systems, are often overlooked and not considered for design or anchorage, or are incomplete in terms of material specification (Wang et al., 2021).

As a result, even in buildings that remain structurally intact, NSE failures can cause severe injuries, fatalities, economic losses, and psychological trauma.

An examination of public discussions and media coverage after disasters shows that the main focus was mostly on “collapsed buildings” and “structural system failures.” Both traditional and digital media mainly shared images of rubble and destruction to highlight the scale of the tragedy. However, from the very first moments of the disaster, thousands of posts circulated on social media and news platforms. These posts showed interior furnishings knocked over, building services systems broken, and dangerous conditions caused by these failures. Yet, these visuals and stories about NSEs were often used just as dramatic backdrops. The root causes of risk, the preventability of these failures, and the design responsibilities linked to them were rarely discussed in a technical or professional context .(Underwood et al., 2020).

Despite the fact that recent years have seen a dramatic rise in the engineering and architectural research on the seismic behavior of NSEs, a systematic study of the way this technical knowledge is presented to the general population via the media, the framing mechanisms applied, and the effects on social risk perception, has not been established. This is a serious deficiency in relation to the phenomenon of risk communication and design awareness which is also crucial to the development of disaster-resistant communities.

Even though the damages in the aftermath of the earthquakes are permanent and severe, the structural elements are often associated with the damage, whereas injuries and loss of the functionality of a building are closely connected with non-structural ones. In 1999, 50 percent of injuries and 3 percent of deaths in the İzmit earthquake were as a result of non-structural elements, according to Demir et al., 2024 all the building components and contents that do not comprise the load-bearing system are referred to as non-structural elements. They do not support any vertical or horizontal loads, but they are subjected to the identical seismic forces as structural elements and can collapse during the shaking of the ground (İpek, 2015). Such elements include architectural systems, mechanical systems, electrical systems, and plumbing systems, furniture, fixtures, equipment, and other contents (FEMA, 2017). A very broadest list of non-structural elements is offered by FEMA (2012), which includes three categories of them:

- Architectural Components: doors and windows, suspended ceilings, service floors, interior partitions, parapets, façade elements and glazing systems, cladding materials, stairways, architectural ornaments, shopfronts, railings, and similar components.
- Mechanical, Electrical, and Plumbing Components: pumps, chillers, heaters, HVAC units, pipes, generators, and related systems.
- Furniture, Fixtures, and Equipment (FFE): shelving units, cabinets, desks, chairs, ceiling-mounted televisions or monitors, hazardous materials, workshop equipment, museum artifacts, and collection items.

In the TÜBİTAK 1001 (2023) project numbered 121K927, non-structural elements were classified into three main categories: architectural elements, furniture and accessories, and electromechanical equipment. A total of 11 modules were identified, including 6 in architectural elements, 2 in furniture and accessories, and 3 in electromechanical equipment.

Like structural failures, the malfunction or displacement of non-structural elements can be life-threatening. Moving systems, equipment, and furniture may pose serious risks to occupants during an earthquake. However, when both structural and non-structural components are properly designed and installed by qualified professionals, the built environment can provide significantly safer conditions—particularly for vulnerable populations. For instance, furniture can create protective spaces during earthquakes, increasing the survival chances of older adults, individuals with disabilities, and children (Polat & Gül, 2023).

This study aims to address precisely this gap. Its central focus is to examine how NSEs were represented in Turkish news portals) during the first three months following the 6 February earthquakes—a critical period for public communication and meaning-making.

- The study seeks to answer the following research questions:Through which thematic frames (safety, responsibility, resilience, drama, etc.) were non-structural elements in interior spaces represented in post-earthquake digital media? (Nkrumah et al., 2025).
- Which actors (contractors, the state, users, experts) were foregrounded in NSE-related representations, and what roles were attributed to these actors? (Blum, 2024).
- How do these media representations influence the perceived role and societal relevance of the interior architecture discipline in reducing disaster risk? (Soriano et al., 2025)

Responding to these questions, the study will present an interdisciplinary contribution that will be found at the point of contact between the post-disaster communication and the media studies and interior architecture. The final objective will be to learn the effects of media narratives on the overall risk perception and protection behavior in the population, and to come up with recommendations on communication in the designing of disaster-resilient interior environments.

This paper explains the theoretical framework of a media discussion of the depictions of NSEs following an earthquake. In this regard, the notions of disaster studies, interior architecture and media studies were used. In the present work, the concept of NSEs, its purpose in disaster risk reduction (through the prism of interior architecture), media framing theory, and the influence of social media on disaster communications will be discussed (Bonati et al., 2023).

The media are an important participant in public opinion and policy processes and have a strong role in disasters. A framework that helps us understand how media create reality is Entman (1993). He defines framing as a process in which communication texts "select, emphasize, exclude, and organize" aspects of the perceived reality to promote a particular interpretation of an issue or object. This process serves four main functions

- Problem Definition: Defining and clarifying a problem.
- Causal Interpretation: We can explain the problem.
- Moral Evaluation: Making value judgments about the issue.
- Treatment Recommendation: Proposing solutions or interventions (Ercan et. al., 2022).

Frames used in disaster journalism are often "drama", "heroism", "helplessness", and "blame attribution" (Devès et al., 2019). Issues of the technical nature, such as with a non-structural issue, are often used for illustrative purposes within these dramatic frames without mentioning the technical nature and the cause of the problem. This narrows the public's understanding of risk, and hampers efforts at preparedness.

Unlike the one-directional structures of customary media, media platforms allow for a multilayered and participative approach to disaster communication (Bruns & Burgess, 2012).

- Rapid Information Flow: Real-time updates during crisis moments.
- Emotional Solidarity: A space for sharing trauma and expressing collective grief.
- Alternative Discourses: Dissemination of information that challenges or complements official narratives.

- Social Accountability: Opportunities for citizens to provide direct critical input with the goal to hold contractors or authorities accountable.

Existing scholarship has explored the technical performance of non-structural elements (FEMA, 2012), the role of interior environments in disaster management (Lizarralde et al., 2015), and media representations of disasters (Entman, 1993; Hasan et. al, 2017). Yet, there is no study that integrates these three strands to systematically examine how NSEs are represented in digital media following an earthquake—particularly within the context of Türkiye.

This research seeks to address this interdisciplinary gap and to initiate a discussion on how media representations shape public perceptions of the interior architecture discipline.

2. Materials and Methods

The study examines the media discourses of the NSEs in Türkiye using qualitative research techniques that analyze the media discourses created after the Kahramanmaraş earthquakes of 6 February 2023 (Aktuna & Bahar-Özvarış, 2023; Özbilgin et al., 2023). The article uses a descriptive content analysis research design as suggested by Krippendorff (2018), to determine the content, context, and themes of the media discourses.

Figure 1. Data Analysis Process

News Portals: All three news portals with the highest traffic and the most reports posted immediately after the earthquake such as NTV, BBC Türkçe, and Sözcü, were chosen due to their different media positions: mainstream commercial media, public broadcasting, and popular press.

This study seeks to examine, through qualitative content analysis, how non-structural elements (NSEs) were represented and discussed on digital platforms that include news websites following the earthquakes that struck on February 6, 2023. Analyzes were conducted through Excel spreadsheets specialized software was not used.

Content was retrieved using keywords such as *earthquake*, *furniture*, *interior*, *suspended ceiling*, *#deprem*, and *#mobilyasabitleme*. A total of 50 items were included in the dataset, consisting of 50 media posts. The analysis followed main steps:

All the gathered texts of news, and other related visuals were systematized in one folder. A unique identifier was given to each item, e.g., the news items were labeled with H1.

Table 1. Each content item was examined and coded under five categories in an Excel spreadsheet

Coding Category	Description	Example Codes
Theme	The overall subject of the content	"Safety Threat", "Accountability" "Resilience" "Drama"
Actor	Prominent individual or organization	"Contractor", "Government", "Disaster Survivor", "Expert"
Space	Depicted location	"Residence", "Office", "Hospital"
Emotion	Dominant emotion conveyed	"Anger", "Sadness", "Solidarity", "Neutral"
Visual Focus	Most salient NSE in images	"Overturned Cabinet", "Collapsed Ceiling", "Broken Glass"

Excel's filtering and pivot table functions were used to identify:

- The most frequently occurring themes
- Dominant emotions on each platform
- NSEs most commonly highlighted (e.g., overturned cabinets)

These analyses allowed the construction of thematic frameworks supported by quantitative summaries.

3. Findings and Discussion

As analyses of digital contents created during three months after the earthquakes that happened in February 6, 2023 show, there were specific patterns of how non-structure elements worked to reproduce them, with the differences between the traditional news portals.The results are discussed below.In news portals, NSEs were mostly deemphasized by structural collapse and placed in a small number of thematic lenses.

analyses of 50 digital contents created within the 3 months after the earthquakes on February 6, 2023 will demonstrate significant trends in the way non-structural elements (NSEs) were committed to each media platform.

There is a strong inbalance in the activity on the platform, with social media taking over the conversation after the earthquake (80% of the content). This implies that the role of the traditional media in disaster communication is somewhat reduced in comparison to its social media. The few content production of the news portals can be explained by the resource constraints and more time-consuming editorial process, as the communications at social media can create content that is instant and has mass production, making it a more efficient medium in emergency cases.

Table 2. Thematic Distribution Across All Contents

Theme	Frequency (n)	Percentage (%)
Drama/Helplessness	22	44%
Responsibility/Accountability	15	30%
Safety Threat	8	16%
Design Awareness	3	6%
Resilience/Survival	2	4%

The thematic analysis shows that close to 44% of the content is focused on drama and helplessness which is a classical tendency in disaster coverage. The high ranking of responsibility/accountability theme (30%) can be explained by the desire of the population to find justice and blame someone. On the contrary, the fact that design awareness is represented with the bare minimum (6%), shows that very little attention is paid to the technical and design components of NSEs and this is a sign of a discourse that places more emphasis on results than prevention.

Table 3. Thematic Comparison by Platform

Theme	News Portals (n=10)
Drama/Helplessness	6
Responsibility/Accountability	2
Safety Threat	1
Design Awareness	0
Resilience/Survival	1

Comparison of platforms reveals that they have varied differences in the themes covered. Newsportals underline the drama, which is in line with the traditional journalistic behaviors. Remarkably, every example of design consciousness can be found on media, indicating that these sources not only criticize but also encourage solutions and raise awareness of people, traditional media do not accommodate such content, which could be explained either by editorial decisions or simply by the lack of such viewpoints expressed by experts.

Table 4. Emotional Tone Distribution

Emotional Tone	Frequency (n)	Percentage (%)
Anger/Blame	20	40%
Sadness/Helplessness	18	36%
Neutral/Informative	8	16%
Solidarity/Hope	4	8%

The analysis of emotional tones shows that 76 percent of the content contains negative emotions (anger and sadness), which were the traumatic experience of the population after the earthquake. The prevalence of anger and blame is very high indicating that the society wants to hear its accountability. Information is neutral and objective (16%), which implies that rational and solution-oriented texts are less eminent. The very low ratings of solidarity and hope (8%) demonstrate that media reporting is mostly problem-oriented.

Table 5. Most Prominent Non-Structural Elements in Visual Content

NSE Category	Frequency (n)	Percentage (%)
Furniture (cabinets, shelves, beds)	25	50%
Architectural Elements (suspended ceilings, partition walls)	12	24%
Mechanical/Plumbing (AC, water systems)	8	16%
Other (chandeliers, windows, mirrors)	5	10%

Visual content analysis demonstrates that the most represented NSE is furniture (50%), probably because of its daily appearance and visual effects. Shelves and cabinets that have collapsed visually appeal and are directly connected to living spaces, which is why they feature in the media features. Suspended ceiling and partition walls have an architectural contribution of 24, which means that they are relevant as visual materials. Mechanical systems are underrepresented (16%) because of its hidden form and less impressive visual appearance. By and large, such distribution means that media focuses on NSEs that have great visual and dramatic potential.

Figure 3. Summary of Main Findings

These results propose that NSEs are mostly discussed in references of emotional and blame-related narratives instead of technical or design-oriented approaches.

4. Conclusion and Recommendations

This research shows that the design and safety of the non-structural aspects of design are not brought out clearly in the post disaster media coverage. The fact that dramatic and blame-oriented stories take the center stage of media coverage undermines the process of changing the topic of discussion to constructive and solution-driven discussions by the people. This low profile of the possible contributions of the interior design field in this respect can be seen as the lack of visibility, which, in addition to a professional gap, is also a serious weakness in the context of safety and resilience of the society.

To further studies, it would be of interest to carry out comparative studies of media representations of various disasters and in different cultural settings. Moreover, the experimental research investigating the effect of media content on the perception and behavior of the population may have a practical contribution towards establishing more effective disaster communication strategies.

Finally, it is necessary to have a combined effort that cuts across the media, design disciplines, and policymakers to develop disaster-resilient communities. The safety of non-structural elements should be the primary focus of this strategy because these elements are vital in minimizing damages, saving lives, and enhancing the general resilience of the constructed environment.

Abstract

"Sayfiye" areas emerged in 19th-century Europe to escape urban pressures and seek renewal. In Türkiye, this culture gained popularity after the 1950s, initiating a new spatial transformation through widespread second-home developments in coastal areas. Unlike large-scale tourism practices on the Marmara and Aegean coasts, development in the Edremit Gulf is dominated by individual second homes, fundamentally changing the region's olive-based rural character. This area has recently undergone a deeper transformation driven by luxury housing demand, particularly from Istanbul. This study examines the spatial hybridization of Edremit Gulf settlements, interpreted through the regional urbanization literature. The methodology includes mapping and spatial analyses to reveal growth and change, while zoning plans and demographic data assess the transformation. Consequently, the emergence of hybrid spatialities can be observed where rural landscapes intersect with second-home developments. This process involves the conversion of olive groves into residential areas, leading to transformations in traditional production patterns and the blurring of the urban–rural boundary, reflecting an ongoing process of regional urbanization.

Keywords: Second homes, rural settlements, spatial hybridization, Edremit Gulf, seasonal urbanism

1.Introduction

Places located outside the city but connected to it, which are visited for recreational purposes at certain times of the year, are defined today as secondary residences, while historically this phenomenon was known as "sayfiye." Derived from the Arabic words "sayf" (summer season) and "sayfi" (belonging to or related to summer), 'sayfiye' is defined by the Turkish Language Association as "a place or house where one spends the summer season" or "a rural area close to the city" (Türk Dil Kurumu, 2025). This concept has a conceptual depth that encompasses not only the structure used solely for spending the summer season, but also the region where this structure is located.

In Türkiye, the modern understanding of "sayfiye" seasonal leisure retreats used by urban residents began to take shape in the everyday practices of the urban elite in Istanbul from the 18th century onward. Throughout the 19th century, with the development of transportation, the transformation of leisure culture, and increasing class differentiation, areas such as Bosphorus waterfront mansions (*yalı*), garden pavilions, Adalar, and Kadıköy emerged as spatial manifestations of the seasonal movement from the city toward the countryside (Alkan, 2014). From the mid-century onward, improved transportation networks facilitated the emergence of "sayfiye" zones in regions beyond the Marmara area as well (Yağan, 2015, p. 115).

This state-supported process accelerated the discovery of Anatolia's coastal and rural areas, enabling a broader segment of society across different income groups to acquire second homes along the coast or in rural settings. Although initially perceived as a positive development, this trend turned into uncontrolled growth toward the end of the century, generating serious challenges. These dwellings, used only during certain periods of the year, remained vacant for the rest of the time, effectively transforming into "ghost settlements" a condition that continues to pose significant issues today (Çoban, 2012).

Today, second home mobility has evolved from a seasonal vacation practice into a multi-layered phenomenon that permanently alters regional economies, land use, and demographic structures. Unlike the rapid urbanization and tourism-focused large-scale projects observed along the Aegean and Mediterranean coasts, especially over the past twenty years, regions such as the Edremit Gulf, which have preserved their unique rural production structures, are being transformed primarily by individual second homes and, more recently, by increasing demand for luxury housing (Birol, 2017). This process is fragmenting the traditional fabric of coastal and rural areas, increasing real estate values, and accelerating regional urbanization processes that blur the distinction between urban and rural areas.

The primary objective of this study is to analyze the spatial hybridization experienced by rural settlements in the Edremit Gulf through second home development and the effects of this process on local identity. The study aims to evaluate the findings in light of the regional urbanization literature, demonstrating how rural areas integrate with new urban extensions.

2.Materials and Methods

2.1. Area of the Case Study

The Northern Aegean Region, as a significant part of the Mediterranean basin, encompasses the coastal strip extending from the Dardanelles Strait to the Foça district of İzmir on the map of Türkiye. This broad geography includes the provinces of Balıkesir and Çanakkale, as well as part of İzmir, offering a distinctive landscape where rural, coastal, and urban dynamics intertwine (Figure 1).

Figure 1. Edremit Gulf Area (Prepared by Authors)

The Edremit Gulf within this region has been designated as the main area of study due to its unique spatial development characteristics. Unlike other popular coastal areas in Türkiye, the

transformation in the Gulf is almost entirely focused on individual secondary residences rather than large tourism facilities. This situation provides a suitable ground for examining the direct impact of second homes on the rural character. The Edremit Gulf has been a holiday destination for the middle class from Istanbul and the Marmara Region, especially since the 1980s, and today it has established a deepening relationship with the demand for luxury housing from large cities.Within this unique context, the study covers the Edremit district of Balıkesir province and its coastal and rural neighborhoods in detail. The district of Edremit offers the opportunity to observe the process of spatial hybridization at different scales and layers, as it has both inner neighborhoods that maintain a strong rural production structure based on olive cultivation and coastal neighborhoods with a high concentration of second homes. The intersection of these two distinct fabrics forms a critical section where concrete problems such as the destruction of olive groves and the transformation of traditional structures are most clearly visible.

2.2. Methods

In this study, mapping, demographic analysis, and archival research were employed as the main methodological tools to examine the spatial transformation of the Edremit district through a multi-layered approach. In the first section, the historical evolution of summer resort areas and their transformation into second-home zones is explained. The subsequent section discusses the pressures on coastal areas and the Integrated Coastal Zone Plan developed to mitigate these pressures.

In the following part of the study, the spatial dimension of transformation in the Edremit district is analyzed by identifying the growth boundaries of coastal and rural settlements through satellite imagery from different periods. This mapping process concretely reveals the land-use changes, particularly in areas where olive groves have been destroyed and opened to residential development. To evaluate the legal framework of spatial change, the Balıkesir–Çanakkale Integrated Coastal Zone Plan was examined.

Additionally, by using periodic demographic data obtained from TÜİK, the long-term changes in rural and urban populations were analyzed. Ultimately, all findings derived from the mapping, legal review, and demographic analyses were interpreted in light of the regional urbanization literature, and the resulting spatial hybridization and the transformation of local identity were assessed.

3.Historical Development of “Sayfiye Houses’’

Structures located outside urban settlements and used for temporary dwelling can be traced back to Ancient Rome (Alkan, 2014, p. 16). The Roman aristocracy developed a seasonal lifestyle in which they could simultaneously maintain agricultural production and leisure, particularly through the construction of rural residences such as *villa rustica* and *villa urbana*, built to escape the heat and the intensity of the city during the summer months (Alkan, 2014, p. 16). In terms of both their functions and spatial configurations, these building typologies can be considered the earliest precursors of what is today conceptualized as sayfiye houses.

From the 15th century onwards, this concept has been maintained in various forms across Europe. For example, wealthy Florentine families in the Tuscany region had summer residences built outside the city, surrounded by nature; while in the 16th century, Venetians in the Veneto region built summer villas in rural areas, turning towards nature while also reproducing their urban identity in the countryside. These structures were not merely summer residences; they also functioned as representative spaces where art, landscape, and architecture converged.

"Sayfiye" areas that emerged in the 17th and 18th centuries began to proliferate rapidly after World War II, as the middle class discovered these places as recreational destinations (Özgüç, 1977, p. 13). Factors such as rapid economic growth in economically strong countries, urban expansion and increasing building density, the growing difficulties of urban life, advances in transportation technologies, the widespread ownership of automobiles, increased individual mobility, reduced working hours, and lower retirement ages all encouraged people to acquire a second home (Gündüz, 2003, p. 1).,

The formation of "sayfiye" culture in Türkiye has developed in parallel with the historical continuity of settlement traditions in Anatolia. The recreational practices observed during the Roman period through coastal palaces, bathhouses, and thermal springs continued in various forms throughout the Seljuk and Ottoman periods (Kuru & Yazıcıoğlu Halu, 2020).

In Türkiye, the modern notion of "sayfiye" began to take shape in the everyday practices of the urban elite in Istanbul from the 18th century onward. Although the "sayfiye" culture in Istanbul is known to have existed since the Byzantine period, it became more widespread among the general population in the 19th century under Ottoman rule (Yağan, 2015, p. 92). Throughout the 19th century, improved transportation opportunities, transformations in leisure culture, and increasing class differentiation led areas such as Bosphorus waterfront mansions (*yalı*), garden pavilions, Adalar, and Kadıköy to emerge as spatial expressions of the seasonal movement from the city toward the countryside (Alkan, 2014, p. 22).

The establishment of Şirket-i Hayriye, the city ferry company, in 1851 marked a turning point in accessing "sayfiye" areas (Yağan, 2015, p. 93). During this period, the Bosphorus and the Adalar developed as prominent "sayfiye" settlements. As "sayfiye" life became more common among the public in the 19th century, new spaces such as hotels, sea baths, beaches, summer cinemas, and waterfront entertainment venues also began to appear in addition to summer houses (Figure 2) (Özkahraman Şen, 2024, p. 47).

Figure 2. Sea Baths in İstanbul (Url-1)

During the Republican Period, with the dissolution of the Ottoman Empire and the establishment of the new state, Türkiye underwent extensive transformation processes across many domains. These changes also influenced *sayfiye* houses; particularly the innovations in

social and cultural life, along with the opportunities brought by technological developments, redefined both the architectural typology and the spatial distribution of *sayfiye* dwellings (Yağan Köylü, 2024, p. 1840). During this period, owners of traditional wooden summer pavilions began to demolish their houses and replace them with new modern villas (Özkahraman Şen, 2024, p. 48).

In Istanbul, Florya became an important *sayfiye* settlement especially for the general public. During the Republican Period, a decision was made to transform Florya into a coastal recreational facility. In this context, the Florya Public Beach was constructed in 1935, along with the Florya Sea Pavilion (*Florya Deniz Köşkü*), designed as Atatürk's summer residence (Figure 3) (Özkahraman Şen, 2024, p. 48).

Figure 3. Florya Atatürk Marine Mansion (URL-2)

From the mid-20th century onward, as intercity transportation opportunities improved, *sayfiye* areas began to emerge in various regions beyond the Marmara Region. Many of the *sayfiye* areas within Istanbul lost their recreational character as they became engulfed by rapid urbanization and were absorbed into the expanding city center. This transformation of *sayfiye* settlements also led to profound changes in the meanings attributed to these spaces by society. Traditionally, *sayfiye* areas were defined as places that allowed individuals to escape the pressures of urban life, rest, and reconnect with nature (Bora, 2014). Accordingly, these areas were expected to maintain limited construction, preserve the natural environment, and offer a lifestyle far from urban density.

As people sought to move away from the increasing pressures of the city, they began to turn toward coastal zones in different regions (Yıldız, 2011). In the 1960s, various holiday destinations in Türkiye started to be promoted through newspapers and brochures, and the first planned second-home settlements in the country began to be developed in Çeşme (Şuta, 2020).

The planning flexibilities and investment incentives provided by the 1969 Cooperatives Law and the Tourism Encouragement Law enacted in 1982 enabled state policies to be shaped in a way that supported the use of coastal areas for tourism purposes (Yıldız, 2011).

In 1969, the coastal strip between the provinces of Çanakkale and Balıkesir was designated as a Tourism Region, and tourism-oriented planning was envisaged for this area. From the 1980s onward, second-home practices began to spread across much of Türkiye's coastal zone.

An examination of the development of *sayfiye* areas in Türkiye reveals that the 1950s marked a significant turning point, after which these areas increasingly transformed into second-home zones. This shift profoundly altered the spatial organization, user profiles, and functional character of coastal settlements. As a result, the traditional *sayfiye* culture historically rooted in seasonal leisure and rest was gradually replaced by denser construction patterns, tourism-oriented developments, and a new coastal settlement model that supports continuous population mobility (Figure 4).

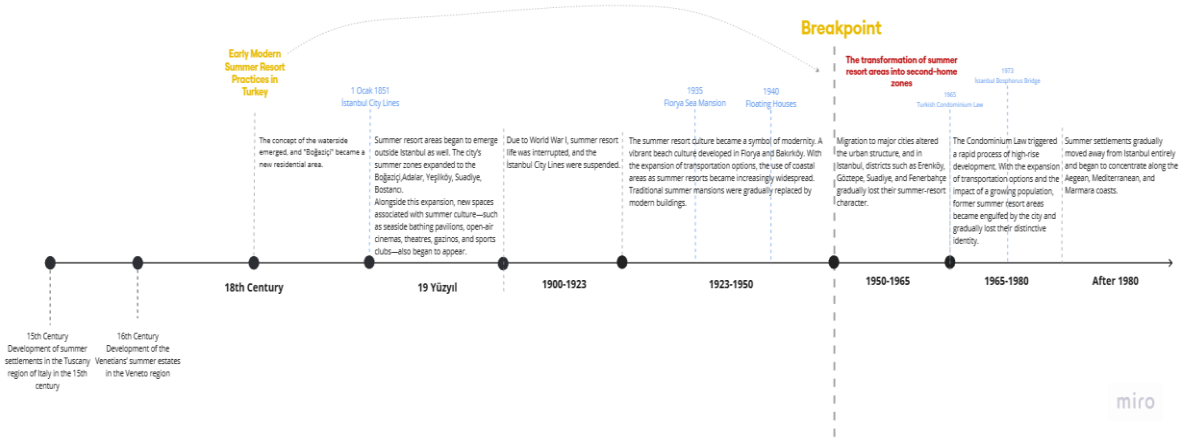

Figure 4. Historical development of summer resort areas (Prepared by the authors)

4. Threats to Coastal Areas and Integrated Coastal Management

The coast is defined as a transition zone between land and sea and has historically been an attractive area of settlement due to its natural characteristics and ecological opportunities. Coastal areas have become significant spatial focal points throughout different periods, preferred for settlement, production, and recreation owing to their transportation and trade advantages as well as their climatic and environmental benefits.

Coastal areas in Türkiye are confronted with a range of challenges. The primary sources of these issues can be identified as urbanization, tourism activities, specialized industrial uses, and the search for identity within coastal zones (Figure 5). The intense rural-to-urban migration of the 1960s brought about unplanned urbanization and informal construction, and coastal regions became some of the most affected areas in this process. The rapid expansion of cities, insufficient environmental control mechanisms, and infrastructural deficiencies weakened the fragile structure of coastal ecosystems in a short period of time. In addition, recent transformations in the energy, transportation, and housing sectors have further increased the pressure on coastal areas (Gülbitti & Özüduru, 2020).

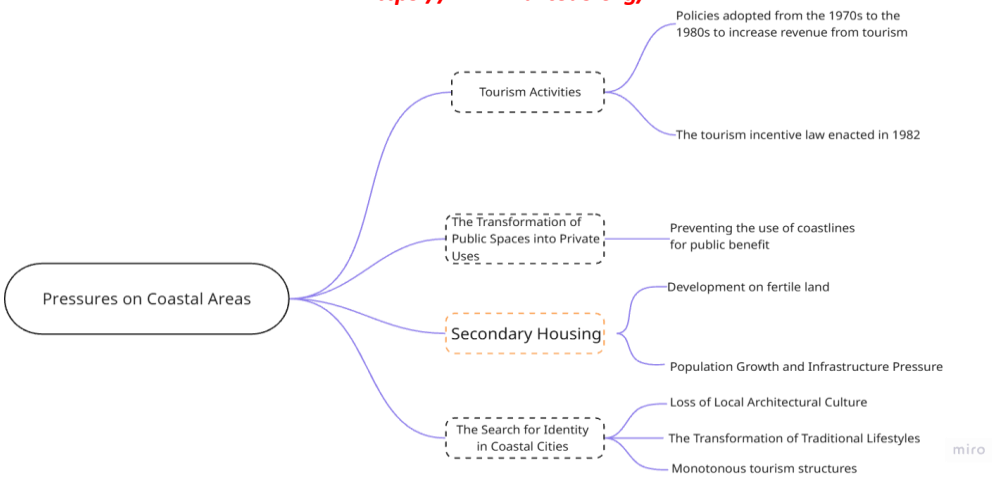

Figure 5. Pressures on Coastal Areas (Prepared by the authors)

Since the 1980s, state-led tourism policies have stimulated mass tourism along coastal zones and opened extensive areas to construction (Alkay, 1995). During this period, tourism centers expanded rapidly with the development of hotels and holiday complexes, while the growing number of second homes further intensified urban pressures on coastal regions. Consequently, coastal areas have increasingly lost their natural and cultural qualities and have become zones whose sustainability is seriously threatened by the combined impacts of tourism facilities and second-home development.

Ensuring the sustainability of coastal areas is closely tied to planning practices and coastal management. To support the sustainable use and controlled governance of these zones, the concept of Integrated Coastal Zone Management has emerged. According to the Spatial Plans Construction Regulation (2014), Integrated Coastal Zone Plans are defined as strategic plans prepared specifically for coastal and interaction zones, operating outside the formal spatial planning hierarchy and guiding lower-level zoning plans.

In Türkiye, Integrated Coastal Zone Plans have been prepared for various regions since 2007. The distribution of the 1/100,000-scale planning studies developed for different parts of the country is presented in Figure 6.

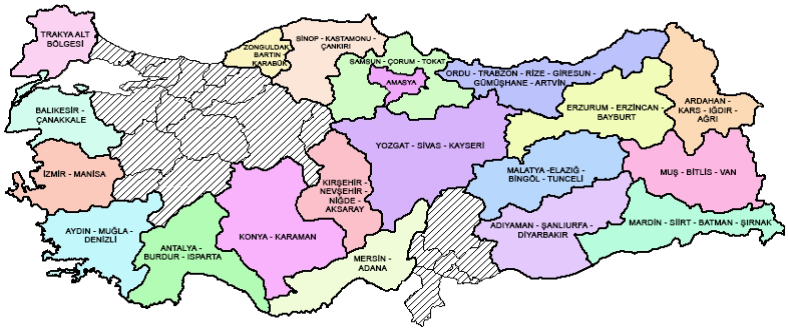

Figure 6. 1/100,000-scale Environmental Plan and the Integrated Coastal Zone Plans covering the coastal provinces (MPGM, 2023).

According to the seven main coastal regions defined in the Integrated Coastal Zone Plan for the Çanakkale–Balıkesir provinces, the area examined in this study the Edremit Gulf falls within Regions 5 and 6 (MPGM, 2023). Planning studies have been conducted for regions 5 and 6,

which are divided into sub-regions. Region 5 consists of an area rich in natural values. The most important value in the region is Kaz Mountains National Park (Uzun Aydın, 2024). While residential areas constitute the settled use of Region 5, the predominant non-settlement use areas consist of agricultural areas and forests. Among the settlements in the Fifth Region, the two districts with the highest population density are Edremit and Burhaniye. These districts are subdivided into sub-regions, with sub-region 5.1 covering Edremit and sub-region 5.2 covering Burhaniye district.

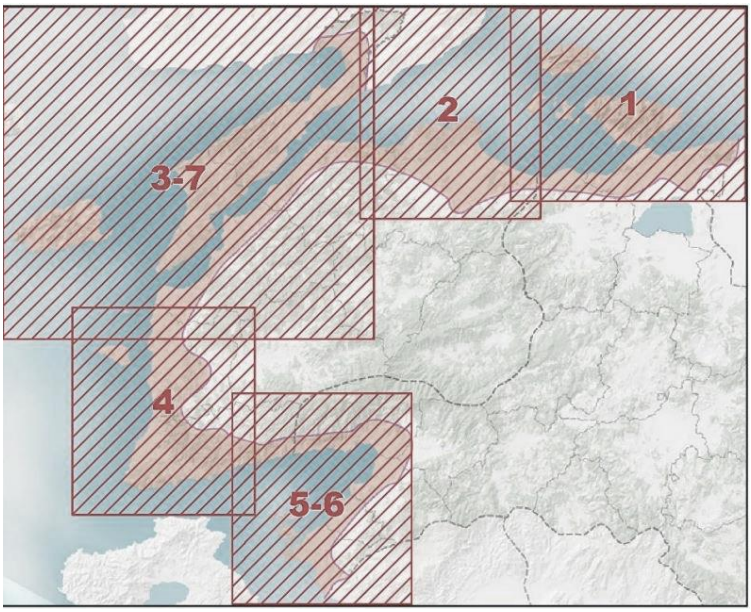

Figure 7. Seven main coastal regions defined in the Integrated Coastal Zone Plan for the Çanakkale–Balıkesir provinces (MPGM, 2023).

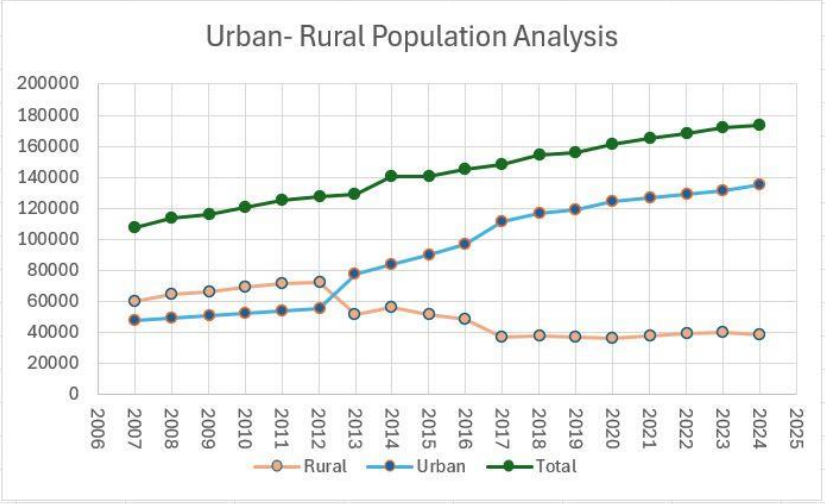
5. Spatial Hybridization and the Transformation of Identity in the Edremit Region

Within the scope of this study, the Edremit Region located in the fifth zone of the Integrated Coastal Zone Plans prepared for the Çanakkale–Balıkesir provinces was examined, with a particular focus on the spatial transformation and identity change occurring between rural and urban areas as a result of second-home development.

Located in the northwest of the Aegean Region, Edremit District is a settlement with 5 towns, 15 neighborhoods, and 20 villages belonging to the province of Balıkesir. However, with the law enacted in 2012, all settlements in the district have been granted neighborhood status as part of Balıkesir's process of becoming a metropolitan municipality. Currently, there are 47 neighborhoods. The district is located 10 km inland from the Edremit Gulf, which shares the same name. The neighborhoods of the district are lined up from the slopes of the Kaz Mountains overlooking the gulf to the Ayvacık district of Çanakkale (Şimşir, 2020).

The region is characterized by a Mediterranean climate, with hot and dry summers and mild, rainy winters. Most of Edremit’s vegetation consists of forested areas and olive groves (Kocadağlı, 2009). Olive groves account for 85% of the total agricultural land (Edremit Chamber of Commerce, 2021). According to data from the Edremit District Directorate of Agriculture, since 1990 a large portion of these olive-producing areas has been degraded due to second-home developments and tourism activities. Tourism in the region is known to have begun in 1969, when the Turban Holiday Village was leased by a French company (Uzun

Aydın, 2024). Following this period, the construction of second homes increased, accompanied by the development of boutique hotels, campgrounds, and summer housing complexes.



According to data obtained from TÜİK, the population of Edremit in 2024 is 173,689. Of this total, 15 neighborhoods are classified as urban, while 32 neighborhoods have a rural character (Table 1).

While the overall population of the settlement has continued to increase, an examination of the changes in urban and rural populations over the years shows that the population in urban neighborhoods has grown, whereas the population residing in rural neighborhoods has declined (Table 2).

Table 2. Edremit Urban/Rural Population

This situation is directly linked to the concentration of second-home oriented development along the coastal zones, the shift of the population withdrawing from agricultural production toward the service and tourism sectors, and the increasing development pressure on rural areas (Birol, 2017). The decline in the rural population leads to the weakening of traditional production practices and the transformation of rural identity, while the growth of the urban population—particularly in coastal neighborhoods—introduces new dynamics such as seasonal density, infrastructure pressure, and spatial hybridization. Among the urban neighborhoods of Edremit, Altınoluk and Akçay are located along the coastline and rank among the most populated districts in the region. As one moves inland from the coast, rural neighborhoods become more prominent; among these, Güre and Zeytinli maintain a rural character yet exhibit intensive second-home development (Figure 8).

Figure 8. Edremit Region Rural and Urban Neighbors (prepared by the authors based on Google Earth image)

An examination of the 2017 Çanakkale–Balıkesir Integrated Coastal Area Design reveals that land use in coastal zones has been largely allocated for development purposes. Residential and tourism-oriented development areas located immediately behind the shoreline constitute the uses that exert the greatest pressure on the coastal ecosystem. In contrast, moving inland from

the coast, forested areas and extensive olive groves dominate the landscape, indicating a stronger preservation of natural and agricultural environments. This spatial differentiation highlights the pronounced tension between the intense development pressure along the coastline and the agricultural production zones that remain protected in the inland areas.

According to the planning data, the Güre and Zeytinli neighborhoods examined within the scope of this study are marked in yellow and designated as "areas open to development" (MPGM, 2023). This indicates that these neighborhoods lie within potential development corridors where both current construction trends and second-home demand are expected to increase further in the future (Figure 9). The fact that olive groves in these areas are exposed to such development pressures presents a critical risk in terms of the weakening of rural character, the fragmentation of the natural landscape, and the acceleration of urban sprawl. Accordingly, the land-use pattern outlined in the plan provides important insights into the coastal–rural interaction across the Edremit Gulf and illustrates the deepening imbalance between dense coastal development and the preservation of agricultural and natural areas further inland.

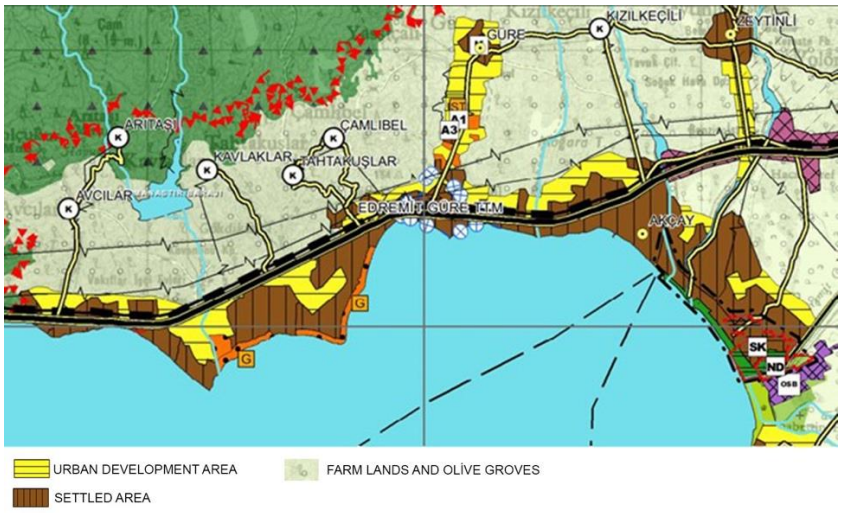

Figure 9. I17 Sub-Region of the 1/100,000-Scale Environmental Plan for the Balıkesir–Çanakkale Planning Area (MPGM, 2025).

An examination of the change in built-up areas over the years shows that, as indicated in the Çanakkale–Balıkesir Integrated Coastal Area Plan, the neighborhoods of Güre and Zeytinli have increasingly been opened to development. Coastal settlement areas, which were already subject to intensive use, have grown even denser over time, and the expansion of the building stock has produced a continuous urban fabric along the shoreline. This increase in density has reinforced second-home–oriented development trends spreading inland from the coast; consequently, agricultural landscapes particularly olive groves have begun to fragment, disrupting the continuity of the natural environment (Figure 10).

Moreover, the shift of development toward rural areas contributes to the blurring of spatial boundaries between the coast and the countryside, the erosion of traditional settlement character, and the increasing visibility of the region's vulnerability associated with seasonal population growth. This rise in building density intensifies pressure on infrastructure services, strains carrying capacity, and threatens the long-term sustainability of coastal ecosystems (Birol, 2017).

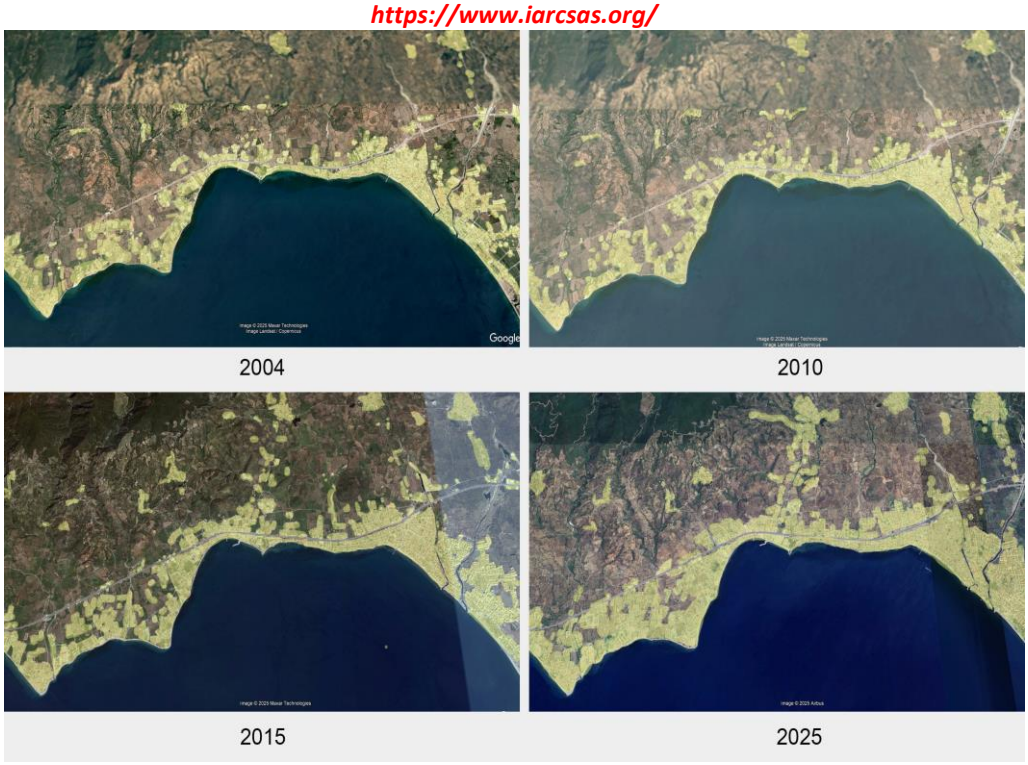

Figure 10. Temporal Transformation of the Built Environment in the Edremit Region (prepared by the authors based on Google Earth image)

The expansion of second-home oriented development into inland areas increasingly undermines the region's distinctive rural character. Güre Neighborhood possesses a unique settlement structure, shaped by its historical fabric that includes houses inherited from the Greek communities who once lived in the area, as well as traces of an olive-based production culture (Kahyaoğlu, 2021). However, the recent intensification of development pressure has made it difficult to perceive this distinctive character in a coherent and holistic manner (Figure 11).

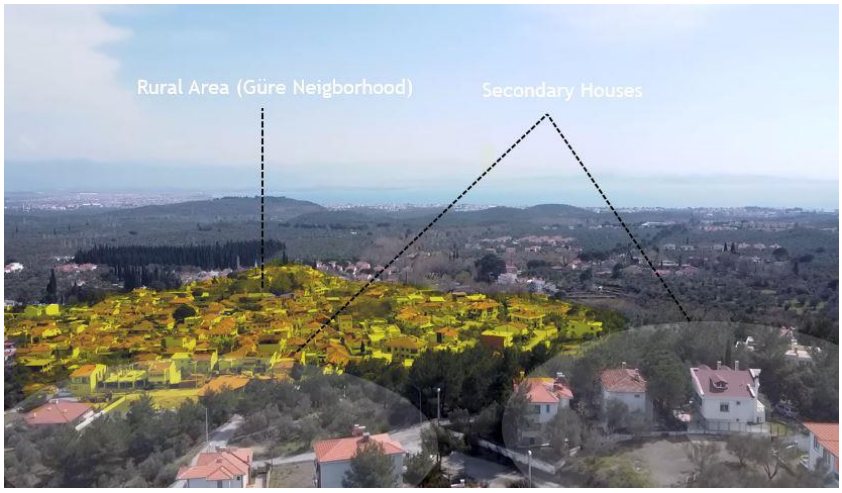

Figure 11. Temporal Transformation of the Built Environment in the Edremit Region (prepared by the authors)

The traditional houses built with stone or adobe construction techniques, which constitute the unique spatial character of the settlement, have gradually been replaced by new buildings of

low architectural quality, standardized forms, and weak connections to the local context. This transformation not only results in a loss of physical and architectural quality in the environment but also visibly erodes the historical identity and cultural memory of the settlement.

Figure 12. Example of traditional housing (left) and new building typology (right) (Aysu Çakır personal archive, 2024).

Identity-defining elements such as the traditional street layout, the use of courtyards, the material vocabulary, and the scale of buildings are increasingly fading under the pressure of new development; the unique rural spatial character is fractured and replaced by a homogeneous, repetitive, and often "everywhere-like" anonymous housing typology. This process generates both morphological and socio-cultural ruptures within the settlement: while the olive-based production culture weakens, seasonal second-home use introduces a new population profile and lifestyle into the neighborhood. Consequently, the historical and local identity is gradually pushed into the background, and the settlement assumes an intermediate character that can be described as spatial hybridization.

6. Conclusion and Recommendations

This study comprehensively reveals how the second-home development that accelerated particularly after the 1980s in the Edremit Region has transformed the spatial organization between the coastal and inland areas and how it has affected rural identity. The findings indicate that second-home–oriented growth is not merely a dynamic of physical expansion; rather, it represents a multilayered transformation process that redefines the interaction between coastal and rural zones.

Urry's (1995) approach, which argues that space is continually reproduced through consumption practices, provides an important framework for understanding this transformation in Edremit. According to Urry, modern individuals are drawn to certain places in their desire to escape the pressures of everyday life; however, this very act of consumption eventually triggers a transformation that erodes the unique qualities of those places (Urry, 1995). The rapid proliferation of second homes in the Edremit Gulf has evolved in a similar manner: coastal settlements initially chosen for their appeal as places "away from the city" have, under the pressure of rising demand, been reshaped into areas that reproduce urban lifestyles, housing typologies, and expectations. Consequently, these coastal settlements have gradually lost their inherent *sayfiye* character and, in line with Urry's conceptualization, have become spatial commodities that are consumed and continually reproduced (Urry, 1995).

The spatial analyses of the study show that second-home developments concentrated along the coastline have gradually expanded inland, leading to significant fragmentation of the agricultural landscape, particularly the olive groves. Urbanization advancing toward the Kazdağları National Park has also begun to pose a threat to protected sites over time (Uzun Aydın, 2024).

In rural neighborhoods characterized by traditional stone and adobe housing patterns, the local architectural identity has weakened, giving way to standardized, low-quality, and contextually detached building typologies. This shift can be regarded as a significant rupture that undermines the historical continuity of the settlement and accelerates the erosion of rural identity. Population analyses based on TÜİK data reveal a steady population decline in inland neighborhoods, in contrast to the increasing urban population in coastal areas. This pattern creates a fragmented settlement structure shaped by seasonality and second-home use, leading to marked changes in the region's socio-economic fabric. The sharp rise in population during the summer months places considerable pressure on infrastructure and challenges the carrying capacity of these settlements, while the dramatic population decline in winter prevents the maintenance of a coherent year-round settlement cycle.

Planning documents indicate that the neighborhoods of Güre and Zeytinli are designated as "areas open to development," signaling that current pressures are likely to intensify in the future. In this context, the protection of olive groves, the ecological management of the coast–rural transition zone, and capacity-based planning for second-home development are of critical importance for the sustainability of the region.

To mitigate the adverse effects of second-home driven spatial hybridization in the Edremit Region, there is a need for planning strategies grounded in carrying-capacity–based coastal–rural management. Protecting olive groves and agricultural landscapes through clear regulatory measures, limiting building density, height, and parcel-based development in "areas open to development" such as Güre and Zeytinli, and concentrating new second-home growth in designated zones while strictly restricting construction in ecologically sensitive areas would help preserve both the coastal ecosystem and the continuity of the rural landscape.

Furthermore, managing the ongoing transformation of local identity requires tools not only at the planning scale but also at the level of architectural character and participatory governance. Design guidelines that reference the traditional stone and adobe housing patterns, street layouts, material use, and building scales, along with mechanisms supporting the registration and maintenance of culturally significant structures, can strengthen the visibility of rural architectural heritage. Ensuring that these processes involve local governments, professional chambers, civil society actors, long-term residents, and second-home users will allow seasonality, infrastructure pressures, and identity-related challenges to be addressed more holistically. Such an approach also creates a foundation for comparative research on spatial hybridization dynamics across other coastal regions in Türkiye.

Abstract

Traditional wall construction techniques have produced solutions of high value in terms of functionality, aesthetics, and culture across different geographical regions by adapting to local materials and climatic conditions. Methods known as "Bağdadi" and "Çörten" in Turkiye, "Wattle and Daub" in Europe, and "Oeyeokki" in Korea have resulted in structures that are both durable and visually striking through the creative combination of natural materials such as wood and earth. A review of the literature reveals that traditional wall techniques not only address local needs but also play an important role in social memory, craftsmanship knowledge, and cultural continuity. These systems directly reflect sustainable design approaches through their contributions to moisture management, thermal insulation, and material efficiency. The study compares the historical origins, structural characteristics, and environmental contexts of these techniques to explain why similar methods developed in different regions. It also discusses how these traditional techniques can inspire modern architectural practices in terms of sustainability, material efficiency, and the preservation of cultural heritage. The results indicate that these construction methods are not only a reflection of the past but also an important resource for environmentally friendly and innovative designs. Consequently, the preservation of traditional wall construction methods and their adaptation to contemporary architectural practices are considered important approaches that can contribute both to the preservation of regional identities and to the development of sustainable building practices.

Keywords: Bağdadi, wattle and daub, oeyeokki, traditional wall construction, cultural heritage.

1. Introduction

Traditional timber construction methods can look quite different from one region to another, but they almost always reflect the everyday life and values of the people who built them. The wooden buildings in the Dong community, for example, have very unique shapes and meanings. They clearly show how their cultural traditions affected how they built (Huang & Qin, 2023). In Korea, the method is a little different. Builders often used gently curved wood pieces to make the building stronger and because it looked more elegant (Ryoo & Youn, 2019). These kinds of examples suggest that traditional builders had a strong understanding of their environment and materials, and they tried to design in a way that felt natural and appropriate for where they lived.

Environmental factors also shaped timber systems in many places. In Aceh, Indonesia, people used hardwood species that could stand against pests and decay (Novita et al., 2020). Most traditional wooden buildings make use of local materials, which bring advantages like insulation and even better acoustics (Shabani et al., 2020). Still, they are not perfect; wooden structures can be affected by biological problems. For instance, climate change has made

termites more active in Korea, which puts many old wooden sites in danger and shows that better ways to protect them are needed (Kim & Kim, 2023).

In different regions, wooden buildings also carry cultural and symbolic meaning. The old wooden houses in Istanbul are a prime example. They reflect centuries of local life, but many are now under pressure because of rapid urban development (Ergün & Mazlum, 2015). Understanding these structures enables us to appreciate their significance. The traditional craftsmanship, small details and decorative features also show how important it is to protect regional architectural identity, especially today when cities are becoming more uniform.

Traditional wooden buildings can even support the local economy. Some regions use their timber heritage as part of ecotourism, drawing visitors who are interested in culture and sustainability. This can help local businesses and, at the same time, support the preservation of these buildings (Okan et al., 2016). When traditional architecture is understood as both a cultural and an economic resource, communities are more encouraged to protect it and promote sustainable tourism.

Traditional timber construction still has a strong influence on modern architecture. Using local materials and older carpentry techniques can help cut down on transportation-related carbon emissions and support more sustainable building practices overall (Bartha & Olarescu, 2020). These approaches also keep traditional skills in use and allow local communities to stay involved in the construction process.

The design of wooden buildings is also influenced by environmental factors. In places with plenty of forests, people usually take advantage of the wood species they can find nearby. A clear example of this is the “serender” barns in Türkiye’s Eastern Black Sea region, which are built from local timber and carefully adapted to the climate there (Erarslan, 2020). These barns show how the availability of local materials affects not only the form but also the function of a building.

Cultural and social elements are just as important. Local traditions, beliefs, and aesthetic preferences influence how wooden structures take shape. For instance, Korea’s traditional bracket systems are not only useful as structural components but also carry symbolic cultural meanings and often catch the interest of visitors (Ryoo & Youn, 2019). Many traditional timber systems around the world also share similar construction practices. Mortise and tenon joints seen in ancient Chinese temples are a good example of carpentry techniques that have been passed down for many generations (Zhang et al., 2024).

Environmental factors like climate, terrain and the materials people have around them all play a big part in shaping wooden architecture. Even if the cultures are completely different, they can develop strikingly similar building styles when they are subjected to similar conditions (Huang & Xue, 2024). At the same time, architectural styles help build a sense of cultural identity and history for a place (Xie et al., 2023). A single building can follow global design trends while still showing its local character and maintaining its connection to the region (Aly & Lotfi, 2023).

In this study, traditional wall-building methods that developed in different regions under similar cultural and environmental situations were examined. The main goal is to compare buildings that use the wattle and daub technique and to point out the shared principles that make this method environmentally sustainable. Within this scope, systems known as Bağdadi and Çöten in Türkiye, Wattle and Daub in Europe, and Oeyeokki in Korea were analysed. In order to

support sustainable architectural design in the modern era, recommendations were made regarding how traditional construction knowledge could be modified to accommodate their material use, structural behavior, and environmental compatibility.

2. The Historical Development of Traditional Wall Construction Techniques

One of the oldest and most common techniques in timber construction is the mortise and tenon joint (MTJ), where two wooden elements interlock without the need for metal fasteners. This method has been used in major historical buildings such as the Daxiong Hall in China and provides a strong and durable connection between wooden parts (Zhang et al., 2024). Timber construction methods vary by region. For example, in northern Europe and the Alpine areas, people built log walls using solid timber to withstand cold and harsh climates (Steiger, 2020). These structures show how communities adapted their building traditions to their environment. In southern China, where humidity is high, timber panel walls became common because their moisture and thermal performance better suits the local climate (Zhao & Künzel, 2023). These examples illustrate how timber construction responds to both cultural needs and environmental conditions.

Recently, interest in timber buildings has grown due to the development of engineered wood products such as cross-laminated timber (CLT) (Tonyalı et al., 2024). In the past, stone and brick were often preferred because of their fire resistance and durability (Leszczyszyn et al., 2022). However, improvements in wood preservation and construction technologies have made wood an important sustainable option for modern architecture. Studies also show that timber has a low carbon footprint and is suitable for mid-rise buildings (Chen et al., 2020; Akkan Çavdar & Vural, 2024). This indicates that traditional timber knowledge can be successfully applied in contemporary sustainable design.

Wooden wall systems have been around for thousands of years. This long use shows that wood is a flexible and dependable material. In very early periods, wood was used for many parts of a building, including walls, foundations, and load-bearing elements. Some early cultures even used timber to build wells (Kovács & Hanke, 2015; Tegel et al., 2012). Over time, each region created its own wall types based on local traditions and practical needs.

In medieval Europe, one of the most recognisable techniques was the half-timbered system. Builders framed the structure with timber and filled the spaces with brick or plaster, giving the buildings both strength and a unique look.This method became especially widespread between the 14th and 16th centuries (Escobar et al., 2020; Staveley, 2000). In Northeast Asia, timber framing stayed influential in housing design. Korean wooden homes followed local traditions but slowly adopted certain ideas from North American and European construction (Lee et al., 2020). All of these examples remind us that architecture is always in motion, shaped and reshaped as cultures interact and learn from one another.

Existing research further demonstrates the strong seismic behaviour of wooden walls. Findings suggest that timber systems offer greater resistance than unreinforced masonry, particularly in earthquake-prone regions (Hariyanto et al., 2022). In several countries, builders added wooden components to stone or brick structures to make them more resistant to earthquakes. Historical buildings in Italy are a good example: timber supports hidden within the walls helped increase their durability during seismic events (Touliatos, 2015). Such examples demonstrate how adaptable timber systems are to various climates and soil types.

As climate conditions change, traditional timber structures need to be reinterpreted with modern knowledge while still protecting their historical value (Erarslan, 2019; Zhao et al., 2023). Restoring traditional wooden walls with local materials and contemporary construction approaches can contribute to safeguarding cultural heritage while also improving structural behaviour (Brimblecombe et al., 2011).

3. Primary Wall Construction Techniques Used in Different Regions

Traditional woodworking techniques can primarily be classified according to the type of work being done. One such technique involves joining wooden pieces without the use of nails or screws. Methods such as mortise and tenon, tail and finger joints reflect a deep understanding of the characteristics and structural strength of wood (Aguilera & Martin, 2001; Sandak & Sandak, 2021). These techniques go beyond their functional role; they also reflect the craftsmanship that influences how the final product looks. Equally important are finishing methods that enhance the wood's appearance and extend its lifespan. Traditional methods include varnishing, oiling, and coating with natural dyes or stains (Baysal et al., 2013). For example, the yaki-sugi (Shou Sugi Ban) technique used in Japan blackens the wood by burning it; this method both gives the wood a unique visual texture and protects it from the weather (Fahrussiam et al., 2023; Kerdiati, 2021).

Traditional timber wall construction techniques can generally be categorised as log structures, solid timber structures, frame structures, and infilled frame structures. Güneş (2014), who provides a broader classification, initially divided traditional timber wall systems into timber block and timber frame. Timber block walls are further divided into timber log walls and block timber infill walls, while frame walls are divided into Timber Frame Walls with cross elements (Çatkı) and Timber Frame Walls without cross elements (Çatkısız), depending on whether or not they contain supporting cross-timber elements. The walls created using the wattle and daub technique and concept examined in this study fall under the Timber Frame Walls with cross elements (Çatkı) wall system. The *Bağdadi* (Lath and plaster wall) wall system is a non-filled (containing compressed air) system, while *Çöten, Wattle and Daub*, and *Oeyeokki* are included in this classification as filled frame wall systems. This broad classification is shown in Figure 1.

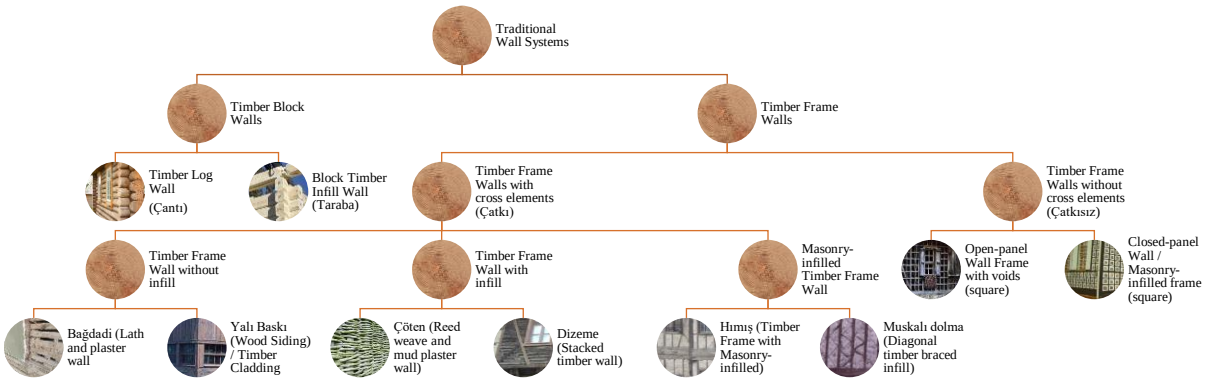

Figure 1. Classification of wall systems in traditional timber constructions (Güneş, 2014; *recreated*).

In log house construction, which is common in Finland and other Scandinavian countries, the logs are stacked horizontally to form the walls. Thanks to wood's natural insulating qualities,

these buildings are well suited to cold climates. Log structures are a sustainable traditional method that requires minimal processing using local materials (Ilgın & Karjalainen, 2023). Solid timber systems incorporate engineered timber materials to create thick, load-bearing walls. They combine traditional methods with modern materials science and offer a lower carbon footprint compared to concrete or steel (Ilgın & Karjalainen, 2023; Buchanan & Honey, 1994).

Timber frame structures utilise a framing system composed of timber posts and beams. The frame bears the load of the structure, while infill materials such as stone, adobe, or wattle and daub are placed between the frames. These systems have been favoured, particularly for their earthquake resistance, in regions such as northern China, Portugal, Türkiye, and Mediterranean countries (Vasconcelos & Poletti, 2015; Shen et al., 2022). Historic timber-framed structures not only offer a traditional aesthetic appearance but also demonstrate long-lasting resistance to earthquakes. In infilled timber frame systems, the timber frame is combined with infill materials. For example, adding stone and adobe to walls increases the energy efficiency and thermal performance of the structure (Shen et al., 2021; Shen et al., 2022; Poletti & Vasconcelos, 2014). These systems provide both structural and thermal advantages and adapt to local climate and material conditions.

In Türkiye, timber wall construction systems are similarly classified into three types: masonry, frame (skeleton), and timber-framed (Sümerkan, 1990). In masonry wall systems, timber is used as the main element of the wall, while in frame systems, timber only serves as a frame, and the voids within the frame can be filled with different materials to provide some insulation. In Türkiye, particularly in the Black Sea and Central Anatolia regions, the ‘hımış’ technique is widely used as a method of placing infill material into a wooden frame. In this technique, timber frame walls are first constructed, then materials such as stone and adobe found in the surrounding area are filled into the voids. This both completes the structure of the walls and reduces heat loss (Aşanlı, 2021).

An example of a skeleton system similar to the hımış wall technique is the ‘bağdadi’ system. In this system, the inner and outer surfaces of the walls are covered in an airtight manner and plastered with a special plaster, thus trapping air inside the wall. In addition, infill materials such as adobe, wood or stone can be used to provide additional insulation (Şenol & Akan, 2011). Similar to the plastered *Bağdadi* system in Türkiye, in Korea, wooden panels are plastered with mud to provide insulation in walls (Cho, 2010). In traditional techniques, organic materials such as straw bales or infill materials such as adobe, stone and wood are used for insulation (Kafesçioğlu, 1955). It can be said that these methods, known as ‘Bağdadi’ and ‘çöten’ in Türkiye, “Oeyeokki” in Korea, ‘Wattle and Daub’ in England, and ‘Zhúbiān Tǔ Qiáng’ in China, are both widespread and locally applied in different geographical areas (Güneş, 2014; Akkan Çavdar & Lakot Alemdağ, 2024).

3.1. An examination of the wall techniques ‘Bağdadi’, ‘Çörten’, “Oeyeokki” and ‘Wattle and Daub’

The names of these wall techniques directly reflect not only the construction systems themselves, but also the cultural thinking and material logic behind these systems. Each one, with its root meaning in the local language, defines the fundamental action of the construction process: the *Bağdadi (lath and plaster)* system refers to the structure formed by binding wooden slats together; the *Çöten* system (*reed tissue + mud plaster*) refers to the weave formed by thin branches; *Oeyeokki (woven on the outside)* technique, in its literal sense, the ‘weaving on the

outside' method; *Wattle and Daub (woven and mud plaster)*, the process of 'plastering the woven branch skeleton with mud'. These names emerge as a linguistic reflection of craftsmanship knowledge in each culture; despite the formal differences between the systems, they show that they are united around a common action of 'weaving, binding and covering'.

Bağdadi and Çöten system:

The *Bağdadi* system is created by covering both sides of the wooden frame with battens approximately 3 cm thick, placed at intervals of 2–2.5 cm, and then covering the surface with lime-based plaster. The *Bağdadi plaster* (horasan mortar) applied to the gaps between the slats seeps back, ensuring the integrity of the wall, and the air layer remaining inside the frame acts as thermal insulation. In some examples, these gaps are filled with earthen mortar. The plaster, made with lime binder and brick aggregate Horasan mortar, prevents rain from seeping in while providing a breathable structure (İpekoğlu, Böke & Çizer, 2007; Erman, 2000). The system adapts well to the region's humid-temperate climate due to its lightness, moisture-resistant properties, and the possibility of large window openings (Aşanlı, 2021).

Historically concentrated in the Trabzon and Giresun areas, this technique is defined as a building system that provides thermal comfort by keeping buildings warm in winter and cool in summer (Tuna, 2008; Şahin, 2013). This system provides resistance in earthquakes thanks to flexible connections; in Anatolia, 'Bursa-type' (close spacing) (1.5-2 cm) and 'Antalya-type' (more sparse) (4-7 cm) applications are common. In the Black Sea region, a similar system called 'çöten' exists, where the wall is constructed in a lattice pattern (Erarslan, 2019; Erman, 2000). *Çöten* structures generally refer to barns in the region and are used without plastering to allow crops to dry and moisture to be removed. Figure 2 shows examples of *Bağdadi* and *Çöten* walls.

Figure 2. An example of a bağdadi building and a çöten building with crumbling plaster (Erarslan, 2019).

The *Çöten* timber-filled wall system (*reed tissue + mud plaster*) refers to a filling technique in which the gaps between timber framework elements are filled with thin branches woven horizontally to a thickness of 2–3 cm, and then covered with plaster on both the inside and outside to create a solid wall (Güneş, 2014). This construction technique is also known in the Balkans and has been observed in Anatolia since the early Neolithic period (Gündoğan, 2018). Figure 3 shows examples of *bağdadi* walls and *çöten* walls using the lattice technique and the different uses of wood in walls. *Bağdadi* battens are placed in front of and behind the wooden posts, creating an air gap in the interior, while the branches used for *çöten* walls are interwoven between the intermediate posts to fill the interior void.

Figure 3. Example of a *Bağdadi* wall and a *çöten* wall (Güçhan, 2017; Güneş, 2014; *Original: Arun, 2013*).

Wattle & daub system:

The *wattle and daub* system is defined as *"a framework of woven branches covered with a clay-based plaster"* and is considered the most characteristic wall type in rural English architecture due to its flexibility, moisture permeability and repairability (Graham, 2009). It is a traditional infill system created by placing vertical poles (staves) between wooden frames, weaving hazel or willow branches (withy) horizontally around them, and plastering the surface with a daub layer consisting of a mixture of clay, straw, dung, and lime. Studies of the Wiltshire region indicate that the staves are usually made of oak or hazel, with a diameter of approximately 20–30 mm; the weave spacing varies between 250–450 mm and the plaster thickness averages 30–50 mm (Graham, 2003). This technique, traces of which have been found in Europe since the Neolithic period, was widely used, particularly in rural dwellings and granaries (Shaffer, 1993). The woven part forming the inner part of the wall — the 'wattle' — is usually made of flexible willow, hazel or oak branches. This wattle serves as a filler that carries the daub rather than the load. The daub applied over it is a mortar consisting of clay, straw and sometimes lime, providing both insulation and surface protection. While wet, it is pressed onto the wall by hand or with a trowel, hardening as it dries, with cracks being filled with new layers. With these characteristics, the system offers a breathable and renewable building envelope (English Heritage, 2009) (Figure 4).

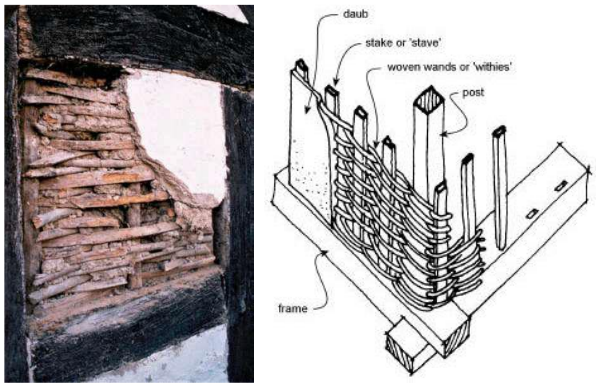

Figure 4. Wattle and daub system within a timber wall (Graham, 2009).

Archaeomagnetic studies, particularly investigations conducted on structures belonging to the Stentinello culture in the Calabria region of Italy, have revealed that such structures were occasionally deliberately burned to harden the walls. The sintered clay fragments resulting from

the burning were reused as filler in the mortar of new walls. This situation is interpreted as a prehistoric example of material recycling (Shaffer, 1993). In recent conservation practices, field studies in the Wiltshire region of England have documented in detail the maintenance requirements of wattle and daub walls against climatic conditions. The cracking of the plaster layer over time is remedied by the natural renewal of the material in response to moisture and frost cycles. This technique is considered an important historical reference for bio-based wall systems in contemporary sustainable architecture (Harrison, 2018).

Oeyeokki system:

Oeyeokki, literally meaning 'woven from the outside,' is a woven infill wall system in traditional Korean architecture, created by weaving horizontal and vertical branches, bamboo, or reeds between wooden frames. In construction, horizontal pieces called *nulhoi (*눌외*)* and vertical elements called *seolhoi (*설외*)* are tied together with string or reeds to form a net-like skeleton; this surface is plastered with a mixture of clay, straw, lime and funori (seaweed extract). This natural mixture increases both flexibility against cracks and vapour permeability (Cho, 2014).

Widespread during the Joseon Dynasty (1392–1897), this system was used particularly in temples and government buildings. Internal reinforcement posts called *joongkit (*중깃*)* and horizontal spiked elements called *sakmok (*槊木*)* support the woven layer. Studies reveal that examples of this system have been documented in the Huireung Jeongjagak, Heungneung Jeongjagak, Yulgok-sa and Yongmun-sa structures. These elements are placed approximately 500 mm apart in the walls, with 30×15 mm vertical 'spike' elements and 10–20 mm horizontal battens woven between them. The mud plaster layer applied over them strengthens both the load-bearing capacity and the heat-moisture balance of the wall (Lee & Jang, 2019) (Figure 5).

Figure 5. Elements and mesh appearance in the *Oeyeokki* system (Lee & Jang, 2019).

In some examples, it has been observed that the wall is constructed in a two-layered (front and back) manner with an air gap in between (Cho, 2014). This system adapts to Korea's humid climate conditions while also increasing seismic resistance due to its lightness and flexible structure. However, Lee & Jang (2019) emphasise that in cultural heritage restoration, bamboo weaving techniques sometimes replace the traditional *Oeyeokki* weave, and this change may undermine the original Joseon-era understanding of materials (Figure 6).

Figure 6. The *oeyeokki* walls of Yongmunsa and Jongmyo Shrine (Cho, 2014; Lee & Jang, 2019).

4. Comparison of Lath And Plaster Techniques and Common Points

The wall techniques examined in this study—*Bağdadi/Çöten* (Turkiye), *Wattle and Daub* (Europe), and *Oeyeokki* (Korea)—are based on similar principles, despite having developed in different regions. In all three methods, the basic structure consists of a lath and plaster system based on a wooden frame and earth-based plaster/filling. These similarities demonstrate that people in each region developed similar solutions, taking into account local materials, climatic conditions and daily needs. Table 1 provides a comparison of traditional lath and plaster wall construction techniques.

Table 1. Comparative table of traditional lath and plaster wall construction techniques

				
Feature	**Bağdadi (Turkiye)**	**Çörten (Turkiye)**	**Wattle & Daub (England / Europe)**	**Oeyeokki (Korea)**
Main Material	Wooden laths + lime plaster	Thin branches + mud plaster	Willow / hazel rods + clay–straw mix	Bamboo + clay–lime–seaweed mix
Structural System	Timber frame with double-sided lath covering	Timber frame with horizontal reed weaving	Timber framework with interwoven rods	Timber / bamboo frame with woven infill
Binder Material	Lime-based mortar (Horasan)	Mud + lime + straw	Clay, straw, dung, lime	Clay + lime + *funori* (seaweed extract)
Climatic Suitability	Humid–mild (Black Sea region)	Humid rural areas	Mild–temperate (Europe)	Humid–rainy (East Asia)
Thermal Performance	Medium–High (air cavity insulation)	High (natural ventilation)	Moderate (thick daub layer)	High (double-layer wall)
Flexibility / Earthquake Resistance	High	Medium	High	High
Material Availability	Local timber and lime easily accessible	Reed and clay widely available	Organic materials common	Bamboo and lime regionally available

Maintenance Requirement	Moderate	Low	High (requires re-plastering)	Moderate
Cultural / Craft Value	High – reflects local identity and craftsmanship	High – rooted in rural culture	Moderate – agricultural heritage	High – temple and palace tradition

In terms of materials, the fundamental aim in all three regions is to utilise locally available natural materials. In Turkiye, the *Bağdadi* and *çöten* walls are constructed using local tree species to form the framework, thanks to the abundant forests of the Eastern Black Sea region; the gaps are then filled with mortar, clay, or a mixture of straw and earth, or in some structures, they are left without plaster. In the European *wattle and daub* technique, a woven surface made from flexible willow branches is covered with straw-mixed earth mortar. In the Korean *oeyeokki* system, a wooden frame is used in combination with a mixture of earth and gravel. These examples show that the 'wood + earth' combination is interpreted in a similar way in different geographical areas.

From a climatic perspective, it can be seen that all three systems are shaped by the humidity, temperature and rainfall conditions of their respective regions. In the humid-temperate climate of the Eastern Black Sea, the air gap and lime-based plaster used in *Bağdadi* walls both protect against rain and help the wall release moisture. In the Çöten system, leaving the walls unplastered allows products to dry, especially in barns, and facilitates the renewal of indoor air. In the European wattle and daub technique, thick earth fill stores heat during the day and releases it at night, balancing temperature differences. *Oeyeokki* walls in Korea are designed to be breathable yet water-resistant, adapting to rainfall and seasonal humidity changes. Therefore, although these three techniques developed in different geographical regions, they represent a common approach to passive climate control.

Structurally, the seismic behaviour of wattle and daub walls is quite similar. In such structures, the timber frame provides the main support, and the earth or mud filling works mostly as a shell that controls heat and moisture. Thanks to the flexible structure of the wooden frame, the walls can move under horizontal loads, and any cracks that form are generally easy to repair. Studies in the literature also indicate that such timber frame-infill walls, when constructed with appropriate details, can perform well in earthquakes. Therefore, the *Bağdadi*, *wattle and daub*, and *oeyeokki* systems exhibit similar seismic behaviour based on the common principle of 'timber frame + flexible infill,' even though they use different materials.

From a social and cultural perspective, wattle and daub techniques are not merely a method of wall construction, but also part of traditional craftsmanship and anonymous architectural knowledge. The techniques used in these systems are based on manual labour passed down from master to apprentice and have been sustained across generations. In Turkiye, *Bağdadi* and *çöten* walls have become a cultural element of rural life, while *wattle and daub* structures in Europe reflect the historical identity of villages. In Korea, *oeyeokki* walls are an important part of cultural continuity in temples and traditional dwellings. Therefore, wattle techniques can be considered cultural elements that not only produce structures but also shape local memory and regional identity.

Despite these similarities, there are some important differences between the systems. In *Bağdadi* walls, the outer surface is usually plastered and smooth; in contrast, in *wattle and daub* examples, the wattle texture is partially visible on the façade, particularly in barns and agricultural structures. In Korea, *oeyeokki* walls are applied with more meticulous

craftsmanship and a regular modular system in special structures such as temples. Furthermore, binding materials, infill thicknesses, and the position of openings vary according to climate and cultural needs in each region. However, these differences do not compromise the common structure of the wattle and daub technique in terms of its fundamental characteristics of lightness, flexibility, use of local materials, and repairability; on the contrary, they allow these techniques to be adapted to their own conditions in each geography.

Consequently, the *Bağdadi/çöten*, *wattle and daub*, and *oeyeokki* systems can be considered examples of the wattle and daub technique in different geographical regions. These methods share common characteristics such as the use of local materials, adaptation to climate, structural flexibility, and cultural continuity. These similarities also explain why communities living in distant regions developed similar wall-building techniques.

5. Conclusions

This study looks at traditional wattle-and-daub wall systems—*Bağdadi* and *Çöten* in Türkiye, *Wattle and Daub* in Europe, and *Oeyeokki* in Korea. Its goal is to identify the shared features of these techniques, which arose in different regions but rely on similar principles. The results indicate that these wall systems are important both for understanding past building cultures and for the role they can play in today's sustainable architecture.

The first finding is that the wattle and daub technique provides locally sourced, low-energy and easily repairable wall solutions in all three regions. Using a wooden frame together with natural materials such as earth, clay, straw or stone reduces the carbon footprint during construction. It also allows for simple and low-cost maintenance throughout the life of the building. For this reason, these techniques offer useful ideas for creating building solutions with low embodied energy that can be adapted to modern architectural design.

The second finding is that these traditional walls already used passive ways of managing heat and moisture, shaped by the climate. Breathable plasters, air cavities, thick earth fillings, and sometimes leaving a surface unplastered all helped regulate heat and moisture. Many of the ideas we now label as sustainable design were already part of these traditional techniques long ago.

Another important outcome of the study is the emphasis on the value of wattle and daub techniques in terms of cultural heritage and place identity. *Bağdadi, wattle and daub* and *oeyeokki* systems are structures that embody craftsmanship knowledge, anonymous architecture and everyday life practices. Documenting, preserving and relating these techniques to contemporary designs will contribute to both strengthening local identity and maintaining diversity in architecture. In this context, the main contributions of the study can be summarised as follows:

- Examining wattle and daub techniques, which have developed according to similar principles in different geographical areas, within a comparative framework.
- Revealing the potential of traditional wall systems in terms of sustainable material use, passive climate control, and seismic resistance.
- Proposing these techniques as a reference and source of inspiration for contemporary architectural design and conservation practices.

Future studies should include quantitative performance analyses (such as heat transfer, moisture behaviour, life cycle assessment, and seismic behaviour) of the systems discussed here;

examining them in conjunction with different reinforcement methods; and producing hybrid solutions with contemporary material technologies. Thus, wickerwork techniques can be re-evaluated not only as a legacy of the past but also as a contemporary design tool for sustainable and resilient building production.

Abstract

Building materials have significant negative impacts on the environment due to their intensive energy consumption, carbon emissions, and waste production during raw material extraction, processing, transportation, and use. The high energy consumption and greenhouse gas emissions associated with glass production also contribute to environmental burdens, accelerating the search for sustainable alternative materials in construction. In this context, wood, a renewable resource, is being revaluated and its use expanded thanks to technological developments that improve its physical, mechanical, and optical properties. Transparent wood, in particular, which has been developed to enhance its optical properties and provide light transmittance, is attracting attention as an environmentally friendly building material that can be used as a substitute for glass. In this study, 32 academic studies accessed using the keywords “transparent wood and construction” in the Web of Science database were examined. The literature review revealed that the studies primarily focused on the production methods of transparent wood, the development of its mechanical and optical properties, the degradation processes of the material, and its energy performance. These findings reveal that transparent wood is an important alternative that can contribute to the use of sustainable materials in architecture. The original contribution of this study is that it addresses existing research on transparent wood from a holistic perspective, evaluating both current developments and topics that stand out for future research. In this respect, transparent wood has the potential for wider use in the future as an environmentally friendly solution in architectural applications. Furthermore, increased research in this field will contribute to the widespread use of the material and innovative design applications.

Keywords: Transparent wood, sustainable building material, energy efficiency, renewable material, architectural applications

1. Introduction

Approximately 40% of global energy consumption is accounted for by the construction sector, a significant portion of which is generated by heating and cooling processes to ensure indoor thermal comfort (Kahlout, 2025). In line with increasing energy demand and sustainable development goals, efforts to promote the use of renewable biomass-based alternatives to traditional petroleum-based building materials are gaining increasing importance (Kahlout et al., 2025; Zhu et al., 2023).

The most common transparent material used to allow natural light into buildings is glass (Pandit et al., 2025). However, glass production requires the melting of raw materials such as silica, sodium carbonate, limestone, and magnesium carbonate at temperatures of approximately 1500–1600 °C. This increases energy consumption. Furthermore, glass has several disadvantages, such as glare, fragility, high weight, and high thermal conductivity (Pandit et al., 2025; Kahlout, 2025). Due to these drawbacks that arise during the production and use of

glass, the need for alternative transparent materials with lower environmental impact and higher energy performance has increased. In this context, transparent wood has become an important research topic in recent years.

Wood is widely used in the construction industry due to its renewable nature, low density, processability, and carbon sequestration capacity. It has a multicomponent structure composed of cellulose, hemicellulose, and lignin. Cellulose fibers also increase mechanical strength. Thus, wood provides a suitable basis for the development of new-generation composite materials. Furthermore, wood has a porous structure at the micro- and macro-scales and is highly susceptible to chemical and physical changes (Şanlı & Vural, 2024). Wood's characteristic color stems from lignin and other light-absorbing components. Approximately 80–95% of total light absorption is accounted for by lignin (Pandit et al., 2025).

The first study on transforming wood into a light-transmissive material was conducted by Fink in 1992 (Mariani, 2024). The production of transparent wood begins with chemical pretreatments that involve the complete or partial removal of lignin from its structure. By filling the resulting porous structure with a polymer, light scattering is reduced and optical transmittance is increased (Hai et al., 2025). This preserves the mechanical properties of natural wood. Furthermore, wood, which gains new optical properties, is transformed into a sustainable material that can replace glass.

1.1. Bleaching and Delignification

In the first stage of the transparent wood production process, components within the wood structure that cause light absorption are chemically removed. This process is called bleaching (delignification). Following this process, the wood's natural color is significantly lightened (Chutturi, 2023). Various chemicals such as $NaClO_2$, H_2O_2, NaOH, and acetic acid are used in delignification processes (Hai et al., 2025). The type of chemical applied and the processing time directly affect the optical and mechanical performance of transparent wood.

At this stage, it is crucial for sustainable environmental protection that the chemicals used are derived from renewable sources and are biodegradable. Choosing other agents instead of chlorinated compounds is more environmentally sound. The application of advanced technologies such as delignification shortens processing times, thus reducing energy consumption and environmental impact during delignification (Kahlout et al., 2025). Transparent wood produced this way becomes more environmentally friendly on an industrial scale.

1.2. Polymerization of Bleached Wood

After the delignification process, the lignin in the wood structure is removed, creating pores of various sizes. These pores must provide optical transparency. To achieve this, a polymer material with a refractive index compatible with the wood is used, a process called polymerization (Figure 1) (Chutturi, 2023; Pandit et al., 2025). The polymers penetrate the pores within the wood uniformly. Subsequently, light scattering is reduced. This is one of the key factors determining the optical performance of transparent wood.

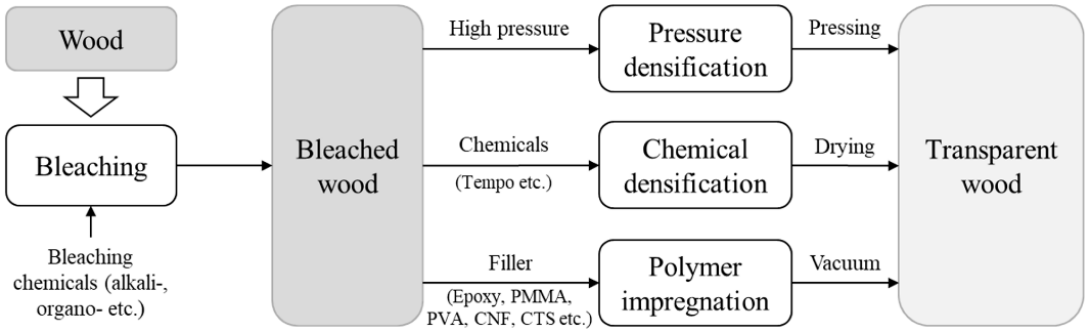

Figure 1. General fabrication methods of TW (Hai et al., 2025).

Chemical compatibility with wood is crucial in polymer selection. Various polymers, including polymethyl methacrylate (PMMA), epoxy resins, polyvinylpyrrolidone (PVP), n-butyl methacrylate, polystyrene, dibutyl phthalate, isobornyl methacrylate, and polyvinylcarbazole, are commonly used in the production of transparent wood (Li et al., 2017).

1.3. Optical Properties of Transparent Wood

The optical performance of transparent wood is primarily evaluated through light transmittance and haze (Zhu, 2023). Light transmittance depends on factors such as wood thickness, cellulose fiber orientation, cellulose volume fraction, degree of delignification, and the optical properties of the polymer used (Pandit et al., 2025). Literature reports that light transmittance values for transparent wood range from 10% to 90% (Hai et al., 2025). Haze, on the other hand, indicates how much of the light passing through the material is scattered. It provides information about image clarity. This value is calculated as the ratio between the intensity of the emitted light and the total intensity of the transmitted light (Zhu, 2023).

Transparent wood offers both high light transmittance and the desired level of haze. It can be considered a valuable material, particularly for energy efficiency, natural lighting, and translucent panel applications, compared to glass and polymer-based alternatives. Optical performance is directly related to delignification and polymerization processes, so careful control of the production stages is essential.

1.4. Mechanical Properties of Transparent Wood

The mechanical properties of transparent wood depend on the wood's density, the quantity and orientation of cellulose fibers, and the annual ring structure (Li et al., 2017). During the delignification process, lignin is removed, and the cellulose fibers that form the wood's structural framework become more pronounced.

The mechanical performance of transparent wood is evaluated using standard tests such as three-point bending tests, tensile strength, and ductility tests (Pandit et al., 2025). Studies have shown that when appropriate polymer selection and the correct production parameters are met, the mechanical properties of transparent wood are comparable to those of natural wood. In some cases, they can even be superior.

Transparent wood has a higher fracture toughness than glass, offering a significant advantage in applications requiring impact resistance. In this respect, transparent wood stands out not only for its optical properties but also for its safety, durability, and lightness, making it a potential material for structural applications.

2. Materials and Methods

In this study, a search was conducted using the keywords "transparent wood" and "construction" in the Web of Science database. 32 academic publications were retrieved and analyzed. To access up-to-date and reliable studies on the subject, searches were conducted within the WoS Core Collection.

The publications identified through the search were categorized by publication type (research article vs. review article), method used (experimental study, simulation, literature review), and content covered. Furthermore, each study was thematically analyzed within the context of transparent wood production methods, optical and mechanical performance properties, and application types.

The classification of the publications is presented in tables. The findings of the content analysis are described under the heading "Findings and Discussion."

3. Findings and Discussion

The methods used in the 32 articles reviewed were literature review, experimental research, simulation, and experimental research and simulation. Of the 32 articles reviewed, 11 were review articles (Table 1), and 21 were research articles (Table 2). When looking at the distribution of publications by year, the highest number of publications was published in 2025, representing 31.2%. The second most publications were published in 2023, representing 25%, and in 2024, representing 15.6%. The classification of the 32 studies examined in terms of journal, publication year and article type is presented in Table 1.

Table 1. Classification of the thirty-two articles reviewed

No	Name of the Journal	Year	Research	Review

After presenting the general classification of studies in Table 1, the names, subject headings and method focuses of the compilation studies are shown in detail in Table 2.

Table 2. Studies Conducted in the Literature Review

No	References	Subject of the Study
1	Katunský, 2018	The study examined two different transparent wood production methods previously developed by KTH (Sweden) and the University of Maryland (USA).
2	Hai, L. V., 2025	This study examines the effects of various transparent wood types, production methods, and polymer impregnation and manufacturing processes on the mechanical and optical properties of transparent wood. Furthermore, advances in nanostructured materials, high thermal conductivity, and thermal insulation are also highlighted. The effects of various chemical reagents and various polymer combinations used in transparent wood production on the properties of their biocomposites are investigated.
3	Zhu, S., 2023	To systematically compile the production processes, microstructural properties, and functionalization methods of transparent wood (TW) and transparent wood film (TWF). To introduce new chemical and physical techniques to make the production process scalable, energy-efficient, and environmentally friendly.
4	Pandit, K. H., 2025	This study systematically examines the delignification techniques, polymer infiltration methods, optical and mechanical performance, application areas, and future research directions used in transparent wood production.
5	Jele, T. B., 2023	This study describes how transparent wood production, wood species, wood density, wood thickness, fiber orientation, cellulose volume fraction, polymer type, delignification degree and type affect the morphological, functional, mechanical, optical, thermal and photodegradation properties of transparent wood.
6	Yang, H., 2023	The study produces multilayer laminated panels with phase change material (PEG) and PMMA polymer by taking advantage of the porous nature of the wood structure and evaluates their optical, mechanical and thermal properties.
7	Chutturi, M., 2023	The study systematically examines the delignification techniques, polymer infiltration methods, optical and mechanical performance, application areas and future research directions used in transparent wood production.
8	Mariani, A., & Malucelli, G., 2024	The multilayered hierarchical structure of wood, naturally composed of cellulose, hemicellulose, and lignin, is described. The study reviews methods used to produce optically clear and mechanically durable materials through delignification (lignin removal) and resin infiltration.
9	Kahlout, A.F. 2025	This article examines the viability of transparent wood (TW) as a next-generation window material in the construction industry. It is a comprehensive review, specifically evaluating transparent wood in terms of its thermal transmittance (U-factor), solar heat gain coefficient (SHGC), and energy performance.
10	Li, Y., 2018	This article is a comprehensive review of the optical, mechanical, and functional properties of transparent wood. The study describes the process of making natural wood transparent through delignification and polymer infiltration.

11	Zhou, J., & Xu, W. 2025	In this study, the heat storage, optical control and energy saving potential of transparent wood panels produced using dodecanol (DO) phase change material and epoxy resin (EP) were evaluated.

After examining the compilation studies, Table 3 includes studies using experimental methods.

Table 3. Studies Conducted Experimental Research

No	References	Original Contribution
12	Wang, H., 2023	By eliminating the use of environmentally harmful chlorinated chemicals (e.g., $NaClO_2$) in the production of transparent wood, a highly permeable transparent wood was developed by in situ removal of lignin chromophores with UV-assisted H_2O_2 (Hydrogen Peroxide) and a hydrophobic (dual-function PDMS surface modification).
13	Liu, K., & Li, C. 2025	Transparent wood, highly resistant to heat, flame, and water, was developed thanks to the N-P-Si hybrid network formed by the interaction of sodium silicate (LSS) and PHF (phosphorus-nitrogen-based flame retardant).
14	Bisht, P., & Pandey, K. K. 2024	2 mm transparent wood layers were stacked in 2 (4 mm), 3 (6 mm), and 4 (8 mm) layers, pressed between a polyester sheet, and cured for 24 hours. Thick transparent wood was obtained.
15	Li, M., 2024	The wood was filled with a mixture of epoxy resin (EP), polyethylene glycol (PEG), and triethyl phosphate (TEP) using a vacuum-pressure impregnation method. The phase change material (PEG) and flame retardant (TEP) were integrated simultaneously.
16	W. Ren, 2025	Transparent panels were produced solely from bamboo-sourced holocellulose, without any polymer additives. The ability of water molecules to transform the hemi-acetal network, increasing plasticity, was clearly explained for the first time. Partial oxidation with 5% $NaIO_4$ (sodium periodate) controlled cellulose crystallinity, resulting in a thermoformable (heat-pressable) structure.
17	Wang, X., 2018	For the first time, a blend of fibers was used instead of whole wood, eliminating thickness and size limitations. Large transparent panels measuring 300 × 300 × 10 mm were successfully produced. The random orientation of the fibers eliminated the anisotropic behavior of traditional wood. They were produced using a fiber-based Polymethylmethacrylate (PMMA) impregnation method.
18	Zapico-Benavides, B., 2025	This study is one of the first to experimentally demonstrate the effect of fiber orientation on light transmission in transparent wood. Panels made from balsa wood provided higher natural illuminance in interior spaces when the fiber orientation was parallel to the sun's movement.
19	Wu, J., 2023	Transparent composites were produced using delignified wood particles (0.15–0.2 mm) impregnated with PVA instead of solid wood, followed by hot pressing
20	Pan, Y., 2024	This study developed transparent and highly fire-resistant biocomposites by flame-retarding wood aerogel using the LbL (layer-by-layer) method and creating a 3D network structure within the epoxy

21	Piedra-Ambriz, B. K., 2025	Transparency was increased only by UV + H_2O_2 oxidation, without completely removing lignin. A green and low-energy method was developed without the use of toxic chemicals such as $NaClO_2$.
22	Tan, Y., 2022	The article deals with the production of shape-manipulable and high-performance transparent wood (TW).
23	Wu, J., 2023	In this study, a partial polymer impregnation + compression method was developed for the production of multilayer (laminated) translucent wood. Compared to full polymer infilling reported in the literature, a higher wood ratio (41%) was achieved using less polymer. This reduced environmental impact and resulted in more natural mechanical behavior.
24	Mi, R., 2020	Compared to traditional fully delignified translucent woods, this method bleaches only the earlywood regions, partially preserving the lignin in the latewood regions. This allows the wood's natural annual ring patterns (aesthetic patterns) to remain visible. Large-size translucent wood panels up to 320 mm × 170 mm × 0.6 mm were produced. This was limited to laboratory-scale production (≤100 mm) in most previous studies.
25	Yang, L., 2021	Instead of PMMA/epoxy, acrylic acid–choline chloride-based deep eutectic solvent filling is used; this system is low-cost, non-toxic, and rapidly cured by UV light. The resulting TW is both mechanically flexible and ionically conductive, making it suitable for electronic skin or sensor applications.
26	Wachter, I., 2023	For the first time in the literature, UV-C, biological, fire, and thermogravimetric analysis (TGA) tests were compared on the same sample series. The resulting material was identified as a biocomposite suitable for exterior cladding or glass replacement due to its low CO emissions, fungal resistance, and UV stability.

In addition to experimental methods, some studies have used purely simulation-based approaches. Table 4 shows studies that used only simulation.

Table 4. Studies Using Simulation Programs

No	References	Original Contribution
27	Rai, R., 2022	For the first time, the environmental impacts of transparent wood production processes (delignification + infiltration + scaling-up) were investigated using a holistic LCA model. The energy efficiency of the laboratory-to-industrial scale transition was quantitatively demonstrated, and it was calculated that scaling-up reduced environmental impacts by 28–97%. The study's methodology is based on artificial intelligence-based LCA and simulation-based Excel analyses. The study quantitatively demonstrates the sustainability potential of transparent wood.
28	Pang, J., 2021	COMSOL Multiphysics 5.5 was used. This study represents the most comprehensive numerical model ever developed to understand the orientation, scattering, and refractive indices of light in transparent wood.

	These results are directly applicable to the design of future optical devices, translucent façade materials, and energy-efficient glazing alternatives.

Some studies provided a more comprehensive evaluation using a combination of experimental and simulation methods (Table 5).

Table 5. Studies Conducted Using Simulation and Experimental Research

No	References	Original Contribution
29	Wu, J., 2024	The study presents a pioneering and original model that demonstrates the "high-performance transparent wood with low polymer" approach at both scientific and environmental levels. The simulation part (SimaPro + BEES) strengthened the sustainability analysis.
30	Mi, R., 2019	For the first time, a transparent wood window system (double-pane) was evaluated with EnergyPlus. Energy savings in buildings were demonstrated numerically with WINDOW 7.6 + EnergyPlus 8.2.0.
31	Wu, J., 2024	It is based on the production of three-layer transparent wood (MTW). This structure is obtained by cross-compressing partially impregnated wood layers containing silica-stabilized PEG (polyethylene glycol) in the middle layer and PMMA (polymethyl methacrylate) in the outer layers. The three-layer structure, consisting of a PEG/SiO_2 core and PMMA outer layers, provides both phase change energy storage and thermal insulation.
32	Guo, M., 2025	The general method of the study is based on the production of a flame-retardant transparent wood composite by treating delignified wood aerogels with phosphorylated cellulose and then impregnating them with UV-curable polyurethane acrylate (PUA) resin. The phosphorylation of the cellulose mimics the natural "carbon barrier" mechanism. Self-extinguishing under flame and continuous char formation were achieved.

4. Conclusion and Recommendations

This study comprehensively examined 32 academic publications obtained through a search of the Web of Science database using the keywords "transparent wood" and "construction." Eleven of the studies were compilations; 15 used experimental methods, two used only simulation methods, and four used both experimental and simulation approaches. The majority of the reviewed publications were produced by researchers working in the fields of materials science, chemical engineering, biomaterials, and architectural engineering. An examination of the publication distribution reveals a significant increase, particularly between 2023 and 2025, indicating a rapid increase in academic interest in transparent wood.

Based on the analysis results, three main areas of transparent wood research stand out:

1. Developing delignification and polymer infiltration proceses,

2. Improving the optical, mechanical, and functional properties of transparent wood,

3. Evaluating transparent wood in terms of energy performance and sustainable architectural use.

Studies show that transparent wood is no longer considered solely a laboratory-scale material. It is increasingly being explored for architectural applications such as window systems, heat-storing composite elements, and energy-efficient designs. Hybrid composites, in particular, have been shown to exhibit good performance in heat storage, thermal insulation, and light control. PMMA and epoxy resins are still widely used for their optical properties and mechanical stability, but in recent years, interest in bio-based, recylable, and low-carbon-footprint polymers has also increased.

Additionally, sustainability is supprted by environmentally friendly approaches, such as low-chemical consumption processes, in the transparent wood production process. Simulation-based studies reveal that transparent wood has the potential to reduce building energy consumption in window and facade applications. In conclusion, transparent wood can be used as a sustainable building material of the future thanks to its renewable structure, mechanical strength, optical performance, and energy-saving potential. However, for this material to be widely used in the construction sector, some critical issues need to be considered:

• Developing scalable and cost-effective production processes,

• Increasing resistance to UV light, moisture, and biological degradation,

• Improving fire resistance,

• Improving optical and thermal performance for different climate zones.

Future transparent wood research is expcted to focus particularly on nanotechnology, life cycle assessment, artificial intelligence-based material optimization models, and bio-based polymer development. Strengthening collaborations between materials scientists, engineers, and architects will accelerate the transition of transparent wood from laboratory environments to architectural applications. Thus, transparent wood will become an innovative, environmentally friendly, and economical alternative in the sustainable construction sector.

Thanks and Information Note

The article complies with national and international research and publication ethics. All authors contributed equally to the article.

Abstract

Virtual Reality (VR) tech has come up as a game-changer in landscape design, giving deep and hands-on ways to see and feel space better. By letting people see and walk through places in 3D, VR boosts how we see space and helps make smart choices when designing. It aids in checking space set-ups, material picks, and plant plans better than old flat images. Also, VR helps people work together by making talks between designers, clients, and others better through sharing and getting feedback in design meet-ups. In learning spots, VR gives a safe and fixed place for students to try things, increasing how well they understand space and critical thinking skills. However, despite its growing use in architecture and urban planning, research focusing on landscape-specific VR applications remains limitless. Overall, VR has significant potential to change landscape design by encouraging engagement, enhancing spatial understanding, and aiding collaboration and education. Future research should look into landscape-specific VR applications, examining both technical and experiential aspects to get the most out of technologies in design practice and teaching.

Keywords: Virtual reality, landscape design, spatial perception, technologies.

1. Introduction

Advances in digital technologies have greatly influenced modern design fields, with Virtual Reality (VR) becoming one of the most impactful innovations. VR creates three-dimensional environments that let users interact with spaces in real time. This fosters deeper engagement and understanding of design concepts (Serna-Mendiburu et al., 2024; Johnson-Glenberg, 2018). In landscape architecture, using VR has opened new ways to visualize complex spatial relationships, test design options, and encourage collaboration among designers, clients, and stakeholders (Hill, 2019).

VR technologies allow landscape architects to simulate and evaluate design scenarios with high spatial accuracy. This gives an experiential understanding that traditional two-dimensional methods often do not provide. These simulations help designers assess site topography, material choices, and plant composition in realistic spatial and environmental settings. As a result, VR improves the communication of design ideas and supports participatory design processes, where users can actively explore and give feedback on proposed landscapes (Roupé et al., 2021).

Recent studies on landscape architecture education make it clear that full VR immersion helps students grasp realism and spatial details much better. This works way ahead of those semi-immersive setups. (Ha et al., 2024).

On top of that, students who build their own VR elements right in design classes end up more engaged. They collaborate in stronger ways too. All this stands out against the usual old teaching approaches. (Andalib & Monsur, 2024).

2. Materials and Methods

This study is based on a qualitative literature review and case analysis of VR applications in design disciplines. Research materials include peer-reviewed articles, academic theses, and design experiments integrating visualization tools (Çalışkan & Aslan, 2022).

Academic papers, design experiments, and educational applications involving Virtual Reality (VR) in architectural and landscape contexts were systematically reviewed to understand how environments enhance design processes. Data were categorized into three analytical themes: Spatial perception (how VR affects users' understanding of space and scale), collaboration and participation (how VR tools facilitate communication among designers and stakeholders) and education and practice (how VR contributes to design learning and experimentation).

Changes in human life are evolving many of the elements they interact with. Technological advancements and changes in the human profile have led to the realization that design can no longer be conveyed through hand-drawn sketches, leading to the creation of 3D designs in virtual environments. Design in landscape projects begins with the ability to imagine. This is fundamentally developed through 3D perception and cognitive skills.

Landscape Design

Landscape design is an ongoing process that reacts to changes in the environment, economy, and culture. It involves shaping and changing spaces through a system that blends physical structures with cultural and ecological connections. This field needs teamwork among design professionals to craft sustainable, inclusive, and adaptable landscapes. These landscapes should welcome new relationships and be ready to evolve as local conditions change. In essence, landscape design combines the art and science of planning outdoor spaces where natural and built elements exist together harmoniously (Occhiuto & Vanore, 2024).

Perceptual experience includes representations of worldly elements and the relational and perspective-dependent properties of external objects and can be explained in biological terms. It encompasses phenomenology, cognitive states, and their relationships to epistemic norms, contributing to knowledge and justification. (S. Tepesi, 2022) The study revealed that the perceptual experience of long distances outdoors often results in perceptual compression, where distances appear shorter than they actually are. Individual differences were significant; some observers perceived distances accurately, while others exhibited varying degrees of inaccuracy. (Norman, 2024).

Despite the absence of a narrative or game cue, the design encourages self-exploration, thus enriching the perceptual experience. Landscape perceptual experience involves the process of perceiving, perceiving, and comprehending the biophysical features of a geographic area.

Virtual Reality

Computer technology began to develop in the 1980s and quickly grew after the 1990s. It has become a key part of modern life. These scientific and technological improvements have increased the value of information. This shift has led to the rise of an information-based society. As people looked for new ways to process and present information using computers, many new ideas emerged. One of the most important is virtual reality (VR). Virtual reality refers to

computer-generated, immersive, and interactive three-dimensional environments. These environments let users engage with and manipulate simulated spaces in real time (Abbas et al., 2023).

This technology goes beyond simple visuals by allowing individuals to experience and interact with digital representations of real-world settings through special tools and interfaces. In today's education and research, VR has become a central focus for developing new teaching and learning methods. These methods aim to improve spatial understanding and hands-on learning.

Considering that traditional approaches are inadequate in overcoming the challenges faced in solving problems in education today, it is inevitable to take advantage of the opportunities provided by information technologies, one of the most effective approaches to overcome these problems. Virtual reality, which emerged alongside this technology, offers a new perspective on educational methods. Old methods and techniques in education are rapidly losing their effectiveness. Given that traditional approaches are inadequate in overcoming the challenges faced in solving these problems, the best approach today is to utilize the opportunities provided by information technologies. Virtual reality, which emerged alongside this new and modern technology, has brought a new perspective to educational methods (Çavaş and Huyugüzel; İşmen 2005).

Table 1. The Effects of VR Technology on Landscape Design Process

Design Stage	Traditional Approach	VR-Supported Approach	Contribution
Site Analysis	2D plans, sections, physical models	3D virtual site exploration	Enhanced spatial realism
Design Decisions	Fixed drawings and models	Interactive parameter control and iteration	Faster feedback and evaluation
Material Selection	Visual estimation	Realistic lighting and texture simulation	Accurate material perception
User Feedback	Verbal or visual presentation	Immersive experience and observation	Increased participation and empathy
Educational Applications	Theoretical explanation	Experiential learning in virtual studio	Improved spatial and cognitive skills

5. Findings and Discussion

Thematic Findings from the Literature

The literature review yielded common findings focused on various topics related to the use of virtual reality (VR) technology in landscape design. The majority of these studies demonstrate that VR technology offers positive contributions, particularly in terms of education, spatial perception, and user experience.

• Design experiences in a VR environment enhance students' three-dimensional thinking skills and develop the concept of design scale (Şahin, 2021; Yuan, 2023).

• Participants indicate that VR technology increases the perception of spatial depth compared to traditional 2D representations (Ha et al., 2024).

• The sense of reality and freedom of navigation create a difference in how users evaluate designs (Tan, 2023; Kuliga et al., 2015).

Conceptual Model and User Scenario:

A system is envisioned that will allow users to interactively experience the landscape design. The developed model operates in the following steps:

1. When the user starts the project, they are immersed in the environment using VR headsets.

2. They observe the design under different conditions by changing parameters such as daylight, season, or viewing angle from the menu panel.

3. They access design descriptions through information panels by stopping at specific areas.

4. At the end of the design process, the system provides the user with a feedback form regarding the experience (a future implementation goal**).**

The written content discusses the role of VR in design processes and its capacity to improve communication between designers and clients. VR enables the exploration of multiple scenarios through real-time interaction, which enriches both aesthetic and functional decision-making (Smith & Chou, 2022).

According to (Fernandez et al.2020), these visual methods not only enhance design presentation but also increase empathy and understanding between stakeholders. The visuals aim to demonstrate the connection between digital immersion and spatial experience in landscape settings.

6. Conclusion and Recommendations

Landscape architecture is a discipline that shapes the interaction between humans and nature, supports environmental sustainability, and offers aesthetic values. Today, with the rapid advancement of technology, landscape architecture is utilizing these innovations to create more effective and innovative solutions. In this context, Virtual Reality (VR) technology stands out as a tool with the potential to change the future of landscape architecture.

Virtual Reality technology allows for three-dimensional, interactive visualization of landscape designs. Moving beyond traditional two-dimensional drawings and physical models, designers can realistically present their projects in a virtual environment. This makes designs more understandable, and potential errors in the design process can be identified early. By experiencing projects in a virtual environment, clients and other users can better understand the spatial relationships, scale, and aesthetic qualities of the design.

From an educational perspective, Virtual Reality can be used as a powerful tool in landscape architecture. Students can examine various landscape designs in a virtual environment, create their own designs, and test them. This provides students with real-world experience, helping them develop their professional skills. Additionally, VR allows students to explore normally inaccessible areas, such as historical landscapes or remote geographic areas.

The disadvantages of VR technology include the potential for high initial costs. Hardware and software investments can be challenging for small businesses. However, these challenges are expected to diminish over time as the technology becomes more widespread and costs decrease.

Technical knowledge and skills are required for the effective use of virtual reality technology. This may increase training and professional development requirements. Companies may need to allocate additional training and resources to adapt their staff to these new technologies.

Some users may experience difficulty adapting to new technologies. Adopting virtual reality can be time-consuming and require adaptation. This transition can be challenging, especially for designers and clients accustomed to traditional methods.

Finally, the use of virtual reality technology in landscape architecture is increasing and is expected to become even more widespread in the future. The realism it offers in the design and planning processes, the cost and time savings it offers, and the potential to increase customer base will ensure its wider use in the future. However, successful implementation requires careful management of technological investment, training, and adoption processes. While shaping the future of landscape architecture, virtual reality will enable the implementation of more sustainable, innovative, and effective projects. In the future, further expanding the capabilities offered by virtual reality technology will allow landscape architecture to expand its reach even further.

Because virtual reality technology has not yet become widespread in education, particularly in departments requiring architectural design disciplines, there are no previous applications to compare or analyze. Therefore, some shortcomings arose during the design and construction process, including controls. Through trials, corrections have been made to minimize these shortcomings.

Curricula focused on traditional teaching methods do not encourage the use of new technologies like virtual reality and do not provide adequate training in these technologies. Inadequate curriculum is another factor preventing students from learning about VR technology. Many students lack sufficient knowledge about how VR can be used in architectural education and the advantages it offers. Educational institutions may be inadequate in promoting VR and providing information about it. This lack of student knowledge about VR may reduce student interest in the technology. Because the testing phase of the application was voluntary, students lacked knowledge and experience in the field, leading to reservations about participating.

If the study is repeated, creating introductory content for participants could help alleviate these concerns.

Although some challenges persist such as equipment costs, technical skills, and limited landscape-specific research, the potential benefits are substantial. Integrating VR into landscape design encourages a more human-centered, creative, and experiential approach, bridging the gap between concept and reality. As technologies evolve, their thoughtful use will allow landscape architects to create environments that are not only functional and sustainable but also emotionally engaging and deeply connected to human experience.

This study has demonstrated that the integration of virtual reality (VR) technology into landscape design processes provides significant contributions to design perception, user experience, and education. Based on the findings of the research, the following recommendations are offered:

• Dissemination of VR Applications in Landscape Architecture Education: Research results indicate that VR technology more effectively develops students' spatial perception and concepts

of scale. In this context, the integration of VR-supported studio work and basic design courses into landscape architecture education programs is recommended (Ha et al., 2024; Şahin, 2021).

• Software Development Processes Prioritizing User Experience: While the user-friendly interface of the developed software has been positively received, it is recommended that the software be customizable to different user profiles to further enhance the user experience (Güzelkahraman, 2019; Yuan, 2023).

• Interdisciplinary Collaborative Development Models

Given that virtual reality technology can provide similar benefits not only in landscape architecture but also in disciplines such as architecture, interior architecture, and urban design, it is important to encourage collaborative software development processes through interdisciplinary application projects (Brandao et al., 2018).

• Real-Time Environmental Data Integration

The navigation module in the VR environment, supported by environmental data such as daylight simulation and seasonal changes, will create more realistic scenarios, enhancing the user experience and contributing to design evaluation processes (Chen, 2024; Tan, 2023).

• Encouraging Local Software and Content Production

Turkish-language software has facilitated user adaptation. Therefore, supporting local content and software development will contribute to the technology's wider reach (Benliay & Soydan, 2020).

• Long-Term Impact and Monitoring Studies

It is recommended that the effects of virtual reality technology on landscape design be examined not only through short-term experiences but also through long-term user habits and learning processes. In this context, sustainability-focused monitoring studies should be conducted (Şarkışla, 2022).

Thanks and Information Note

The authors declare that the study complies with national and international research and publication ethics. All authors contributed equally to the preparation of this paper. Ethics Committee approval was not required for the study.

Abstract

Artificial Intelligence (AI), defined as the capacity of machines to learn from data and perform tasks that traditionally require human intelligence such as recognizing patterns, producing images, and assisting in decision-making has become an emerging force in landscape architecture. Recent literature highlights AI's ability to expand the boundaries of visualization, improve efficiency, and encourage innovative approaches in sustainable design. These advances are transforming professional practice by supporting designers in exploring alternatives quickly, enhancing communication with stakeholders, and integrating data-driven insights into planning processes. In landscape architecture, visualization has always been central to bridging the gap between ideas and experience. The integration of AI-assisted tools into this process introduces new opportunities to generate realistic imagery, test different scenarios, and democratize participation by making design outcomes more accessible to diverse audiences. Such tools complement, rather than replace, conventional methods by offering flexible, rapid, and often more affordable pathways to communicate design intent. Although the potential of AI in this field is increasingly recognized, literature and practice remain at an early stage. Questions about accuracy, visual quality, ethical use, and the implications for education and professional workflows continue to shape the discourse. Ongoing studies, including explorations of different software and hybrid approaches, point toward a future in which AI becomes an integral partner in creative processes. Understanding these trends is crucial for fostering innovation and preparing designers, educators, and stakeholders to harness AI's transformative potential for more responsive and collaborative landscape design.

Keywords: Algorithm, text input, landscape design, presentation techniques, artificial intelligence

1. Introduction

The visualization of landscape design has long served as an essential medium for translating conceptual ideas into spatial experience. Through this process, designers are able to communicate both the functional logic and the aesthetic intent behind a project (Bell, 2012; Marcus & Francis, 2013). Over time, advances in digital technology particularly in Artificial Intelligence (AI) and three-dimensional (3D) modeling have expanded visualization beyond simple representation. It now functions as a dynamic mode of interpretation and interaction that supports design analysis, simulation, and presentation of complex environmental relationships (Ahern, 2013; Wang & Chen, 2022).

The rapid evolution of AI has brought forward generative and text-to-image models capable of producing highly realistic renderings within seconds. Research by Fernberg and Chamberlain (2023) as well as Ye et al. (2025) demonstrates that these systems can aid designers in exploring a broader range of design possibilities testing materials, forms, and atmospheric conditions that would otherwise demand extensive manual modeling. Unlike conventional 3D visualization,

which relies heavily on geometric precision and rendering parameters, AI-assisted visualization operates through algorithmic interpretation of text or visual prompts. This shift marks a fundamental transformation in design workflows, privileging conceptual flexibility and data-informed synthesis over technical modeling (Zhang, 2022).

Among the various tools shaping this new landscape, Twinmotion stands out as a real-time visualization software tailored for architectural, urban, and landscape professionals. Its main advantage lies in converting CAD and BIM models into high-quality images, cinematic videos, and immersive Virtual Reality (VR) experiences. Developed by Epic Games and powered by Unreal Engine, Twinmotion allows designers to instantly observe their design modifications with photorealistic accuracy. The software integrates seamlessly with platforms such as Revit and Archicad through Direct Link synchronization and provides an extensive library of over 10,000 assets including materials, animated figures, and dynamic vegetation. Twinmotion's development history reflects a broader ambition to make high-end visualization accessible by merging advanced game technology with an intuitive, icon-based interface.

In parallel, OpenAI's ChatGPT represents another transformative tool, operating on the GPT (Generative Pre-trained Transformer) architecture. Since the introduction of the first GPT model in 2018, followed by GPT-2 (2019) and GPT-3 (2020), the system has grown exponentially in scale and linguistic sophistication. The release of ChatGPT in late 2022, fine-tuned from GPT-3.5, brought conversational AI into public use, quickly reshaping digital communication. Later versions GPT-4 (2023) and GPT-5 (2025) further enhanced reasoning, creativity, and multimodal understanding, positioning ChatGPT as a flexible platform for education, research, and design-related dialogue.

Google's Gemini also contributes to this evolving ecosystem. As a large-scale language model developed with deep learning and Natural Language Processing (NLP) technologies, it is designed to process human language, answer questions, summarize information, and generate creative outputs across diverse subjects. Built upon a Transformer-based architecture and trained on trillions of words, Gemini embodies Google's approach to developing AI that learns, adapts, and refines its responses through continuous interaction, turning it into a sophisticated instrument for accessing and synthesizing knowledge.

In the domain of image editing, Image FX offers another application of AI's generative potential. The software automates time-consuming manual retouching tasks by using deep learning to remove unwanted elements and reconstruct missing background details seamlessly. By enabling users to create clean, professional-quality visuals quickly, Image FX illustrates how AI can optimize visual workflows and democratize high-quality image editing.

Despite these technological advances, AI does not replace the cognitive and spatial reasoning central to the design process. As Leach (2022) notes, creativity remains inherently human, while AI functions as a collaborative partner that expands the designer's imagination rather than dictating outcomes. The convergence of such systems points toward a hybrid visualization paradigm one that merges the precision and control of 3D modeling with the generative adaptability of AI. Understanding this evolving interaction is vital for promoting innovation, fostering communication, and enhancing education within the discipline of landscape architecture.

2. **Materials and Methods**

This study was structured to examine how the relationship between conventional three-dimensional (3D) modeling tools and Artificial Intelligence (AI)-assisted visualization systems is evolving within landscape design. The methodological framework was guided by three main objectives:

(1) to identify how visualization workflows differ in terms of process and time management,

(2) to evaluate the visual and perceptual distinctions between 3D-rendered and AI-generated outcomes, and

(3) to discuss the implications of these differences for design communication and education.

A comparative approach was adopted to analyze the two visualization modes, focusing on three core parameters of time, realism, and communication. The process emphasized how AI tools and 3D modeling platforms diverge not only in their technical structures but also in the way they shape creative decision-making.

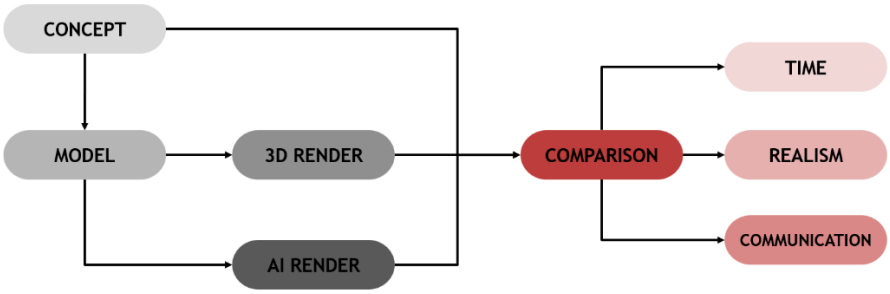

Figure 1. Used a comparative approach, observing time, realism, and communication aspects between 3D and AI workflows.

In the 3D visualization stage, the workflow relied heavily on manual adjustments by the designer. Elements such as lighting, materials, and spatial depth were carefully refined to achieve visual precision and environmental coherence. By contrast, the AI-driven process transformed written prompts into expressive, atmospheric visuals that emphasized concept and emotion rather than technical exactness. Together, these distinct approaches reveal an essential contrast: while 3D modeling highlights control and craftsmanship, AI-based visualization introduces speed, interpretation, and exploratory potential to the design process.

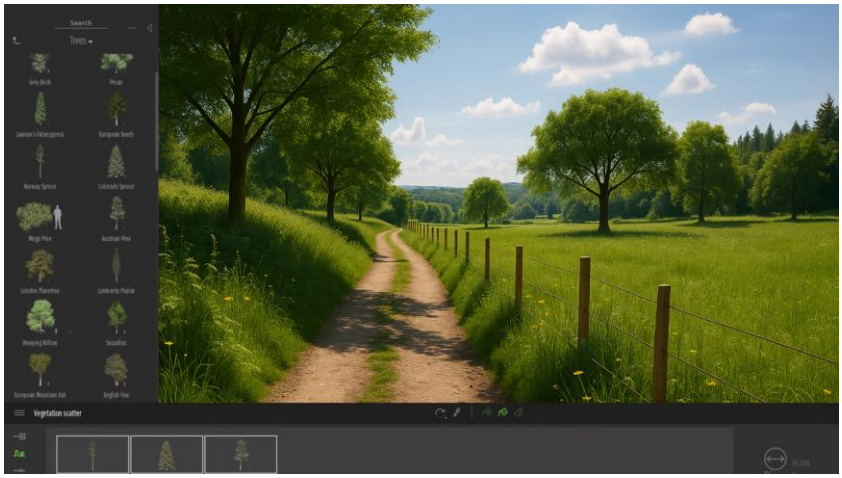

Figure 2. Screenshot of a 3D modeling interface Twinmotion

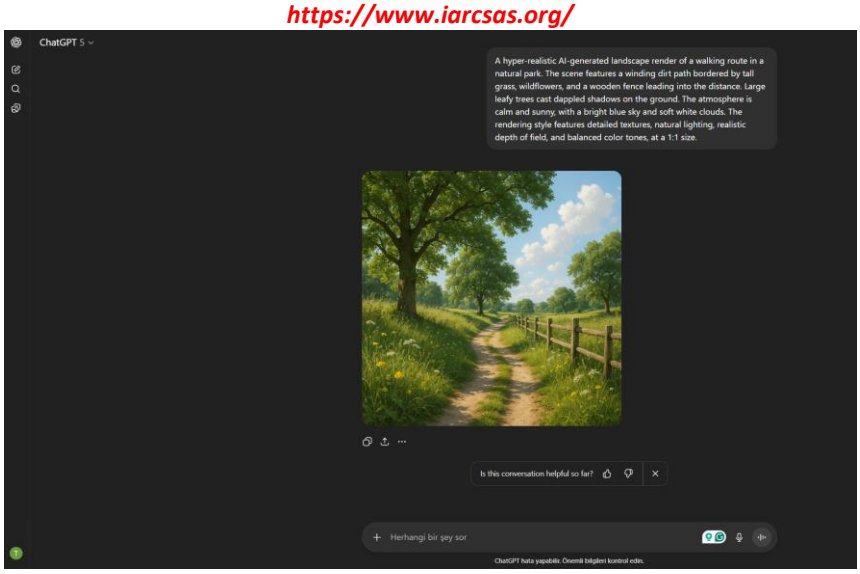

Figure 3. Screenshot example of a text prompt for AI generation ChatGPT Plus

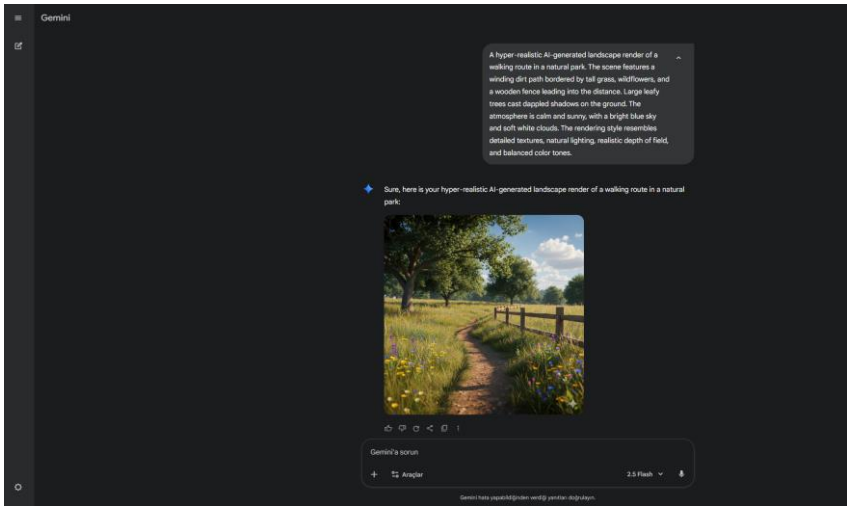

Figure 4. Screenshot example of a text prompt for AI generation Gemini Pro

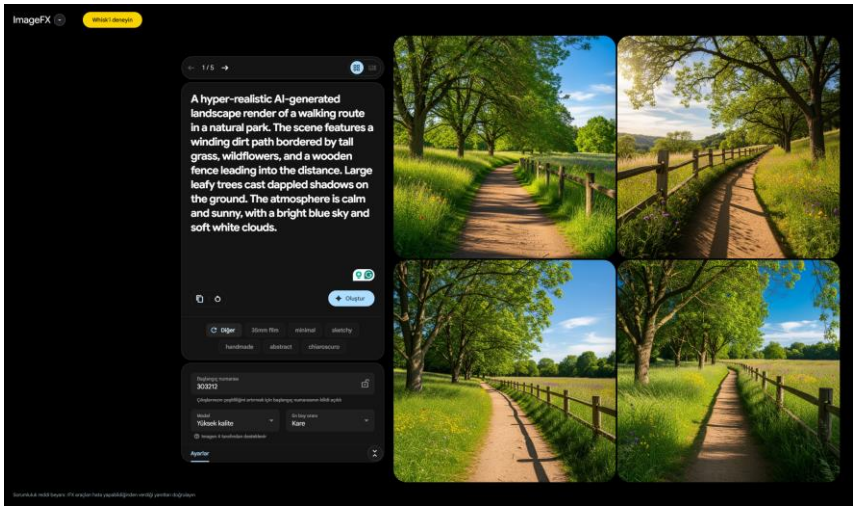

Figure 5. Screenshot example of a text prompt for AI generation ImageFX

To illustrate these differences, several platforms were used. Twinmotion served as the representative 3D modeling software due to its real-time rendering capacity and its widespread use in architectural visualization. AI-based visualizations were generated through ChatGPT Plus, Gemini Pro, and ImageFX, each providing different forms of algorithmic interpretation. Screenshots were captured from each platform (Figures 2–5) to document both workflow and outcome, including interface design and the visual qualities of the generated images. To address the outlined objectives, the study integrated comparative and exploratory research methods grounded in visual analysis and design theory. Following Bell's (2012) framework on perception and pattern recognition in landscape representation, both 3D and AI outputs were examined based on realism, atmosphere, and narrative expression. In line with Marcus and Francis (2013), the communicative dimension of design and user perception was treated as a critical part of the evaluation. A review of relevant literature (Zhang, 2022; Wang & Chen, 2022; Ye et al., 2025) informed the analytical criteria used to distinguish between algorithmic generation and human-directed modeling. Each approach was assessed through parameters of workflow efficiency, iterative flexibility, and visual fidelity. This analysis helped clarify how emerging AI systems such as text-to-image and generative fill Technologies can either complement or challenge traditional visualization pipelines. Additionally, the methodological framework incorporated a reflective layer inspired by Ahern's (2013) sustainability perspective and Leach's (2022) discourse on the creative limits of AI. This layer focused on educational and ethical implications, exploring how these tools influence professional adaptation and the cognitive aspects of design practice. Ultimately, visualization was considered not merely a technical outcome but a communicative and intellectual process that evolves through an ongoing dialogue between human designers and artificial intelligence (Fernberg & Chamberlain, 2023).

3. Findings and Discussion

In this research, four distinct comparative cases were conducted, each derived from a different real-life landscape photograph. For every scene, a corresponding text prompt was written to describe its spatial composition, atmosphere, and key visual elements. These prompts were then processed through five separate visualization approaches: the original photograph, a 3D render produced in Twinmotion, and AI-generated images created with ChatGPT Plus, Gemini Pro, and ImageFX. This structure allowed a consistent comparison of how different platforms interpreted the same conceptual input under varied visual and contextual conditions. Through this method, variations in realism, creativity, and visual coherence were systematically observed and recorded.

Figure 6. Comparison 1 - (1) Photo, (2) Twinmotion, (3) ChatGPT Plus, (4) Gemini Pro, (5) ImageFX

Prompt: A hyper-realistic AI-generated landscape render of a walking route in a natural park. The scene features a winding dirt path bordered by tall grass, wildflowers, and a wooden fence leading into the distance. Large leafy trees cast dappled shadows on the ground. The atmosphere is calm and sunny, with a bright blue sky and soft white clouds. The rendering style resembles detailed textures, natural lighting, realistic depth of field, and balanced color tones, at a 1:1 size.

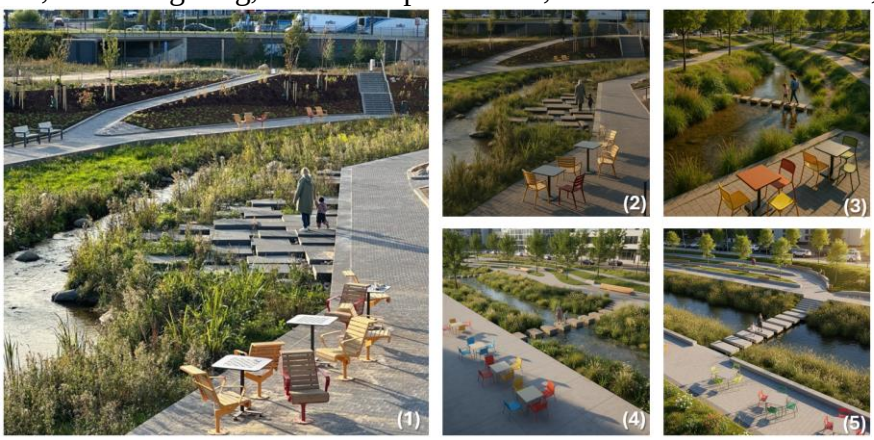

Figure 7. Comparison 2 - (1) Photo, (2) Twinmotion, (3) ChatGPT Plus, (4) Gemini Pro, (5) ImageFX

Prompt: A realistic render of an urban riverside park viewed from an elevated diagonal perspective, facing slightly downward toward the stream. The camera angle captures both the paved walkway and the natural watercourse in the same frame, with a balanced foreground and background depth. In the foreground, colorful modern chairs and square café tables are arranged along a paved path. In the middle ground, a woman and child walk across rectangular stepping stones over a shallow stream surrounded by tall grasses and riparian vegetation. The background shows gently curved pedestrian paths, young trees, and benches placed on terraced levels with soft slopes. Cars and buildings are visible beyond the park at the top of the frame. Warm afternoon sunlight casts long shadows from the right side, emphasizing textures of concrete, plants, and water reflections. Realistic materials, natural lighting, ecological planting design, and detailed rendering, at 1:1 ratio.

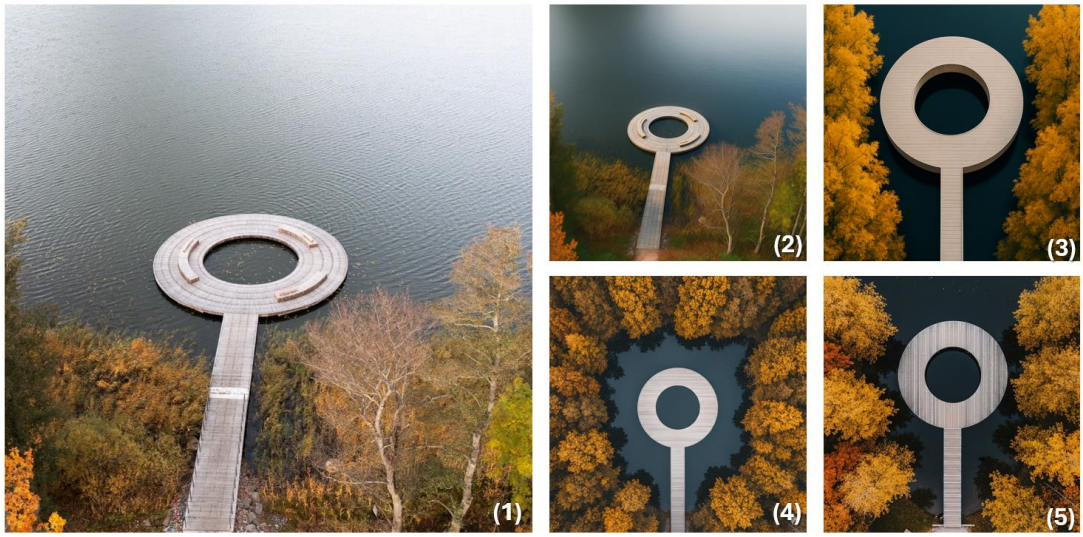

Figure 8. Comparison 3 - (1) Photo, (2) Twinmotion, (3) ChatGPT Plus, (4) Gemini Pro, (5) ImageFX

Prompt: Overhead (top-down view), centered composition featuring a minimalist circular wooden platform on dark, calm water. The straight wooden walkway leads from the bottom edge of the image directly to the center of the scene. The frame is bordered by saturated autumn trees (yellow, gold, orange) on the left and right, creating a natural frame. Clean, geometric, symmetrical composition, cold light. Ratio 1:1

Figure 9. Comparison 4 - (1) Photo, (2) Twinmotion, (3) ChatGPT Plus, (4) Gemini Pro, (5) ImageFX

Prompt: Overhead (top-down view), centered composition featuring a minimalist circular wooden platform on dark, calm water. The straight wooden walkway leads from the bottom edge of the image directly to the center of the scene. The frame is bordered by saturated autumn trees (yellow, gold, orange) on the left and right, creating a natural frame. Clean, geometric, symmetrical composition, cold light. Ratio 1:1

The comparative framework revealed clear perceptual and procedural distinctions between AI-assisted visualization and conventional 3D modeling. Although both methods aim to translate conceptual design ideas into visual form, their underlying mechanisms and cognitive demands differ substantially. Traditional 3D modeling depends on geometric accuracy, material calibration, and physically based rendering. In contrast, AI-driven systems rely on linguistic and algorithmic interpretation, translating textual descriptions into imagery through probabilistic synthesis.

Regarding time and cost, notable contrasts emerged. Twinmotion, recognized for its realistic and detailed results, required roughly six hours to complete each render and operates under annual licensing fees ranging from $445 to $1,850 USD per seat. Conversely, AI-based tools delivered images within minutes. ChatGPT Plus generated visuals in about two minutes, offering free, Plus ($20 per month), and Pro ($200 per year) tiers. Gemini Pro produced results in approximately three and a half minutes, with subscription costs varying between $19.99 and $249.99. ImageFX, the fastest of all, completed rendering in about one and a half minutes and is available free of charge. These findings underline how AI substantially reduces both production time and financial investment, enabling designers to allocate more effort toward conceptual development rather than technical rendering.

From a qualitative standpoint, traditional 3D modeling platforms such as CAD-based and rendering-oriented software continue to prioritize spatial precision, geometry control, and

physically accurate illumination (Zhang, 2022). Although these systems require significant technical expertise and time, they offer designers a high level of authorship and iterative control over scale, materiality, and perspective. As Bell (2012) observes, this manual construction process strengthens spatial understanding and enhances sensitivity to proportion, texture, and environmental context. Nevertheless, such workflows may limit experimentation because of time and computational constraints.

AI-assisted visualization tools, on the other hand, introduce a fundamentally different mode of production. By employing algorithmic interpretation instead of manual modeling, text-to-image and diffusion-based systems can produce multiple visual alternatives almost instantly. This capability allows designers to explore broader conceptual directions at early design stages (Ye et al., 2025). Leach (2022) characterizes this as AI acting as a "creative accelerator," expanding ideation while simultaneously challenging traditional notions of authorship. Yet the same adaptability raises concerns regarding accuracy, authenticity, and ethics, which are particularly significant in academic and professional contexts (Fernberg & Chamberlain, 2023).

Perceptual differences were also evident in the aesthetic and narrative dimensions of the outputs. Three-dimensional models tend to communicate structure, hierarchy, and measurable realism, whereas AI-generated imagery conveys atmosphere, emotion, and conceptual interpretation. According to Wang and Chen (2022), this shift from physical accuracy toward experiential imagination can enhance participatory design processes by engaging non-expert audiences in more intuitive ways. Similarly, Ahern (2013) highlights that such technologies may strengthen resilience-oriented and adaptive design approaches by allowing faster testing of sustainable scenarios.

From an educational perspective, incorporating AI into design studios may reshape how visualization is both taught and practiced. These systems encourage students to prioritize design intent, spatial storytelling, and critical reflection rather than focusing solely on technical skills. As noted by Fernberg and Chamberlain (2021), this shift calls for a re-evaluation of the balance between tool mastery and conceptual reasoning, a balance that remains at the heart of landscape architecture.

Taken together, these findings demonstrate that AI-assisted visualization does not replace traditional modeling but rather complement it by extending creative capacity and reconfiguring design workflows. The most promising outcomes appear within hybrid methodologies, where the precision of 3D modeling is merged with the generative adaptability of AI systems. Such integration can foster more expressive, efficient, and inclusive forms of visual communication within both professional and educational contexts.

4. Conclusion and Recommendations

This study explored the intersection of Artificial Intelligence (AI) and three-dimensional (3D) modeling as emerging visualization approaches within landscape design. The findings suggest that while 3D modeling remains essential for achieving precision, spatial control, and material accuracy, AI-assisted systems introduce new possibilities for conceptual exploration, efficiency, and participatory engagement. The comparative results demonstrate that these two visualization modes are not competing but rather complementary. When integrated, they enhance both the expressive and analytical capacities of design practice.

AI-based visualization supports designers by enabling rapid generation of multiple design iterations during early conceptual stages. This allows more time to be devoted to critical

evaluation, narrative development, and design decision-making. In contrast, 3D modeling continues to reinforce spatial reasoning and ensures technical reliability in the final outcome. The balance between these approaches emphasizes the value of hybrid workflows that blend creativity and precision an increasingly relevant approach in both professional and academic design environments.

In the context of education, incorporating AI into landscape architecture curricula could nurture creativity and inclusivity while promoting reflection on ethics, authorship, and digital literacy. These discussions are crucial, as the growing reliance on automated systems challenges traditional understandings of originality and the designer's intellectual contribution. Educators and practitioners should therefore remain open to innovation but also critically aware of the limitations of automation.

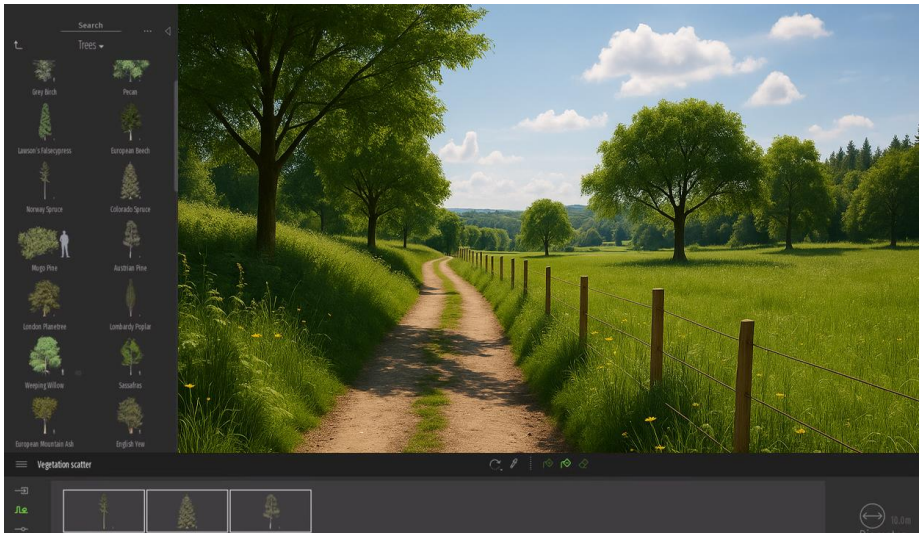

Figure 10. Screenshot of a 3D modeling interface Twinmotion

Future research can extend this inquiry by examining how designers perceive AI-generated visualizations in terms of authenticity, emotional resonance, and cognitive engagement. Further studies could also investigate the sustainability implications of AI-driven workflows, particularly regarding energy use, data management, and environmental impact. Through such continued exploration, discipline can better align technological progress with the human-centered values that define landscape architecture.

Ultimately, AI does not replace design, it transforms how we visualize, communicate, and collaborate within the discipline. Among the tools compared, Twinmotion continues to provide the most stable and professional results, particularly in achieving photorealistic quality. However, in cases where time is limited, prompt-based rendering can serve as an effective alternative. While ImageFX tends to generate oversaturated and exaggerated visuals and Gemini remains somewhat inconsistent in its responses, both illustrate the diversity of AI's generative potential. ChatGPT, though more disciplined in following prompts, can occasionally display interpretive rigidity. These distinctions underline that each tool carries its own strengths and limitations, and understanding these nuances enables designers to make more informed choices.

In conclusion, the evolving synergy between AI and 3D visualization signals a paradigm shift in landscape architecture. It not only redefines representational techniques but also encourages

a more reflective, inclusive, and collaborative design culture one in which technology acts as a partner rather than a substitute for human creativity.

Abstract

Natural carbon sinks are essential components of the global climate system, sequestering and storing carbon dioxide (CO_2) and other greenhouse gases through biological, chemical, and physical processes. Forests, oceans, wetlands, mangrove forests, seagrass meadows, tundra regions, permafrost areas, and soils form the primary ecosystems that regulate the global carbon cycle. Each ecosystem contributes to carbon sequestration and carbon storage through different mechanisms. Forests store carbon through photosynthesis, oceans and wetlands through biological production and sedimentation, mangrove forests and seagrasses via coastal processes, tundra and permafrost areas through frozen organic carbon, and soils through the accumulation of organic matter. Human-induced pressures such as deforestation, land degradation, pollution, ocean acidification, and global warming increasingly threaten the stability and carbon storage capacity of these ecosystems. These impacts disrupt the carbon balance between the atmosphere and the biosphere, increase greenhouse gas concentrations, and accelerate climate change. The degradation of natural carbon sinks also reduces biodiversity, causes soil erosion, and destabilizes water cycles, undermining overall ecosystem resilience. Consequently, the conservation and restoration of natural carbon sinks are critical for mitigating climate change and maintaining essential ecosystem services. Integrating ecosystem-based approaches into land-use planning, supporting scientific research on carbon sequestration and carbon storage, implementing nature-based solutions, and raising public awareness are key strategies. Sustainable management of natural carbon sinks enhances climate resilience, ensures environmental stability, and provides a foundation for a low-carbon, sustainable future.

Keywords: Carbon storage, nature-based solutions, ecosystem services, climate change mitigation

1. Introduction

Atmospheric carbon dioxide (CO_2) concentrations increased significantly after the Industrial Revolution. Increased fossil fuel use, deforestation, and changes in land use have affected the natural flow of the carbon cycle. Global temperature increases, ocean warming, glacial retreat, and an increase in the frequency of extreme weather events are among the observable consequences of this change (IPCC, 2021). Carbon is an element that constantly moves between the biosphere, atmosphere, oceans, and soil, and this movement constitutes one of the fundamental regulatory processes of the climate system. Natural ecosystems limit atmospheric CO_2 accumulation by storing carbon in biomass, organic matter, and sediments. Therefore, the status of natural carbon sinks directly determines the course of the climate crisis. The carbon storage capacity of these ecosystems varies depending on environmental conditions. Terrestrial and aquatic ecosystems have different mechanisms of operation in the carbon cycle. Forests draw carbon from the atmosphere through photosynthesis and store this carbon in the biomass of trunks, branches, leaves, and roots (Pan et al., 2011). In wetlands, low-oxygen environments cause organic matter to decompose slowly, enabling the long-term accumulation of carbon in

sediments (Mitsch & Gosselink, 2015). Coastal ecosystems such as mangrove forests and seagrass meadows have high carbon storage capacity as a result of sediment accumulation processes (Fourqurean et al., 2012). Tundra and permafrost regions retain frozen organic carbon due to low temperatures (Hugelius et al., 2014). Soil constitutes one of the largest terrestrial carbon pools on a global scale (Lal, 2004).

With the increasing impacts of climate change, protecting and maintaining the functioning of natural carbon sinks has become increasingly important. In recent years, ecosystem-based approaches have become prominent in climate change adaptation and mitigation efforts. These approaches are based on the preservation and restoration of natural processes. The goal is to ensure that ecosystems can sustain their own carbon cycles and reduce the carbon load in the atmosphere (IPCC, 2019; Seddon et al., 2020).

Government policies, land planning decisions, the balance between conservation and utilization, economic activities, and management practices determine carbon storage potential (Griscom et al., 2017). Forest management programs, agricultural production methods, wetland protection strategies, coastal zone planning, and soil fertility practices directly impact the sustainability of the carbon cycle (IPCC, 2019). Protecting natural carbon sinks is considered not only an ecological but also a managerial and societal process (Seddon et al., 2020).

The aim of this study is to explain the mechanisms of carbon storage and the functioning of different ecosystem types within the carbon cycle and to demonstrate the strategic importance of natural carbon sinks, such as forests, wetlands, peatlands, blue carbon ecosystems, soil, and permafrost regions, in combating climate change. The study also assesses the threats these ecosystems face due to anthropogenic pressures and highlights the role of ecosystem-based conservation, restoration, and planning approaches in strengthening carbon storage capacity. This aims to provide a scientifically based framework for the protection and sustainable management of natural sinks in the fight against climate change.

2. Natural Carbon Sinks and Their Functioning Mechanisms

The carbon cycle is driven by a continuous movement of matter between the atmosphere, biosphere, soil, and oceans. Within this cycle, some ecosystems have the capacity to store CO_2 they absorb from the atmosphere for long periods. A natural carbon sink is used for systems where the amount of carbon absorbed from the atmosphere is stored greater than the amount released. To be defined as a carbon sink, an ecosystem must demonstrate a net carbon gain in terms of its annual carbon budget. This process relies on ecological mechanisms such as photosynthesis, biomass accumulation, the transfer of organic matter to the soil, and the limitation of decomposition (Randerson et al., 2002).

Natural carbon sinks are found in different ecosystem types and sequester carbon in different ways. Forests store carbon in biomass and soil; wetlands store carbon through organic matter accumulation; and coastal mangrove and seagrass systems store carbon in both plant tissue and sediments (Donato et al., 2011; Duarte et al., 2013). In tundra and permafrost regions, low temperatures slow the decomposition of organic carbon, enabling long-term storage (Hugelius et al., 2014).

These ecosystems also provide ecosystem services such as water cycling, soil conservation, and biodiversity. A decrease in carbon storage capacity means a weakening of these services (MA, 2005). Therefore, the protection and restoration of natural carbon sinks has become a fundamental component of nature-based climate policies.

a. Forest Ecosystems

Forest ecosystems constitute one of the largest terrestrial carbon storage areas in the global carbon cycle. Atmospheric CO_2 is taken up by plants through photosynthesis and converted into organic compounds. As a result of this process, carbon is stored for many years in the trunk, branch, leaf, and root tissues of trees. Forest soils also accumulate significant amounts of carbon through the decomposition of dead plant material and humus formation. Therefore, forests are considered two-way sink systems capable of sequestering carbon in both biomass and soil (Jobbágy & Jackson, 2000; Luyssaert et al., 2008; Pan et al., 2011).

The carbon storage capacity of forests varies depending on variables such as species composition, age distribution of trees, biomass production rate, light and moisture conditions, and soil properties. Tropical forests store large amounts of carbon due to their high biomass production and exhibit a rapid carbon cycle. Temperate forests, on the other hand, contain slower-growing but longer-living tree communities, sequestering carbon in both biomass and soil for longer periods (Bonan, 2008).

Deforestation and forest degradation cause stored carbon to rapidly return to the atmosphere. Expansion of agricultural land, increased settlements, road construction, mining expansion, fires, and unregulated felling reduce carbon stocks. This leads to the loss of existing carbon stocks and reduces the capacity to capture carbon from the atmosphere in the future. When combined with climate change-related risks such as fires, rising temperatures, and drought, carbon loss appears to accelerate (Anderegg et al., 2020).

Forest management practices constitute one of the key anthropogenic factors shaping the carbon storage potential of ecosystems. Supporting natural regeneration processes, promoting mixed species composition, appropriate forest spacing arrangements, and reforestation in degraded areas can increase carbon sequestration capacity. At the same time, maintaining long rotation periods and retaining dead wood material in the ecosystem supports soil carbon accumulation (Griscom et al., 2017). Long-term global monitoring studies have shown that maintained and aging forests tend to maintain their carbon storage capacity. Young forests sequester high amounts of carbon during periods of rapid growth, while mature forests have the capacity to retain their stored carbon for extended periods (Luyssaert et al., 2008). This demonstrates that preserving intact forests is as important as reforestation.

b. Wetlands and Peatlands Ecosystems

Wetlands and peatlands are among the ecosystems with long-term carbon storage capacity in the global carbon cycle. A key characteristic of these ecosystems is that water-saturated and oxygen-limited conditions slow down organic matter decomposition processes (Gorham, 1991; Mitsch & Gosselink, 2015). Organic tissues produced by plants accumulate in soil and sediment layers due to their slow decomposition rate, transforming carbon into a long-term storage form. This process is particularly pronounced in peatlands, where organic residues accumulate over thousands of years to form carbon-rich structures called peat (Yu, 2012).

Wetlands and peatlands are among the ecosystems with long-term carbon storage capacity in the global carbon cycle. A key characteristic of these ecosystems is that water-saturated and oxygen-limited conditions slow down organic matter decomposition processes (Gorham, 1991; Mitsch & Gosselink, 2015). Organic tissues produced by plants accumulate in soil and sediment layers due to their slow decomposition rate, transforming carbon into a long-term storage form.

This process is particularly pronounced in peatlands, where organic residues accumulate over thousands of years to form carbon-rich structures called peat (Yu, 2012).

Despite covering only approximately 3% of the global land surface, peatlands on Earth have a carbon storage capacity greater than all forests combined, storing a significant portion of the world's soil carbon (Gorham, 1991). Hydrological conditions and water table levels are critical factors determining the carbon balance of wetland and peatland ecosystems. Lower water levels allow organic matter to come into contact with oxygen, increasing the rate of decomposition and returning carbon to the atmosphere in the form of CO_2 and CH_4 (Turetsky et al., 2014; Günther et al., 2020). Therefore, the hydrological regime is considered one of the most important determinants of the carbon storage capacity of peatlands. Draining wetlands, agricultural drainage practices, uncontrolled water management, peat extraction, and land use changes are among the primary anthropogenic impacts that weaken carbon storage (Joosten & Clarke, 2002; Leifeld & Menichetti, 2018). Disturbance in these ecosystems can result in carbon stored for thousands of years being released back into the atmosphere in a short timeframe.

Wetland and peatland restoration is an effective ecosystem-based approach for restoring carbon storage capacity. Re-raising water levels allows peat-forming vegetation to return and slows the rate of decomposition, increasing carbon sequestration. Long-term monitoring studies show that the carbon sequestration capacity of re-wetted peatlands increases significantly over time (Günther et al., 2020; Tanneberger et al., 2011). Therefore, restoring the functionality of degraded peatlands, along with protecting wetlands, is considered a fundamental strategy in combating climate change.

c. Blue Carbon Ecosystems

Mangrove forests, seagrass meadows, and tidal flat ecosystems are considered within the scope of the "blue carbon" concept as systems located in coastal areas with high carbon storage capacity. Blue carbon refers to the processes by which coastal and marine plant communities store carbon from the atmosphere over long periods of time, both in their biomass and, particularly, in sediment layers (Nellemann et al., 2009; Duarte, Losada, Hendriks, Mazarrasa, & Marbà, 2013). Carbon accumulation in these ecosystems occurs through the interaction of the intensity of plant production, the sediment retention capacity of root systems, and oxygen-limited environmental conditions that slow the decomposition rate of organic matter. Therefore, the carbon stored in blue carbon ecosystems can often reach higher levels than the amount of carbon stored in terrestrial forest ecosystems (McLeod et al., 2011). Mangrove ecosystems, thanks to both their high biomass production and dense and complex root systems, serve as important coastal carbon sinks, retaining carbon for long periods. The location of mangrove roots in the transition zone between water and sediment limits the contact of organic matter with oxygen and slows the rate of decomposition, allowing carbon to accumulate in sediments for long periods (Donato et al., 2011). Similarly, seagrass meadows, thanks to their extensive rhizome networks and sediment retention capacity, can store carbon in both plant tissue and subsoil sediment layers for thousands of years (Fourqurean et al., 2012).

One of the most important determinants of carbon storage capacity in coastal ecosystems is the continuity of the sedimentation process. Waves, currents, and tidal movements directly affect sediment transport and deposition, while plant roots stabilize this sediment, reducing coastal erosion (Barbier et al., 2011). Therefore, blue carbon ecosystems not only function as carbon

sinks but also provide critical ecosystem services such as coastal protection, mitigating storm wave energy, maintaining habitat continuity, and supporting biodiversity.

However, anthropogenic factors such as sea level rise, coastal development, tourism pressure, water pollution, agricultural drainage, and industrial filling practices threaten the integrity of blue carbon ecosystems. Disruption of these systems can not only deplete existing carbon stocks but also cause carbon accumulated in sediments over thousands of years to quickly return to the atmosphere, thereby increasing additional greenhouse gas emissions (Pendleton et al., 2012). Therefore, restoring natural hydrodynamic processes, locating mangrove seedlings in suitable microtopographic conditions, and seagrass planting practices are crucial in restoration efforts. Long-term monitoring studies have demonstrated that when favorable conditions are met, the carbon storage capacity of these ecosystems increases over time (Wylie et al., 2016).

d. Ocean Ecosystems

The oceans are considered one of the largest and most dynamic carbon storage systems in the global carbon cycle. Atmospheric CO_2 is transferred to ocean surface waters through physical dissolution processes, where it is converted into inorganic carbon forms. This process is described as a physical carbon pump operating in conjunction with atmosphere-ocean gas exchange (Sarmiento & Gruber, 2006). Furthermore, photosynthesis by phytoplankton forms the basis of biological carbon production in the oceans; some of the organic carbon produced is transferred to the food chain, while the remaining portion sinks to the deep ocean floor as dead biomass, contributing to long-term carbon storage through the biological carbon pump (Falkowski, Barber, & Smetacek, 1998).

The carbon storage capacity of the oceans is shaped by environmental variables such as water temperature, dissolved gas concentration, ocean circulation, and phytoplankton productivity. Deep ocean layers can store carbon for hundreds or even thousands of years without interacting with the atmosphere (Sigman & Haug, 2003). However, global warming directly affects the oceans' carbon sink function. Increasing seawater temperatures limit the transfer of carbon from the atmosphere to the ocean by reducing the solubility of CO_2 (Riebesell, Zondervan, Rost, Tortell, Zeebe, & Morel, 2000). In addition, ocean acidification impairs the biomineralization processes of plankton with calcium carbonate skeletons and disrupts the biological carbon cycle (Doney, Fabry, Feely, & Kleypas, 2009).

Protecting and enhancing ocean carbon sinks requires the integrated implementation of policies for marine ecosystem management, pollution control, limiting overfishing, and combating climate change. Oceans play a central role in global climate stability not only as passive carbon reservoirs but also as active carbon flow systems that regulate the atmosphere-biosphere interaction.

e. Soil Organic Carbon

Soil constitutes one of the largest carbon storage pools in the global carbon cycle, directly affecting both terrestrial and atmospheric systems (Batjes, 1996; Jobbágy & Jackson, 2000). Soil organic carbon is formed by the accumulation within the soil profile of organic matter resulting from the decomposition of plant roots, leaf litter, dead plant and animal tissues, and microbial biomass. This organic carbon, concentrated in the upper soil horizons, supports the continuity of the nutrient cycle and serves as a key component of ecosystem productivity (Carter & Gregorich, 2007). Soil serves as a carbon buffer system between the atmosphere and the biosphere. While plants absorb atmospheric CO_2 through photosynthesis, a portion of the

organic matter is returned to the atmosphere through microbial respiration and decomposition, while the remainder is transferred to the soil organic carbon pool (Lal, 2004). The stability period of carbon accumulated in the soil depends on: It depends on environmental and edaphic factors such as temperature, moisture, soil texture, mineral composition, and microbial activity (Six, Conant, Paul, & Paustian, 2002). Clay minerals, in particular, contribute to long-term carbon sequestration by binding organic matter to the mineral surface (Lehmann & Kleber, 2015).

Soil organic carbon plays a critical role not only in the climate system but also in fundamental soil functions such as soil structure, water retention capacity, aeration, and nutrient cycling (Franzluebbers, 2002). Organic-rich soils are more resistant to erosion and provide more favorable conditions for plant growth. Therefore, a decrease in soil carbon can negatively affect both ecosystem productivity and the stability of the carbon cycle (Carter & Gregorich, 2007).

Agriculture and land use patterns are among the primary anthropogenic determinants of soil carbon balance. Practices such as deep plowing, monoculture production, and stubble burning can increase the rate of organic matter decomposition, leading to a decrease in soil carbon (Lal, 2004). Conversely, conservation tillage, cover crops, organic material applications, and agroecological production systems contribute to the preservation and reaccumulation of soil organic carbon (Paustian et al., 2016). Rising temperatures associated with climate change have the potential to accelerate soil-based carbon release by increasing the rate of organic matter decomposition (Crowther et al., 2016). The risk of soil carbon loss is becoming more pronounced, particularly in arid and semiarid regions. However, long-term agricultural trials indicate that soil carbon can be restored with appropriate management practices (Conant et al., 2017). This demonstrates that soil is a carbon sink capable of recapturing carbon.

f. Tundra ve Permafrost Ecosystems

Tundra and permafrost regions are ecosystems where organic carbon accumulates for long periods without decomposing due to low temperature conditions. While plant production is limited in these areas, low temperatures and microbial activity slow the rate of decomposition and allow organic carbon to be retained in soil and permafrost layers for thousands of years (Tarnocai, Canadell, Schuur, Kuhry, Mazhitova, & Zimov, 2009). Permafrost refers to soil layers that remain frozen year-round and contain large amounts of frozen organic matter. Therefore, tundra and permafrost regions are considered one of the largest carbon reserves on a global scale (Hugelius et al., 2014).

The preservation of carbon accumulated in permafrost soils depends on the continuity of the permafrost structure. When global temperature increases accelerate permafrost thawing, frozen organic matter is exposed to microbial decomposition, causing carbon to return to the atmosphere in the forms of CO_2 and CH_4 (Schuur et al., 2015). This process is defined as the "permafrost carbon feedback" and poses a critical risk due to its potential to further accelerate climate change by increasing atmospheric greenhouse gas concentrations. Because methane has a much higher short-term global warming potential than CO_2, CH_4 emissions from permafrost thawing have a significant impact on the climate system (Walter, et al., 2018).

The carbon cycle in tundra and permafrost ecosystems is determined by temperature changes, snow cover thickness, soil moisture status, and the seasonal phenology of vegetation (Natali, et al., 2019). Increasing temperatures accelerate microbial decomposition, creating a positive feedback mechanism that leads to continued carbon release and accelerated climate change.

The effects of permafrost thawing are not limited to the carbon cycle. Thawing of frozen ground can lead to a decrease in surface stability and an increase in geotechnical risks for infrastructure, buildings, and transportation networks (Streletskiy et al., 2015). Furthermore, thawing can lead to increased lake and marsh formations, altered habitat structures, and reshaping of regional biodiversity (Jorgenson et al., 2006). Therefore, the degradation of tundra and permafrost ecosystems is of global importance, with both ecological and socioeconomic dimensions.

While direct ecosystem-based methods for completely halting permafrost thawing are limited, preserving vegetation, maintaining surface snow cover to slow melting, and maintaining hydrological balances can contribute to reducing carbon emissions (Natali et al., 2019). However, current scientific findings indicate that the recoverability of permafrost carbon loss is quite low compared to other ecosystems (Schuur et al., 2015). Therefore, tundra and permafrost systems are considered as fragile carbon stores in scenarios where climate change cannot be controlled.

3. Ecosystem-Based Approaches and Management Practices

g. Forest Restoration and Renewal

Forest restoration is an ecosystem-based practice that aims to restore the structural and functional characteristics of degraded forest ecosystems. This process encompasses not only the restoration of tree cover but also the improvement of nutrient cycles, soil organic matter, and habitat continuity (Chazdon, 2014). The carbon storage capacity of forests is associated with the increase in biomass and the accumulation of soil organic carbon. The high rate of biomass increase, particularly in young and medium-aged forests, contributes to the increased rate of carbon absorption from the atmosphere (Lewis et al., 2019). Within the scope of restoration efforts, it is important to prioritize native species, maintain species diversity, and support natural regeneration processes. While single-species plantation systems may exhibit high biomass production in the short term, they can lead to a decrease in ecosystem resilience, soil carbon accumulation, and biodiversity in the long term (Benayas et al., 2009). In contrast, mixed species compositions strengthen ecosystem resilience to stress conditions by increasing root system diversity and soil microbial activity (Forrester & Bauhus, 2016). Therefore, forest restoration requires a holistic planning approach that considers plant diversity and ecological functions together.

Increasing temperatures and drought conditions associated with climate change are increasing the frequency and severity of forest fires, which can cause stored carbon to quickly return to the atmosphere and delay restoration processes (Bowman et al., 2009). Therefore, selecting fire-resistant species, reducing fuel loads, and integrating landscape fire management strategies are critical in restoration planning. Long-term observational studies reveal that soil carbon tends to reaccumulate in degraded forest areas when management supports and natural processes work together (Griscom et al., 2017). This suggests that restoration not only preserves existing carbon stocks but also enables carbon recovery.

Afforestation efforts in urban and semi-urban areas also provide important ecosystem services such as carbon sequestration, heat island mitigation, and air quality improvement. Urban trees contribute to microclimate regulation through shading and evapotranspiration, and improve air quality by trapping atmospheric particulate matter (Nowak & Crane, 2002; Escobedo et al., 2011). Therefore, forest restoration is considered a multi-layered process encompassing not only rural areas but also urban landscape planning.

h. Wetland Rehabilitation

Wetland rehabilitation is an ecosystem-based approach that aims to restore water-saturated conditions and maintain carbon storage by slowing the rate of organic matter decomposition. Carbon accumulation in wetlands occurs due to high water tables, anaerobic conditions, and limited organic tissue decomposition rates (Chmura et al., 2003; Craft, 2016). The primary goal of rehabilitation is to restore the degraded hydrological regime to its natural state as closely as possible. Maintaining a stable water table, supporting sediment accumulation, and supporting vegetative cover are critical for maintaining long-term carbon storage capacity (Merritt & Wohl, 2006). Wetland losses are largely the result of anthropogenic pressures such as drainage practices, agricultural expansion, water control projects, and peat extraction. As the water level drops, organic matter comes into contact with oxygen, which increases the rate of decomposition and causes carbon to return to the atmosphere in the form of CO_2 and CH_4 (Waddington et al., 2015). This process can lead to the loss of carbon accumulated over thousands of years in a very short period of time. Therefore, the first step in rehabilitation practices is to control the raising of the water table and restore the wetland's water-holding capacity (Moreno-Mateos et al., 2012).

Restoring the vegetative cover with natural species is crucial in rehabilitation efforts. Reeds, reed communities, and water-tolerant macrophyte species constitute key ecological components of carbon sequestration through both biomass production and sediment stabilization (Brix, 1994). Root and rhizome systems limit the decomposition of organic matter and strengthen the physical integrity of the sediment, increasing ecosystem resilience to hydrological changes (Craft, 2016). Long-term monitoring studies demonstrate that wetland rehabilitation is an effective method for carbon recovery. It has been demonstrated that soil organic carbon in rehabilitated wetlands increases significantly, particularly in the first 5–15 years, and that carbon can reaccumulate in sediment layers (Moreno-Mateos et al., 2012). Thus, wetland rehabilitation not only restores disrupted carbon cycles but also strengthens the capacity to adapt to climate change.

Wetland rehabilitation also provides simultaneous ecosystem services such as water cycle regulation, flood control, habitat continuity, and biodiversity support (Zedler & Kercher, 2005). In this respect, wetland rehabilitation is considered a strategic application that not only increases carbon storage capacity but also strengthens ecological resilience at the landscape scale.

i. Carbon Management in Blue Carbon Areas and Ocean Ecosystems

Coastal ecosystems such as mangroves, seagrass meadows, and salt marshes are highly efficient carbon sinks capable of storing carbon in both plant biomass and sedimentary layers for long periods. The carbon density stored in these ecosystems can be higher per unit surface area than in most tropical forest ecosystems (Donato et al., 2011; Nellemann et al., 2009). Restoring these systems, defined as blue carbon, is considered an effective ecosystem-based climate strategy for reducing atmospheric carbon and increasing carbon sequestration (McLeod et al., 2011).

The degradation of blue carbon ecosystems poses a significant carbon release risk. Human-induced disturbances such as coastal development, seawalls, interruptions to sediment flow, and water pollution limit sediment accumulation, preventing the long-term retention of carbon in sedimentary layers (Hamilton & Friess, 2018). Therefore, during the restoration process,

restoring topography, ensuring sediment inputs, and replanting suitable vegetation are key practices for restoring carbon storage capacity (Lovelock & Brown, 2019).

Practice-based monitoring studies reveal that blue carbon systems experience a return to increased carbon accumulation rates after restoration. Sediment carbon density has been determined to increase in restored mangrove areas, and root systems have been shown to enhance sediment stabilization, supporting long-term carbon storage (Wylie et al., 2016). This suggests that blue carbon restoration not only provides habitat improvement but also offers an important carbon recovery mechanism in combating climate change. Therefore, coastal zone planning should integrate the protection of blue carbon areas and ecosystem restoration with land-use decisions (Duarte et al., 2013).

The oceans serve as the largest carbon sink in the global carbon cycle, absorbing a significant portion of atmospheric CO_2 through physical dissolution and biological production processes (Sarmiento & Gruber, 2006). However, the oceans' function as carbon sinks is sensitive to climate change. Increasing seawater temperature reduces CO_2 solubility, while ocean acidification impairs the biomineralization processes of carbonate-bearing organisms, reducing the efficiency of the biological carbon pump (Doney et al., 2009; Riebesell et al., 2000). In addition, overfishing and pollution pressures can alter phytoplankton community structure, reducing the ecological efficiency of the ocean-based carbon cycle (Falkowski et al., 1998). Therefore, ocean-based carbon management requires the combined implementation of multi-layered management tools, such as expanding marine protected areas, reducing pollution pressures, and protecting coastal ecosystems (Gattuso et al., 2018). Maintaining the healthy functioning of the oceans is critical not only for balancing atmospheric CO_2 but also for habitat continuity and global ecosystem resilience.

j. Soil Carbon Management and Agricultural Practices

Increasing soil organic carbon content and preserving existing stocks stands out as an important strategy in combating climate change. Conservation agriculture practices, the use of cover crops, and organic fertilizer and compost applications support the accumulation of soil organic carbon, strengthening both soil fertility and the stability of the carbon cycle (Lal, 2004; Paustian et al., 2016). These methods increase biomass inputs and slow the rate of decomposition, allowing carbon to be retained in the soil for longer periods.

Conversely, land use changes and intensive agricultural production models threaten soil carbon stores. Deep plowing, monoculture production, and intensive chemical inputs accelerate microbial decomposition, leading to carbon being returned to the atmosphere as CO_2 (Six et al., 2002). Erosion processes, in turn, accelerate carbon loss by transporting organic-rich topsoil. Therefore, regulating agriculture-forest transition zones and observing carbon targets in land-use planning are critical (Guo & Gifford, 2002).

At the policy level, measuring, monitoring, and promoting soil carbon management practices is crucial. Soil carbon recovery should be integrated into national carbon budgets and climate policies, alongside fossil fuel reduction strategies (Smith et al., 2020). Carbon credit mechanisms, agricultural support programs, and monitoring-reporting-verification (MRV) systems for monitoring land-use changes support the sustainability of soil carbon storage processes. Examples of implementation demonstrate that annual soil carbon increases are possible with appropriate management options, but the sustainability of these increases depends on management stability and supportive policy mechanisms (Paustian et al., 2016).

k. Planning and Policy Context

The protection and restoration of natural carbon sinks is not only an ecological process, but also a managerial and political one. Maintaining carbon storage capacity requires the combined operation of land use planning, local government practices, legal regulations, and financial incentive mechanisms (Seddon, Chausson, Berry, Girardin, Smith, & Turner, 2020). Planning processes that consider the carbon functions of ecosystems are critical for shaping spatial decisions in a way that enhances carbon capture (Ostrom, 2009).

Measurement-Monitoring-Reporting (MRV) systems play a central role in the policy development process for protecting carbon sinks. Identifying carbon stock changes in sinks with traceable data sets strengthens both the effectiveness and accountability of policy instruments (Griscom et al., 2017). Achieving a balance between development and conservation objectives; This requires planning practices such as agriculture-forest transition zones, water management, coastal development, and forest restoration in line with carbon targets (Keenleyside, Dudley, Cairns, Hall, & Stolton, 2012). National-scale greenhouse gas inventories and sink-source balance models increasingly include the integration of natural sinks into the carbon budget. Carbon credit trading, financial support programs, and public-private partnership mechanisms are used as important policy tools in this process (Wylie, Sutton-Grier, & Moore, 2016). However, as emphasized in the literature, the success of these practices depends not only on the planning level but also on the implementation of decisions appropriate to the local context, stakeholder participation, and the continuity of long-term monitoring processes (Ostrom, 2009; Seddon et al., 2020).

Conclusion and Recommendations

Natural carbon sinks play a fundamental role in regulating the global carbon cycle. Forests, wetlands, peatlands, coastal ecosystems, and permafrost regions enable the long-term storage of carbon in biomass and soil tissue. The carbon storage processes occurring in these ecosystems contribute to reducing atmospheric CO_2 concentrations and maintaining a more balanced climate system. However, human-induced land use changes, urban expansion, intensive agricultural practices, drying and drainage, increased fire risk, and temperature increases associated with climate change are weakening the carbon storage capacity of these sink systems. This can cause carbon accumulated over long periods in the past to quickly return to the atmosphere, contributing to the acceleration of climate change.

The ecosystem-based approaches discussed in this study offer practical methods for protecting and restoring the functionality of natural carbon sinks. Approaches that support species diversity in forest restoration, maintain natural regeneration processes, and utilize methods that reduce fire risk contribute to maintaining carbon storage capacity. In wetland rehabilitation, rebalancing the water table and restoring natural vegetation strengthens the sustainability of carbon sequestration by limiting the rate of organic matter decomposition. In the recovery of blue carbon ecosystems, preserving coastal morphology and supporting sediment accumulation enable the reaccumulation of plant and sediment carbon. In soil carbon management, conservation agricultural practices, maintaining organic matter input, and aligning land-use planning with carbon targets are crucial.

Protecting natural carbon sinks is not merely an ecological issue. It is directly related to land planning, economic activities, local government decisions, and national greenhouse gas inventory policies. Therefore, measurement, monitoring, and reporting processes for sink

management must be maintained at the institutional level. Assessing the carbon storage capacity of ecosystems with traceable data allows planning processes to be based on scientific data. At the same time, local stakeholder participation strengthens the social acceptance of decisions shaping land use and supports the sustainability of these practices. The information obtained demonstrates that protecting natural carbon sinks is not sufficient alone in climate change mitigation efforts, but is a necessary component. Along with reducing fossil fuel-related emissions, the carbon storage capacity of existing ecosystems must be preserved and degraded ecosystems must be restored. Furthermore, the long-term maturation dynamics of these processes must be considered, and continuous ecological monitoring and management approaches must be pursued rather than short-term expectations.

In conclusion, protecting natural carbon sinks and implementing ecosystem-based approaches are considered processes that support both mitigation and adaptation capacity in combating climate change. When the necessary conditions are provided for ecosystems to maintain their functions, carbon storage processes are revitalized and the continuity of ecosystem services is preserved. Therefore, maintaining ecosystem management and integrated land planning approaches supported by scientific data is crucial for achieving long-term climate goals.

Abstract

Urbanization is accelerating worldwide, making the conservation and monitoring of biodiversity in cities increasingly critical. However, measuring biodiversity in urban ecosystems remains challenging due to habitat fragmentation, heterogeneous species distributions, and limited research resources. In this context, citizen science offers an innovative and complementary approach to assess and monitor urban biodiversity. This study explores the contributions of citizen science initiatives to the measurement of urban biodiversity. International examples such as iNaturalist, eBird, the City Nature Challenge, and the Big Butterfly Count are reviewed to demonstrate how species richness, spatial distribution, and temporal changes can be effectively tracked. In addition, mobile applications and community-based "bioblitz" events provide valuable datasets that can be analyzed through biodiversity indices and GIS-based methods to better understand urban ecological dynamics. Citizen science provides low-cost and large-scale biodiversity data and fosters environmental awareness among urban residents, thereby contributing to the protection of urban ecosystems. Nevertheless, challenges such as data accuracy, spatial and temporal biases, and sustaining long-term public participation must be considered when applying these approaches. In conclusion, citizen science represents a powerful tool to complement traditional scientific methods in measuring urban biodiversity. Expanding the use of such approaches could strengthen scientific research capacity while also enhancing public engagement with nature in urban environments.

Keywords: Urban biodiversity, citizen science, ecosystem monitoring, species richness

1. Introduction

The acceleration of urbanization in the Anthropocene has resulted in a profound restructuring of ecosystems, altering the composition, distribution, and functioning of biodiversity across the planet (Grimm et al., 2008). Urban areas now occupy approximately 3% of the Earth's land surface but exert disproportionately large impacts on global ecological processes, including habitat fragmentation, pollution, and altered hydrological cycles (Elmqvist et al., 2015; McKinney, 2008). The United Nations (2019) projects that by 2050, nearly 68% of the global population will live in cities, intensifying pressures on natural resources and increasing the urgency of integrating biodiversity considerations into urban planning and management.

Urban biodiversity—defined as the variety of living organisms and their ecological interactions within urban environments—provides crucial ecosystem services such as air purification, climate regulation, stormwater retention, and mental health benefits (Goddard, Dougill, & Benton, 2010; Aronson et al., 2017). Yet, the effective assessment and conservation of biodiversity in urban settings remain constrained by methodological and logistical limitations. Conventional ecological monitoring techniques, including transect surveys and species inventories, often require substantial expertise, time, and funding, limiting their applicability in complex urban mosaics (Deguines et al., 2012). Furthermore, the spatiotemporal variability of

urban ecosystems complicates the establishment of standardized monitoring frameworks (Niemelä, 2014).

In response to these challenges, citizen science, a participatory research approach involving the systematic contribution of non-professional volunteers to scientific data collection and interpretation, has emerged as a promising tool for urban biodiversity assessment (Bonney et al., 2009; Kobori et al., 2016). Citizen science democratizes environmental research by engaging local communities, expanding spatial coverage, and generating large-scale datasets that complement formal scientific surveys (Dickinson, Zuckerberg, & Bonter, 2012). Recent technological advancements, particularly the proliferation of smartphones, geolocation technologies, and open-access platforms, have significantly enhanced the accuracy, accessibility, and analytical potential of citizen-generated biodiversity data (Newman et al., 2017).

Projects such as eBird (Sullivan et al., 2014), iNaturalist (Mason et al., 2025), and the City Nature Challenge (Palma et al., 2024) demonstrate how citizen science can mobilize large and diverse populations to contribute observations that reveal spatial patterns of species richness, phenological trends, and urban habitat use (Callaghan et al., 2019). These platforms generate critical ecological data and foster environmental awareness and stewardship among citizens, aligning with the goals of the Convention on Biological Diversity and the UN Sustainable Development Goals (United Nations, 2015).

In this context, the present review synthesizes current knowledge on the use of citizen science in urban biodiversity monitoring. It examines conceptual foundations, evaluates global applications and methodologies, and discusses opportunities for implementation.

2. Conceptual Background: Citizen Science and Ecological Knowledge

Citizen science, although widely recognized as a contemporary innovation, has deep historical roots in natural history and amateur scientific observation. During the nineteenth century, networks of volunteer observers contributed to large-scale data collection in ornithology, meteorology, and botany, laying the foundations for participatory science (Miller-Rushing, Primack, & Bonney, 2012; Silvertown, 2009). The modern resurgence of citizen science is associated with the democratization of knowledge and the emergence of digital technologies that facilitate distributed data collection, sharing, and validation (Haklay, 2013; Hecker et al., 2018).

2.1. Defining Citizen Science

The definitional scope of citizen science varies across disciplines, but its core principles emphasize openness, inclusivity, and collaborative knowledge production (Bonney et al., 2016; Follett & Strezov, 2015). According to Shirk et al. (2012), citizen science projects can be categorized along a continuum of public participation: from contributory models, where citizens collect data for professionally designed studies, to collaborative and co-created models that integrate public actors into research design, data analysis, and policy application. This spectrum reflects the epistemological diversity of citizen science, spanning from crowdsourced data generation to participatory action research (Haklay, 2013).

2.2. Knowledge Co-production and Public Engagement

The concept of knowledge co-production has become central to understanding how citizen science contributes to sustainability science (Armitage et al., 2011; Wyborn et al., 2019). By

integrating local ecological knowledge (LEK) and professional expertise, citizen science enhances the relevance and legitimacy of environmental data (Conrad & Hilchey, 2011). In urban contexts, where ecological processes intersect with social and political dynamics, such hybrid knowledge systems facilitate more inclusive and adaptive management approaches (Kullenberg & Kasperowski, 2016).

Empirical studies demonstrate that participation in citizen science can transform public attitudes toward biodiversity, fostering environmental literacy and stewardship (Jordan, Ballard, & Phillips, 2012; Bonney et al., 2016). These outcomes contribute to a broader "social learning" process that aligns with the principles of environmental education and participatory governance (Armitage, Marschke, & Plummer, 2008).

2.3. Citizen Science in the Digital Era

Technological advancements have dramatically expanded the scope and precision of citizen science. The widespread availability of mobile applications, equipped with high-resolution cameras, GPS, and machine-learning-based species identification tools, has enabled large-scale ecological observation networks (Newman et al., 2017). Platforms such as iNaturalist use computer vision algorithms to provide automated taxonomic suggestions, while eBird employs expert review systems and spatiotemporal filters to enhance data reliability (Sullivan et al., 2014).

The integration of these datasets into geographic information systems (GIS) and remote sensing frameworks supports multi-scalar analyses of biodiversity patterns, allowing researchers to assess the impacts of urbanization, climate change, and land-use transformation (Theobald et al., 2015; Hochachka et al., 2021). Moreover, the emergence of open data infrastructures and FAIR (Findable, Accessible, Interoperable, and Reusable) data principles has facilitated the interoperability of citizen science data with institutional biodiversity databases such as GBIF (Global Biodiversity Information Facility) (Bowser et al., 2020).

In sum, citizen science in the digital era represents a data-collection strategy and a transformative mode of ecological knowledge production, connecting technology, participation, and policy. Integrating urban biodiversity monitoring has the potential to reconcile scientific rigour with social participation, an important prerequisite for sustainable and resilient cities.

3. Applications of Citizen Science in Urban Biodiversity Monitoring

Citizen science has become an indispensable instrument for ecological monitoring in cities, generating unprecedented quantities of biodiversity data and engaging millions of participants worldwide. Its applications extend from large-scale, globally coordinated programs to local community initiatives that integrate ecological observation with education and urban planning (Newman et al., 2017). This section reviews the most prominent international platforms, evaluates data quality and technological advances, and discusses the role of citizen science in environmental education and public participation.

3.1. Global Programs and Datasets

The most successful citizen science programs share three defining features: open data access, standardized methodologies, and scalable technological infrastructures. These elements allow data comparability across spatial and temporal scales while maintaining participant inclusivity (Sullivan et al., 2014).

3.1.1. eBird

Launched by the Cornell Lab of Ornithology in 2002, eBird represents one of the largest biodiversity databases globally, encompassing over 1.5 billion bird observations contributed by more than 900,000 users (Callaghan et al., 2019; Hochachka et al., 2021). Its integration of real-time data submission, expert verification, and automated spatial filters has made eBird a cornerstone for avian ecology and urban biodiversity research. Studies leveraging eBird data have mapped migratory patterns (La Sorte et al., 2018), quantified urbanization impacts on avifauna (Callaghan et al., 2019), and modeled temporal changes in species distributions under climate change scenarios (Johnston et al., 2021).

In urban environments, eBird's citizen-derived datasets have enabled fine-scale analysis of habitat preferences and the identification of biodiversity hotspots within metropolitan areas (Belaire et al., 2015). Furthermore, the integration of eBird with remote-sensing products such as the Global Human Modification Index (Kennedy et al., 2019) facilitates the assessment of anthropogenic pressures on bird communities across cities.

3.1.2. iNaturalist

The iNaturalist platform, jointly managed by the California Academy of Sciences and the National Geographic Society, enables participants to upload georeferenced photographs of organisms for expert or AI-based identification (Mason et al., 2025). As of 2024, it has recorded over 180 million observations across more than 400,000 species (iNaturalist, 2024). The platform's open API structure allows researchers to extract data for spatial modeling, species distribution mapping, and conservation prioritization (López-Guillén et al., 2024).

Urban biodiversity studies using iNaturalist data have revealed clear gradients in species richness across socioeconomic and land-use variables (Beninde et al., 2023), offering valuable insights into environmental justice dimensions of urban ecology. The ability to crowdsource such data enables rapid detection of invasive species, pollinator declines, and shifts in flowering phenology; such patterns might otherwise require extensive field studies (Barve et al., 2020).

3.1.3. City Nature Challenge and Regional Bioblitzes

The City Nature Challenge (CNC), initiated in 2016 by the Natural History Museum of Los Angeles and the California Academy of Sciences, exemplifies how citizen science can mobilize urban populations for biodiversity documentation (Palma et al., 2024). Held annually, CNC invites cities worldwide to compete in recording the greatest number of species within a defined timeframe, transforming biodiversity assessment into a social event.

Similar initiatives, often called bioblitzes, combine education, recreation, and data collection. Research indicates that such events not only produce valuable species occurrence records but also strengthen social networks and community attachment to local green spaces (Meeus et al., 2023). For instance, in 2023 the CNC documented over 1.8 million observations across 480 cities globally, providing an unparalleled snapshot of urban biodiversity at a planetary scale (City Nature Challenge, 2024).

3.2. Data Quality and Technological Innovations

The scientific value of citizen-generated biodiversity data depends heavily on its accuracy, consistency, and representativeness. Despite the large volume of records, biases related to spatial distribution, observer expertise, and species detectability are persistent concerns (Isaac

et al., 2014; Boakes et al., 2016). Therefore, maintaining data quality has become a key research focus in the field.

3.2.1. Addressing Biases and Validation Mechanisms

Spatial bias often arises because citizen scientists preferentially record species in accessible, recreational, or aesthetically appealing locations, leading to overrepresentation of urban parks and underrepresentation of private or industrial sites (Troudet et al., 2017). Temporal bias occurs when data collection peaks during specific events or weekends, producing uneven time series (Arazy & Malkinson, 2021).

To mitigate these biases, advanced analytical frameworks have been developed. Statistical models such as occupancy modeling (Isaac et al., 2020) and Bayesian hierarchical inference (Johnston et al., 2021) allow researchers to correct for uneven sampling effort and detectability errors. Moreover, cross-validation with professional surveys or historical datasets enhances the robustness of citizen-derived information (Boakes et al., 2016).

3.2.2. Role of Artificial Intelligence and Machine Learning

Recent advances in AI and computer vision have dramatically improved taxonomic verification. Platforms like iNaturalist employ deep convolutional neural networks trained on millions of labeled images to identify species with accuracy rates exceeding 85% in common taxa (Van Horn et al., 2018). Likewise, eBird integrates algorithmic filters that flag spatial outliers or improbable records for expert review (Hochachka et al., 2021).

These systems enhance data quality and streamline feedback to participants, reinforcing engagement through immediate validation. Machine learning algorithms also facilitate predictive modeling of biodiversity trends, enabling the anticipation of ecological changes in urban systems (Barve et al., 2020).

3.2.3. Integration with Remote Sensing and GIS

The fusion of citizen science datasets with remote sensing and geospatial analysis tools has unlocked new opportunities for urban ecological research. For example, eBird data combined with Landsat-derived vegetation indices allows the assessment of habitat quality at city scales (Belaire et al., 2015), while iNaturalist records integrated with Sentinel-2 imagery support species distribution modeling in fragmented landscapes (Beninde et al., 2023). Such integrative approaches are central to the emerging paradigm of urban socio-ecological systems, wherein biodiversity data inform spatial planning, green infrastructure design, and ecosystem service valuation.

3.3. Citizen Science and Environmental Education

Beyond data production, citizen science acts as a catalyst for environmental education, awareness, and behavioral change (Jordan et al., 2012). Participants not only contribute to research but also acquire ecological literacy, enhancing their understanding of biodiversity and conservation issues (Bonney et al., 2016).

Educational benefits are particularly significant in urban contexts, where exposure to nature is often limited (Miller, 2005). Participation in citizen science can mitigate the so-called “extinction of experience,” the declining direct interaction between people and nature, by providing structured opportunities for observation and learning (Soga & Gaston, 2016). Empirical studies show that engagement in biodiversity monitoring projects increases pro-

environmental attitudes and volunteer retention in conservation activities (Pandya, 2012; Toomey & Domroese, 2013).

Moreover, schools and universities increasingly integrate citizen science into curricula as an experiential learning tool. For example, programs like BirdSleuth in the United States and Schools in Nature in Europe use eBird and iNaturalist data to teach ecological methods, data literacy, and environmental ethics (Bonney et al., 2016; Turrini et al., 2018). These pedagogical applications exemplify how citizen science bridges formal education with community engagement, thereby nurturing the next generation of urban environmental stewards.

4. Integrating Citizen Science into Urban Planning and Policy

Urban biodiversity management is no longer confined to ecological research; it has become a central concern of urban planning, environmental governance, and policy formulation. The growing recognition that biodiversity underpins urban resilience and human well-being has led to an increased demand for spatially explicit and socially inclusive data (Elmqvist et al., 2015; Niemelä, 2014). In this context, citizen science provides a novel pathway for integrating public participation into planning processes, enabling cities to co-produce ecological knowledge that informs land-use decisions, conservation priorities, and adaptive management strategies (Burgess et al., 2017; Newman et al., 2017).

4.1. Citizen-Generated Data for Urban Planning

The integration of citizen science into urban planning frameworks has been facilitated by the rise of open data policies and digital platforms that allow interoperability between crowd-sourced datasets and spatial decision-support systems (Bowser et al., 2020). In many cities, biodiversity data collected through iNaturalist or eBird are now used as complementary layers in Geographic Information Systems (GIS) and green infrastructure planning tools.

For instance, eBird data have been incorporated into the US National Ecological Observatory Network (NEON) and local land-use planning processes to identify urban biodiversity hotspots and guide habitat restoration (La Sorte et al., 2018; Hochachka et al., 2021). Similarly, in Europe, citizen-derived data support the implementation of the EU Biodiversity Strategy for 2030, particularly in mapping and monitoring the Natura 2000 network within urban and peri-urban contexts.

From a methodological standpoint, such integration relies on standardized metadata structures, georeferencing accuracy, and temporal consistency (Pettibone et al., 2016). The development of FAIR (Findable, Accessible, Interoperable, Reusable) data principles has further enhanced the usability of citizen science outputs for planning and governance (Wilkinson et al., 2016).

Example: London and Barcelona

In London, the London Wildlife Trust collaborates with local councils to use iRecord and iNaturalist submissions for habitat inventories and biodiversity action plans (Miller et al., 2022). The Barcelona Green Infrastructure Strategy (2021–2030) similarly integrates City Nature Challenge data to identify underrepresented species and ecological corridors, illustrating how participatory monitoring can guide landscape-scale interventions (Calaza-Martinez et al., 2025).

These cases illustrate that citizen science contributes both data and democratic legitimacy to urban ecological decision-making, aligning public participation with environmental objectives (Hecker et al., 2018).

4.2. Participatory Governance and Policy Integration

Citizen science aligns closely with the emerging paradigm of participatory environmental governance, which emphasizes co-production of knowledge and shared decision-making between institutions and communities (Armitage et al., 2011). In policy terms, this approach reflects the principles of Agenda 21, the Aarhus Convention, and the UN Sustainable Development Goals (particularly SDG 11 and 15) that advocate inclusive, science-based, and transparent environmental management (UNEP, 2022).

Citizen science thus functions both as a data-gathering mechanism and as a political instrument that enhances the legitimacy of environmental governance. By involving local communities in monitoring and decision-making, it helps build trust between scientists, planners, and the public (Conrad & Hilchey, 2011; Hecker et al., 2018).

4.3. Policy Uptake Examples

Several countries have formalized the integration of citizen science into national biodiversity frameworks. The United Kingdom's National Biodiversity Network (NBN) and France's Vigie-Nature Program are institutional models where citizen data feed directly into policy assessments and biodiversity indicators (Levrel et al., 2010; Pocock et al., 2015). The European Citizen Science Association (ECSA) has also developed guidelines for ethical data governance and policy relevance (ECSA, 2020).

At the municipal level, participatory platforms such as GreenUp in Helsinki and CityLab in Amsterdam engage citizens in co-designing urban green spaces using real-time biodiversity feedback, linking ecological monitoring with participatory spatial planning (van der Jagt et al., 2019). These examples highlight the potential of citizen science for multi-level governance, from neighborhood greening initiatives to international biodiversity reporting.

4.4. From Data to Decision: The Role of Digital Infrastructure

The success of citizen science in influencing urban policy depends on how effectively data are transformed into actionable information. Tools such as GeoNode, QGIS, and OpenStreetMap can integrate citizen-generated biodiversity layers with urban planning datasets, facilitating the identification of ecological corridors, habitat connectivity zones, and ecosystem service hotspots. Artificial intelligence and data visualization dashboards are increasingly used to translate raw data into accessible narratives for policymakers and citizens alike. The development of interactive urban biodiversity observatories, such as the Urban Nature Atlas by ICLEI Europe, exemplifies how data aggregation and visualization can support cross-sectoral collaboration between planners, ecologists, and the public (ICLEI, 2021).

In Türkiye, the adoption of similar open-source observatories by municipalities and universities could significantly enhance transparency and facilitate data-driven environmental governance.

4.5. Toward Inclusive Urban Biodiversity Policy

Integrating citizen science into urban biodiversity governance requires moving beyond data collection toward institutional embedding. This entails:

Establishing long-term partnerships between universities, local governments, and NGOs,

Creating incentive mechanisms for sustained citizen participation,

Including citizen science indicators in national biodiversity strategies and urban sustainability frameworks (UNEP, 2022).

Ultimately, citizen science represents the principle that sustainable cities depend not only on technological innovation but also on collective ecological intelligence, the capacity of communities to observe, understand and act upon their environment. Embedding this principle within urban planning and policy can transform cities into laboratories of participatory sustainability.

5. Future Perspectives and Recommendations

As the ecological and technological dynamics of the twenty-first century continue to evolve, citizen science is poised to become a cornerstone of urban biodiversity monitoring and governance. The convergence of rapid urbanization, digital transformation, and global environmental crises has created both the necessity and the opportunity to rethink how ecological knowledge is produced and applied in cities (Hecker et al., 2018). In this context, citizen science transcends its traditional role as a tool for data collection and emerges as a collaborative model of environmental governance, one that links science, policy, and society in the co-production of sustainable urban futures.

Future efforts must prioritize the consolidation of methodological rigor and technological innovation. Despite remarkable progress, citizen-generated data still face challenges of validation, representativeness, and interoperability across institutional systems (Isaac et al., 2020; Boakes et al., 2016). To fully unlock the potential of these datasets, harmonization with professional surveys and remote sensing products is essential. Integrating advanced statistical frameworks, such as Bayesian occupancy modeling and machine learning algorithms, will enable more robust interpretation of large-scale, volunteer-derived biodiversity data (Hochachka et al., 2021; Barve et al., 2020). Likewise, coupling citizen observations with real-time environmental sensing, satellite imagery, and open geospatial platforms can transform dispersed observations into continuous ecological intelligence that informs adaptive management at multiple scales (Pocock et al., 2019).

The digital transformation of urban governance also provides new possibilities for embedding citizen science within data-driven planning systems. Artificial intelligence–assisted platforms such as iNaturalist and eBird already demonstrate how automation and crowd verification can enhance the reliability of ecological information (Seltzer et al., 2023). Expanding such technologies into municipal planning portals and smart city dashboards could bridge the gap between public participation and evidence-based policy.

Beyond technical and methodological improvements, the long-term success of citizen science will depend on its inclusivity and cultural integration. Ensuring equitable participation across gender, age, and socioeconomic groups is fundamental for producing socially representative ecological data (Kullenberg & Kasperowski, 2016). Education and environmental literacy should thus become integral components of citizen science programs, linking observation-based learning with curriculum design in schools and universities (Bonney et al., 2016; Turrini et al., 2018).

Equally important is the recognition of citizen science as a cultural practice that restores human–nature relationships in urban settings. Scholars have warned of the “extinction of experience,” referring to the growing disconnect between people and the natural world in modern cities (Soga & Gaston, 2016). By enabling direct engagement with biodiversity, citizen

science offers an antidote to this phenomenon, cultivating empathy, environmental ethics, and collective stewardship. When supported by inclusive digital platforms, transparent governance, and participatory education, it can evolve into a sustained movement that redefines urban environmental citizenship.

In conclusion, the future of citizen science in urban biodiversity monitoring lies in its ability to balance scientific credibility, technological advancement, and social inclusion. This balance represents both a challenge and an opportunity: a challenge to reform institutional structures and build trust in participatory knowledge, and an opportunity to lead as a model of citizen-driven environmental governance. If effectively institutionalized, citizen science can transform cities from passive consumers of nature into active co-creators of biodiversity knowledge and sustainability. As Bonney et al. (2009) eloquently noted, when scientists and citizens work together, both science and society advance, an idea that remains profoundly relevant for the ecological and civic transformations of the coming decades.

Abstract

Low Earth Orbit (LEO) satellites play a critical role in enabling global communications and remote sensing technologies. Positioned at altitudes ranging from approximately 200 to 2000 kilometres, these satellites can provide high-speed data transmission with low latency due to their proximity to Earth. The high-resolution image processing capabilities of LEO satellites and the wide coverage area of the LEO constellation are rapidly increasing their use in spatial analysis of cities, infrastructure planning, remote sensing applications such as agriculture and natural disaster management, and scientific research. The increasing complex requirements of these satellites have made the integration of artificial intelligence (AI)-based methods into LEO satellite systems inevitable. AI algorithms can process image and sensor data from satellites to detect disasters such as fires, floods and air pollution at an early stage, optimise the energy performance of buildings, and develop sustainable design strategies by modelling the environmental impacts of cities. Convolutional neural networks (CNN) are widely used to monitor environmental factors such as air pollution, forest fires, and humidity levels in satellite images. Deep Reinforcement Learning (DRL) algorithms provide efficient solutions for tasks such as the deployment of aerial vehicles and the management of communication resources in post-disaster areas, even under conditions of limited energy and bandwidth. Furthermore, Federated Learning (FL) techniques enable the training of global AI models in collaboration with ground stations while maintaining satellite data security. In addition, generative artificial intelligence methods automatically detect patterns in satellite data, enabling faster and more accurate environmental analysis. Consequently, it is anticipated that AI-integrated LEO satellite systems have the potential to become a fundamental component of decision support mechanisms in smart city planning, sustainable architecture applications, and comprehensive urban design processes by advancing data collection and analysis capabilities. This study has made a unique contribution to the literature by addressing the effects of AI integration with LEO satellite systems at the urban planning and architecture scale, and has provided a framework to guide future research.

Keywords: Artificial intelligence, LEO satellites, space technologies, urban planning applications

1. Introduction

LEO satellites play a critical role in global communications and remote sensing technologies today. Positioned at altitudes of 200–2000 km, these satellites can provide low latency and high-speed data transmission due to their proximity to Earth. LEO satellite constellations are effectively used in remote sensing applications such as spatial analysis of cities, infrastructure

planning, agriculture, and natural disaster management, as well as in scientific research, thanks to their high-resolution imaging capabilities and wide coverage areas (Candoğan, 2024). However, the increasing data volume and complex mission requirements of these satellites limit the data processing capacity of traditional methods, thus necessitating the integration of AI-based methods. AI algorithms can extract information quickly and accurately by automating data filtering, classification, and pattern recognition processes (Kazanskiy et al., 2025). Furthermore, Deep Learning (DL) and reinforcement learning algorithms play a critical role in real-time analysis and predictions for applications such as disaster detection, air pollution monitoring, and emergency response (Boroujeni et al., 2024). AI also enables the development of decision support mechanisms in urban planning and sustainable architecture applications; for example, it offers scalable and accurate solutions for tasks such as urban heat island analysis or energy consumption optimisation (Furuya et al., 2023).

The primary objective of this study is to examine the contributions of AI integration to urban planning and sustainable architecture applications in light of the increasing data volume and complex mission requirements of LEO satellite systems. The study refers to work carried out in the field of urban planning applications using algorithms such as CNN, DRL, FL, and Generative AI, leveraging the high-resolution imaging and wide coverage capabilities of LEO satellites. The aim is to contribute to the development of AI-based decision support systems in applications such as disaster management, environmental monitoring, and sustainable urban design. In this context, the study aims to reveal the contributions of AI integration with LEO satellites to data collection, analysis, and urban design processes. Furthermore, the study aims to present a unique framework to the literature by revealing the interdisciplinary potential of the integration of AI and LEO satellite systems and to guide future research.

2. Materials and Methods

The methodological framework followed in this study is based on a comprehensive analysis of the literature on the integration of LEO satellite systems and AI algorithms. Findings from the literature review indicate that the integration of LEO satellite systems and AI is used in a wide variety of areas in the context of urban planning and sustainability (SatNow, 2025). In this context, the analysed studies are broadly grouped under the headings of urban environment monitoring, disaster management, infrastructure planning and optimisation, energy efficiency, and agricultural-rural applications. These themes cover a wide range, from urban heat island and air pollution analysis to the assessment of environmental factors such as flood risk, green space monitoring, and land use change; and from building energy performance and transport density to the optimisation of smart city infrastructure. Furthermore, the combined use of high-resolution images provided by LEO satellite data and AI-based models in disaster early warning, damage assessment, and reconstruction processes significantly enhances the accuracy and effectiveness of decision support systems (Doshi et al., 2018). In this context, the literature reveals that LEO-AI integration offers strategic contributions not only in data collection but also in critical areas such as urban sustainability, carbon footprint analysis, and environmental resilience. Furthermore, it demonstrates that LEO-AI integration not only improves data collection processes but also provides important contributions in critical areas such as urban sustainability, carbon footprint reduction, and increased environmental resilience (Jain, 2025).

3. Findings and Discussion

This section presents an analysis of the current literature on the integration of LEO satellite systems with AI-based methods (Table 1). The studies reviewed indicate that FL, DRL, image

processing, and edge computing-based approaches are particularly prominent in this rapidly developing field between 2022 and 2025. The research reveals that LEO satellites have become a powerful tool for transformation not only in global communication infrastructures but also in urban-focused applications such as smart city planning, disaster management, environmental monitoring, and urban sustainability. It has been determined that FL and DRL-based models, in particular, enable privacy-focused and low-latency processing of sensor data at the city scale, while deep learning-based image inference approaches allow for high-accuracy analysis of urban morphology, building density, traffic patterns, and green space distribution. In this context, LEO-AI integration is seen to offer new opportunities in data-driven decision support systems, resource optimisation, and real-time environmental monitoring in urban management.

Table 1. Current Literature Studies

Year	Brief Description
2025	This study highlights that global coverage and high-resolution measurements provided by Earth observation satellites such as Terra, Aqua, Sentinel-5P, and TEMPO enable the identification of air pollutant sources and the implementation of more effective air quality strategies (Kuttippurath & Patel, 2025).
2025	This study examines the role of LEO satellites in monitoring climate change and tracking its effects in critical areas such as air pollution, atmospheric humidity, and forest fires. It also highlights how AI integration accelerates the collection and analysis of satellite data, enabling a more efficient and advanced climate monitoring process (Jain, 2025).
2025	This study has facilitated the rapid development of LEO satellites in the fields of communication, navigation, and remote sensing by reducing satellite payloads and lowering launch costs, thereby creating significant opportunities in urban planning and urban management applications. This article examines the development of LEO satellite communication payloads and the challenges encountered, highlighting opportunities and future research directions in areas such as smart city applications, urban transport management, and environmental monitoring (Hui et al., 2025).
2025	This study examines the use of LEO satellites (Starlink) and cellular internet networks for Internet of Things (IoT) Smart Farming applications in agricultural areas in Indonesia. Experimental results reveal that both networks performed well in terms of overall service quality, but the LEO network exhibited lower performance than the cellular network in terms of latency, particularly in rainy weather. (Ramadhani et al., 2025)
2025	This study summarises the use and applications of satellite data in air quality and related health assessments. It also highlights advances over the past 15 years, providing guidance for future applications. (Holloway et al., 2025)
2025	This study examines in detail the role of satellite IoT in developing smart city infrastructure and services, its architecture, applications, and the challenges encountered. (Shahi et al., 2025)
2024	This study examines the applications of AI-supported unmanned aerial vehicle (UAV) systems in pre-fire, active and post-fire management processes, summarising the contributions of remote sensing, ML and DL techniques to fire classification, detection and monitoring tasks (Haeri Boroujeni et al., 2024).
2024	This study proposes the integrated use of machine learning and physical and socio-demographic data to mitigate urban heat island (UHI) effects in hot and arid cities such as San Antonio, Texas. The results provide practical strategies for different urban areas, such as increasing green spaces, reducing impervious surfaces, and improving building design, thereby guiding policymakers and urban planners towards sustainable and equitable UHI management (Syeda, Castillo Villar, & Alaeddini, 2024).
2023	This study proposes the integration of LEO satellites and multiple aerial vehicles to provide rescue services in post-disaster areas. The proposed genetic algorithm approach ensures the fair and efficient

	deployment of aerial vehicles and the optimisation of communication performance with limited battery and bandwidth resources (Mohamed, Hashima, Hatano, & Khallaf, 2023).
2022	This study suggests that machine learning models, combined with large-scale image and sensor data collected by LEO satellites, could be used to solve global problems such as real-time disaster management. Due to data download and model training limitations, the model training time can be reduced by 1-7 days by collaborating between satellites and ground stations using the FL framework they named FedSpace. (So et al., 2022).

Based on the table compiled from the 10 academic articles examined in this study, the implications of LEO satellite and AI-based analyses in 10 thematic application areas, such as urban heat islands, disaster early warning, air pollution, water resource management, green space monitoring, building energy performance, transport density, sustainability analysis, smart infrastructure optimisation, and urban agriculture area monitoring, are evaluated below. The results obtained demonstrate that integrating LEO satellites with AI-supported decision-making mechanisms contributes significantly to the development of a data-driven, environmentally sensitive and sustainable approach in urban planning and architectural design processes.

3.1. Urban Heat Island Analysis

High-resolution thermal and optical images obtained from LEO satellites can be effectively used in urban heat island (UHI) analyses. By mapping temperature differences between satellite data and urban areas, the effects of factors such as dense construction, asphalt surfaces, and lack of green space on the urban microclimate can be determined (Wang et al., 2025; Chintalapati et al., 2025). AI algorithms can automatically classify and visualise heat intensities in different regions by processing temperature data from satellite images. This enables urban planners and architects to make data-driven decisions for energy consumption optimisation, green space placement, and sustainable urban design (Wang et al., 2025). Furthermore, DRL-based models simulate different urban design scenarios to suggest the most suitable planning strategies for minimising the heat island effect (Lozano-Cuadra et al., 2024). These methods can be used both to optimise existing urban structures and to reduce environmental impacts in new urban projects.

3.2. Disaster Early Warning

High-resolution optical and radar-based imagery provided by LEO satellites plays a critical role in the early detection of disaster processes such as forest fires, floods, landslides, and post-earthquake situation assessments. The short revisit time achieved due to these satellites' low orbital altitudes enables the observation of disaster areas within minutes, significantly reducing the coverage and access limitations of traditional ground-based monitoring networks.

In recent years, AI-based models have come to the fore in disaster detection and prediction. For example, CNN-based image classification models enable the automatic detection of fire starting points from satellite images, while Long Short-Term Memory (LSTM) and other time series prediction algorithms can predict the spread rate and direction of a disaster in a temporal dimension by correlating meteorological data, wind models, and terrain structure. The integration of these models with disaster management centres' early warning systems enables shorter response times, optimised evacuation plans, and dynamic resource allocation to emergency teams. Thus, it becomes possible not only to reduce damage after a disaster but also to increase risk management and preparedness levels before a disaster (Lozano-Cuadra et al., 2024).

3.3. Air Pollution Monitoring

LEO satellite sensors can create detailed air quality maps at city scale by monitoring the concentration of key air pollutants such as nitrogen dioxide and carbon dioxide in the troposphere with high spatial resolution. The low orbital altitude of these satellites and their short revisit times enable continuous monitoring of intraday fluctuations and seasonal changes in pollution. The data obtained not only allows for the observation of pollution levels but also contributes to the modelling of pollutant sources (e.g., traffic density, industrial facilities, meteorological transport effects). In this process, CNN-based image processing models automatically detect the spatial distribution of pollution by classifying satellite data, while regression-based and hybrid AI models can produce short- and medium-term air pollution forecasts by learning temporal trends. Thus, city administrations can shape environmental policy decisions, such as urban transport regulations, green space planning, industrial emission quotas, and emergency health alerts, in a data-driven manner. This approach enables both the protection of public health and the enhancement of long-term environmental resilience in line with the vision of sustainable urbanism (Matthiesen & Soret, 2022).

3.4. Urban Water Resources and Flood Risk Analysis

LEO satellites provide critical spatial data for identifying flood risks and water accumulation in cities, thanks to their high-resolution optical and Synthetic Aperture Radar (SAR) sensors. SAR imagery, in particular, offers uninterrupted observation during disasters, as it can detect surface water accumulation regardless of cloud cover and night-time conditions. When time-series data obtained from satellites is evaluated in conjunction with variables such as rainfall intensity, surface permeability, topography, urbanisation density, and drainage lines, it becomes possible to comprehensively model flood formation processes (Wang, 2025). In this context, CNN-based image analysis models automatically classify water accumulation and flood areas, while DRL algorithms can predict flood probability, spread direction, and severity scenarios based on dynamic environmental conditions (Tsuboi, 2019). The resulting flood risk maps provide decision support to city administrations, particularly in rapidly urbanising areas, for infrastructure planning, capacity design of stormwater drainage systems, positioning of flood prevention structures, and development of emergency response plans, contributing to the resilient and sustainable design of cities (Tsuboi, 2019).

3.5. Green Space and Vegetation Cover Monitoring

Satellite imagery serves as a crucial data source for monitoring the spatial distribution and temporal changes of urban green spaces. The high-resolution optical sensors of LEO satellite systems enable detailed classification of park areas, tree cover, grass surfaces, and other types of natural vegetation. CNN-based image classification and object-based image segmentation algorithms performed on these images can automatically detect the boundaries, density, and ecological continuity of urban green spaces (Neyns & Canters, 2022). Furthermore, the vitality, stress levels, and seasonal changes of vegetation cover can be analysed using the Normalised Difference Vegetation Index (NDVI) and similar vegetation health indices. The outputs obtained can serve as a decision support mechanism in sustainable urban planning applications such as reducing the heat island effect in cities, planning recreational areas, increasing carbon sink capacity, and creating ecological corridors. Thus, city administrations can adopt a science-based approach to the protection, development, and design of environmental rehabilitation strategies for green spaces (Neyns & Canters, 2022).

3.6. Building Energy Performance Analysis

Thermal infrared data obtained from LEO satellites play a significant role in assessing energy efficiency by analysing the surface temperature distribution of buildings in cities. Factors such as roof coverings, facade materials, insulation quality, and building density directly affect heat loss from external surfaces. These data obtained in thermal bands can be automatically processed using CNN-based image classification algorithms to detect temperature anomalies in building structures (Wang et al., 2025). This approach can contribute to energy rehabilitation studies for existing structures and guide energy-efficient and climate-responsive architectural design decisions in new urban development projects (Wang et al., 2025).

3.7. Traffic and Transport Density Forecast

High-resolution LEO satellite imagery enables the large-scale and continuous monitoring of urban traffic flow and road usage intensity. Spatial and temporal traffic data obtained from these images can be classified using CNN into vehicle density, traffic congestion zones, and road usage patterns (Wang et al., 2025). In addition, time series analyses and LSTM-based prediction models can forecast how traffic flow will change at different times of the day or during special circumstances (holiday periods, disasters, events, etc.). The Split FL architecture, which enables distributed model training on LEO satellite networks, allows traffic and mobility data to be processed locally, reducing latency while preserving data privacy (Wu & Huang, 2025; Zhang et al., 2024). Thus, decision-making processes such as urban transport planning, public transport route reorganisation, alternative route suggestions, and traffic signal optimisation can be based on scientific data. This approach provides a critical data infrastructure for urban mobility management, a fundamental component of smart city systems, contributing to both the reduction of traffic-related carbon emissions and increased time and energy efficiency in transportation (Wang et al., 2025; Wu & Huang, 2025).

3.8. Urban Sustainability and Carbon Footprint Analysis

High-resolution data obtained from LEO satellites and AI algorithms enable detailed modelling of cities' energy consumption profiles, greenhouse gas emissions, and other environmental impacts (Furuya et al., 2023). These data are analysed to cover variables such as heat loss from buildings, carbon emissions from transport, the carbon sink capacity of green spaces, and urban heat island effects (Wang et al., 2025). CNN, LSTM, and DRL-based models can process these data spatially and temporally to generate energy and environmental performance predictions, thereby enabling data-driven decision-making processes in urban planning, such as renewable energy deployment, passive design strategies, green infrastructure planning, and transport optimisation (Furuya et al., 2023). This approach can support sustainable urban design at the city scale, enabling the development of energy-efficient and environmentally friendly design solutions in architectural projects. Consequently, satellite-based AI analyses can create scientific decision support mechanisms in both the planning and implementation stages while minimising the environmental impacts of cities (Furuya et al., 2023; Wang et al., 2025).

3.9. Smart City Infrastructure Optimisation

The effective monitoring and optimisation of energy, water, and transport infrastructure is one of the fundamental requirements for sustainable and smart cities. High-resolution data obtained from LEO satellites provides critical information about the spatial distribution, usage intensity, and performance indicators of urban infrastructure (Wang et al., 2025). These data automatically analyse the condition of infrastructure components (power lines, water pipelines,

road and bridge networks) through CNN-based image processing algorithms, while DRL models optimise infrastructure usage and resource allocation by considering dynamic variables such as energy consumption, water loss and traffic flow. This process enables city administrations to make data-driven strategic decisions, such as increasing energy efficiency, managing water resources sustainably, reducing traffic congestion, and determining maintenance priorities for critical infrastructure (Furuya et al., 2023). Consequently, LEO satellite data and AI-based analyses have become an important tool for enhancing the performance of smart city infrastructure, thereby supporting the effectiveness and sustainability of urban services (Furuya et al., 2023; Wang et al., 2025).

3.10. Agriculture and Rural Areas Monitoring

Monitoring agricultural areas around cities is of strategic importance in assessing the impact of urban growth on ecosystems and food production. LEO satellites can enable the regular monitoring of indicators such as plant density, chlorophyll levels, soil moisture, and crop development stages through high-resolution multispectral imagery (Neyns & Canters, 2022). These data, combined with CNN-based image classification and plant indices such as NDVI, can be used to derive the spatial distribution of agricultural productivity (Neyns & Canters, 2022; Furuya et al., 2023). Furthermore, time series analysis can be used to predict irrigation needs, drought risk, and plant stress conditions at an early stage. This approach provides a critical data foundation for protecting agricultural areas in urban planning, controlling urban sprawl, developing food security policies, and supporting sustainable land use decisions. Thus, while maintaining the ecological balance between urban and rural areas, it becomes possible to increase local production capacity and efficiently manage environmental resources (Furuya et al., 2023; Neyns & Canters, 2022).

4. Conclusion and Recommendations

Recent research in the field of LEO satellites and AI integration has revealed that these technologies are not only critical for global communication and remote sensing, but also play a vital role in urban planning and architectural design processes. AI algorithms are effectively used in satellite image processing, data filtering, classification, and pattern recognition; they enhance decision support systems in tasks such as disaster detection, air pollution monitoring, energy optimization, and urban infrastructure planning (Furuya et al., 2023; Li et al., 2024). Particularly in applications such as urban heat island analysis, urban sustainability assessments, building energy performance optimization, and modeling the environmental impacts of urban spaces, the processing of data from LEO satellites using AI increases the accuracy and efficiency of planning and architectural design decisions (Furuya et al., 2023; (Neyns & Canters, 2022). Furthermore, AI-based methods in the orbital optimization, coverage improvement, and data transmission processes of LEO satellite constellations increase efficiency under limited energy and bandwidth conditions, providing reliable data sources for urban planning and smart architectural applications (Tsuboi, 2019; Candoğan, 2024). The integration of onboard AI and in-orbit cloud computing in small satellite missions enhances global remote sensing capabilities and supports strategic decisions in urban areas, such as sustainable design, infrastructure development, and disaster management. Consequently, findings in the literature indicate that AI integration with LEO satellites has become a fundamental component of data-driven, rapid, and effective decision-making mechanisms in urban planning and architectural applications, suggesting that future work in this field will advance toward more comprehensive and integrated solutions (Furuya et al., 2023).

Abstract

Cultural landscapes are multidimensional environmental constructs that acquire identity not only through their visual and spatial characteristics but also through their sensory layers. Among these layers, sound emerges as a powerful element in the experience and remembrance of place, occupying a distinctive position in relation to collective memory, spatial belonging, and the production of identity. Sound functions as a medium that carries cultural memory across a broad spectrum—from everyday life practices to nature, from religious rituals to social interactions—thereby reinforcing the meanings that societies attribute to place. Local sounds are regarded as unique components of place identity; when intertwined with memories extending from the past to the present, they strengthen the sense of belonging that communities develop toward their environments. The murmur of a historic bazaar, the everyday sounds of a public square, the call emanating from a religious structure, or the natural sounds of coastal areas together produce a distinctive layer of acoustic identity that differentiates one landscape from another. Acoustic identity, integrated with everyday practices, cultural rituals, and the natural environment, evokes both individual and collective memories, ensuring the continuity of the emotional bond established with the cultural landscape. Consequently, it becomes evident that the sense of attachment and belonging to a place is constructed not solely through visual indicators but also through a multisensory experience mediated by sound. In this context, understanding how the concept of acoustic identity is formed within cultural landscapes and which components shape the perceptual integrity of the landscape emerges as a fundamental research question. This study aims to explore the formation of acoustic identity in cultural landscapes through a literature-based examination encompassing theoretical approaches, comparative examples, and experiential dimensions. Furthermore, it discusses how acoustic identity can be preserved from the perspective of intangible cultural heritage and how it can be integrated into design and planning processes.

Keywords: Acoustic identity, cultural landscape, sensory experience, intangible heritage, spatial attachment

1. Introduction

In general terms, sound is the propagation of vibrations in an environment as waves, the human brain interpreting these waves as meaningful sound, and establishing a sensory and existential relationship with space as a social, environmental, and identity-related element (Rossing, 2007; Zwicker & Fastl, 2007; Schafer, 1977; Ingold, 2007). When considered in its cultural dimension, sound is defined as a form of expression of a living relationship established with the environment as a result of the convergence of natural (wind, birds, water, etc.) and cultural (language, religion, music, humans, industry, etc.) values. In this sense, sound produces an existential bond that describes the sensory interaction established with space (Ingold, 2007). Sound clarifies its role in the emotional, ritual, and spatial meaning production of society through this bond (Feld, 2012). This bond, nourished by social dynamics, emphasizes the

understanding of sound as the 'flow of the environment' and the continuity of the sensory experience (Ingold, 2007).

As a cultural landscape element, sound represents a perceptible reflection of human activities, social relationships, and environmental processes, and with this characteristic, it is accepted as both a natural and cultural element (Schafer, 1977; Pijanowski et al., 2011; Ingold, 2007). From this perspective, sound exists not only as a physical component of the cultural landscape, but also as a social, historical, and sensory layer. Furthermore, sound contributes cultural meaning as part of the social element while constructing the identity and memory of a place. Therefore, it is undeniable that sound is:

• the spatial archive of memory,

• an indicator of identity,

• a vehicle for sensory experience (Schafer, 1977).

Therefore, as a cultural landscape element, sound is a conceptual key that determines not only how a space looks, but also how it is felt and remembered. With this feature, sound removes the concept of cultural landscape from visual centrality, directs us to read space experientially and multisensorily, and deepens social memory, identity, and belonging relationships with its acoustic dimension (Rodaway, 1994).

• removes it from visual centrality,

• directs us to read space experientially and multisensorily,

• deepens social memory, identity, and belonging relationships with its acoustic dimension (Rodaway, 1994).

The meaning of sound in the cultural landscape becomes visible and legible through certain acoustic subcomponents. These components are background sounds, signal sounds, and vocal cultural signs or sound signs. Background sounds mostly include sounds that are perceived more sensually than visually, such as wind, rustling leaves, birds chirping, the rhythmic sound of raindrops, traffic noise, and the distant sound of construction machinery. Signal sounds, as the name suggests, are sounds that exist to convey a message, attract attention, or carry/transmit information. These include the call to prayer, school bells, the shouts at the market, and the vibrational sound of the subway or train coming from afar. The last subcomponent, also known as cultural sound markers, refers to sounds that are culturally specific to a place. In other words, it defines the sounds that form the sound memory of a city and are engraved in its cultural landscape identity. These are sounds that give a sense of belonging to the place, such as ferry whistles, the buzz of the market, the seaside, neighborhood sounds, festival music, etc. This final component is particularly considered in detail when determining the acoustic identity of a cultural landscape (Labelle, 2010).

All subcomponents produce a cultural memory and sense of belonging, creating an 'acoustic identity'. When the sound characteristics of a place change, its identity and, consequently, its social memory also transform (Labelle, 2010). Therefore, sound shifts the understanding of the cultural landscape from the visual to the auditory. This ensures that the space is approached not as a visual form but as a lived environment.

Acoustic identity is the unique set of sound patterns that form over time within a space or cultural community, creating a sense of belonging (Schafer, 1977; Labelle, 2010; Cerwén,

2017). Based on this definition, the acoustic identity of a landscape is explained as a multi-sensory experience, not just a visual one, as a dynamic layer of this experience that changes over time, as a combination of natural sounds such as wind, water, and animal sounds, and cultural sounds such as speech, music, industrial noise, and rituals resulting from human activities. To elaborate further, the acoustic identity of the landscape is formed by the convergence of different conceptual layers. The first is the physical layer. This layer determines the reverberation and propagation of sound through the physical elements of the landscape, such as geographical structure, topography, materials, and vegetation (Truax, 2001). Another layer, the cultural layer, shapes human-generated sounds such as local language, rituals, and transportation sounds for the purpose of producing social belonging and memory (Labelle, 2010; Feld, 1996). The sensory or perceptual layer, on the other hand, concerns how individuals within a society perceive sounds, what meanings they assign to these sounds, and the psychoacoustic dimension of the identity created. Furthermore, this layer is not just about 'the sounds that are there', but how they are felt (Ingold, 2007). Although these layers are considered separately, they are interconnected at a certain point and enable the concept of acoustic identity to be evaluated in terms of its dimensions.

2. Materials and Methods

This study examines the formation of acoustic identity within the context of cultural landscapes. Within this scope, a literature-based research method has been adopted, incorporating theoretical approaches, comparative examples, and experiential dimensions related to the subject. Furthermore, the study includes applications demonstrating how acoustic identity is addressed in cultural landscapes from the perspective of intangible cultural heritage.

3. Findings and Discussion

Sound manifests itself in various forms in cultural landscape studies and in the creation of the perceptual integrity of the landscape. Some of these forms are particularly influential in guiding current studies. In this context, sound can serve as an urban reading tool or take the form of acoustic mapping that reveals the sound layers of a space. Furthermore, sound can be used as a design input in these studies or integrated into participatory research and social memory studies. The place of the concept of sound in the perceptual integrity of the landscape and its form in cultural landscape studies are explained in more detail with the examples below. For example, sound walks are used as an urban reading tool. In a study conducted by Öner (2021), users' perception of space was investigated through soundscape experiences in sound walks conducted specifically in Kadıköy Square (Figure 1).

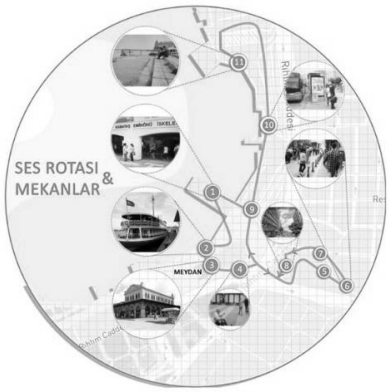

Figure 1. Sound walk route and stops (Öner, 2021)

A similar study was conducted by Sun et al. (2023) in an urban park. In this study, the soundscape perceived by participants was evaluated according to different walking routes defined within the park boundaries (Figure 2).

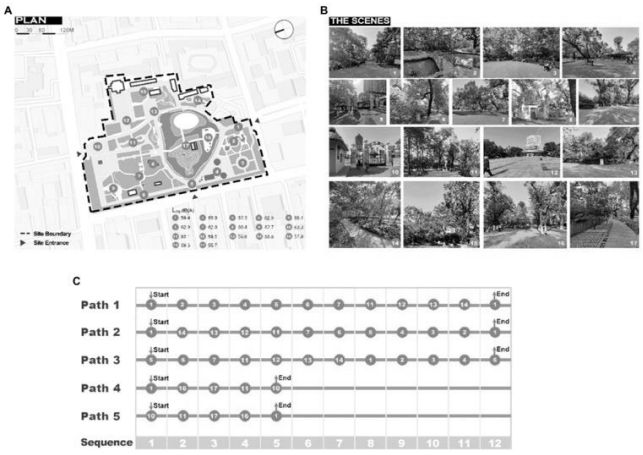

Figure 2. Park boundaries and walking routes (Sun et al., 2023)

Another form of sound within the perceptual integrity of the landscape is acoustic mapping, which aims to document the sonic layers of a space. Between 2010 and 2012, a TÜBİTAK-supported study produced sound maps for five different parks by conducting sound pressure level measurements, surveys and observational studies (Akpınar et al., 2010–2012).

Sound can also be considered as a design input within a cultural landscape; aspects such as acoustic comfort, reverberation, directionality, and areas of silence are defined within this context. In a study by Özçevik (2016), the concept of the auditory landscape is addressed conceptually and discussed in the context of acoustic comfort, offering suggestions on what kind of input sound can be in design work. Furthermore, social memory is revealed and clarified through participatory research such as sound diaries or recordings. In this way, sound creates a layer of auditory meaning in a cultural landscape, forming the identity of the space.

These studies are not merely about visible physical forms, but rather a holistic understanding that derives meaning from the sensory, historical and social relationships people establish with a space. In this context, sound exists as a constantly functioning component of this holistic understanding. Therefore, sound-focused research and design strategies are also considered important tools for revealing, strengthening and sustaining the semantic integrity of the landscape in the public experience.

Sound-focused strategies have been grouped and explained under five categories:

• Site-specific sound analyses and soundwalks

• Sound installations and speaker architecture

• Control/masking with acoustic materials and topography (Buitenschot Park)

• Integration of ecological sound science / soundscape ecology (monitoring biological sound recordings in conservation projects and tracking restoration success using sound data – the work of Bernie Krause is the most prominent reference example)

• Social/cultural participation and identification of cultural sound markers (Sound-memory studies conducted with local communities determine which sounds should be preserved and emphasised.)

In addition to all this, sensory landscapes, which include acoustic ecology explaining the relationship between sound and the environment, social memory defined as an individual and collective memory spatial archive, and sensory-acoustic mapping, are accepted as interpretations of sound in the cultural landscape.

In short, acoustic identity characterises the unique sound signature of a place or community and is formed by the convergence of ecological, cultural and sensory layers. Therefore, in cultural landscape studies, sound should be considered not as a complement to visual identity, but as a defining dimension. Within this scope, key studies that emphasise acoustic identity on a global scale and in the cultural landscape have been cited as examples.

The first of these is the work titled Audio Walks & The Forty-Part Motet, created by Janet Cardiff in 2001. It is a work in which sound recordings, pre-designed by the artist within an urban space, are conveyed to the listener in relation to the location. This work features audio walks and sound installations utilising multiple speakers distributed throughout the space. Furthermore, it enables the user to re-experience the space by walking through it. This work combines monumental and spatial orientation with sound, transporting the landscape experience into a temporal and narrative dimension (Figure 3). The fundamental logic of the work is to blur the boundaries between reality and virtuality by creating a layer between the listener's physical movement, immediate spatial experience, and sound recordings. The aim here is to manipulate ambient sounds to superimpose urban memory, lost narratives, and individual stories, thereby re-layering reality.

Figure 3. Sound installation in the workplace (Cardiff, 2001)
(https://cardiffmiller.com/installations/the-forty-part-motet/)

A similar work, entitled Sound Sculptures, was carried out by Fontana (1990). It deals with the spatial reorganisation or reinterpretation of real-time or recorded sounds from sources such as bridges, water/industrial infrastructure, described as urban elements, in the form of sound sculptures. It makes the sounds of the city aesthetically and contextually audible and conveys

the acoustic data of the cultural landscape to the other side through art (Figure 4). According to the artist, a sculpture is not merely a physical object. The acoustic potential of the space, surface vibrations, environmental sound flows, and human movement within the space are conveyed through a sculptural experience. The work emphasises the fluidity of sound, reinterpreting the concept of sculpture acoustically. In other words, the acoustic identity of the space is the sculpture itself. As the viewer moves through the space, the 'sculpture' shifts and is reproduced through sound.

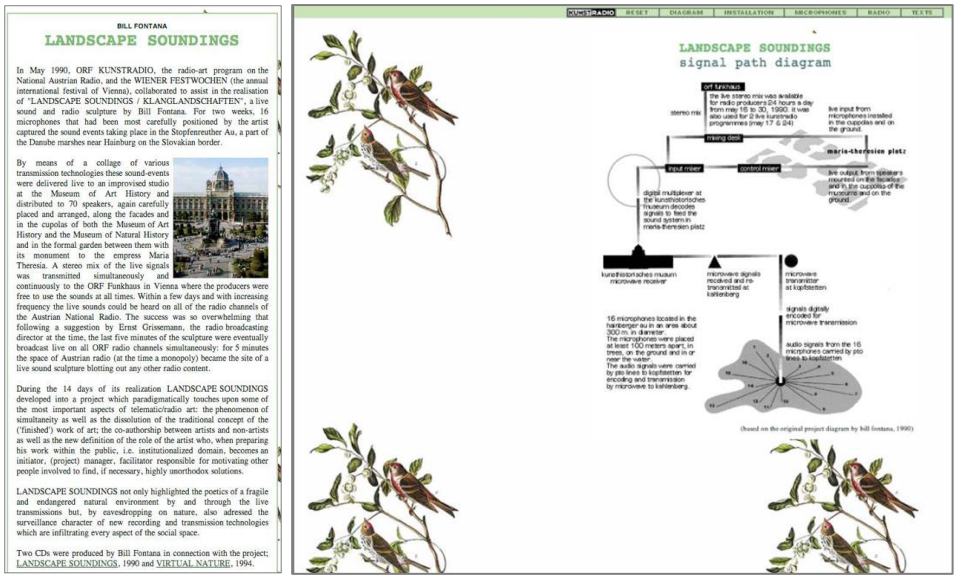

Figure 4. Exhibition catalogue describing the work content and signal path diagram (Fontana, 1990) (https://www.resoundings.info/landscape-soundings)

Another study conducted by Kubisch (2003) under the name Electrical Walks (EM field soundwalks) with numerous stakeholder cities on a global scale focuses on acoustic mapping. This study is actually known as a series of site-specific sound walks. Participants wear specially developed magnetic induction headphones to walk around the city and hear invisible but constantly present electromagnetic fields such as metro networks, security cameras, Wi-Fi signals, ATMs, and billboards (Figure 5). In other words, it is an auditory walking project in which electromagnetic fields are converted into sound data. The main objective of the study is to create an acoustic map of the city's digital, technical and infrastructure systems, while also making invisible electromagnetic energy audible, thereby creating a new urban awareness.

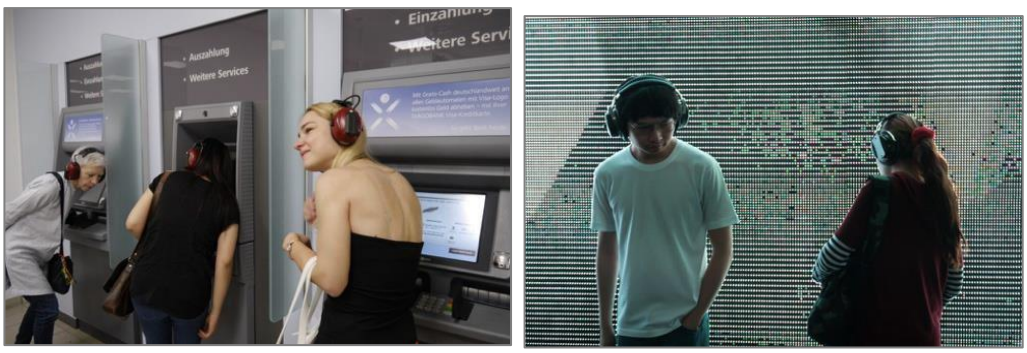

Figure 5. Participants' auditory experience of the electromagnetic field in front of the ATM and advertising board (Kubisch, 2003) (https://christinakubisch.de/electrical-walks)

Unlike the examples mentioned, another work, also known as a cultural sound sculpture, was constructed in Burnley, England, in 2006. It takes its name from both its tree-like appearance and the melodic, ringing, humming sounds it produces when the wind blows. The work is described as a 'Singing-Ringing Tree'. It is actually designed as a wind sound sculpture that produces sound by interacting with the wind (Figure 6). The work is located on a hill overlooking the rural landscape, in a position visible from the city centre. Therefore, it is perceived both as a visual city image and an acoustic landmark. The work is based on the idea of making the auditory character of urban and rural areas audible through a single structure and turning it into a symbolic structure that blends in with the landscape. It is an important work in terms of materialising the sound of the wind and revealing natural flows as an auditory layer of the landscape. Furthermore, within the sculpture, the wind functions as both a design input and an energy source, as well as a sound generator. Consequently, the boundary between the landscape and the structure dissolves, and the wind activates the work.

Figure 6. The singing-ringing tree (cultural sound symbol) (Burnley, İngiltere) (https://en.wikipedia.org/wiki/Singing_Ringing_Tree%2C_Burnley)

A similar work is also referred to as a cultural sound sign. Known as the Cobar Sound Chapel and carried out in Australia, the work is a permanent installation room that combines architecture and sound composition (Figure 7). The work offers both a visual and auditory experience with its concrete walls, sky-facing window, and interior volume, illustrating the mutual interaction between landscape and sound. Some of the sound processes in the work also feature approaches generated by artificial intelligence.

The structure, which is the subject of the work, is not just a concert venue, but is described as a 'sound chapel' where architecture and music come together to materialise sound. Therefore, the work conveys the natural and cultural landscape of a town as an auditory layer. In this context, the work provides local cultural depth.

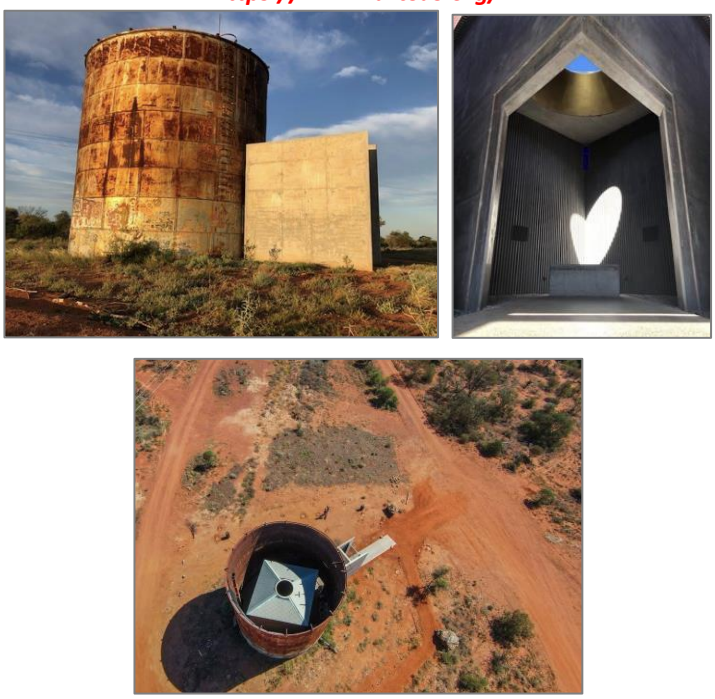

Figure 7. Cobar Sound Chapel (cultural sound landmark) (Australia)
(https://en.wikipedia.org/wiki/Cobar_Sound_Chapel)

The Soundscape Park, designed by West8 in 2011, is larger in scale than other projects and was conceived with a direct urban focus. Based on the principle of concretising the integration of sound into design in terms of acoustic identity and cultural landscape, the project is described as one of the best sound-focused design projects on an urban scale. This urban park is public in nature, an open-air sound and image park based on the principle of 'the socialisation of sound', created with the integration of the New World Symphony Orchestra (Figure 8). The park not only creates a physical green space but also an acoustic landscape area that combines space and sound. The work contains both spatial and symbolic meanings that will nourish the cultural identity of the area in which it is located. In this context, the work refers to the concept of multisensory perception through acoustic identity by bringing together street life, culture and nature as part of the urban public space.

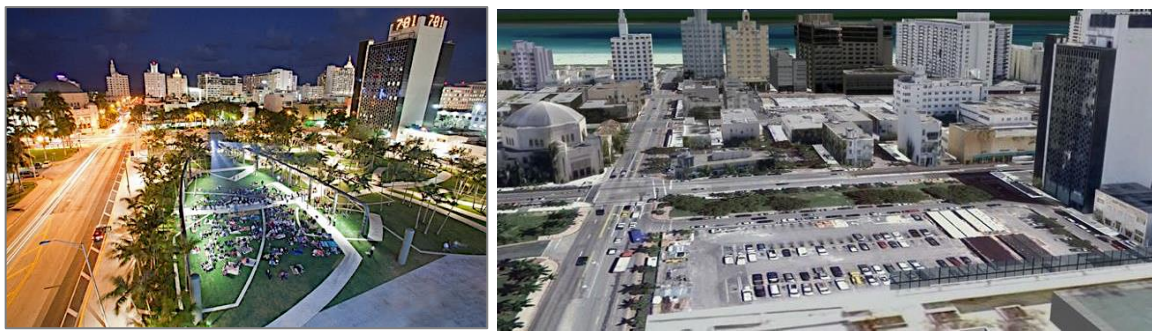

Figure 8. SoundScape Park (left-current and right-before design) (Miami)
(https://www.landscapeperformance.org/case-study-briefs/soundscape-park)

The final example is an acoustic identity study known as the Paris Sound Atlas. The study documents the city's acoustic identity by recording and archiving its sounds. It takes the form

of a digital soundscape library created from the sounds of local cafés, restaurants, squares and parks (Figure 9). It thus reveals the city's auditory landscape. The sound maps prepared as part of the study invite the local population to contribute, enabling the emergence of a practice of listening to, discovering and reimagining the city. The audio recording and mapping of regional languages is a powerful tool for preserving cultural diversity in the study area. In this context, sound maps visualise both noise sources and the city's acoustic identity, creating ecological awareness.

Conclusion and Recommendations

The concept of cultural landscape has long been approached and incorporated into studies primarily through visual and formal dimensions. However, recent studies have revealed that landscapes are not only ‘seen’ but also ‘heard’ and ‘experienced’ environments (Ingold, 2007; Labelle, 2010). In this context, the concept of ‘acoustic identity’ emerges as a new way of reading that brings together the cultural, ecological and sensory components of a place.

Particularly when examining studies conducted since the second half of the twentieth century, sound has been evaluated within the framework of concepts such as acoustic environment, environmental awareness, silence, and noise balance. In such studies, the concept in question has been regarded as an ‘environmental value that must be protected’ However, this situation has changed since the beginning of the twenty-first century. With the contributions of many researchers, sound has been redefined as an active element in the production of cultural identity, social memory and belonging, and has been the subject of studies. This approach has ensured that acoustic identity is accepted not only as a physical environmental phenomenon but also as a form of cultural representation.

In general, current studies are pioneering the integration of auditory landscapes into design and conservation processes by making the acoustic character of cities visible through documentation (Cerwen, 2017). These studies emphasise that sound can be treated as a ‘plannable environmental and cultural layer’, contributing to the aesthetic, psychological and social experiences of public spaces.

However, significant gaps in the literature are also noteworthy. As most studies are conducted in Western-centric cities, the effects on acoustic identity in terms of local and cultural diversity

are not sufficiently researched. Similarly, the auditory identity of non-urban areas such as rural landscapes, industrial areas, and ecological corridors is often overlooked. Furthermore, there is limited research on the integration of acoustic identity studies into more nuanced perceptual layers such as sensory thresholds, gender, and socio-economic differences.

In future scenarios, it is crucial that acoustic identity-based studies progress with an interdisciplinary approach that recognises them not merely as an environmental element, but as a tool for cultural production, spatial belonging, and forms of social interaction. Comprehensive research combining acoustic ecology and digital mapping methods, particularly within the discipline of landscape architecture, will enable both more accurate documentation of acoustic identity and the creative incorporation of sound into design processes.

Ultimately, the concept of 'acoustic identity' highlights the multisensory nature of the cultural landscape, reminding us that sound must be repositioned as cultural data within the disciplines of design and planning. In this context, any new work undertaken holds significant potential for both the preservation of auditory heritage and the sensory redefinition of spatial identity.

Abstract

Urban areas are both major contributors to and highly vulnerable to climate change. The 2025 Turkish Climate Law (No. 7552) establishes a legal framework for national climate mitigation and adaptation policies, indirectly highlighting the strategic role of urban open and green spaces. Although the law does not explicitly define "urban green areas," it emphasizes concepts such as carbon sinks, sustainable management, green growth, just transition, and climate justice, which collectively support the ecological, social, and economic value of these spaces. This study employs qualitative content analysis of the Climate Law alongside national planning legislation, including the Zoning Law (No. 3194) and the Spatial Plans Regulation, to evaluate the law's implications for urban green infrastructure. Findings indicate that green areas, including parks, urban forests, green corridors, and green roofs, serve as multifunctional urban systems that provide carbon sequestration, heat island mitigation, ecosystem services, and social benefits. The law's just transition and climate justice provisions reinforce the importance of accessibility, equitable distribution, and prioritization for vulnerable populations, integrating social inclusivity into urban climate strategies. However, the analysis reveals a limited direct legal integration between the Climate Law and existing spatial planning regulations, rendering its impact primarily guiding rather than binding. To fully realize the law's objectives, local governments must proactively incorporate urban green infrastructure into municipal plans, climate action strategies, and development projects. Strengthening this integration would enhance Türkiye's ability to achieve net-zero emissions while simultaneously improving urban resilience, social equity, and quality of life.

Keywords: Türkiye's Climate Law, urban green spaces, urban landscapes.

Introduction

Cities today function both as principal drivers of climate change and as spatial units most adversely affected by its impacts. Factors such as increasing population density, fossil fuel consumption, rising energy demand, and the expansion of impervious surfaces elevate greenhouse gas emissions in urban areas and disrupt local climate systems, thereby intensifying the urban heat island effect (Gill et al., 2007; IPCC, 2022). This process directly affects not only the ecological balance but also the social, economic, and public health dimensions of urban life (Carter et al., 2015). In particular, rising global temperatures, the increasing frequency of extreme weather events, and the depletion of water resources weaken the resilience capacity of urban ecosystems (Bowler et al., 2010; Báthoryné Nagy, 2024).

In this context, urban open and green spaces emerge as critical ecological components for climate change adaptation and mitigation. By providing multifunctional ecosystem services-such as carbon sequestration, stormwater retention, air quality improvement, and the conservation of biodiversity-these areas enhance the climate resilience of cities (Nowak et al., 2013; Corgo et al., 2024). Research demonstrates that urban forests, park systems, green roofs, and permeable surfaces regulate microclimates by reducing the urban heat island effect,

lowering energy demand, and increasing carbon storage capacity (Elmqvist et al., 2015; Wamsler et al., 2016; Seidu et al., 2025; Sheng et al., 2025). Additionally, when evaluated within the framework of nature-based solutions, green infrastructure planning is regarded as one of the fundamental instruments for sustainable adaptation in urban areas (Kabisch et al., 2017; Raymond et al., 2017).

In Türkiye, the Climate Law (No. 7552), which entered into force in 2025, represents a significant milestone in establishing a comprehensive national legal framework for combating climate change. The law incorporates principles aimed at strengthening ecosystem-based approaches, increasing carbon sink capacity, promoting the sustainable management of natural resources, and institutionalizing climate adaptation policies (Official Gazette, 2025). Within this scope, open and green spaces are regarded as strategic components due to their carbon storage potential, their role in reducing the urban heat island effect, their contribution to the continuity of ecosystem services, and their importance for biodiversity conservation (Khalili et al., 2024).

The aim of this study is to examine the explicit and implicit references to urban open and green spaces within the framework of the Türkiye Climate Law and to evaluate the institutional and spatial interactions of these areas with the law's goals and strategies. The study also provides assessments of how green infrastructure planning, nature-based solutions, and urban ecosystem management can be more effectively integrated into legal and institutional frameworks in order to enhance the law's effectiveness. In doing so, it offers a perspective that supports ecological sustainability and the development of climate-responsive urbanization policies.

Materials and Methods

This study aims to reveal possible events in the planning and design of light green modules presented by the Climate Law No. 7552, adopted on 9/7/2025. The primary material of the research consists of the text of the Law as published in the Official Gazette. By analyzing the Law's objectives, principles, and implementation provisions, direct and indirect references related to green spaces and ecological planning were identified. Additionally, national policy documents such as the Zoning Law No. 3194 (1985) (Official Gazette, 1985) and the Regulation on Spatial Plans (2014) (Official Gazette, 2014) were reviewed as supporting sources. The study employs documentary analysis and qualitative content analysis methods (Bowen, 2009). The texts were examined with the focus on the keywords "climate adaptation", "green infrastructure", "nature-based approach" and "ecosystem services". The findings were then compared with existing planning legislation to interpret the potential implications of the Climate Law for green space management.

Findings and Discussion

The Türkiye Climate Law (No. 7552) is a fundamental regulation that codifies the country's net-zero emissions target and establishes a legal framework for climate change mitigation and adaptation policies (Official Gazette, 2025). Although the law does not explicitly use the term 'urban open-green space,' it provides a supportive framework for the ecological, economic, and social value of such areas through concepts such as 'sink areas,' 'sustainable management,' 'green growth,' 'climate adaptation,' and 'climate justice.' Examining the provisions that indirectly reference these areas offers strategic insights for local governments and urban planners:

Article 1 – Purpose: Article 1 of the Law aims to address climate change in line with the vision of green growth and the national net-zero emissions targets. This provision offers a strategic framework for urban open and green spaces. Parks, urban forests, green belts, and ecological corridors directly contribute to carbon sequestration, the mitigation of the urban heat island effect, and the maintenance of ecosystem services (Bowler et al., 2010; Khalili et al., 2024). Although Article 1 does not legally define the presence of open and green spaces, it situates them within climate policy, thereby providing guidance at the higher policy level.

Article 2 – Definitions (Mitigation and Sink Areas): Article 2 of the Law specifies, within the scope of mitigation, the protection, enhancement, and improvement of sink areas. In this context, urban green spaces—such as parks, green roofs, and afforested corridors—function as carbon sink areas. This provision offers legal support for making green spaces a mandatory component of climate action plans developed by local governments (Bolund & Hunhammar, 1999; Costanza et al., 2017).

Article 2 – Definitions (Just Transition and Climate Justice): When considered together, the definitions of just transition and climate justice in Article 2 of the Law indicate that climate policies should be grounded not only in environmental sustainability but also in principles of social equity, economic transformation, and spatial justice. These two concepts provide a holistic framework for the planning of urban open and green spaces. Urban green areas function as multifunctional urban systems that embody both the socio-economic objectives of just transition and the spatial requirements of climate justice. The principle of just transition envisions a shift toward a low-carbon and green economy that includes, rather than excludes, vulnerable groups (women, children, the elderly, persons with disabilities, and low-income communities) (McCauley & Heffron, 2018). In this context, urban open and green spaces are not only tools for environmental improvement but also spaces where social benefits—such as employment generation, social cohesion, and enhanced public welfare—are realized (Newell & Mulvaney, 2013). Green infrastructure investments—such as park rehabilitation, urban afforestation, and ecological corridor projects—simultaneously support climate adaptation and social inclusivity, thereby strengthening the spatial dimension of just transition (IPCC, 2022).

Meanwhile, the principle of climate justice aims to ensure that environmental risks caused by climate change, as well as the solutions developed to address these risks, are distributed equitably across societal groups. Within this framework, the accessibility and spatial distribution of urban open and green spaces are of critical importance. Inequities in access to green areas represent a visible form of environmental and social injustice and increase the climatic vulnerability of cities (Kabisch & Haase, 2014; Anguelovski et al., 2020). Conversely, balanced and equitably planned green infrastructure systems reduce climate disparities among urban residents by mitigating the urban heat island effect and distributing ecosystem services fairly (Wolch et al., 2014; Shi et al., 2016). The approach reflected in the definitions of just transition and climate justice in Article 2 establishes a foundation for a climate response that is not only technical but also socially equitable and comprehensive.

Article 6 – Sustainable Management of Sink Areas: This article provides a critical provision for the sustainable management of sink areas established outside of forests, thereby strengthening the legal status of urban open spaces. Urban forests, recreational green areas, and green belts acquire the function of sink areas under this article, creating an obligation for local governments to manage these areas sustainably. Consequently, Article 6 ensures the protection of urban

ecological infrastructure and its management in alignment with climate targets (Wamsler et al., 2016; An & Dedekorkut-Howes, 2025).

Article 7 – Integration in Plans, Programs, and Strategies: Article 7 of the Türkiye Climate Law (No. 7552) stipulates that institutions and organizations must consider the vision of green growth and net-zero emission targets in the development of their plans, programs, and strategies. At the urban scale, this article functions as a policy directive requiring that green space planning be integrated with principles of carbon balance and landscape ecology. Although the term 'plan' is general and does not explicitly refer to binding spatial plans under the Zoning Law or the Regulation on Spatial Plans, the content of the article offers broader potential for integration between urban open and green spaces and planning processes. Accordingly, this provision provides a significant framework for strategic guidance and planning coherence regarding urban open and green spaces:

- *Integration of Urban Green Infrastructure into Planning Documents:* Article 7 mandates that climate objectives be considered in plans and strategies developed at both national and local levels. This approach emphasizes that urban open spaces should be regarded not only for their aesthetic or recreational values but also as elements of ecological infrastructure due to their climate-related functions, including carbon sequestration, biodiversity conservation, and mitigation of the urban heat island effect (Gill et al., 2007; Khalili et al., 2024).
- *Functional Integration of Green Spaces:* Article 7 promotes the integration of green spaces with urban ecosystem services. In this context, planning parks and groves in relation to population density, air quality, and water management, as well as incorporating green roofs, vertical gardens, and ecological corridors into the planning process, aligns with the green growth vision envisaged by the article (Raymond et al., 2017; Sheng et al., 2025).
- *Planning and Adaptation Obligation:* Although the phrase "shall be considered" does not carry direct binding authority, it exerts a strong guiding influence. This places a responsibility on local governments to integrate urban open and green spaces into planning decisions in accordance with climate adaptation strategies, carbon reduction targets, and principles of ecological resilience (Wamsler et al., 2016; An & Dedekorkut-Howes, 2025).
- *Spatial Planning Perspective and the Role of Local Governments:* While Article 7 does not explicitly reference master or implementation plans, it can be interpreted as a guiding principle in terms of urban and landscape planning. The article encourages municipalities to take initiative in strategic planning and decision-making processes, develop projects that increase the quantity of urban open spaces, design green infrastructure based on ecological planning principles, and transform the urban fabric in alignment with climate objectives (Sevinçli, 2025).

Articles 9 and 10 – Climate Adaptation Planning and Local Governments: These articles establish the responsibility of local governments to develop climate adaptation plans. Municipalities can devise strategies to increase the quantity of urban green spaces, mitigate the urban heat island effect, and strengthen carbon sink networks. These provisions position urban open and green spaces as the physical and functional infrastructure of climate action at the local level (Raymond et al., 2017; Sheng et al., 2025). This regulation provides a guiding framework for integrating urban open and green spaces into climate adaptation policies through spatial planning instruments and contributes to the development of an ecological planning vision at the local level.

When examining the integration between the Law and the country's spatial planning legislation, the following observations can be made:

The concept of 'plans, programs, and strategies' in Article 7 stipulates that institutions and organizations must take into account the vision of green growth and net-zero emission targets in the policy documents they prepare. However, this provision does not establish a direct connection with the Zoning Law No. 3194, the Regulation on Spatial Plans, or municipalities' master and implementation zoning plans. Therefore, the effect of Article 7 remains primarily advisory and guiding, without binding authority over local zoning processes, planning decisions, or implementation practices (Sevinçli, 2025). This situation provides local governments with broad discretion in planning and managing urban open and green spaces in alignment with climate policies. Indeed, legal and institutional analyses of urban green infrastructure and nature-based solutions in Türkiye support this observation. Tuğaç (2023) emphasizes that urban infrastructure policies do not demonstrate full coherence at the legislative and implementation levels, and that local green infrastructure practices are not entirely aligned with existing legislation. Within this framework, while Article 7 of the Climate Law provides significant strategic guidance, it highlights the need to strengthen institutional and legal mechanisms for its integration into the spatial planning system.

Similarly, Article 6 regulates the 'sustainable management of sink areas established outside forests.' This provision allows elements such as urban forests, green belts, and recreational green spaces to be recognized as carbon sink areas. However, this article does not provide explicit or detailed guidance for mandating the identification of such sink areas in local zoning or master/implementation plans, nor does it link them directly to planning decisions. Consequently, the systematic integration of green spaces into planning processes largely depends on the capacity and implementation willingness of local governments at the regional level.

The effectiveness of climate legislation relies on addressing green infrastructure plans and nature-based solutions in an integrated manner through legal and institutional mechanisms. As frequently emphasized in the literature, the success of climate policies largely depends on the effective integration of these elements into local governments' spatial planning processes. Such integration not only supports environmental sustainability but also forms the foundation for a holistic planning approach that enhances urban climate resilience, strengthens ecosystem services, and supports carbon reduction targets (Benedict & McMahon, 2006; Kabisch et al., 2017; Raymond et al., 2017; Demiroğlu et al., 2019; Khalili et al., 2024; Li & Carter, 2025).

When the study's findings are evaluated holistically, it can be concluded that the law provides a framework supporting the importance of urban open and green spaces in climate change mitigation and adaptation policies. However, this framework is primarily guiding and strategic rather than establishing a direct and binding integration with spatial planning processes. Therefore, the effective reflection of provisions regarding urban open and green spaces in planning decisions largely depends on local governments' technical and administrative capacity, municipal council decisions, and the scope of implementation regulations. This indicates that the local applicability of the policy objectives set forth by the law is closely linked to the interaction between institutional capacity, planning practice, and administrative will.

Conclusion and Recommendations

In conclusion, although Türkiye Climate Law (No. 7552) does not explicitly define urban open and green spaces, it indirectly underscores their strategic importance for climate change mitigation and adaptation policies. Through concepts such as 'just transition,' 'climate justice,' 'sink areas,' and 'green growth,' the law addresses the ecological, social, and economic functions of urban open and green spaces from a holistic perspective. Nevertheless, the lack of direct integration with existing spatial planning legislation (i.e., Zoning Law No. 3194 and the Regulation on Spatial Plans) limits the full realization of this potential in practice.

This indicates that the law's influence on urban planning processes remains primarily guiding rather than binding, serving as a strategic framework rather than a legal mandate. Within this context, local governments are expected to voluntarily integrate the principles and objectives defined in the Climate Law into planning documents. In particular, reflecting the carbon sequestration capacity, ecosystem services, and social justice dimensions of urban open and green spaces in municipal climate action plans, environmental plans, and master zoning plans constitutes a critical step toward achieving the law's objectives.

In this regard, defining urban green infrastructure as a functional component within planning documents would enhance the implementability of climate objectives while contributing to the promotion of spatial justice. Furthermore, in line with the principles of just transition and climate justice, prioritizing the accessibility, equitable distribution, and planning of green spaces for vulnerable groups provides a policy framework that supports social inclusivity.

In conclusion, the Türkiye Climate Law positions urban open and green spaces as a key instrument of climate policy; however, realizing this potential requires stronger integration with spatial planning legislation and implementation-oriented sub-regulations. Ensuring such integration would not only facilitate the achievement of Türkiye's net-zero emissions targets but also simultaneously strengthen the ecological resilience, social equity, and overall quality of life in urban areas.

Abstract

The extraordinary speed and efficiency of the "reconstruction" processes prioritized following disasters pose a serious threat to the legal framework safeguarding Türkiye's most valuable natural assets. This study focuses on the intersection of Natural Resource and Environmental Protection Laws (including the Soil Conservation and Land Use Law, Forest Law, Pasture Law, Coastal Law, National Parks Law, and Environmental Law) and Disaster Management and Spatial Planning Laws (specifically the Law on the Transformation of Areas under Disaster Risk and the Law on Measures and Aid to be Provided Due to Disasters Affecting Public Life). Our primary objective is to thoroughly examine, from a landscape architecture perspective, how concepts such as "public interest", "urgency", "exception" and "reserve area" intensify the pressure on ecological assets and create new legal vulnerabilities by rendering conservation law dysfunctional. The findings reveal that the post-disaster legal effect is primarily shaped by the principles of "centralization, exception, and urgency". Based on these findings, recommendations have been developed to mitigate legal fragility.

Keywords: Legal vulnerabilities, law in ecological protection, protection of natural assets, Türkiye.

1. Introduction

Natural and anthropogenic disasters constitute an ancient reality that the modern world is constantly tested by and which inflicts profound wounds. Each year, geological tensions accumulating beneath the Earth's seemingly unshakeable crust are unleashed through major earthquakes. Simultaneously, meteorological storms accelerated by climate change lead to floods and droughts, threatening ecosystems and the livelihoods of billions of people. These devastating events do not merely result in immediate loss of life and hundreds of billions of dollars in economic ruin; they also collapse healthcare systems, deepen social inequalities, and displace millions, ultimately evolving into chronic social crises that severely test the limits of human resilience. The true impact of disasters lies beyond the collapsed buildings, leaving behind a global legacy of instability and uncertainty that effectively holds the development potential of future generations hostage.

A disaster is the general term given to the consequences of events that cause large-scale physical, social, economic, cultural, and environmental damage to a society and significantly disrupt the flow of daily life. Such events create a crisis so profound that the affected region is incapable of coping with its own local facilities and resources. Therefore, disasters are defined as situations requiring a specialized crisis management approach and external support (Kadıoğlu, 2011). Disasters are generally categorized into three main groups based on their causes: Natural disasters (natural events such as earthquakes, floods, avalanches, tornadoes, and volcanic eruptions), Technological disasters (those resulting from human-made system failures such as nuclear or chemical accidents and dam failures), and Human-Caused disasters

(large-scale crises stemming from direct human actions or negligence, such as social unrest, major building collapses, or acid rain) (Kadıoğlu, 2008).

Global disaster data for 2023, when compared to the 2003-2022 period averages, reveals significant dynamic shifts in the frequency and impact area of natural disasters. In terms of frequency of occurrence, floods, storms, and earthquakes were the most prevalent disaster types. However, a noticeable increase in the number of storm events (from 104 to 139) and earthquake events (from 27 to 32) during this period suggests that atmospheric and tectonic risks pose a growing global threat. Parallel to this increase, the dramatic rise in fatalities observed across earthquake, storm, and flood categories indicates an increase in the average lethality of disasters. Specifically, the rise in earthquake deaths from 35,124 to 62,451 and in storm deaths from 10,017 to 14,668 underscores the critical importance of robust risk reduction and early warning systems.

In terms of the number of people affected, there was a significant decrease compared to the previous period for those impacted by floods (from 74.6 million to 32.4 million) and droughts (from 57.1 million to 21.8 million). This reduction might be attributed to the partial success of adaptation strategies implemented against climate variability or a change in the geographical distribution of events. However, the surge in the number of people affected by earthquakes from 5.6 million to 20.2 million during the same period suggests that major tectonic events in 2023 were concentrated in highly populated or infrastructurally vulnerable regions.

The examination of economic losses confirms the increasing global economic risk, as costs rose across all storm, earthquake, and drought disaster types. The increase in storm-related losses from $95.6 billion to $100.8 billion, earthquake losses from $39.9 billion to $51.9 billion, and drought losses from $9.6 billion to $22.1 billion demonstrates that the interactions between urbanization, asset concentration, and the climate crisis are heightening the pressure on the insurance and reinsurance sectors. The concentration of the most affected populations in 2023 in countries such as Indonesia, India, and Türkiye highlights the high vulnerability of these regions to specific disaster types. The fact that 18.8 million people in Indonesia were affected by drought, 10.2 million people in India by floods, and 9.2 million people in Türkiye by earthquakes proves the necessity of specialized national disaster risk management strategies based on regional hazard profiles (hydro-meteorological or geological) (Senir, 2024).

An examination of disaster events occurring in Türkiye between 1900 and 2022 reveals that disaster frequency varies by year. The highest number of disasters during this period was recorded between 1996-2008 and 2008-2020, followed by the 1984-1996 period. The total number of disasters (1900-2022) was 376, of which 206 were natural in origin and 170 were technological. This data clearly demonstrates that Türkiye confronts a wide and complex spectrum of risks (Usta, 2023). According to published statistics, a total of 29,503 events occurred in Türkiye in 2024, including 8,058 natural disasters, 3,976 human/technology-related incidents, and 17,469 other events (such as being trapped, lost, etc.). When 205 natural disasters that occurred in Türkiye between 1900 and 2021 were examined, it was determined that a total of 97,086 people lost their lives and 9,787,122 people were directly affected as a result of these catastrophes (Şahan, 2024).

2. Materials and Methods

This study aims to reveal the legal vulnerabilities arising from the interaction between the Natural Resources and Environmental Protection Laws-which include the "*Law on Soil*

Conservation and Land Use (No. 5403), Forestry Law (No. 6831), Pasture Law (No. 4342), Coastal Law (No. 3621), National Parks Law (No. 2873), and Environmental Law (No. 2872)"- and the Disaster Management and Spatial Planning Laws-which include the "Law on the Transformation of Areas Under Disaster Risk (No. 6306) and the Law on Measures and Aid to be Taken Due to Disasters Affecting Public Life (No. 7269)".

All legal texts subjected to examination were downloaded from the database of the T.R. Presidency Legislation Information System (www.mevzuat.gov.tr). To ensure the currency of the analysis, all texts were included in the dataset in their latest updated versions effective as of 14.11.2025.

The research employed a qualitative content analysis method. From a landscape architecture perspective, a deductive approach was used to examine key concepts-such as "public interest", "urgency", "urgent expropriation", "exception", and "risky/reserve area"-that increase pressure on ecological assets/natural resources, thereby weakening conservation efforts and creating legal vulnerability. The resulting findings were interpreted through comparison against the backdrop of ecological sensitivities.

3. Finding

The protection objectives of the laws evaluated within the scope of the study are given below.

- Soil Conservation and Land Use Law: The primary objective of this Law is the protection and enhancement of soil. It also aims to determine the procedures and principles for the classification of agricultural lands, the designation of their minimum and financially sufficient sizes, the prevention of their subdivision, and their planned use in accordance with the principle of environmentally-prioritized sustainable development (Soil Conservation and Land Use Law, 2005).

- Forest Law: The fundamental purpose of the Forest Law is to ensure the continuity of forest assets within the borders of the Republic of Türkiye. In line with this purpose, the Law establishes the principles for the conservation, improvement, and sustainable management of forests (Forest Law, 1956).

- Pasture Law: The objective of the Pasture Law is to ensure the identification, delimitation, and subsequent allocation of all grazing areas (pastures, summer pastures, wintering grounds, meadows, and rangelands) designated by various laws or traditionally used, assigning them to the relevant village or municipality. Furthermore, the Law regulates the proper use of these areas, their improvement to enhance productivity, continuous supervision, conservation, and, when necessary, the procedures for changing their designated use (Pasture Law, 1998).

- Coastal Law: The Coastal Law aims to preserve the natural and cultural characteristics of the coasts of seas, lakes, and rivers, along with their connected coastal strips, and to determine the principles for the use of these areas in a manner that allows the public to benefit freely, while observing the public interest (Coastal Law, 1990).

- National Parks Law: The purpose of the National Parks Law is to establish the principles that ensure the identification of globally and nationally significant nature conservation areas (such as national parks, nature parks, nature monuments, and nature protection areas) in Türkiye, their preservation without alteration of their unique characteristics, and their development and management.

- Environmental Law: The Environmental Law aims to ensure the protection of the environment, which is the common heritage of all living beings, in line with the principles of sustainable environment and development. This legal regulation also covers the procedures for managing hazardous and debris waste generated, especially after major disasters, without causing harm to the environment (Environmental Law, 1983).

The objectives of the laws examined under the basis of disaster management and spatial planning that impact conservation processes are presented below:

- Law on the Transformation of Areas under Disaster Risk: The objective of this Law is to determine the principles for transformation, liquidation, and renewal processes to create safe and healthy living spaces in compliance with scientific and technical standards, both in regions posing a disaster risk and in areas outside these regions containing risky structures (Law on the Transformation of Areas under Disaster Risk, 2012).

- Law on Measures to be Taken and Aid to be Provided Due to Disasters Affecting Public Life: This Law provides the necessary legal basis for all processes carried out immediately following a disaster, including emergency response, rescue operations, temporary and permanent sheltering, and the overall re-establishment of life (Law on Measures to be Taken and Aid to be Provided Due to Disasters Affecting Public Life, 1959).

When the relevant laws were analyzed through qualitative content analysis based on the provisions concerning “public interest”, “urgency”, “urgent expropriation”, “exception clauses”, and “risky/reserve area”, the mechanisms introduced by the disaster laws were found to erode conservation law under three main themes. The post-disaster legal impact has been primarily shaped by "centralization, exception, and urgency.

a) Centralization (Central Authority Use in Disaster Laws): Centralization manifests as the transfer of planning authority from local governments directly to the central administration, consequently weakening local control mechanisms.

- Transfer of Planning Authority to the Central Administration: Post-disaster reconstruction laws largely consolidate the power of implementation within the central administration (specifically, the Ministry of Environment, Urbanization and Climate Change). This effectively transfers the authority granted by the Metropolitan Municipality Law and the Municipality Law to the central authority.
- Weakening of Local Control: Centralization removes the planning process for ecologically significant assets such as forests, agricultural lands, and pastures from the jurisdiction and control of institutions responsible for their protection (such as the General Directorate of Forestry, the Ministry of Agriculture and Forestry, etc.). Instead, this authority is shifted to the central administration, resulting in a weakening of local oversight.

The consolidation of planning and site selection decisions within the central administration weakens the institutional resistance and local control mechanisms established by laws protecting forests, agriculture, pastures, and coasts. This consequently increases the risk that the principle of protecting ecological assets will be overlooked.

b) Exception (Exemptions to Ecological Protection Provisions): The term “Ecological Protection” serves as the core pillar of legal texts, promising to carry nature, forests, agricultural lands, and coasts into the future. However, a closer examination of the legal provisions that safeguard Türkiye’s most critical natural assets reveals a dangerous opening behind this rigid shield of protection-a door that threatens the integrity of ecosystems and is often justified by

powerful reasons like “public interest” and “urgency”: The Exceptions. The situations that lead to exceptions in the conservation process are detailed below.

- Forest Law Additional Article 13 (2012): This provision introduces an exception to the fundamental conservation principle of forests, based on disaster and social need. It allows the use of forested areas, first in urban centers and their immediate surroundings, and subsequently for temporary sheltering. At this point, the provision permits the introduction of infrastructure services, thereby enabling structural changes. This authority is exercised by the General Directorate of Forestry (OGM) or other administrations (local or central) deemed appropriate by the central administration. This situation creates pressure for permanent construction and devastation on forest ecosystems, justified by “public interest” and “urgency” grounds.

- Soil Conservation and Land Use Law, Article 13(b): The clause concerning the "need for temporary settlement areas arising after a natural disaster" is an exception provision that bypasses the strict conservation rules on the most productive agricultural lands by prioritizing public interest and disaster urgency. It permits these lands to be rapidly opened up for development. Although applications for such projects are reviewed by the relevant Provincial Soil Conservation Boards, the final and most critical decision-making authority rests with the Ministry of Agriculture and Forestry.

- Pasture Law, Article 14(g): The clause concerning the “need for settlement areas in natural disaster zones” can prioritize the urgent post-disaster settlement requirement over the primary intended use of pastures, which is livestock farming. The relevant article allows the purpose of use of pasture-qualified lands to be changed for the establishment of new settlements, whether permanent or temporary.

- Coastal Law: The Law (including Articles 1, 2, 5, 6, and 7) provides a legal framework and basis for the utilization and planning of coasts, and for carrying out all types of structural activities such as infilling, ports, piers, and fishing shelters, despite the Law’s fundamental conservation provisions. These activities are usually legitimized by obtaining a “public interest” decision. In this context, Article 1 establishes the basic principle regarding public interest, Article 2 dictates the conditions of use, Article 5 functions as the door to exceptions, and Articles 6 and 7 establish the planning effect.

- National Parks Law: Due to its core philosophy prioritizing conservation, this Law has a more restricted structure compared to others regarding exceptions that permit construction based on “public interest” or disaster. Any measure taken in park areas to prevent the potential consequences of disasters must comply with the park's main management plan. The priority here is the conservation of the natural ecosystem as much as human safety. However, the centralized structure and indirect provisions of the law can be associated with these concepts.

- Environmental Law: Within the Environmental Law, “public interest” represents a superior principle embodying the right to a healthy and clean environment. “Disaster” is a critical area of application where the inspection authority of this Law intersects with other disaster laws, specifically in the fields of post-disaster environmental risk management and pollution control.

Disaster laws create a normative conflict by introducing exceptional provisions against special protection laws that prohibit the misuse of ecological assets. Disaster laws pose the risk of forested areas being declared “Reserve Construction Areas”; agricultural lands being subject to exceptional provisions and opened to development due to their need for settlement and infrastructure; pastures being rapidly relegated to development status due to the overriding

public interest; and coastal areas being breached through the exception mechanism in infrastructure and reconstruction projects.

c) Urgency (Acceleration of Legal Processes): The inherently rapid pace of post-disaster reconstruction processes often results in the bypassing of detailed scientific procedures required by environmental conservation laws. This is because the accelerated procedures for the prompt identification of risky structures under the Law on the Transformation of Areas under Disaster Risk and the fast-tracked planning and implementation processes mandated by the Law on Measures to be Taken and Aid to be Provided Due to Disasters Affecting Public Life concentrate the decision-making mechanism around the concepts of "public interest" and “urgency” rather than scientific data.

The principle of "urgency" functions as a tool to accelerate and bypass legal processes, planning, and environmental assessments that would normally be lengthy. Urgency drives the process through urgent expropriation and the shortening of legal timelines, as disaster situations necessitate immediate measures and rapid implementation.

In contrast, conservation laws such as the Soil Conservation and Land Use Law, the Forest Law, and others, mandate long-term, scientifically-based study and assessment processes. Consequently, the urgency embedded in disaster laws renders the scientific planning, impact assessment, and detailed permitting processes envisaged by conservation laws impossible to implement. This situation legally weakens the protection of ecological assets. Furthermore, it either makes the application of processes like Environmental Impact Assessment (EIA) impossible or superficial. Accelerated administrative actions (such as the declaration of a risky area/reserve building area, and zoning plan changes) narrow the periods for objection and litigation or increase the risk of rendering judicial review ineffective by implementing decisions directly.

As a result, the scientific and legal control mechanisms vital for the conservation of ecological assets are rendered ineffective when confronted with the principle of urgency.

4. Conclusion and Recommendations

The mechanisms of centralization, exception, and urgency introduced by post-disaster reconstruction laws (particularly the Law on the Transformation of Areas under Disaster Risk) carry the risk of rendering inoperative the absolute protection provisions within laws safeguarding the legal status of ecological assets. This situation demonstrates a tendency for the post-disaster goal of “safe reconstruction” to override the principle of “ecological sustainability”, thereby creating a serious area of legal vulnerability for Türkiye's ecological assets.

The ecological vulnerabilities are particularly concentrated in the following areas:

- Planning Authority: Transfer of power to the central administration and the weakening of local oversight.
- Ecological Allocation: Changes in the use designation of forest, agricultural, and pasture lands, and their opening up to development.
- Coastal Areas: Pressure for construction and development.
- Legal Processes: Bypassing of environmental assessment procedures and restriction of judicial review.

To address these legal vulnerabilities, recommendations are presented under three main themes, aimed at increasing the legal protection of ecological assets while maintaining the speed and efficiency of post-disaster processes:

Strengthening Local Oversight Against Centralization

- Authority Sharing and Coordination: In planning processes such as the declaration of Reserve and Risky Areas, mandatory approval and oversight by local governments and relevant expert institutions (Forestry, Agriculture, Waterworks) should be required, in addition to the central administration's authority. This measure will increase institutional resistance.

- Ecological Constraint Report: Before any post-disaster zoning plan changes, the submission of a report containing the area's ecological asset inventory and carrying capacity, approved by local governments and professional chambers, must be made mandatory. This will render scientific data binding for legal decisions.

- Ecological Disaster Management Unit: An interdisciplinary unit should be established within the relevant Ministry to monitor and oversee the long-term ecological impacts of post-disaster demolition and reconstruction processes.

Limiting Exception Clauses

- Categorical Conservation Priority: The special protection provisions of the Soil, Forest, Pasture, and Coastal Laws must be regulated to hold priority over disaster laws within the hierarchy of norms. Barriers against the use of highly protected areas, even as a "last resort", should be increased by mandating the selection of ecologically less sensitive areas for settlement location.

- Expansion of Absolute Protection Rule: The principle of "absolutely unsuitable" designation, currently applied to Drinking-Water Supply Basins, should be extended to the core protection zones of Absolute Agricultural Lands, Forest Ecotopes, and Pastures/Wintering Grounds.

- Transparency and Compensation (Ecological Offset): The use of exception clauses must be publicly disclosed with scientific and socio-economic justifications. A condition should be imposed requiring the mandatory rehabilitation of an equivalent area at least twice the size of the destroyed ecological asset, or the declaration of a new protected area.

Subordinating Urgency to Legal Safeguards

- Accelerated Ecological Impact Assessment (AEIA): Instead of completely bypassing EIA processes due to post-disaster urgency, a brief, legally binding procedure that reviews fundamental ecological risks must be made mandatory.

- Enhancing Judicial Review: The swift and effective use of the injunction authority in lawsuits filed against post-disaster decisions must be ensured. Specialized administrative courts should be designated to guarantee the technical and rapid processing of judicial reviews.

- Ecological Constraint in Urgent Expropriation: The authority for urgent expropriation must be limited to prevent arbitrary use in first-priority protected ecological assets (Absolute Agriculture, Forest, Water Basins).

This comprehensive set of recommendations will ensure that ecological assets are brought under a comprehensive protection mechanism and their legal safeguards are enhanced, all while preserving the speed and efficiency required by post-disaster reconstruction.

Leadership, Communication, and Cognitive Skills as Drivers of Project Performance: Prioritizing Soft Skills in the Construction Industry

Greg Odee IKWE [1]*

ORCID 1: 0009-0006-6296-2266
[1]Bingham University, Faculty of Environmental Science, Department of Quantity Surveying
ikwegreg@gmail.com (Responsible Author)

Abstract

Project success depends not only on technical proficiency but also on a project manager's ability to mobilize people, coordinate diverse teams, and navigate uncertainty across the project life cycle. Although soft skills are increasingly recognized as essential competencies for project delivery, their phase-specific relevance remains insufficiently explored in construction research, particularly in developing countries. This study identifies the soft skills that most significantly influence project outcomes and determines how their importance varies across project phases. Drawing on data from 276 Nigerian construction practitioners and a two-round Delphi ranking exercise involving 11 senior experts, the study evaluates the prioritization of soft skills for initiation, planning, execution, and closure phases. Findings indicate that leadership and communication are indispensable during project initiation, fostering clarity, trust, and stakeholder alignment. Teamwork emerged as the dominant skill during execution due to high collaboration demands. Cognitive skills—though relatively underdeveloped among practitioners—were identified as the most critical for planning, scheduling, resource allocation, and risk management. Interpersonal and motivational skills, while positively rated, played mainly supportive roles. The study proposes a soft skill–life cycle alignment framework designed to guide training and competency development in the construction industry. The findings emphasize the transformative potential of strengthening soft skills to improve project outcomes, especially in developing contexts where human-related performance gaps persist.

Keywords: Leadership, communication, cognitive skills, project life cycle, construction project management

Introduction

Construction project management involves the integration of human, financial, and material resources to achieve project objectives under constraints of time, cost, and quality. Despite improvements in professional standards and digital technologies, the construction sector in developing economies continues to experience underperformance—manifesting as delays, cost overruns, quality deficiencies, and stakeholder dissatisfaction (Aibinu & Jagboro, 2002; Olaniran, 2015).

These recurring issues demonstrate that technical skills alone are inadequate for addressing dynamic project complexities. Soft skills—such as leadership, communication, teamwork, interpersonal competence, and cognitive reasoning—have gained increasing recognition as fundamental to project success. Because construction projects are highly collaborative, human-centered, and uncertainty-prone, the ability of project leaders to engage, influence, and coordinate people is crucial.

Despite this recognition, the literature provides limited empirical insight into how the importance of soft skills shifts across different project phases. This study addresses this gap by examining phase-specific soft skill needs for construction project success in Nigeria.

2.0 Literature Review

Soft skills comprise non-technical competencies enabling effective communication, leadership, team collaboration, problem-solving, and adaptability (Robles, 2012). In construction, they complement technical skills and enhance managerial effectiveness (Crawford, 2005).

2.1 Soft Skills in Construction Management

- **Leadership** facilitates shared vision, team alignment, and strategic guidance (Müller & Turner, 2010).
- **Communication** ensures information clarity, stakeholder engagement, and conflict reduction.
- **Cognitive skills** enable analytical thinking, decision-making, and risk evaluation—critical for planning.
- **Teamwork** drives coordination and productivity in multidisciplinary project environments.

2.2 Soft Skills and the Project Life Cycle

The project life cycle comprises initiation, planning, execution, and closure.

- **Initiation:** Leadership and communication are vital for establishing direction.
- **Planning:** Cognitive skills underpin problem-solving, scheduling, and resource allocation.
- **Execution:** Teamwork and communication support coordination and task interdependence.
- **Closure:** Interpersonal and communication skills facilitate handover, documentation, and evaluation.

Despite their importance, there is little empirical evidence on which skills matter most at each stage—particularly in developing construction industries. This study provides such evidence.

3. Methodology

3.1 Survey of Practitioners

A quantitative survey was administered using structured questionnaires:

- 360 questionnaires distributed
- 276 valid responses used for analysis (76.6% response rate)
- Respondents: project managers, engineers, architects, quantity surveyors, site supervisors

Competencies assessed using a 5-point Likert scale included:

1. Leadership
2. Communication
3. Teamwork
4. Interpersonal skills

5. Motivational skills
6. Cognitive skills
7. Conflict management

3.2 Delphi Expert Ranking

A Delphi panel comprising 11 senior construction professionals participated in two iterative rounds to:

- Rank soft skills by importance per project phase
- Reach consensus using ≥80% agreement threshold

3.3 Data Analysis

- Descriptive statistics
- Mean scores
- Correlation analysis (Pearson's r)
- Consensus tracking for Delphi responses

4. Results

4.1 Practitioner Soft Skill Proficiency

Table 1. Mean scores of soft skills among practitioners

Soft Skill	Mean Score	Interpretation
Leadership	4.32	High proficiency
Communication	4.28	High proficiency
Teamwork	4.19	Good proficiency
Interpersonal Skills	4.12	Good proficiency
Motivational Skills	4.03	Good proficiency
Cognitive Skills	3.76	Moderate proficiency
Conflict Management	3.68	Moderate proficiency

Practitioners recorded strong interpersonal attributes but comparatively lower cognitive competencies.

4.2 Phase-Specific Soft Skill Prioritization (Delphi Results)

Table 2. Soft Skills by Project Phase (Ranked by Experts)

Project Phase	Most Important Skill	2nd Most Important	3rd Most Important
Initiation	Leadership	Communication	Interpersonal skills
Planning	Cognitive skills	Leadership	Communication
Execution	Teamwork	Communication	Motivational skills
Closure	Communication	Interpersonal skills	Leadership

4.3 Correlation Between Soft Skills and Project Success

Table 3. Correlation Analysis Results

Soft Skill	Correlation with Project Success (r)
Leadership	0.69
Communication	0.66
Teamwork	0.64
Cognitive Skills	0.73
Interpersonal Skills	0.58
Motivational Skills	0.54

All correlations were statistically significant at **$p < 0.01$.**

5. Discussion

The results demonstrate that soft skills are not uniformly critical across project phases; instead, their importance is contingent on project demands.

Leadership & Communication

These skills dominate early project phases, ensuring:

- Clear objectives
- Stakeholder alignment
- Risk-awareness initiation

This supports findings by Clarke (2010) that emotional and leadership competencies drive early-stage clarity.

Cognitive Skills

Strongly correlated with project success ($r = 0.73$), cognitive skills:

- Support analytical decision-making
- Strengthen planning accuracy
- Reduce risk exposure

The moderate proficiency reported indicates a gap requiring targeted training.

Teamwork

Teamwork is most vital during execution due to:

- High coordination
- Multidisciplinary collaboration
- Task interdependence

Communication in Closure

Ensures:

- Clear reporting

- Smooth handover
- Stakeholder satisfaction

These findings align with the argument that communication influences overall project perception.

6. Conclusion

This study confirms that leadership, communication, teamwork, and cognitive skills significantly influence project performance, with their relative importance shifting across the project life cycle. Leadership and communication dominate initiation; cognitive skills drive planning; teamwork is most influential during execution; and communication is essential for closure.

Recommendations:

1. Develop phase-specific soft skill training programs.
2. Integrate soft skills into professional certification requirements.
3. Improve cognitive skill development in university curricula.
4. Use soft skill assessments in recruitment and project assignment.
5. Strengthen CPD initiatives focusing on leadership, communication, and teamwork.

Thanks and Information Note

The article complies with national and international research and publication ethics. This study complies with all national and international standards for research and publication ethics. Ethics Committee approval was not required, as the research involved non-sensitive questionnaire responses from adult professionals and did not include any personal or medical data. The author expresses sincere appreciation to the construction practitioners and expert panelists who participated in the survey and Delphi exercises. Their insights and professional contributions were instrumental to the success of this study. No external funding, grants, or financial sponsorship were received for this research. The study was conducted independently without influence from any organization or commercial entity. The author declares no conflict of interest. Abstract

Artificial Intelligence (AI) has emerged as a transformative technology across industries, and architecture is no exception. The integration of AI tools in architectural design processes has redefined how architects conceptualize, simulate, and optimize the built environment. This paper reviews the evolution, applications, and challenges of AI in architectural design, emphasizing generative modeling, Building Information Modeling (BIM), environmental performance analysis, and smart construction workflows. It explores how machine learning (ML), deep learning (DL), and generative design algorithms enhance creativity, accelerate decision-making, and improve energy efficiency. Furthermore, it discusses the key software tools enabling this transformation—such as Autodesk Revit, Spacemaker AI, Finch 3D, Midjourney, and ClimateStudio—and examines the limitations and future trajectory of AI-driven architectural practice.

Keywords: *AI, ML, BIM, design, architecture*

I. Introduction

Architectural design has traditionally combined artistic intuition with engineering precision. However, the growing complexity of urban environments, sustainability requirements, and computational advancements have driven a shift toward data-informed and automated design processes. Artificial Intelligence (AI), encompassing techniques such as machine learning, deep learning, and generative algorithms, now plays a central role in optimizing design workflows [1], [2].

AI assists architects not only in visualizing conceptual ideas but also in simulating material performance, energy efficiency, and user behavior. Unlike conventional Computer-Aided Design (CAD) tools, AI systems can learn from data, recognize patterns, and propose alternative solutions based on defined objectives and constraints. This capability allows architects to explore a vast design space, reduce manual effort, and generate innovative, performance-driven outcomes [3].

The following sections examine the operational frameworks of AI in architecture, focusing on generative design, BIM automation, sustainability modeling, and construction optimization. The discussion integrates conceptual understanding with references to specific AI tools currently reshaping professional practice.

II. AI-Driven Design Workflow

The AI-driven architectural workflow can be divided into four primary phases: **concept generation, design optimization, environmental simulation,** and **construction management**.

1. **Concept Generation:** Generative design algorithms—powered by reinforcement learning and genetic optimization—enable the creation of multiple design alternatives based on input parameters such as site geometry, budget, daylight access, and spatial efficiency [4]. Autodesk's Generative Design and Spacemaker AI exemplify this approach, allowing architects to rapidly evaluate thousands of spatial configurations [5].

2. **Design Optimization:** Once preliminary concepts are established, AI tools refine geometry, materials, and spatial layouts through multi-objective optimization. Finch 3D, for example, adapts building forms in real time as parameters change, maintaining spatial logic while improving structural efficiency [6].

3. **Environmental Simulation:** Machine learning algorithms predict environmental performance, including daylight availability, solar gain, and ventilation efficiency. Tools such as ClimateStudio and Sefaira employ AI to automate thermal simulations and energy-use predictions, enabling sustainable design decisions at early stages [7].

4. **Construction and Lifecycle Management:** During execution, AI-powered systems like Buildots and nPlan use computer vision and predictive analytics to track construction progress, identify delays, and forecast risks [8]. Integration with BIM platforms allows real-time synchronization of physical and digital environments, creating a continuous feedback loop throughout the building lifecycle.

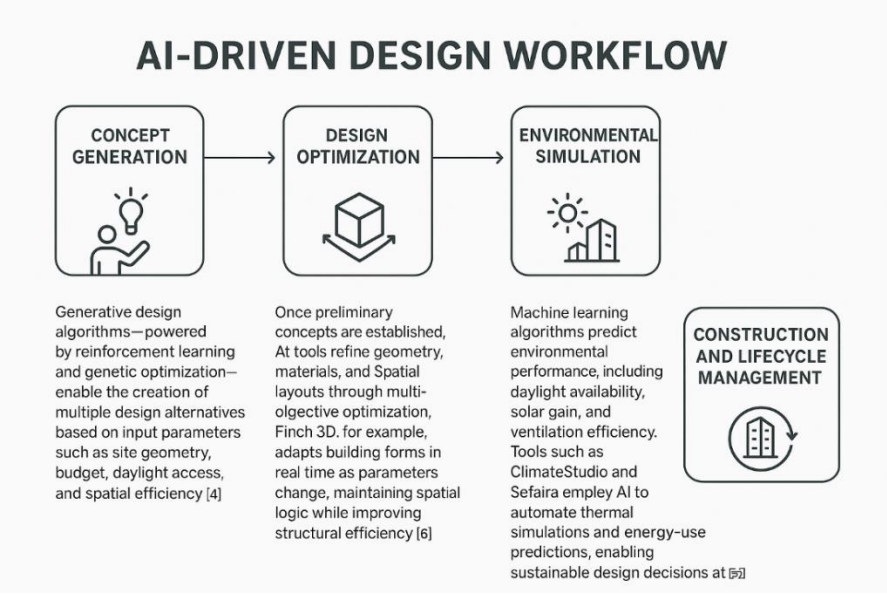

Fig. 1. AI-Driven Design Workflow

III. Key AI Tools and Techniques

AI in architecture operates through several computational paradigms—each addressing specific challenges across the design and construction continuum.

1. **Generative Design:** Generative design combines evolutionary algorithms with ML to create design options that optimize for performance metrics. Autodesk Generative Design and

Hypar allow users to specify constraints (e.g., daylight, energy use) and produce form alternatives evaluated through fitness functions [9].

2. **Machine Learning and Data Analytics:** ML models analyze historical data to identify design correlations and predict outcomes. In BIM, predictive ML tools automate clash detection, cost estimation, and scheduling. Revit's Dynamo scripts and Rhino's Grasshopper plugins increasingly incorporate ML modules for real-time analysis [10].

3. **Deep Learning and Visualization:** Deep learning models, particularly Convolutional Neural Networks (CNNs), enhance visual rendering and spatial recognition. Platforms like NVIDIA Omniverse and D5 Render utilize AI to produce photorealistic imagery faster than traditional rendering engines [11].

4. **AI-Enhanced Visualization Tools:** Midjourney, Stable Diffusion, and Runway ML facilitate conceptual visualization through text-to-image synthesis, bridging early-stage ideation and client communication [12].

5. **BIM and Digital Twin Integration:** AI-integrated BIM platforms generate predictive digital twins that simulate building performance in real time. These systems enhance facility management by predicting maintenance schedules and resource demands [13].

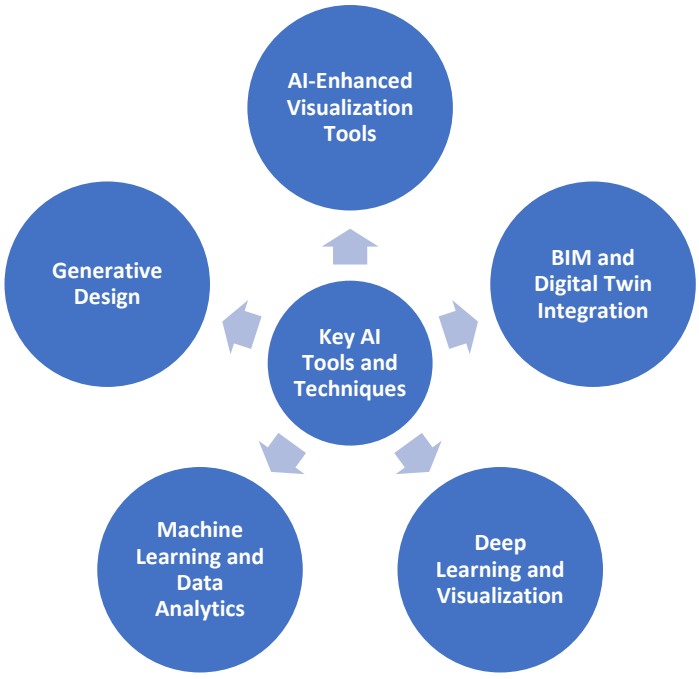

Fig 2. Key AI Tools and Techniques

IV. AI for Sustainability and Smart Design

Sustainability has become a defining priority in architectural practice, and AI is instrumental in achieving performance-driven environmental outcomes.

1. **Energy Optimization:** AI models assess the impact of orientation, shading, and façade materials on energy consumption. Tools like Cove.Tool and ClimateStudio use ML algorithms to optimize envelope design for passive heating and cooling [14].

2. **Material and Structural Efficiency:** Deep generative models are used to identify lightweight, high-strength material combinations. Reinforcement learning frameworks adapt material selection dynamically to minimize embodied carbon [15].

3. **Urban-Scale Applications:** At city scales, AI-driven simulation models predict microclimate effects, optimize traffic flow, and assess renewable energy potential. Spacemaker AI and Sidewalk Labs apply multi-agent systems to evaluate urban density and pedestrian comfort [16].

4. **Integration with Smart Cities and IoT:** AI-enhanced buildings can interface with Internet of Things (IoT) systems to monitor energy consumption, air quality, and occupancy patterns. Predictive analytics supports adaptive systems that optimize performance autonomously [17].

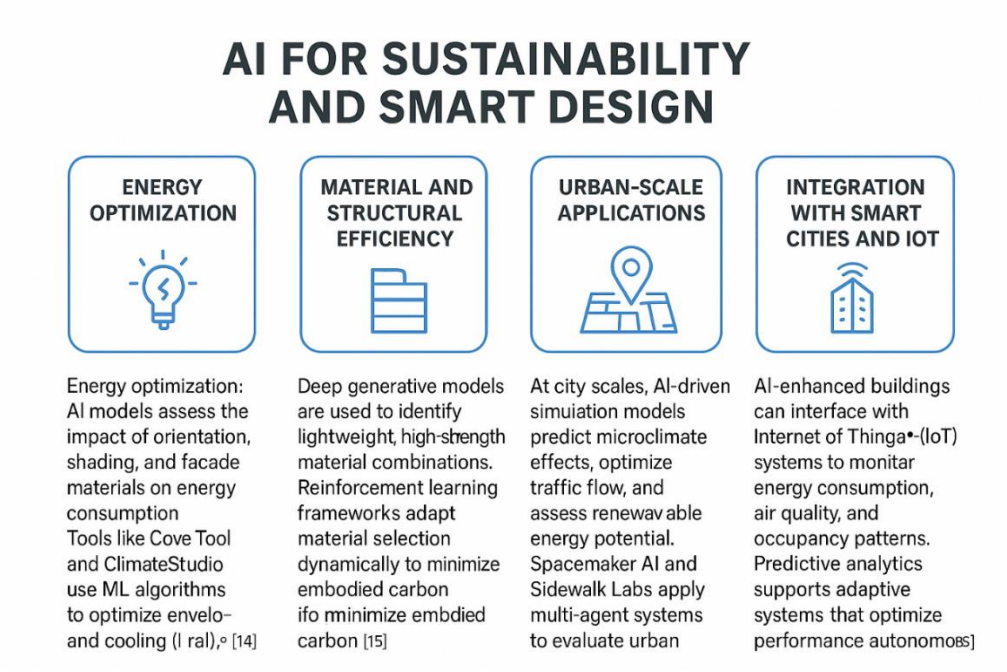

Fig 3. AI for Sustainability and Smart Design

V. Challenges and Limitations

Despite its transformative potential, the integration of AI into architecture faces several challenges:

- **Data Scarcity:** Architectural datasets are often small and proprietary, limiting model training and generalization [18].
- **Black-box Nature:** Deep models lack interpretability, raising ethical and accountability issues in design decisions [19].
- **Standardization and Compatibility:** Interoperability between AI tools and BIM platforms remains limited [20].
- **Overreliance on Automation:** Excessive algorithmic control may constrain human creativity, necessitating careful balance between automation and authorship [21].

- **Resource Intensity:** High computational costs and limited AI literacy in architecture firms pose barriers to widespread adoption [22].

VI. Future Directions

The next generation of AI-driven architectural design will prioritize **explainability, hybrid modeling, and autonomous optimization**.

- **Physics-Informed Machine Learning:** Combining AI with physical simulation models will yield hybrid systems capable of producing accurate, generalizable results with minimal data [23].
- **Explainable AI (XAI):** Transparent models will allow architects to understand how algorithms make design decisions, reinforcing trust and ethical accountability [24].
- **Self-Driving Design Systems:** Integration of AI with robotic fabrication and 3D printing could lead to self-evolving design-construction ecosystems [25].
- **Cloud-Based Collaboration:** AI-driven cloud platforms will enhance multidisciplinary collaboration across design, engineering, and construction domains [26].

VII. Conclusion

AI tools have fundamentally reshaped architectural practice, shifting the focus from manual drafting to intelligent, performance-driven design exploration. By combining data analytics, generative algorithms, and predictive modeling, AI empowers architects to create sustainable, efficient, and contextually adaptive environments. Although challenges in data standardization, interpretability, and resource management persist, the trajectory of AI in architecture is clear: a future of collaborative intelligence, where human creativity and machine computation converge to redefine the built environment.

Quantitative Effects of Soft Skills on Project Success: Evidence from Construction Practitioners in Nigeria

Greg Odee IKWE [1]*

ORCID 1: 0009-0006-6296-2266
[1]Bingham University Karu-Naarawa Nigeria, Faculty of Environmental Science, Department of Quantity Surveying
ikwegreg@gmail.com (Responsible Author)

Abstract

The construction industry continues to face cost overruns, project delays, rework, and client dissatisfaction, particularly in developing countries such as Nigeria. While technical skills remain essential, research increasingly highlights the critical role of soft skills—communication, leadership, teamwork, cognitive ability, interpersonal competence, and motivation—in achieving project success. However, empirical evidence on their quantitative contribution to project outcomes remains limited in developing contexts. This study examines the extent to which Nigerian construction practitioners possess soft skills and evaluates the impact of these competencies on project performance. A structured questionnaire survey was administered to 360 practitioners across different organizations, yielding 276 valid responses (76.6% response rate). In addition, a two-round Delphi exercise involving 11 project management experts was conducted to reach consensus on the most essential soft skills for effective project delivery. Data were analyzed using descriptive statistics, Mean Item Scores (MIS), ANOVA, and Pearson's correlation techniques. Results reveal that practitioners scored highest in interpersonal and motivational skills but significantly lower in cognitive abilities such as analytical reasoning and decision-making. Delphi ranking identified leadership, communication, and teamwork as the three most essential competencies throughout the project life cycle. Correlation analysis revealed a strong, positive, statistically significant relationship between soft skills and project success ($r = 0.67$, $p < 0.01$). Cognitive skills showed the strongest individual correlation with project outcomes ($r = 0.74$). The study concludes that soft skills are fundamental—not supplementary—to construction project success. It recommends integrating soft-skill capacity-building into professional development, accreditation programs, and organizational training frameworks.

Keywords: Soft skills, project success, leadership, communication, construction management, Nigeria

1. Introduction

Project success has traditionally been assessed using parameters such as cost, time, quality, and stakeholder satisfaction. Despite advancements in construction technology and project management tools, Nigerian construction projects continue to experience cost overruns, delays, and poor client satisfaction (Aibinu & Jagboro, 2002; Olaniran, 2015). These persistent challenges demonstrate the inadequacy of relying solely on technical competencies.

Soft skills—leadership, communication, teamwork, interpersonal skills, motivation, and cognitive abilities—have emerged as essential drivers of project performance. They influence team coordination, decision-making, conflict resolution, planning efficiency, and stakeholder engagement. However, their uptake and prioritization in Nigeria remain underreported. This study provides empirical evidence on soft skills and their direct contribution to project success among Nigerian construction professionals.

2. Literature Review

Soft skills refer to interpersonal, behavioural, and cognitive attributes that enable effective human interactions. According to PMI (2021), soft skills now constitute the *Power Skills* of modern project managers.

Key literature insights include:

- Leadership and communication are the most consistent predictors of project success (Crawford, 2005; Müller & Turner, 2010).
- Emotional intelligence, a component of soft skills, enhances team relationships and increases project success (Clarke, 2010; Rezvani et al., 2016).
- Cognitive skills, particularly analytical reasoning, have been linked with improved planning and execution quality.

In Nigeria, practitioners' emphasis remains largely on technical competencies, creating a skills gap in communication, leadership, and decision-making (Ameh & Odusami, 2010). This study contributes by quantifying this gap and establishing the importance of soft skills statistically.

3. Methodology

A quantitative survey design complemented with Delphi expert analysis was employed.

3.1 Questionnaire Survey

- 360 questionnaires distributed
- 276 valid responses (76.6% response rate)
- Respondents included: project managers, architects, engineers, quantity surveyors, and site supervisors
- Soft skills assessed using a 5-point Likert scale (1 = Very Low to 5 = Very High)

Seven soft skill categories were measured:

1. Leadership
2. Communication
3. Teamwork
4. Interpersonal skills
5. Motivational skills
6. Cognitive skills
7. Conflict management

3.2 Delphi Expert Survey

- 11 senior project management experts
- Two rounds of ranking
- Consensus threshold = 80% agreement
- Objective: prioritize soft skills based on importance to project success

3.3 Data Analysis

- Mean Item Score (MIS)
- Descriptive statistics
- ANOVA
- Pearson's correlation (significance level: $p < 0.01$)

4. Results

4.1 Mean Item Score (MIS) for Soft Skills

Table 1 presents the ranking of soft skills based on MIS:

Table 1: Mean Item Scores (MIS) for Soft Skills

Soft Skill	Mean Score	Rank
Leadership	4.31	1
Communication	4.26	2
Teamwork	4.18	3
Interpersonal Skills	4.11	4
Motivational Skills	4.05	5
Cognitive Skills	3.78	6
Conflict Management	3.64	7

Practitioners scored highest in leadership and communication but lowest in cognitive and conflict management skills.

4.2 Correlation Between Soft Skills and Project Success

Key correlation outcomes:

- Overall soft skills ↔ project success: $r = 0.67$ ($p < 0.01$)
- Cognitive skills showed the strongest individual correlation: $r = 0.74$
- Leadership correlated strongly with stakeholder satisfaction: $r = 0.69$

This demonstrates that practitioners with stronger soft skills consistently deliver better-performing projects.

4.3 Delphi Expert Ranking

Experts identified the following top soft skills:

Rank	**Soft Skill**
1	Leadership
2	Communication
3	Teamwork
4	Cognitive Skills
5	Interpersonal Skills
6	Motivational Skills
7	Conflict Management

5. Discussion

The results reinforce global findings that leadership and communication shape early project activities such as planning, team formation, and stakeholder engagement. The low cognitive skill rating among practitioners indicates gaps in analytical reasoning and decision-making capacity—a critical weakness in managing complex construction environments.

The strong correlation between cognitive skills and project outcomes highlights their importance in scheduling, cost estimation, risk management, and technical decision-making. The findings suggest that while practitioners exhibit strong interpersonal skills, they lack the analytical depth required for modern construction project management.

6. Conclusion

The study provides strong empirical evidence that soft skills significantly influence construction project success in Nigeria. Leadership, communication, and teamwork emerged as universally essential across project phases, while cognitive skills are the strongest statistical predictor of project performance.

Recommendations:

1. Integrate soft-skills training into professional licensing requirements.
2. Embed soft skills in university construction management curricula.
3. Develop organizational training focused on cognitive and decision-making skills.
4. Use soft-skill competency criteria during project manager recruitment.
5. Encourage CPD programmes focusing on interpersonal and leadership competencies.

Thanks and Information Note

The article complies with national and international research and publication ethics. This study complies with all national and international standards for research and publication ethics. Ethics Committee approval was not required, as the research involved non-sensitive questionnaire responses from adult professionals and did not include any personal or medical data. The author expresses sincere appreciation to the construction practitioners and expert panelists who participated in the survey and Delphi exercises. Their insights and professional contributions were instrumental to the success of this study. No external funding, grants, or financial sponsorship were received for this research. The study was conducted independently without influence from any organization or commercial entity. The author declares no conflict of interest. Abstract

Baths, which are among the significant institutions of Roman social life, constitute one of the fundamental building blocks of the Roman bathing tradition. In the Roman world, baths were not merely places for washing; they were also socializing venues that transcended bathing, positioned at the center of community life, and transformed into symbols of urban living. Unlike other nations, they were not exclusive locations for the elite but took on the identity of structures that benefited all segments of society. The Roman bath in Sebastopolis must have played a crucial role in shaping the social life of this city. The excavation of the Roman bath in Sebastopolis is among the strongest evidence of this. This study evaluates the architectural elements obtained from excavations conducted to date, identifies the components based on the findings, and attempts to propose a historical context using existing Roman bath terminology. Although the ongoing nature of the excavation and the fact that the structure was repurposed for different uses at various periods complicate its dating, the architectural layout has been analyzed in light of similar structures, revealing the innovations it contributed to Roman bath architecture.

Keywords: Black Sea, Tokat, Sulusaray, Sebastopolis, Roman Bath architecture

1. Introduction

The ancient city of Sebastopolis is located within the boundaries of today's Sulusaray district, 69 km south of Tokat province in Türkiye's Central Black Sea Region (Le Guen & Rémy, 2010). Research on the city, which dates back to the 19th century, is primarily based on the observations of travelers (Uyanık, 2023). One of these researchers, Damon, noted in his observations from the 1870s that the city contained significant ancient and Byzantine ruins, well-constructed walls, and foundations of one of the largest churches in Asia Minor to the southeast of the village. He also mentioned the presence of a Byzantine bridge to the east of the village, a Roman bridge made of volcanic stones that connects the shores of Skylax (Figure 1), massive public buildings, and an Early Christian Church with a dome decorated with golden mosaics, located about two thousand paces from the village (Amandry & Remy, 1998; Le Guen & Remy, 2010).

Figure 1. Roman Bridge over Skylax (Çekerek River)

Additionally, he suggested that there must have been an amphitheater or stadium for gladiatorial contests, as well as several temples visible on coins, indicating that the identified Roman and Early Christian remains in Sulusaray and surrounding villages reflect a high population density during Antiquity. He emphasized the city's strategic importance due to its location at a junction connecting the west-east road from Tavium in Galatia to Sebaste and then to Armenia, along with a route linking Central Anatolia to the Black Sea port of Amisos (present-day Samsun) (Cumont & Cumont, 1906; Mitford, 1966; Mitford, 1991; Amandry & Remy, 1998; Le Guen & Remy, 2010).

The Cumont brothers, who visited Sulusaray during their travels in the Black Sea region, indicated that the city began to mint coins during the Traianus period and that Hadrian visited the city in AD 124. They noted that during this period, various structures were built, including a stadium for gladiatorial contests, a portico, a gymnasium, temples, and many more (Cumont & Cumont, 1906). Magie, who conducted research on the city in the 1950s, suggested that contrary to the Cumont brothers, Hadrian may have visited the city in AD 129 and indicated that during this time, the “Hadrian Priesthood” was established in the city, with a portico built in his honor (Magie, 1950; Akşar, 2019).

Epigraphical and numismatic studies conducted in the region provide more information about the socio-economic and cultural structure of the city. It is believed that Herakles was venerated in Sebastopolis, as depicted on coins, and that there may have been a temple and a monumental cult statue dedicated to him in at least two sacred areas (Waddington et al., 1925; Amandry & Remy, 1998; Le Guen & Remy, 2010). Furthermore, it is thought that there were altars dedicated to Asklepios and Apollo for the thermal waters used in modern baths (Cumont & Cumont, 1906; Le Guen & Remy, 2010), and a dedication inscription to Zeus Pylaios suggests the existence of cults related to these gods (Cumont & Cumont, 1906; Mitford, 1991; Le Guen & Remy, 2010; Ful, 2025). In addition to these gods, it is known that Hadrian visited the city during his travels in Anatolia and that an imperial cult was established in Sebastopolis in his honor (Anderson, 1900; 1903; Amandry & Remy, 1998; Le Guen & Remy, 2010). It can be inferred that there was a highly populated community living in prosperity under the influence of Greco-Roman culture, as evidenced by the sending of a statue of Hadrian by the city's ambassadors during the opening of the Olympic Games in Athens and the fact that some of its citizens received "Roman Citizenship" (Le Guen & Remy, 2010).

Inscriptions from the Byzantine period indicate that there was a considerable Christian population in the city before AD 325, and during the Justinian period, the city was connected to the episcopate of Sebasteia. It is known that a bishop affiliated with the Sebasteia Metropolis resided in the city. Although not much is known about the city after the 9th century, tombstones belonging to Jews found in the area suggest that a Jewish population coexisted with Christians in the city (Cumont & Cumont, 1906; Amandry & Remy, 1998). After the Battle of Manzikert, it is known that a small Turkish village named Sulusaray was established over the ancient city, which is still present today.

2. Excavation Activities in the City

The first excavation activities in the city were carried out by the Tokat Museum between 1987 and 1990 as a rescue excavation (Özcan, 1991; 1992). At that time, it was unclear to which structures the excavated areas belonged, leading to these areas being labeled as "Area 1 and Area 2." In subsequent evaluations, these areas were identified as a bath and a church structure (for church studies, see Temür & Gültekin-Genç, 2023; Temür, 2023a; Temür, 2023b; Temür

et al., 2023). Excavations conducted in the area designated as "Area 3," located to the east of the district, revealed large stone blocks that were interpreted as part of a city wall. During excavation work in the south and southwest of the district, a significant amount of pottery from the Hittite and Phrygian periods was discovered in the area termed "Area 4." These findings indicate that part of the ancient city was built on a mound that dates back to the Hittite and Phrygian periods. In "Area 7," located within the borders of Ilıcak Village, approximately 2 km west of the ancient city, excavations revealed a mosaic-floored structure with an apse, featuring floral and geometric motifs dating to the Late Roman/Early Byzantine period, which had been damaged by treasure hunters (Özcan, 1991). The existing remains suggest that the ancient city of Sebastopolis spread over at least 2 km². Based on the presence of thermal waters still in use today, it has been concluded that the structure may have been an Asklepion. Following the rescue excavations conducted by the Tokat Museum, excavation activities resumed in 2010 after a 20-year hiatus; however, these lasted only for one season (Kohl et al., 2012). After a two-year break, excavations recommenced in 2013 and concluded in 2018. Excavations began again in 2021 and are still ongoing.

3. Roman Bath

One of the public structures from the Roman Period in Sebastopolis, the Roman Bath is located in the city center. The excavations carried out in the Roman Bath date back to 1987 (Özcan, 1991). During the rescue excavations conducted by the Tokat Museum between 1987 and 1990, only a small portion of the structure was uncovered, and its exact function could not be determined, leading to its registration as "Excavation Area 1" and its description as a "Columned Structure." Excavations during these years uncovered marble floor tiles, water channels, rubble stone walls, and column bases within the structure.

Figure 2. Roman Baths and Byzantine Church

In 1989, work intensified on the southern side of the building, where it was believed that materials possibly related to the roof—composed of stones and bricks—were found, indicating that the flooring and water channels extended beneath the fill soil. Although the excavation team hypothesized that this structure could be a bath based on drainage channels and a stone

basin, it was also suggested that it might belong to a much larger structure due to the columns aligned in the same direction.

In 1990, while the structure was still described as "Excavation Area 1," efforts were made to remove the fill soil measuring up to 5 meters, resulting in the discovery of stacked bricks on the ground, leading to further speculation that it could be a bath, although a definitive conclusion could not be reached (Özcan, 1992).

Figure 3-4. The Latest Situation of the Roman Baths Before the 2010 Excavations

After a 20-year hiatus, excavations resumed in 2010, during which the areas filled with soil over time were cleaned, revealing the hypocaust system. The praefurnium located at the center of the southern wall of the structure was identified, and it was concluded that the uncovered areas represented the frigidarium, tepidarium, and caldarium sections of a large Roman Bath, although only a small part had been excavated to date (Kohl et al., 2012).

Figure 5-6. The Roman Baths After the 2010 Excavations

After a two-year break, excavations in 2013 were resumed by another team. They focused on understanding the function of the praefurnium located in the center of the octagonal room identified as the caldarium (Figure 7). During leveling work, a significant quantity of ceramic shards dating to the Late Roman and Early Byzantine periods and many roof tile fragments thought to belong to the superstructure were found. Additionally, during these excavations, walls made of large cut stone blocks and mortar rubble stones extending east-west were discovered. Ongoing work revealed the arched rear facade of the praefurnium constructed from double rows of bricks. Excavations in the south of the bath shifted eastward due to the presence of modern houses, leading to work starting on the eastern side of the caldarium, where it was concluded that the area represented an alveus, characterized by walls made partially of bricks. The work resulted in the complete excavation and unveiling of the caldarium (Ful et al., 2014).

Figure 7. 2013 Excavation of the Roman Baths, Caldarium

The focus of the 2014 investigations was to determine the function of the hypocaust system, unveiled in the previous season (Figure 8). Excavations conducted to the east and north of the bath revealed late-period fire and lime layers. Further investigations on the east side of the caldarium, adjacent to the alveus revealed in the 2013 excavation season, concluded that this area was also heated by an octagonal hypocaust system, similar to that found in the caldarium. Although no portions of the bath were uncovered in the northern excavations, coins from the Byzantine period and rubble stone wall remnants from the late period were discovered (Ful et al., 2016).

Figure 8. 2014 Excavation of the Roman Baths, Hypocaust System

In 2015, investigations were conducted on the eastern section of the bath to understand the function of the octagonal area containing the brick supports of the hypocaust system, which had been partially revealed in previous seasons. Work was also carried out in the frigidarium to the west and in areas connected to the waste water channel (Figure 9).

During this excavation, a second praefurnium with a brick arch was uncovered within the octagonal structure. In the section immediately behind this area, remnants of a wall made of cut stone blocks defining the southeastern corner of the bath were also found. The coins from the Byzantine period indicated that the structure had been used in different periods (Şengül et al., 2017).

Figure 9. Roman Bath 2015 Excavation, Frigidarium

The 2016 excavation season primarily took place along the western side of the bath. During these excavations, both Roman-period pottery and Byzantine-era coins, weighing stones, and numerous roof tile fragments were found. The entrance door along the wall that forms the western boundary of the bath was later found to have been blocked with rubble stones, suggesting that the structure had been used for different functions in different periods. The

leveling work conducted in the northwest yielded ceramic finds dated to the Iron Age, indicating that earlier remains may exist beneath the structure (Ful et al., 2018).

In 2017, excavations were conducted in the eastern and northern sections of the bath. In efforts to reveal the palestra section, which was supposed to be located to the north of the bath, remnants of Byzantine and Ottoman coins and bone artifacts were found during the northern section's excavations (Figure 10). In the eastern section, work was done at a site believed to have corresponded to the city wall based on boreholes previously conducted by the Tokat Museum in the 1980s, where a surface paved with irregular stones whose function could not be completely identified was found. However, no identifiable findings related to the palestra were noted in the northern excavations.

Nevertheless, in that area, structures composed of square or rectangular rooms were uncovered, which were thought to have been used as shops or small workshops during the Byzantine period. This indicates that the bath lost its function in the later period and underwent a second phase of use for various purposes (Ful et al., 2019).

Figure 10. Roman Bath 2017 Excavation, Palestra

In the 2018 season, excavations focused primarily on the wall of cut stones defining the eastern boundary of the bath, with the aim of determining how far the stone-paved surface extended in the north-south direction. During excavations in areas showing remnants of modern housing, it was determined that the stone-paved surface continued in a north-south orientation. In both this area and in work on the southern side of the bath, ceramics, glass, weights, and coins from the Byzantine period were found. The discovery of an Ottoman coin during the excavation also underscored the irregular stratigraphy of the area. As a result, it was concluded that, considering the size of the city, this bath represents just one of the baths located within Sebastopolis (Ful, 2018)(Figure 11).

Figure 11. The Condition of the Roman Baths After the 2018 Excavations

In 2018, the excavations of the Roman Bath were paused, and in 2021 another team resumed the work. During this period, the primary objective was to uncover the eastern section of the bath. The excavations revealed the continuation of the foundations belonging to modern houses that had been demolished following expropriations. Following the removal of these foundations, Roman-period red-slipped and Byzantine-period green-yellow slipped pottery fragments, along with numerous roof tile fragments, were found within the fill soil (Figure 12).

Figure 12. Roman Bath 2021-2023 Excavation Columned Street (Road)

Subsequently, sections of the wall made of rubble stones that delineated the eastern side of the bath were also uncovered. In the area where the stone-paved surface was revealed during the 2017 excavation season, cleaning, leveling, and excavation work began, uncovering the stone-paved surface believed to have been used as a road or street (Temür et al., 2024; Temür et al., 2025).

4. Conclusion and Recommendations

The sections and dimensions of the Sebastopolis Bath represent a singular example of Roman bath architecture in Anatolia. The presence of modern buildings over the excavated areas and the issues with expropriations resulted in a slow progress of excavation and occasional halts in the work. The process, which began with rescue excavations by the Tokat Museum in 1987, has seen the structure excavated for a prolonged period by different teams using varying methods. The incomplete state of the excavations, along with the additions made during different periods for varying purposes, presents another challenge. The involvement of various teams, alongside brief excavation periods and long interruptions, poses significant problems for the excavation overall. These ongoing processes complicate the dating of the structure and lead to differing chronological proposals. However, considering the architectural plan and the Greco-Roman style that merges Hellenistic and Italic elements, it can be asserted that the bath was likely constructed in the 2nd century CE and was utilized for various functions up until the late Byzantine period. Establishing a definitive date and accurately identifying the phases experienced by the bath will only be possible once all sections buried under modern structures have been uncovered.

Utilization of Restorative Design Features in The Design Proposal for Resort Centre in Abuja, Nigeria

Ahmed T. KASIM [1*]

[1] Department of Architecture, Federal University of Technology Minna
kasimxahmed@gmail.com **(**Responsible Author)

Abubakar D. ISAH [2]

[2] Department of Architecture, Federal University of Technology Minna

Abstract

In today's fast-paced world, where stress and mental fatigue are increasingly common, restorative environmental design has become crucial in shaping resort spaces that promote psychological recovery and connection to nature. This study investigates the influence of biophilic interventions and spatial configuration on restorative experience within Nigerian resort environments. The research adopts a quantitative methodology, drawing on responses from a varied cohort of resort users reached through multiple digital platforms. Data were analysed using descriptive and inferential statistical methods, including correlation, multiple regression, and exploratory factor analysis (EFA) using PCA with Varimax rotation to examine relationships among Restorative Principles Evaluation (RPE), Biophilic Interventions (BIRE), and Prospect–Refuge Restorative (PRR) constructs. The results revealed strong positive correlations between RPE and both BIRE ($r = 0.763$, $p < 0.01$) and PRR ($r = 0.632$, $p < 0.01$), with BIRE exerting the greater predictive effect on restorative perception ($\beta = 0.659$, $p < 0.001$), while PRR contributed additional but smaller significance ($\beta = 0.138$, $p = 0.034$). The combined model accounted for 59% of the variance ($R^2 = 0.590$), demonstrating that natural elements such as daylight, vegetation, water features and natural materials along with spatial qualities like legibility, prospect and refuge, jointly enhance user well-being and restorative appraisal. Furthermore, demographic factors such as age and frequency of resort use moderated perceptions of restoration, highlighting the importance of user diversity in design evaluation. The study concludes that contextually grounded biophilic design, integrating both natural and spatial restorative features, is essential for fostering relaxation, comfort and psychological well-being in resort settings. It recommends that architects and designers prioritize daylight access, greenery, water features and coherent spatial organization to create environments that harmonize human experience with Nigeria's ecological and cultural context.

Keywords: Abuja, Resort Centre, biophilic design, spatial restorative

Introduction

The 21st century's rapid urbanization, digital saturation, and demanding lifestyles have intensified global levels of stress, anxiety and mental fatigue, underscoring the growing need for environments that foster genuine rest, recovery, and psychological well-being (Ventriglio et al., 2021; Magomedova and Fatima, 2025; Basu et al., 2019; Schumann et al., 2022; Pham and Sanocki, 2024). This shift has redefined the tourism and hospitality industry, as travellers increasingly seek transformative, wellness-oriented experiences that promote reconnection with nature and holistic rejuvenation (Smith and Puczkó, 2016; Zhong et al., 2021). Grounded in environmental psychology, Kaplan and Kaplan's Attention Restoration Theory (ART) and Ulrich's Stress Reduction Theory (SRT) explain how natural environments restore attention and reduce stress through cognitive and physiological mechanisms (Huang et al., 2020; Joye et al., 2018; Jimenez et al., 2021; Reese et al., 2021). These theories inform restorative and biophilic design principles, which integrate nature into architecture through direct, indirect, and spatial connections to enhance human well-being (Ryan et al., 2014; Browning et al., 2020; Brielmann et al., 2022; Lefosse et al., 2023). While such design approaches have demonstrated measurable benefits in healthcare, educational, and corporate settings, their application within hospitality particularly resort design remains limited, despite resorts' inherent potential to

transcend luxury and serve as immersive environments that actively facilitate mental and physiological restoration (Aristizabal et al., 2021; Lei et al., 2022; Akinyemi et al., 2024).

Despite the increasing demand for wellness-oriented travel, many resorts still emphasize luxury and aesthetics over restorative design strategies that support well-being and sustainability. This neglect reflects limited application of principles from Attention Restoration Theory (ART) and Stress Reduction Theory (SRT), which highlight how nature-based design can reduce stress and enhance mental health (Huang et al., 2020; Joye et al., 2018; Jimenez et al., 2021). Consequently, opportunities to create truly restorative and health-supportive environments are often missed, diminishing guest satisfaction and retention. Moreover, many designs fail to consider cultural, climatic and ecological contexts, resulting in generic and disconnected spaces. This study therefore examines how context-responsive biophilic interventions such as natural materials and symbolic connections with nature can be integrated into resort design to foster holistic restoration and sustainability. Thus, the study aimed to assess the utilization of restorative design features towards the design of resort centre in Abuja, Nigeria. This study is justified by growing evidence that restorative design features such as natural light, greenery, and water elements enhance guest well-being, reduce stress, and support sustainable hospitality practices (Lehto et al., 2019; Ifebi et al., 2024). Rooted in biophilic design principles, it emphasizes reconnection with nature to promote holistic wellness (Panagopoulos et al., 2020; Hung and Chang, 2024). By developing a framework for integrating these elements within diverse resort contexts, the research aims to enhance guest experiences while advancing environmental stewardship and sustainability (Suess et al., 2024; Ajeuyjo et al., 2025). This study examines the application of biophilic design strategies in developing a restorative resort centre tailored to Abuja's cultural and environmental context, enhancing well-being, promoting wellness tourism, and providing evidence-based insights for sustainable, health-oriented hospitality design in Nigeria and beyond (Huang et al., 2020; Joye et al., 2018).

Background Study

Restorative design has gained prominence in contemporary architecture and hospitality as a response to the global rise in wellness and experiential tourism, which emphasizes holistic health, cultural engagement, and meaningful connection with nature (Zhong et al., 2021; Dillette et al., 2021; Backman et al., 2023). Integrating biophilic principles, environmental sustainability, and user-centred spaces, restorative design enhances guest well-being, reduces stress, and fosters deeper connections with the natural environment (Purani and Kumar, 2018; Hung and Chang, 2024; Martínez et al., 2021). Resort centres, often located in serene natural settings, are uniquely suited for applying these principles, serving as ideal environments to study how architectural, landscape, and spatial elements can be optimized to promote relaxation, attention restoration, and holistic rejuvenation. As wellness tourism continues to grow, such resorts not only fulfil the demand for health-enhancing experiences but also advance sustainability and restorative design practices in hospitality (He et al., 2021; Singh et al., 2021; Sachin and Dash, 2022).

Theoretical Foundations of Restorative Environments

Attention Restoration Theory (ART) developed by Kaplan and Kaplan (1989), posits that exposure to natural environments replenishes depleted cognitive resources, forming the basis for restorative resort design (Pham and Sanocki, 2024; Tipler and Ruddell, 2025). Its four key components which are being away, extent, fascination, and compatibility guide how biophilic elements like greenery, water, and spatial coherence promote relaxation, mental recovery, and

alignment between user needs and environmental experience (Ohly et al., 2016; Zhang et al., 2021; Yusli et al., 2021; Basu et al., 2019; Marois et al., 2021).

The Perceived Restorativeness Scale (PRS), grounded in Kaplan and Kaplan's (1989) Attention Restoration Theory, assesses how individuals perceive an environment's ability to restore cognitive resources through dimensions such as being away, fascination, extent, and compatibility (Hartig et al., 1997; Ratcliffe, 2021). Widely applied across urban, workplace, and healthcare settings, PRS findings reveal that natural elements especially vegetation, water, and nature sounds all enhance restorative experiences differently, offering designers data-driven insights for creating more health-promoting environments despite cultural and perceptual limitations (Li et al., 2022; San Juan et al., 2017; Lyu et al., 2022; Yildirim et al., 2023).

Stress Reduction Theory (SRT), developed by Ulrich (1983), emphasizes humans' innate, evolution-based tendency to respond positively to unthreatening natural environments, which evoke calmness, pleasure, and reduced physiological stress indicators such as heart rate and cortisol levels (Ulrich et al., 1991; Yao et al., 2021; Geneshka et al., 2021). It highlights the rapid, often unconscious, restorative effects of nature exposure, with studies showing quicker stress recovery in natural settings than in built environments devoid of natural elements (Elsadek et al., 2019; Ulrich, 2023).

The Biophilia Hypothesis, introduced by Wilson (1984) and expanded by Kellert (1993), posits an innate human affinity for nature rooted in evolutionary adaptation, forming the foundation for biophilic design that integrates natural elements, materials, and spatial patterns to enhance well-being (Lencastre et al., 2023; Divya and Naachimuthu, 2020; Barragan et al., 2023). Building on this, Ryan et al. (2015) identified three biophilic design patterns such as Nature in the Space, Natural Analogues and Nature of the Space. For this study, the Natural Analogues category, emphasizing materials like wood and stone and biomorphic patterns, is central, as research shows such indirect nature representations effectively reduce stress, improve cognition, and enhance well-being (Peters and D'Penna, 2020; Bolten and Barbiero, 2020; Kwak and Choi, 2025).

Individual perceptions of biophilic design vary based on personal experiences, cultural background, and cognitive preferences, influencing how people connect with natural elements such as light, water, or materials (Berto et al., 2018; To and Grierson, 2024; Hung and Chang, 2022). Recognizing these subjective differences is essential for creating restorative environments that cater to diverse user needs rather than adopting a one-size-fits-all approach (Plotnikova, 2021).

In addition to ART, SRT, and Biophilia, the Prospect-Refuge Theory (Appleton, 1975) emphasizes the human preference for spaces that balance openness and protection, fostering feelings of safety and relaxation (Dosen and Ostwald, 2016; Suess et al., 2024). Similarly, Place Attachment Theory highlights the emotional and cognitive bonds individuals form with meaningful environments, enhancing identity, belonging, and well-being (Inalhan et al., 2021; Ilovan and Markuszewska, 2022). Together, these theories provide a comprehensive framework for designing resort environments that integrate natural elements, spatial harmony, and cultural connection to promote psychological restoration.

Restorative and sustainable design principles intersect through strategies that enhance both environmental performance and human well-being. Passive design approaches, sustainable

materials, and efficient water management reduce energy use, improve indoor air quality, and promote ecological balance (Grimm et al., 2023). By preserving biodiversity and fostering a connection to natural systems, sustainable resort design supports a holistic model of wellness that benefits both people and the environment (Marselle et al., 2021; Russo and Cirella, 2020).

Resort Centre Evolution, Architecture and Design

The evolution of resort architecture reflects a long-standing recognition of the restorative relationship between humans and nature. From ancient Roman baths and Greek healing sanctuaries that integrated natural elements for wellness (Brodie, 2021; Pavli et al., 2024) to Renaissance spa towns and formal gardens emphasizing beauty, contemplation, and health (UNESCO World Heritage Centre, n.d.; Sillmann et al., 2024), resorts have historically embodied environments of relaxation and renewal. The 18th and 19th centuries saw the rise of nature-oriented retreats for the leisure class, influenced by Romantic ideals celebrating the emotional and spiritual power of nature (Wedekind, 2021; Levytska, 2024). By the 20th and 21st centuries, advances in psychology and environmental science led to the intentional incorporation of restorative and biophilic design principles into resort planning (Ryan et al., 2014; Sachin and Dash, 2022). Contemporary resorts now embrace sustainability, wellness, cultural authenticity, and advanced technology to enhance well-being and connection to nature (Papallou et al., 2024; Dillette et al., 2021; Ukpabi, and Karjaluoto, 2017). These trends collectively demonstrate how resort design continues to evolve toward holistic, health-centred, and environmentally responsive spaces aligned with restorative design principles.

Designing successful resort centres requires a holistic approach that balances environmental sensitivity, functionality, and guest experience. Effective site planning and landscape integration must respect topography, climate, and ecology to enhance restorative potential (Suta et al., 2021; Baranova, and Kegeyan, 2018). Clear circulation and intuitive wayfinding reduce cognitive stress, while thoughtful programming ensures diverse amenities that promote relaxation, social interaction, and engagement with nature and culture (Jiang et al., 2022; Miller and Rafia-Tracy, 2025). The architectural journey from arrival to departure should evoke comfort, sensory delight, and emotional connection (Shahid and Paul, 2022). A strong sense of place achieved through local materials, cultural expression, and contextual design enhances authenticity and guest attachment (Smith and Ram, 2017; Cheer et al., 2022). Additionally, long-term scalability and adaptability are vital to ensure cohesive growth and sustainable operations (Deroos, 2012; Wu et al., 2017).

The Resort Industry in Nigeria

The resort industry in Nigeria is an emerging yet underdeveloped segment of the country's tourism and hospitality sector, characterized by private sector dominance, limited government participation, and growing domestic demand (Esu, 2015; Ajani and Kalu, 2017; Bassey, 2015). Nigerian resorts range from coastal and nature-based facilities to leisure, recreational and conference-oriented establishments, reflecting the nation's diverse geography and cultural richness (Uduma-Olugu and Onukwube, 2015; Mohammed, 2022; Sayyora and Diyora, 2020). The primary market comprises domestic tourists, diaspora Nigerians, and a smaller segment of international visitors (Yusuff and Aliu, 2019; Liu et al., 2019). However, challenges such as inadequate infrastructure, security issues, financing constraints, skill shortages, and inconsistent policy frameworks continue to impede growth (James and Essien, 2019; Kolawole et al., 2020; Ugwukah and Obomanu, 2020). Despite these limitations, Nigeria's abundant natural resources, cultural diversity, and expanding local market present significant

opportunities for developing eco-tourism, wellness tourism, and culturally immersive resort experiences that align with global trends in restorative and sustainable travel (Adeola and Evans, 2019; Adeola et al., 2020).

Theoretical framework

The theoretical framework of this study is rooted in Wilson's (1984) Biophilia Hypothesis and structured around Kellert et al.'s (2008**)** biophilic design framework, which emphasizes *symbolic connections with nature* through the use of natural materials, colours and biomorphic forms that stimulate emotional balance and cognitive restoration. It is further reinforced by complementary theories Attention Restoration Theory (Pham and Sanocki, 2024**),** Stress Recovery Theory (Ulrich, 2023**),** Prospect-Refuge Theory (Appleton, 1975**),** and Place Attachment Theory (Inalhan et al., 2021**)** collectively providing a comprehensive foundation for understanding how nature-inspired environments enhance psychological comfort and overall well-being.

Despite extensive evidence supporting biophilic design's restorative potential, existing studies have predominantly focused on *direct nature interactions* such as vegetation, daylight and outdoor views, while its *symbolic dimension* remains insufficiently explored, particularly within hospitality environments in the Global South. Addressing this gap, the present study investigates how resonant natural materials and forms can be strategically integrated into Nigerian resort design to serve as restorative and health-supportive features where direct engagement with nature is limited (Kellert et al., 2008; Lencastre et al., 2023).

Methodology

This study adopts a quantitative research approach to collect and statistically analyse numerical data, enabling the identification of patterns, relationships and differences among variables (Assaf and Tsionas, 2019; Andayana and Pitanatri, 2023). A cross-sectional survey design will be used to gather data at a single point in time from participants such as resort guests or architects (Punch, 2013; Nwabuko, 2024), while a correlational design will examine the strength and direction of relationships between restorative design features and user perceptions like satisfaction and perceived restorativeness (Cohen, Manion and Morrison, 2002; Gamage, 2025). This approach supports objective measurement and potential generalization of findings within the resort context. Data for this study will be collected through structured online questionnaires distributed to resort guests who have stayed at least one night, enabling efficient and standardized data gathering on perceptions of restorative design features and well-being across diverse locations (Dillman et al., 2014; Altaf et al., 2022; Andayana and Pitanatri, 2023). Utilizing online platforms such as TripAdvisor, Booking.com, TikTok, WhatsApp, Facebook, and email ensures convenience, cost efficiency, and confidentiality while addressing the logistical challenges of surveying a transient population. The questionnaire will employ validated scales to assess perceived restorativeness and evaluate the presence and quality of restorative design elements in resort environments.

The questionnaire comprises eighteen (18) questions across four structured sections combining multiple-choice and Likert-scale formats to capture comprehensive data. The first section gathers demographic information (Gifford, 2007; Creswell and Creswell, 2017), while the second measures perceived restorativeness using the Perceived Restorativeness Scale (PRS) by Hartig et al. (1997). The third section evaluates biophilic design features through a modified Biophilic Environmental Variables (BEVs) framework adapted from Asim and Shree (2019)

and Browning et al. (2015), and the fourth assesses the spatial balance of prospect and refuge in resort environments (Dosen and Ostwald, 2016; El-Metwally et al., 2021; Bornioli et al., 2023). This four-part instrument enables a systematic analysis of restorative design strategies and their relationship to perceived restorativeness in resort settings. The study targets adults aged 18 and above who have stayed at resorts for at least one night, ensuring participants possess direct experience with resort environments and design features. Individuals without such experience are excluded. A random sampling method will be used to ensure representativeness and reduce selection bias, giving each eligible participant an equal chance of selection (Creswell and Creswell, 2017; Mweshi and Sakyi, 2020). This approach strengthens the statistical validity and generalizability of the findings to the broader population of resort guests (Field, 2018; Teeroovengadum and Nunkoo, 2018).

Ethical standards were upheld by ensuring participant anonymity through an online survey that excluded personal identifiers and included an information sheet explaining the study's purpose, voluntary participation, and right to withdraw (Orb et al., 2001; Emami et al., 2019; Collis & Hussey, 2020; Kumar, 2018). Reliability and validity were reinforced through the use of university-approved sources, APA (7th edition) citation standards, and a structured questionnaire tested for internal consistency using Cronbach's alpha (Cronbach, 1951; Sekaran and Bougie, 2016). Pre-testing with academic experts and select respondents ensured clarity and alignment with established research, enhancing both methodological rigor and the validity of the study's conclusions (Malhotra and Dash, 2020; Dauda et al., 2023).

Results and Discussion

This chapter presents and analyses both quantitative and qualitative data to examine how biophilic design and spatial configuration contribute to restorative experiences within resort environments. Quantitative data were analysed using descriptive and inferential statistics, while qualitative insights provided contextual depth. A structured online questionnaire distributed via platforms such as TripAdvisor, Booking.com, WhatsApp, and Facebook yielded 235 responses, of which 227 were valid for analysis. Prior to analysis, a reliability test using Cronbach's Alpha was conducted to confirm internal consistency and the reliability of the measurement scales and the results are presented in Table 4.1 (Rak, and Wrześniowski, 2023).

Table 4.1. Reliability statistics (Source: Author's field work, 2025)

Scale	Items	Cronbach's Alpha (α)	Interpretation
Restorative Principles Evaluation (RPE)	11	0.735	Acceptable internal consistency
Biophilic Interventions & Restorative Experience (BIRE)	17	0.798	Acceptable-to-Good internal consistency (borderline good)
Prospect–Refuge Restorative (PRR)	13	0.707	Acceptable internal consistency

The Cronbach's Alpha values ranged between 0.707 and 0.798. This indicated an acceptable internal consistency across all constructs. The Biophilic Interventions scale (α = 0.798) recorded the highest reliability, followed by Restorative Principles Evaluation (α = 0.735) and Prospect–Refuge Restorative (α = 0.707). According to George and Mallery (2024), values

above 0.7 are considered satisfactory for social science research. Hence, all scales were reliable for subsequent statistical analyses.

4.2.2 Demographic Data Presentation

To understand the composition of respondents, demographic data such as age, gender, occupation, frequency of resort visits, and purpose of stay were summarized. The results are presented in Table 4.2.

Table 4.2: Demographic characteristics of respondents (Source**:** Author's field work 2025)

Variable	Category	Frequency	Percent	Valid Percent	Cumulative Percent
Age	18 – 29	54	23.8	23.8	23.8
	30 – 39	77	33.9	33.9	57.7
	40 – 49	50	22.0	22.0	79.7
	50 and above	46	20.3	20.3	100.0
Total		227	100.0	100.0	
Gender	Male	117	51.5	51.5	51.5
	Female	110	48.5	48.5	100.0
Total		227	100.0	100.0	
Occupation	Business/Corporate	58	25.6	25.6	25.6
	Government Employee	93	41.0	41.0	66.5
	Self-employed	76	33.5	33.5	100.0
Total		227	100.0	100.0	
Frequency of Resort Visits	Rarely	71	31.3	31.3	31.3
	Occasionally	115	50.7	50.7	81.9
	Frequently	41	18.1	18.1	100.0
Total		227	100.0	100.0	
Purpose of Stay	Business	62	27.3	27.3	27.3
	Leisure/Vacation	106	46.7	46.7	74.0
	Conference/Events	59	26.0	26.0	100.0
Total		227	100.0	100.0	

The results show that respondents aged 30–39 years formed the largest group (33.9%), followed by those aged 18–29 years (23.8%). The gender distribution was nearly balanced, with males representing 51.5% and females 48.5%. In terms of occupation, 41% were government employees, 33.5% were self-employed, and 25.6% worked in corporate or business organizations. Most participants (50.7%) reported visiting resorts occasionally, primarily for leisure or vacation purposes (46.7%)**,** followed by business trips (27.3%) and conference or event attendance (26.0%)**.** This demographic composition provides diverse perspectives for evaluating restorative experiences in resort environments.

Factor Analyses

Exploratory Factor Analysis (EFA) was conducted to identify the underlying dimensions of the three main constructs: Restorative Principles Evaluation (RPE), Biophilic Interventions (BIRE), and Prospect–Refuge Restorative (PRR). Principal Component Analysis (PCA) with Varimax rotation was used to determine the core factors that explain each construct.

Factor Analysis of Restorative Principles Evaluation (RPE)

Table 4.3 presents the factor analysis results for the RPE scale, showing sampling adequacy, total variance explained, and identified factors.

Table 4.3. EFA Summary for RPE (Source: Author's field work 2025)

Statistical Test / Factor Summary	Value	Interpretation
KMO Measure of Sampling Adequacy	0.748	Data adequate for factor analysis
Bartlett's Test of Sphericity	$\chi^2 = 439.258$, df = 55, $p < 0.001$	Correlation matrix appropriate
Number of Components Extracted	4	Meets Eigenvalue > 1 criterion
Cumulative Variance Explained	61.19 %	Adequate total variance
Range of Communalities	0.494 – 0.751	Acceptable shared variance
Identified Components	Being Away, Fascination, Extent, Compatibility	Consistent with theoretical model

The four extracted components align with the key restorative factors proposed by Kaplan and Kaplan (1989): Being Away, Fascination, Extent and Compatibility. Together, they explain 61.19% of the total variance, confirming the validity of the RPE scale in capturing core restorative experiences. This finding addresses the research objective, which aimed to evaluate restorative design principles and their relevance to resort environments.

Factor Analysis of Biophilic Interventions (BIRE)

The BIRE construct was tested to confirm its internal structure and relationship to biophilic design theory. Table 4.4 summarizes the factor extraction results.

Table 4.4. EFA Summary for BIRE (Source: Author's field work, 2025)

Statistical Test / Factor Summary	Value	Interpretation
KMO Measure of Sampling Adequacy	0.807	Data suitable for factor analysis
Bartlett's Test of Sphericity	$\chi^2 = 900.818$, df = 120, $p < 0.001$	Correlation matrix appropriate
Number of Components Extracted	4	Meets Eigenvalue > 1 criterion
Cumulative Variance Explained	54.62 %	Adequate total variance
Range of Communalities	0.399 – 0.764	Moderate to strong shared variance
Identified Components	Natural Light, Greenery and Vegetation, Water Features, Natural Materials and Forms	Aligned with biophilic theory

These four distinct dimensions consistent with biophilic design theory which are natural light, greenery and vegetation, water features, natural materials and forms. Together, these factors explained 54.62 % of the total variance and affirms the construct validity of biophilic interventions in resort contexts. This outcome addresses the research objective to assess the role of specific biophilic interventions.

Factor Analysis of Prospect–Refuge Restorative (PRR)

The PRR construct was analysed to explore how spatial layout and configuration influence restorative experience. Table 4.5 presents the results.

Table 4.5. EFA Summary for PRR (Source: Author's field work (2025)

Statistical Test / Factor Summary	Value	Interpretation
KMO Measure of Sampling Adequacy	0.696	Marginal but acceptable
Bartlett's Test of Sphericity	$\chi^2 = 576.807$, df = 78, $p < 0.001$	Correlation matrix appropriate
Number of Components Extracted	4	Meets Eigenvalue > 1 criterion
Cumulative Variance Explained	57.83 %	Adequate total variance
Range of Communalities	0.485 – 0.679	Moderate shared variance
Identified Components	Legibility and Prospect, Refuge and Control, Complexity and Coherence, Restorative Spatial Outcomes	Consistent with Prospect–Refuge theory

The four extracted factors, Legibility and Prospect, Refuge and Control, Complexity and Coherence, and Restorative Spatial Outcomes, represent essential qualities of environmental legibility and safety. These four factors explained 57.83% of the total variance, confirming the multidimensional nature of spatial experience in restorative design.

Correlation Analysis between Biophilic Features, Spatial Configuration and Restorative Experience

A Pearson correlation analysis was conducted to examine the relationships among Biophilic Interventions (BIRE), Prospect–Refuge spatial configuration (PRR), and Restorative Experience (RPE). The results are displayed in Table 4.6.

Table 4.6: Pearson Correlation Matrix

Variables	RPE mean	BIRE mean	PRR mean
RPE mean	1	0.763**	0.632**
BIRE mean	0.763**	1	0.748**
PRR mean	0.632**	0.748**	1

Source: Author's field work (2025)

The correlation coefficients show strong and positive relationships among all constructs. The association between RPE and BIRE (r = 0.763) is particularly strong, indicating that natural features significantly contribute to restorative experiences. The RPE–PRR relationship

(r = 0.632) shows that spatial design also plays a meaningful role. The strong correlation between BIRE and PRR (r = 0.748) further suggests that biophilic design often complements spatial qualities that enhance restoration.

Interrelationship between RPE, BIRE and PRR

The analysis revealed strong positive relationships among Restorative Experience (RPE), Biophilic Interventions (BIRE), and Prospect–Refuge (PRR), highlighting their combined role in shaping restorative perceptions within resort environments. RPE showed a robust correlation with BIRE ($r = .763$, $p < 0.01$) and a moderate correlation with PRR ($r = .632$, $p < 0.01$), indicating that both natural elements and spatial balance enhance perceived restoration. Regression results confirmed BIRE as the strongest predictor ($\beta = .659$, $p < 0.001$), while PRR contributed modestly but significantly ($\beta = .138$, $p = 0.034$). A strong interrelationship between BIRE and PRR ($r = .748$, $p < 0.01$) further suggested that resorts rich in biophilic qualities often exhibit well-structured, prospect-refuge spatial characteristics. Overall, the multiple regression model ($R^2 = 0.590$, $p < 0.001$) demonstrated that integrating biophilic and spatial strategies substantially enhances restorative experiences in resort design.

The results demonstrate that restorative experience (RPE) in resort environments is influenced by two key pathways: biophilic content—comprising daylight, vegetation, water, and natural materials and spatial configuration defined by legibility, enclosure and coherence. Reliability and factor analyses confirmed consistent dimensions across RPE, BIRE, and PRR, validating their theoretical structure. Strong positive correlations were found between RPE,

BIRE (r = 0.763), and PRR (r = 0.632), with a notable link between BIRE and PRR (r = 0.748), indicating synergistic effects between natural and spatial features. Regression analysis showed

that biophilic interventions (β = 0.659) exerted a greater influence on restoration than prospect–refuge qualities (β = 0.138), explaining 59% of the variance. These findings align with Attention Restoration Theory (Kaplan and Kaplan, 1989), Prospect–Refuge Theory (Appleton, 1975), and biophilic design principles (Kellert et al., 2008), underscoring their combined role in promoting restorative experiences.

Conclusions

This study concludes that restorative experiences in resort environments are shaped by the integration of biophilic interventions such as daylight, vegetation, water features and natural materials and spatial configuration features like legibility, prospect, refuge and coherence. The combined influence of these variables explained nearly 60% of the variance in restorative perception, confirming their joint role in enhancing mental well-being and user satisfaction. Aligning with biophilic design and restorative environment theories (Kellert et al., 2008; Kaplan and Kaplan, 1989; Appleton, 1975), the study provides an empirically validated framework (RPE, BIRE and PRR) for assessing restorative quality in hospitality design. It recommends prioritizing natural materials, balanced spatial layouts and locally responsive design approaches to strengthen human–nature connection and sustainability. Future research should incorporate physiological and post-occupancy assessments such as HRV and biometric analyses to objectively validate restorative outcomes and optimize biophilic patterns for Nigerian contexts.

Abstract

The COVID-19 pandemic posed significant health and social challenges, impacting construction and social environments globally. This study reviewed recovery measures in construction companies and empirically assessed a comparative framework for sustainable adaptation of COVID-19 recovery roadmaps to enhance resilience in Nigeria's construction sector. Conducted in Abuja, Nigeria's capital, the research employed a sequential mixed-methods design with a purposive sample of 20 experts, including policymakers, contractors, professionals, and academics ensuring diversity through snowball sampling. Qualitative analysis used NVivo 14 for coding and theme development, with triangulation to strengthen credibility. The socio-demographic data of participants provided context for interpretation. Findings reveal that global COVID-19 recovery roadmaps converge on risk assessment, digital integration, and sustainability. Recommendations include implementing e-portals and legal mandates for Public-Private Partnerships to streamline approvals, adopting hybrid digital tools like offline BIM with solar backup, and establishing vocational hubs for digital upskilling of informal workers. Additionally, professional bodies such as the Nigerian Institute of Building and academics should pilot multi-regional strategies to validate and test roadmap efficacy, thus fostering resilient recovery in Nigeria's construction industry.

Keywords: COVID-19, roadmaps, resilience, e-portals, construction industry, Nigeria

1. Introduction

The COVID-19 pandemic has brought along an untold hardship on humanity presenting itself as both health and human crisis, and has had direct or indirect effects on people's working and social environments (Idakwo et al., 2022; Umar, 2022). The shutting down restrictions were observed due to the pandemic's adverse bearing on all sectors, including construction companies, manufacturing, Agri-allied industries, and finance (Gültekin & Sarı, 2022). This issue caused acute economic contraction in both developing and industrialized nations (Wang et al., 2020). Before the emergence of Covid-19, tackling hunger and insecurity among the Nigerian populace has been one onerous task confronting the Nigerian government (Idakwo et al., 2022). This trend nosedived even further as the country was thrown into recession in 2020 due to the impact of the pandemic; in a nutshell, the pandemic unleashed unprecedented

disruptions across global economies (Idakwo & Oladimeji, 2024), with the Nigerian construction sector facing severe setbacks, including project suspensions, financial distress, and workforce reductions (Aigbavboa et al., 2023). Since the first case of Coronavirus was reported in Nigeria in early 2020, an unprecedented economic situation has followed, giving rise to increasing prices of economic good including construction materials in the country (Idakwo et al., 2022). Construction materials in Nigeria were under serious threat and prices have been rising drastically, and in most cases recording almost double due to the impact of economic lockdown and social distancing imposed by various governments as measures to curtail the spread of Coronavirus. The aim of this study is to assess global Covid-19 recovery roadmaps for enhancing resilience in Nigeria's construction sector and highlight a comparative framework for sustainable adaptation.

2. Materials and Methods

The study was carried out in Abuja, the Federal Capital Territory (FCT) of Nigeria, selected for its representativeness of the national construction industry's recovery dynamics. Its diverse stakeholder ecosystem, encompassing government agencies, multinational contractors, and professional bodies, facilitates access to key informants, while its economic centrality, contributing significantly to national Gross Domestic Product through construction activities, ensures findings are extrapolable to other Nigerian regions facing similar oil-dependent fiscal constraints and infrastructural deficits (Ebekozien & Aigbavboa, 2023). Data collection was confined to Abuja to optimize logistical feasibility without compromising contextual depth.

A sequential mixed-methods design was utilized, integrating qualitative content analysis of global literature with semi-structured expert interviews, followed by a synthetic phase to derive a tailored roadmap. A purposive sample of approximately 20 experts was targeted, determined by the principle of data saturation, wherein recruitment ceases upon redundancy in emergent themes (Guest et al., 2006). This sample size balances depth with practicality, drawing from qualitative research norms where 15–30 participants suffice for thematic richness in specialized domains (Braun & Clarke, 2021). Inclusion criteria encompassed at least 10 years of relevant experience in Nigeria's construction sector and direct involvement in COVID-19 response or recovery initiatives. Participants were stratified across stakeholder categories (e.g., 5 policymakers, 5 contractors, 5 experts/professionals, 5 academics) to ensure representational diversity, with snowball sampling employed to access hard-to-reach informants. Analysis proceeded qualitatively, utilizing NVivo software (Version 14) for systematic coding and theme generation, with triangulation enhancing credibility.

3. Findings and Discussion

The socio-demographic characteristics of the 20 expert interviewees in Table 1 provide a foundational lens for interpreting the qualitative insights, reflecting a diverse yet representative cross-section of Nigeria's construction stakeholders. Participants were purposively selected from Abuja, encompassing policymakers (n=5), contractors (n=5), construction professionals/experts (n=5), and academics (n=5), with data saturation achieved after the 18th interview, as subsequent responses yielded redundant themes.

Demographically, the sample skewed male (75 per cent, n=15), though female representation (25 per cent, n=5) offered nuanced perspectives on inclusive recovery. Ages ranged from 35 to 62 years (mean=48.2, SD=7.4), with the majority (60 per cent, n=12) aged 45–55, indicative of mid-to-senior career stages where experiential depth informs strategic insights. Professional

experience averaged 18.6 years (range=12–32, SD=5.1), enabling rich discussions on recovery dynamics. Educationally, all held at least a bachelor's degree in construction-related fields, with 55 per cent (n=11) possessing master's or doctoral qualifications. Organisational affiliations varied: 40 per cent (n=8) from public sector entities, 35 per cent (n=7) from private firms, and 25 per cent (n=5) from academia/professional bodies. Geographically, while all were Abuja-based, 65 per cent (n=13) had multi-regional project exposure, broadening applicability. These characteristics underscore the sample's robustness, with balanced representation across categories fostering exhaustive insights into contextual adaptations, such as hybrid digital solutions for informal workers and policy reforms for oil volatility.

Table 1: Socio-Demographic Profile of Respondents

Characteristics	Category	Frequency (n=20)	Percentage (%)
Gender	Male	15	75
	Female	5	25
Age group (years)	35–44	8	40
	45–55	12	60
	56–62	0	0
Professional experience	12–20	12	60
	21–32	8	40
Highest qualification	Bachelor's	9	45
	Master's/Doctoral	11	55
Stakeholder category	Policymakers	5	25
	Contractors	5	25
	Professionals/Experts	5	25
	Academics	5	25
Multi-regional exposure	Yes	13	65
	No	7	35

Analysis of existing COVID-19 recovery roadmaps in the global construction industry

This section synthesizes global recovery roadmaps from the literature, employing NVivo thematic coding to extract core elements such as phases, strategies, metrics, and limitations depicts in Table 2. The analysis distils four key roadmaps into a single comparative table, facilitating lucid comparison while discussing alignments and divergences. This approach reveals a predominant emphasis on dynamic capabilities and risk mitigation, aligning with resilience theory (Folke et al., 2016) but diverging in contextual specificity e.g., China's centralized stimuli contrast U.S. firm-level agility.

Table 2: Comparative Synthesis of Global COVID-19 Recovery Roadmaps

Roadmap/ Source	Key Phases/Structure	Core Strategies	Metrics/KPIs	Strengths	Limitations
U.S. (Chih et al., 2022)	Sensing, Seizing, Reconfiguring	Digital tools (BIM), health protocols, supply diversification	Organizational agility scores, cost variance	Firm-level agility, empirical grounding	Large-firm bias, short timeframe, macro neglect
China (Guo et al., 2023)	Assessment, Deployment, Feedback	Innovation, government subsidies, workforce safeguards	25 KPIs (e.g., ROI, safety incidents)	Quantitative prioritization (AHP), holistic CSFs	Small sample, China-specific, descriptive
China (Wang et al., 2022)	Risk ID, Formulation, Monitoring	4M1E-based (e.g., modular prefab, incentives)	Qualitative assessments (e.g., efficiency gains)	Granular risk decomposition, project-specific	No stats validation, infrastructure focus
Malaysia (Gamil et al., 2022)	Mitigation, Recalibration, Reform	Health/safety, tech adoption, policy advocacy	Thematic outcomes (e.g., productivity recovery)	Practitioner insights, multi-domain	Generalized, no longitudinal eval, regulatory-centric

Thematically, roadmaps converge on phased structures: sensing/identification (e.g., risk assessment), seizing/implementation (e.g., digital adoption), and reconfiguring/evaluation (e.g., sustainability metrics). For instance, Chih et al.'s (2022) dynamic capabilities model emphasizes organizational agility, echoing CAS theory (Burns, 2020) by promoting emergent adaptations like BIM integration, which proved effective in mitigating U.S. supply disruptions but assumes robust infrastructure absent in developing contexts. Guo et al. (2023) extend this with 32 CSFs and 25 KPIs, prioritizing government support a strength in China's V-shaped recovery (Wang & Lui, 2022) yet their AHP-based prioritization aligns with game theory (Potutan et al., 2022) for stakeholder optimization, differing from Malaysia's qualitative, practitioner-driven lessons (Gamil et al., 2022) that stress health protocols over quantitative metrics.

Insightfully, these models underscore digital transformation as a universal lever, with Wang et al.'s (2022) 4M1E framework dissecting risks into actionable domains (e.g., Man: labor training), fostering exhaustive risk decomposition absent in earlier disaster recovery curves (Mileti, 1999). However, divergences emerge in scope: U.S. and Malaysian roadmaps focus on short-term operational tweaks, potentially overlooking long-term TBL sustainability (Elkington, 1997), while Chinese variants integrate environmental KPIs, aligning with Zhao et al. (2022) but critiqued for sample biases (e.g., urban-centric). Overall, this synthesis highlights global roadmaps' efficacy in structured recovery but their one-size-fits-all ethos, setting the stage for Nigerian adaptations.

Conclusion and Recommendations

The investigation concludes that global COVID-19 recovery roadmaps provide valuable phased structures and strategies, such as dynamic capabilities from Chih et al. (2022), and risk-focused 4M1E from Wang et al. (2022), their direct applicability to Nigeria is constrained by unaddressed factors like oil dependency, informal labor vulnerabilities, and infrastructural paucities. Implement e-portals and legal mandates for PPPs to streamline approvals for policymakers such as federal ministry of works; adopt hybrid digital tools (e.g., solar-backed offline BIM) and local sourcing incentives for contractors and firms; and develop vocational hubs for digital upskilling, targeting informal workers for professional bodies such as Nigerian Institute of Building are recommended and academics and researchers should employ SEM and multi-regional pilots for strategy validation, and to test roadmap efficacy.

Thanks and Information Note

The authors contributed to the study as follows: Tasleemah Yusuf conceived and initiated the research and carried out the data collection. Peter Gangas Chindo and Mustapha Abdulrazaq contributed to the survey design, methodology development, and the refinement of the results and discussion sections.

Abstract

The human impact on nature is traditionally one of the most important topics in science, due to its direct link with the quality of life, especially in cities, sustainability, sustainable development, and the preservation of nature. Various methods for assessing and evaluating it have been elaborated, some of which are based on remote sensing and GIS data, including air pollution and aerosols, as well as water pollution, and also urban sprawl, land degradation, land fragmentation, etc. This paper aims to present the results of a method developed by the authors, based on reinterpreting the classes of readily available land cover products. In this particular case, this is the CORINE Land Cover product, chosen for its detailed classification. The example area is the city of Sofia, Bulgaria, selected for its size, which is large enough to have a significant human impact on the area of its location, the Sofia Valley. The elaborated method was presented for the first time at the ESRI User Conference in 2025, as a poster entitled Human Impact Index in Education, included in the ESRI Map Gallery. The essence of the method is based on changing the descriptive approach of CORINE Land Cover classes into an interpretative one, in the consequent integration of the assessment index.

Keywords: Human impact, land cover, remote sensing, GIS

1. Introduction

The human impact on nature is traditionally one of the most important topics in science, due to its direct link with the quality of life, especially in cities, sustainability, sustainable development, and the preservation of nature.

Various methods for assessing and evaluating it have been developed, some of which use remote sensing and GIS data, including air pollution and aerosols, water pollution, urban sprawl, land degradation, and land fragmentation.

This paper presents the results of a method developed by the authors, which reinterprets the classes of readily available land cover products. In this particular case, the CORINE Land Cover product was chosen for its detailed classification.

The capital city of Bulgaria, Sofia, is selected as a study area for its size, which is large enough to have a significant human impact on the surrounding area—the Sofia Valley. The city of Sofia is at the foot of the Vitosha Mountain in Southwest Bulgaria. Sofia city is part of the Metropolitan (Sofia) Municipality, which also serves as a district as an administrative territorial unit (Sofia Municipality, 2022). Even though it is the smallest district in Bulgaria, it is home to the biggest city and agglomeration – Sofia, which has the highest population in the country. The territory of the modern city of Sofia covers 210 sq. km, calculated from the construction

border in the master plan of Sofia Municipality (Sofia Municipality Architecture and Town Planning Directorate & Municipal Enterprise "Sofproect – Master Plan", 2009).

Sofia lies in the southern part of the Sofia hollow (field), surrounded by the mountains – Lyulin, Vitosha, Plana, and Lozenska Mountains from west to east (*Sofia – 120 years capital: Jubilee book*, 2000). The landscape of the study areas is characterized by varied relief, including flat areas, foothills, valleys, and mountain areas. The average altitude of Sofia city is approximately 550 m a.s.l., and its southern periphery gradually rises (Sofia Municipality, 2024). The diversity of land cover is also significant, and the Sofia city territories and surrounding areas are occupied by various types of urbanized areas, agricultural lands, forests, shrubs, and open spaces with sparse vegetation. Due to the high rate of urbanization, the natural relief is significantly transformed by anthropogenic factors, resulting in several anthropogenic landforms, including artificial reservoirs (such as Iskar Dam, Pancherevo Dam, Passarel Dam), transport and industrial infrastructure, quarries, embankments, etc. (Stamenova & Stamenov, 2016).

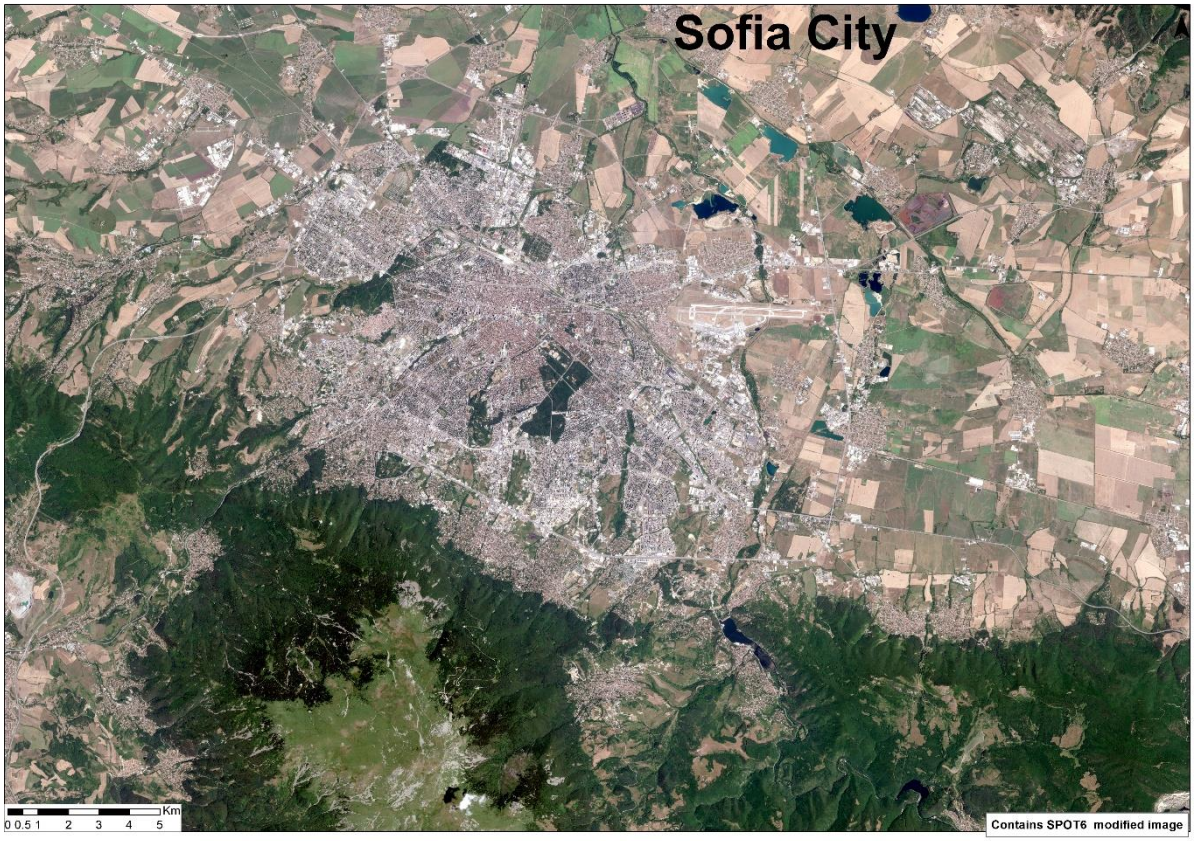

Figure 1. Study area – SPOT 6 satellite image of Sofia city

2. Materials and Methods

The data used for the project include high-resolution satellite images of Sofia City and satellite-derived land cover products for the period 2000-2024. Land cover products from the official land cover mapping of the European countries, CORINE Land Cover, have been used for this study. New datasets have been produced every 6 years since 1990, providing detailed information on land cover. The years chosen for our research are 2000 and 2018. CORINE Land Cover uses a three-level classification system with 44 classes at level 3, but only 24 are

present in the study area (European Environment Agency, 2021; Kosztra, B., Büttner, G., Hazeu, G., & Arnold, S., 2019). The data are obtained from the Copernicus Land Monitoring Service, released in May 2020, in vector format (Copernicus Land Monitoring Service, 2019). The satellite images are needed for visual representation of the study area and to provide an up-to-date snapshot. The approbation and validation of the human impact on the study area require the most recent high-spatial- and high-spectral resolution satellite data, and the chosen sensors are SPOT 6 and WorldView 3. SPOT 6, which provides suitable parameters for urban mapping (eoPortal Directory, *SPOT-6 and SPOT-7 (Azersky)*, is a cloud-free satellite image acquired on August 1, 2024. It covers the territory of Sofia city and its surroundings. WorldView 3 satellite images are also cloud-free and were acquired on 28 July and 23 August 2024. Its very high spatial resolution (European Space Agency, *WorldView-3*) provides a detailed picture of Sofia's urban area, allowing a precise distinction between the built-up areas and the small green patches.

The elaborated method was presented for the first time at the ESRI User Conference in 2025 as a poster titled "Human Impact Index in Education," which was included in the ESRI Map Gallery (Stamenov & Stamenova, 2025). Previous works on the topic of human impact were presented at the same forum in 2022 and 2023 (Stamenov & Stamenova, 2022, 2023). The essence of the method is based on changing the descriptive approach to CORINE Land Cover classes into an interpretative one, thereby enabling the integration of the assessment index. The method is based on five human impact levels, presented in Table 1. These human impact levels, as described, are assigned to the land cover classes for the Sofia city area (Table 2). In the study area, 22 of the 44 CORINE land cover classes are observed, as shown in Table 2.

Table 1. Human impact levels

Human Impact Levels		Description
Level 1	Minimal human influence	Areas with no human influence or minimal human influence. No artificial changes in land surface or underground. These are areas of natural landscapes with no permanent human structures, no artificial land surface changes, and natural vegetation, bare lands, inland waters, and wetlands.
Level 2	Weak human influence	Semi-natural territories with or without single permanent human structures or road networks - natural landscapes and vegetation with no or minimal artificial changes in the land surface, bio-agriculture, perennial crops, pastures.
Level 3	Moderate Human Influence	Regular artificial changes of the land surface - regular land cultivation and use of synthetic chemicals, no permanent human buildings, and agriculture.
Level 4	Strong Human Influence	Permanent human structures - buildings and road networks with artificial coverage, artificial changes of land surface due to construction purposes, urban discontinuous surfaces, small patches of open ground, tailing ponds, and inland waters close to significant industrial zones.
Level 5	Very Strong Human Influence	Areas with constant human influence, permanent artificial surfaces, and artificial relief, including industrial areas and continuous urban surfaces.

Table 2. CORINE Land Cover nomenclature and assigned human impact values (only for 22 land cover classes observed at the study area)

CORINE Land Cover classification			Human Impact value
Level 1	Level 2	Level 3	
1. Artificial Surfaces	1.1 Urban fabric	1.1.1 Continuous urban fabric	5
		1.1.2 Discontinuous urban fabric	4
	1.2 Industrial, commercial and transport units	1.2.1 Industrial or commercial units	5
		1.2.2 Road and rail networks and associated land	5
		1.2.4 Airports	5
	1.3 Mine, dump and construction sites	1.3.1 Mineral extraction sites	5
		1.3.2 Dump sites	5
	1.4 Artificial, non-agricultural vegetated areas	1.4.1 Green urban areas	3
		1.4.2 Sport and leisure facilities	3
2. Agricultural areas	2.1 Arable land	2.1.1 Non-irrigated arable land	3
		2.2.2 Fruit trees and berry plantations	2
	2.3 Pastures	2.3.1 Pastures	2
	2.4 Heterogeneous agricultural areas	2.4.2 Complex cultivation patterns	3
		2.4.3 Land principally occupied by agriculture, with significant areas of natural vegetation	2
3. Forest and seminatural areas	3.1 Forest	3.1.1 Broad-leaved forest	1
		3.1.2 Coniferous forest	1
		3.1.3 Mixed forest	1
	3.2 Shrub and/or herbaceous vegetation associations	3.2.1 Natural grassland	1
		3.2.4 Transitional woodland/shrub	1
	3.3 Open spaces with little or no vegetation	3.3.2 Bare rock	1
		3.3.3 Sparsely vegetated areas	1
4. Wetlands	4.1 Inland wetlands	4.1.1 Inland marshes	1
		4.1.2 Peatbogs	1
5. Water bodies		5.1.2 Water bodies	2

- **Findings and Discussion**

The CORINE Land Cover maps of Sofia city and its surroundings show the land cover distribution, which is determined by the town's location in the southern part of the Sofia valley at the foothills of Vitosha Mountain. Agricultural areas surround the city to the west, north, and east, while on the southern side, it borders the Vitosha Nature Park (Figures 2 and 3). The city comprises most of the Artificial surfaces' classes. Still, the most prevailing are Discontinuous urban fabric (class 112) and Industrial and commercial units (class 121). As shown in the pie charts, the four land cover classes with percentages above 5% are the same in both years: non-irrigated arable land (class 211), discontinuous urban fabric (class 112), broad-leaved forest (class 311), and industrial or commercial units (class 121) (Figures 4 and 5). The most widely represented class is 211, which over these 18 years decreases by about 2.5%, from 38.58% to 36.03%. An increase is observed for class 121, which went from 5.81% to 7.55%. The other two classes (112 and 311) remain almost unchanged from 2000 to 2018, respectively, class 112 (16.29% to 16.27%), and class 311 (10.01% to 9.87%).

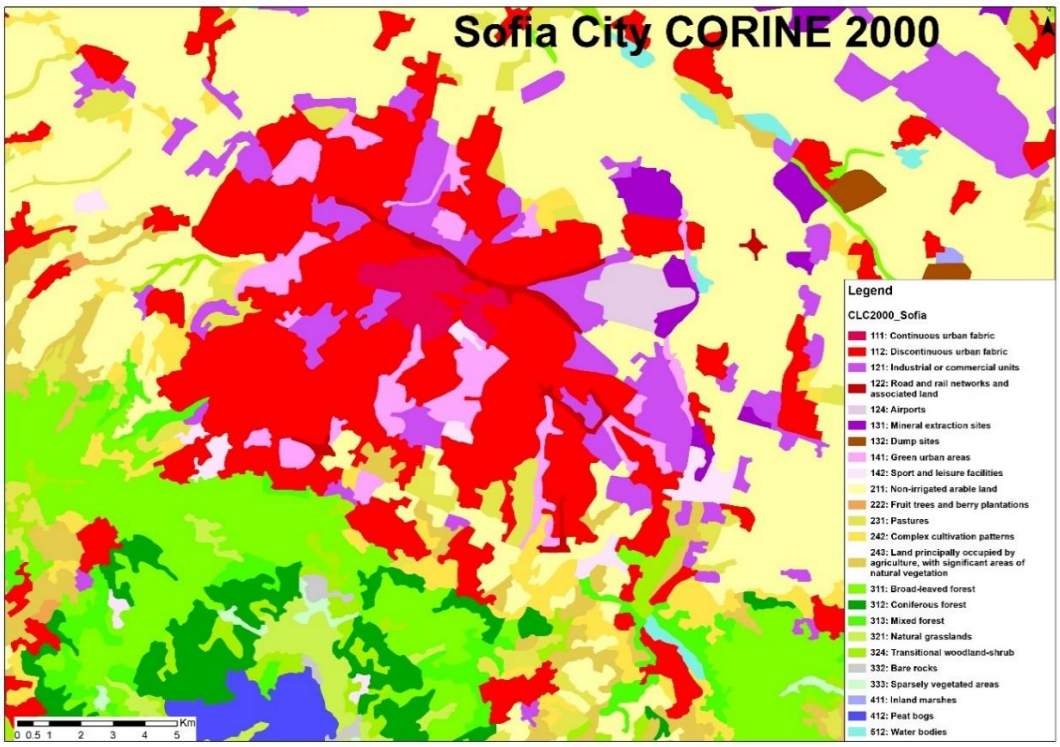

Figure 2. Map of CORINE Land Cover of Sofia city and its surroundings for 2000

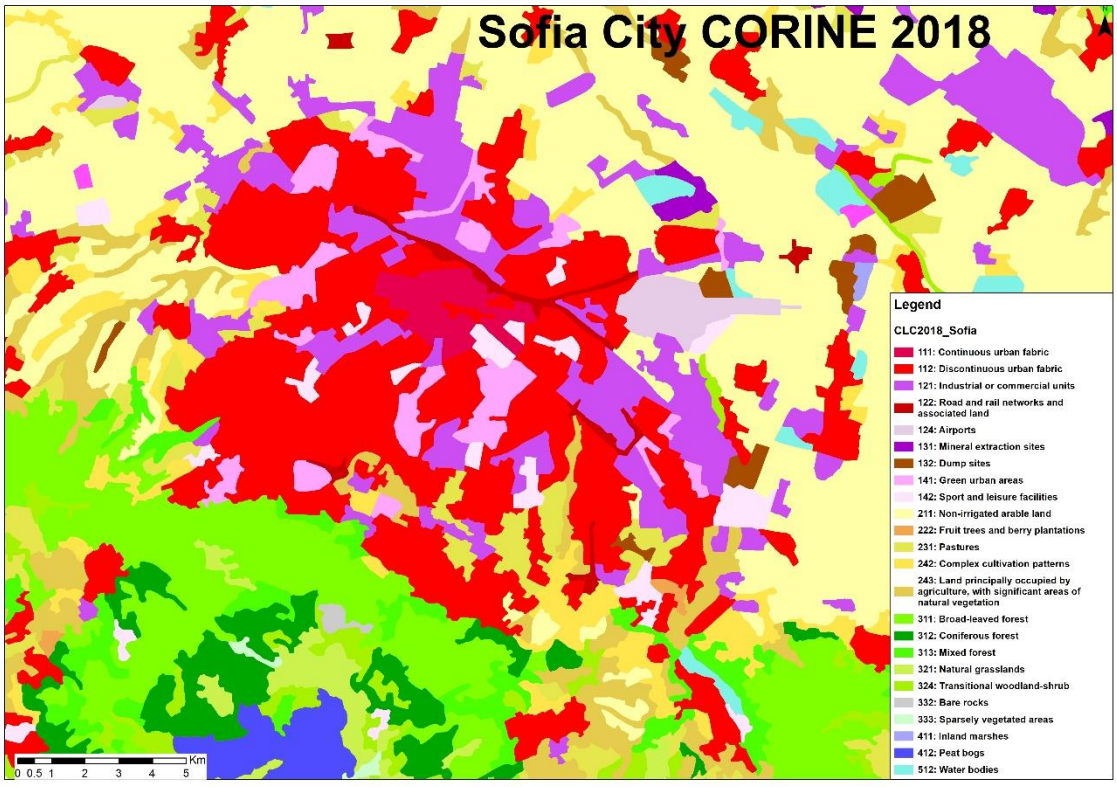

Figure 3. Map of CORINE Land Cover of Sofia city and its surroundings for 2018

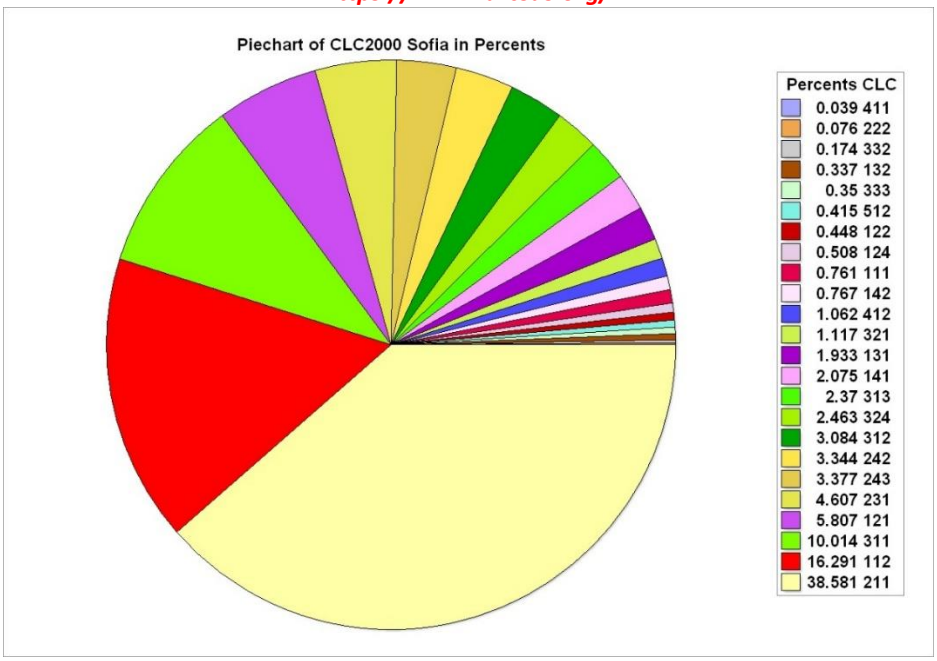

Figure 4. Pie chart of the percentage distribution of CORINE Land Cover classes for 2000

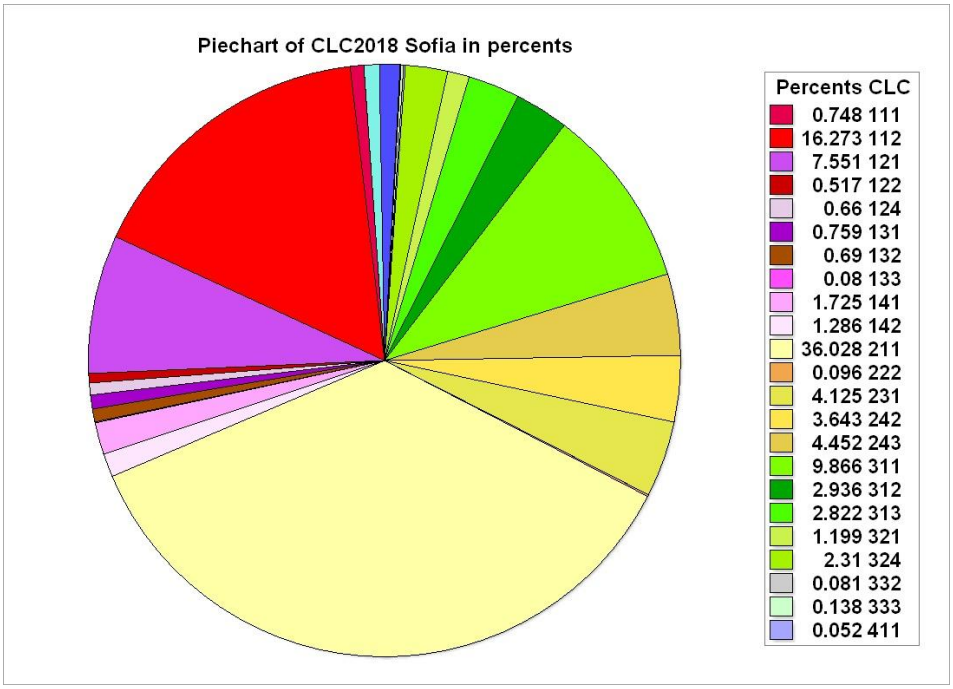

Figure 5. Pie chart of the percentage distribution of CORINE Land Cover classes for 2018

Using the CORINE Land Cover products for 2000 and 2018, along with the abovementioned human impact levels, the human impact index for Sofia city and its surroundings in 2000 and 2018 has been mapped and assessed (Figures 6 and 7). The minimal human impact with level 1 is observed in the southern part of the study area, in the mountainous region of Vitosha, Plana, and Lozenska. As seen on the maps, a significant part of the study area is occupied by territories with substantial human impact—levels 4 and 5. Least presented are areas with human impact values 2 – weak human influence.

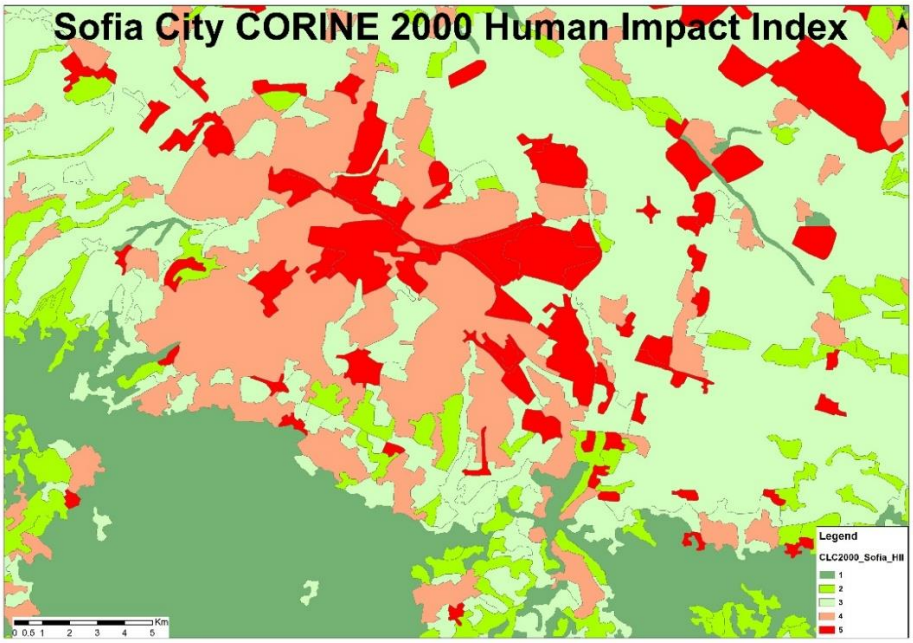

Figure 6. Human impact index map of Sofia city and its surroundings for 2000

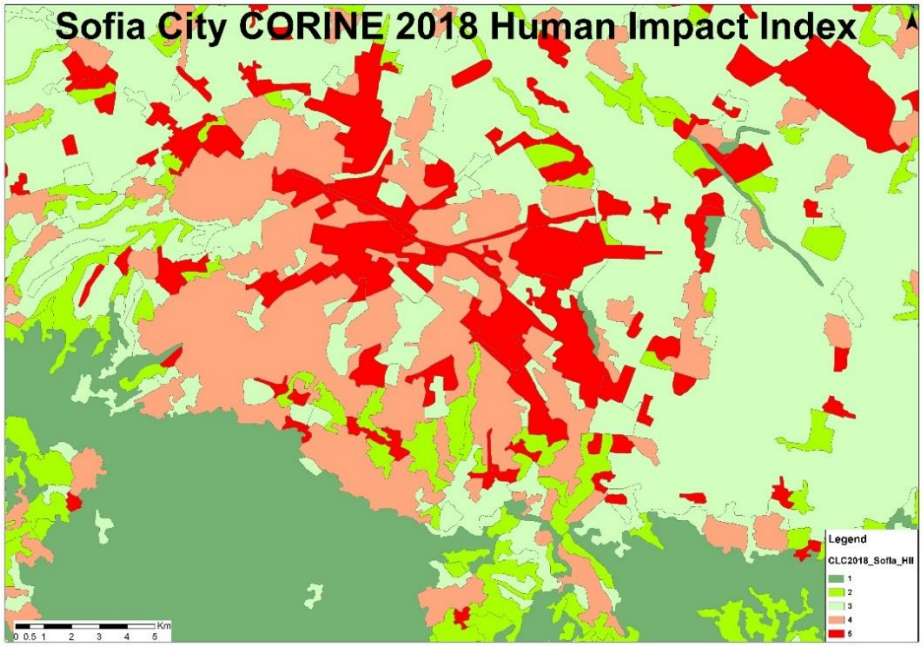

Figure 7. Human impact index map of Sofia city and its surroundings for 2018

As for the maps of human impact for the city of Sofia, within its construction border defined by the General City Plan from 2009, the distribution of impact classes differs (Figures 8 and 9). The least represented are the classes with the lowest impact, 1 and 2, as class one covers a narrow strip in the southern part of the city where the foothills of Vitosha Nature Park are located. The areas with a value of human influence of 3 and 4 are the most widely represented, while the share of 1 and 2 is the smallest.

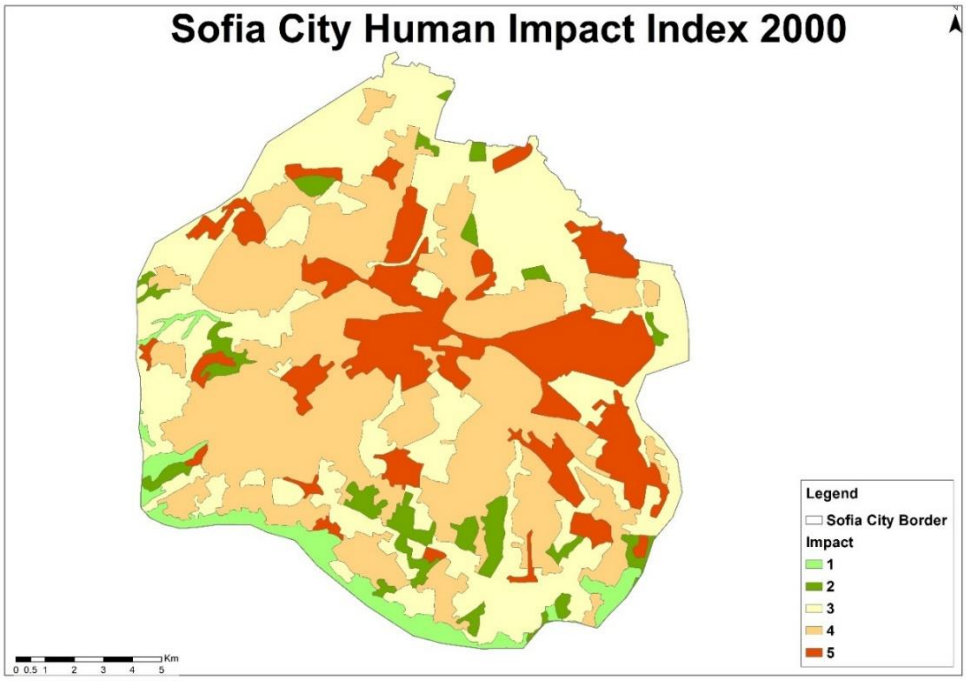

Figure 8. Human impact index map of Sofia city for 2000

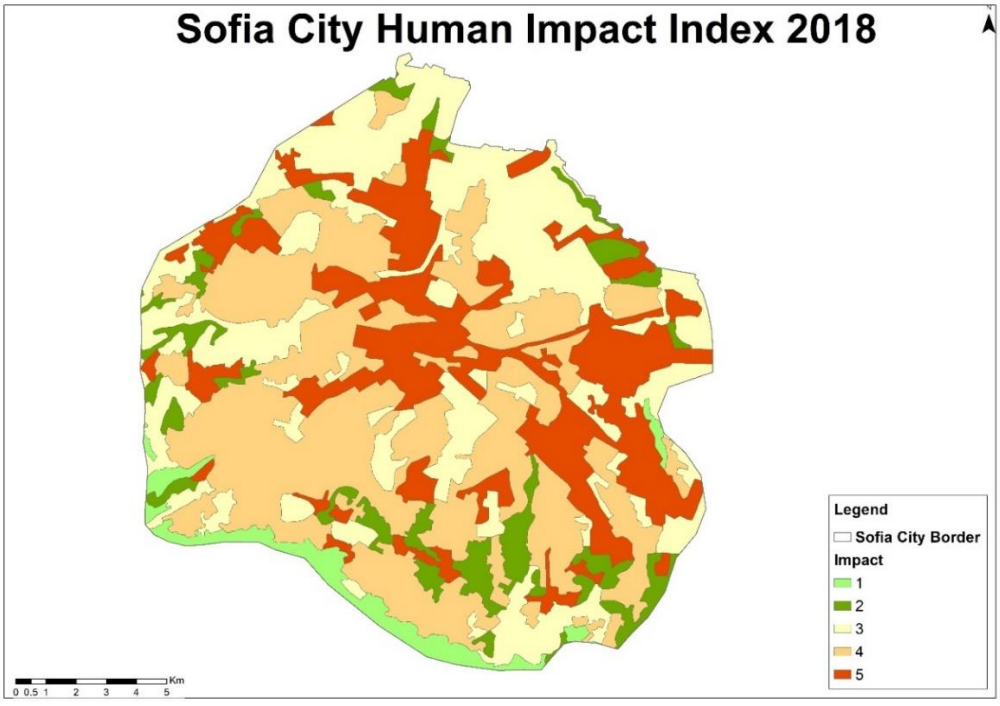

Figure 9. Human impact index map of Sofia city for 2018

In the pie charts of the Human Impact Index for 2000 and 2018, it is noticeable that the areas with the highest human impact value of 5 have increased from 17.7% in 2000 to 22.8% in 2018 (Figure 10). The broadly presented areas with human impact values 3 and 4 show a slight decrease since 2000, respectively for impact value four (4) from 38.9% to 37.6%. For impact value 3, the decrease is approximately 6% from 34.4% to 28.4%. A slight decrease is also

observed in areas with an impact value of 1, but the change is less than 1%. Part of these territories have been transferred to areas with an impact value of 2, increasing their area by about 3%. Some of them have been transformed to areas with a higher impact value – human impact 5.

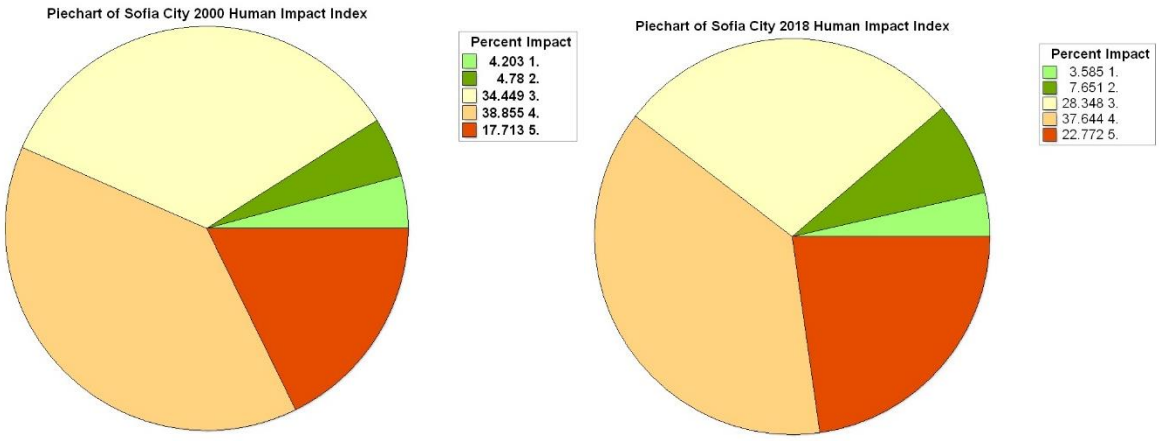

Figure 10. Human impact index map of Sofia city for 2000 and 2018

Conclusion and Recommendations

The analysis, mapping, and understanding of human impact on nature are critically important for sustainable development, environmental preservation and conservation, and the development of smart, sustainable cities. The results of the Sofia city analysis of human impact over almost 20 years (2000-2018) show an increase in areas with very strong human influence, mainly due to urban expansion. The presented Human Impact Index mapping method effectively reinterprets CORINE Land Cover data, enabling the assessment of human impact within a given area. It can be easily applied to other regions, regardless of their size, and the impact values can be adapted and assigned to different land cover products, making it a versatile tool for assessing human impact on nature.

Abstract

Smart buildings integrate networked sensors, building automation systems (BAS), IoT devices, and cloud-based analytics to deliver energy efficiency, occupant comfort, and operational cost savings. However, the IT-OT convergence that enables such benefits also expands the cyberattack surface: unencrypted IoT endpoints, legacy building controllers, and subsegmented networks create routes for attackers to insert physical disruption or exfiltrate sensitive data. This study investigates cybersecurity risks in smart building infrastructure using a mixed-methods design. The key findings illustrate runaway growth of IoT endpoints (tens of billions globally), high and rising percentage of devices with critical vulnerabilities (industry sources report substantial year-over-year increases), and common architectural vulnerabilities such as flat network topologies, default passwords, and unpatched firmware that persist across deployments. From data-driven risk metrics that draw on NIST guidance and industry threat intelligence reports, we show that 10–100 networked BAS/IOT devices in building infrastructure can create numerous high-severity vulnerabilities if proper practices are not being practiced and that attacks can disable HVAC, access control and energy systems with real physical and economic impact. We bring together robust mitigations segmentation, device lifecycle and inventory management, zero trust principles, secure procurement and recommend a research agenda that includes federated intrusion detection for building automation systems and standardized security certification for IoT building infrastructure.

Keyword: Smart buildings, BAS, IoT, cybersecurity, NIST, vulnerability metrics.

Introduction

Smart buildings are buildings that use networked sensors, controllers and analytics to automate HVAC (heating, ventilation and air conditioning), lighting, security and other systems, which have rapidly expanded since 2020. Advances in low-cost sensors, ubiquitous wireless connectivity and cloud analytics made it economical for organizations to deploy dozens to thousands of connected endpoints per facility. Cisco's industry data projects that by 2023 there were tens of billions of networked devices globally, underscoring the scale of endpoints that can be present in urban digital infrastructure. The increasing density of connected devices in buildings has two important security implications: first, the absolute number of potentially vulnerable endpoints rises linearly with adoption; second, heterogeneity of device types (IT devices, OT controllers, IoT sensors) increases integration complexity and misconfiguration risk. Convergence of IT (information technology) and OT (operational technology) in smart buildings create hybrid attack surfaces. Traditionally, BAS and OT systems were air-gapped or on segregated networks; today many controllers communicate over IP, use common protocols

(BACnet, Modbus, OPC UA) and often rely on cloud services for analytics and remote management. This shift introduced new classes of cyber risks: device-level vulnerabilities in embedded firmware, insecure default credentials, exposed management interfaces, and inadequate network segmentation that allows lateral movement from an infected sensor to critical control equipment. Industry analyses show a marked increase in mixed IT/IoT threats and that a nontrivial share (~20–30%) of connected devices in enterprise environments are non-traditional IT devices (OT/IoT), which historically have weaker security controls. Why smart-building security matters beyond data theft. Compromises can result in physical harm, occupant safety risks, operational outages and reputational and financial damage. Attack scenarios range from denial of service on building access control to manipulated HVAC setpoints that cause equipment damage or occupant health hazards. Because building systems are critical infrastructure for enterprises, universities, healthcare and government campuses, their security posture is subject both to regulatory scrutiny and to business continuity risk. Recent NIST guidance for IoT and the NIST Cybersecurity Framework 2.0 stresses risk management and cross-discipline governance; an indication that building cybersecurity is now both a technical and organizational problem (NIST CSF 2.0; NIST IoT guidance). This paper aims to synthesize published evidence (2020-2025), quantify risk exposure using available statistics, and recommend practical mitigations aligned with industry standards.

Literature Review

Academic and industry literature since 2020 has converged on several recurring themes in smart building cybersecurity: (1) proliferation of IoT endpoints and device heterogeneity, (2) systemic architectural weaknesses in BAS deployments, (3) common vulnerability classes (default credentials, unencrypted telemetry, open management ports), and (4) emerging defense strategies (segmentation, zero trust, device certification, testbeds). Several reviews and meta-analyses (Li et al., 2023; Sandor & Rajnai, 2023) summarize the landscape of BAS vulnerabilities, noting that many legacy controllers were designed without security and are still in operation, often with long lifecycles and limited update mechanisms (Li, 2023; Sándor & Rajnai, 2023). Industry threat reports quantify the problem scale. For example, Forescout's analyses (2022-2025) observed increases in mixed IT/IoT threats and reported that a growing percentage of enterprise devices are non-traditional IT endpoints subject to unique vulnerabilities; their research also identified categories of the "riskiest" connected devices (routers, IoT sensors, OT controllers) that disproportionately appear in exploit databases (Forescout, 2022; 2025). The IoT device population itself is large and growing: Cisco and other market trackers estimated tens of billions of connected devices by 2023, while IoT Analytics and similar trackers reported 16.6 billion connected IoT devices in 2023 with projections to increase further — emphasizing the attack surface scale. Quantitative studies place the average number of attacks against IoT devices in the thousands per month across studied environments (PSA Certified / industry estimates). These statistics provide a quantitative basis for risk modeling and motivate prioritized mitigation of the most exploitable classes. Standards & guidance: NIST's IoT guidance (SP 800-213) and the broader Cybersecurity Framework (CSF 2.0) provide device-agnostic risk management guidance that applies to building IoT (NIST SP 800-213; NIST CSF 2.0). These documents encourage lifecycle security, from procurement to decommissioning, and emphasize inventory, secure configuration, and risk-based prioritization. Complementary industry guidance (IoTSF 2023, RICS digital risks) addresses facilities managers and suggests operational controls and procurement checklists specific to built environments (IoTSF, 2023; RICS). Empirical testbeds such as the NREL cybersecurity testbed

for smart buildings demonstrate experimentally how attacks on building controllers manifest in physical metrics (temperature, power consumption) and how detection can distinguish mechanical faults from cyberattacks, offering evidence-based approaches to detection and response (NREL, 2024). Gaps identified across studies include insufficient longitudinal incident datasets specific to buildings, lack of universally adopted security certification for building IoT devices, and limited vendor accountability for secure-by-default design. Many academic studies call for cross-disciplinary approaches combining cybersecurity, controls engineering, and facilities management. This paper addresses these gaps by combining published statistical indicators with architecture-level analysis and a synthetic risk model informed by NIST guidance and industry threat metrics.

Materials And Methods

This study adpts a mixed-methods approach combining systematic literature review, quantitative synthesis of published statistics, and a small secondary-analysis of published testbed attack outcomes. The methods are designed to be reproducible using publicly-available PDFs and datasets from 2020-2025. We collected authoritative PDFs and technical reports from NIST (CSF 2.0, SP 800-213), industry whitepapers (Forescout IoT threat reports, IoTSF guidance), academic papers (peer-reviewed articles on BAS and cyber-physical security), and sector reviews (NREL testbed report; IEA Annex 81). Search keywords included "smart building cybersecurity," "building automation system vulnerabilities," "IoT devices vulnerabilities 2020-2025," and "BAS cyber testbed." Documents were selected for inclusion if they contained empirical or technical data (vulnerability counts, device population projections, attack case studies) and were published between 2020 and 2025. Representative PDFs: NIST CSF 2.0 (2024), NIST SP 800-213 (2021), IoTSF (2023), Forescout threat roundups (2022–2025), HRCAK (Sándor & Rajnai, 2023), and the NREL smart-building testbed (2024). From the collected sources we extracted numerical indicators: global connected device counts (Cisco; IoT Analytics), reported vulnerability growth rates and proportions of non-traditional IT devices (Forescout), attacks-per-month or dataset estimates (PSA/industry), and specific testbed results (NREL). Where reports gave ranges or projections (e.g., 16.6 billion IoT devices end-2023; 13–18% growth), those were recorded with citation and used to compute conservative scenario estimates. For instance, to quantify probable vulnerability burden in a typical medium-sized building, we used published device proportions and vulnerability prevalence rates from industry reports to simulate an expected number of vulnerable endpoints. This produces numerical scenarios (e.g., building with 200 connected endpoints → estimated 20-40 endpoints with medium-to-critical vulnerabilities under reported vulnerability prevalence ranges). We reviewed published NREL testbed experiments and other case studies where cyberattacks on BAS affected physical system metrics (temperature, energy use) to derive impact multipliers, i.e., how a cyber-induced setpoint change translated into energy or occupant comfort deviations. These multipliers allow us to translate a hypothetical compromise of x controllers into projected operational impacts (e.g., % increase in HVAC energy use, hours of occupant discomfort). The testbed reports include logged network and physical sensor traces that informed this mapping. Using NIST CSF and Zero Trust guidance, we created a simple risk scoring method (device criticality × vulnerability severity × exploitability) to prioritize mitigations. Device criticality was informed by facility function (e.g., access control = high criticality), vulnerability severity used published CVE/severity trends from Forescout and industry threat lists, and exploitability considered whether a device is internet-exposed or reachable from enterprise networks (per Forescout findings). We then mapped mitigations

(inventory, segmentation, secure procurement, patch/firmware lifecycle, monitoring/testbed-based detection) to the highest-scored categories.

Results & Discussion

Quantitative findings

Consolidated device population estimates indicate a large and growing attack surface.

Conservative device counts place connected IoT devices in the tens of billions globally (Cisco; IoT Analytics), with industry trackers reporting ~16.6 billion connected IoT devices by end-2023 and projections into 2024-2025 that push totals higher (IoT Analytics, 2024).

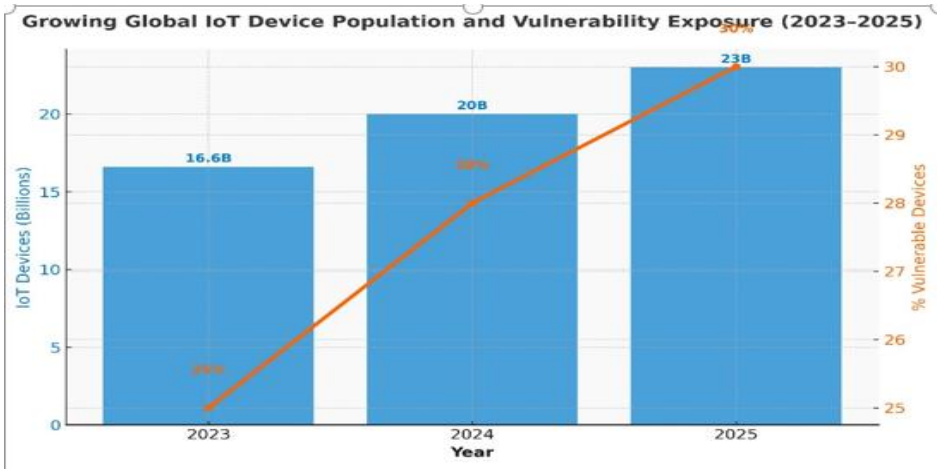

Fig.1. Graph showing the growth of IoT devices and their rising vulnerability exposure (2023–2025).

Forescout's analyses of enterprise environments show that roughly 20-30% of connected devices are non-traditional IT endpoints (IoT/OT), a category that often lacks enterprise-grade security controls, and the number of devices with known vulnerabilities increased notably from 2023 to 2024 (Forescout; IoT vulnerability trackers). Industry data cited by PSA and others also estimate thousands of attacks on IoT devices monthly across studied networks, with millions of records compromised daily in aggregated estimates. These figures illustrate that any smart building deployment that includes tens to hundreds of endpoints is likely to harbor multiple vulnerable devices unless explicit lifecycle controls are applied.

Expected vulnerable endpoints in a typical building

Using the quantitative synthesis method described, a medium-sized office building with ~200 connected endpoints (sensors, controllers, cameras, access controllers, routers) would, under conservative prevalence rates (10–25% vulnerability prevalence), contain approximately 20-50 endpoints with medium-to-critical vulnerabilities. If even 10% of those endpoints expose reachable management interfaces or reside on flat networks, lateral movement could enable attackers to reach high-criticality assets (e.g., building controller, access control server). Tests and case studies in the literature show that such compromises can cause real operational impacts: NREL testbed exercises demonstrated that manipulated HVAC setpoints could cause multi-degree temperature deviations and measurable energy changes; in practice, that can

translate to occupant health risks, comfort complaints, and increased energy cost. These modeled numbers align with industry warnings that mixed IT/IoT attacks are growing in frequency and sophistication.

Common attack vectors & architectural weaknesses

The literature and reports converge on recurring vulnerabilities: default or hardcoded credentials, unpatched firmware, unsecured protocols (unencrypted BACnet/Modbus traffic), exposed management interfaces, and flat network topologies lacking segmentation. Vendor supply-chain issues and remote management platforms (with critical vulnerabilities) also appear in threat histories (e.g., Axeda/Access:7 vulnerabilities affecting embedded device management). Attack patterns often begin with an internet-accessible or internal IoT device compromise and proceed via lateral movement into OT space due to insufficient micro-segmentation.

Evidence-based and prioritized Mitigation

The strongest mitigations indicated by guidance and testbed findings are: (1) complete device inventory and asset classification; (2) network segmentation (separate IT, OT, IoT and guest networks) combined with strict access controls; (3) secure procurement and device hardening (disable default accounts, enforce strong authentication); (4) patch/firmware management and supplier vulnerability disclosure; (5) monitoring and anomaly detection informed by combined network+physical telemetry (testbeds show physical telemetry helps distinguish cyberattacks from mechanical faults); and (6) adoption of zero-trust principles and alignment with NIST CSF outcomes. NIST CSF 2.0 and SP 800-213 give specific outcomes and practices that can be operationalized by facilities teams in collaboration with IT security.

Discussion

Building cybersecurity in smart facilities extends beyond technical controls to encompass deep organizational and policy transformation. Effective protection requires procurement policies that enforce minimum security baselines, cross-functional governance between IT, facilities, and operations, and clear vendor accountability across device lifecycles. Studies emphasize that governance structures bridging traditional silos between operational technology (OT) and information technology (IT) significantly reduce risks by promoting accountability and continuous oversight (IoT Security Foundation [IoTSF], 2023). Procurement plays a critical role, as embedding cybersecurity requirements, such as secure boot, encrypted communications, patchability, and transparent supply chains, into contract terms ensures devices are secure by design. The IoTSF Security Assurance Framework (2021) recommends enforcing supplier clauses mandating vulnerability disclosure, update commitments, and long-term support. Moreover, certification and labeling schemes such as the U.K.'s "secure by design" initiative and PSA labels promote market-wide accountability by rewarding manufacturers who meet high security standards (Morgner et al., 2019). Device lifecycle management, including automated inventory, microsegmentation, and decommissioning protocols, is equally vital; without these, organizations struggle to identify and isolate vulnerable devices (Meidan et al., 2017). Microsegmentation and zero-trust models have been shown to curtail lateral attack movement by 60-90%, offering superior risk reduction per dollar spent compared to ad hoc patching alone (Nardine et al., 2021). This is particularly significant given that patching in IoT contexts is plagued by heterogeneity, delayed updates, and legacy constraints (Dissanayake et al., 2020). Thus, prioritizing investments in comprehensive device

discovery, network segmentation, and structured patch triage yields higher operational resilience and ROI studies indicate security investments can reduce downtime up to 75% and yield 4:1 financial returns (Cybervizer, 2024). At the same time, human capacity building remains crucial: facilities managers, often lacking cybersecurity training, benefit from accessible guidelines like the IoTSF's *IoT Cybersecurity for Facilities Professionals*, which outlines practical steps for enforcing security within building operations. Training and certification programs for facility professionals can institutionalize cyber-awareness and competence, while standardized security labels for IoT devices enhance user trust and purchasing clarity. Despite progress, challenges persist: vendors may resist tighter security requirements, legacy systems create persistent exposure, and balancing patching with operational uptime remains difficult. However, with cross-departmental governance, regulatory incentives, continuous monitoring, and well-defined procurement standards, organizations can systematically raise the cybersecurity baseline of smart buildings. The path forward involves aligning technical defenses with institutional accountability, regulatory compliance, and informed procurement practices, ensuring that every connected endpoint, whether a thermostat or access control sensor, operates within a secure, auditable, and well-managed lifecycle framework, thus transforming building cybersecurity from a reactive IT problem into an embedded organizational function.

Conclusion

Smart buildings deliver substantial benefits in energy efficiency, occupant comfort and operational insight but these benefits come with expanded cyber risk. Between 2020 and 2025, a growing body of literature and industry reports documents increasing device counts, rising prevalence of vulnerabilities in IoT/OT endpoints, and frequent mixed IT/IoT threats that can materially affect building operations (Cisco; Forescout; IoT Analytics). The evidence presented here synthesizes those findings into a clear risk narrative: the more endpoints and the more heterogeneous the device ecosystem, the greater the probability that building infrastructure contains exploitable assets, and the greater the potential for cyber incidents to produce physical effects. From a technical standpoint, the most impactful mitigations are well-known but under-implemented: accurate device inventories, segmentation of IT/OT/IoT networks, secure-by-default procurement requirements, strong authentication, monitored patch lifecycles, and layered detection that includes both network and physical telemetry. NIST guidance (CSF 2.0, SP 800-213) provides a practical framework for prioritization, linking outcomes (identify, protect, detect, respond, recover) to building-specific controls. Deploying testbeds and conducting regular red-team exercises (as NREL and others demonstrate) helps facilities teams validate that detection controls can distinguish between mechanical faults and cyber manipulation, a critical capability for operational resilience. Organizationally, meaningful improvement requires that facilities managers, IT security, procurement and executive leadership coordinate on security requirements and budgets. Policy levers that could accelerate improvement include certification programs for building IoT devices, procurement clauses demanding vulnerability disclosure and update guarantees, and sector guidance tailored to facilities professionals. The industry guidance (IoTSF, RICS) and NIST standards show a path forward, but there remains a gap between guidance availability and real-world adoption that must be addressed through training, incentives and regulatory clarity. Limitations of this study include dependence on publicly reported statistics and industry reports (methodologies vary) and the lack of a centralized incident repository specifically for building-level cyber incidents. Nonetheless, the cross-source convergence on issues and the experimental evidence from

testbeds support the central conclusions: smart buildings are attractive targets because of their scale and heterogeneity, but risk can be materially reduced through prioritized, standards-aligned controls and organizational changes.

Future Research

Building on gaps identified in the 2020-2025 literature, future research should prioritize developing longitudinal, anonymized databases of smart building cyber incidents to support empirical analysis of attack frequency, causes, and impacts. Equally important are studies on certified security baselines and procurement policies that evaluate the effectiveness of secure-by-default requirements, firmware update guarantees, and SBOM integration in reducing vulnerability prevalence. Research should also advance hybrid detection algorithms that merge network data with physical telemetry for enhanced anomaly detection, supported by federated learning models to preserve privacy. Economic modeling of building cyber incidents is needed to quantify financial losses, downtime, and energy inefficiencies. Additionally, human factors research should assess how training, governance models, and policy interventions affect security adoption and sustainability. Finally, establishing standardized, interoperable testbeds across diverse building types would enable consistent benchmarking and accelerate innovation through collaboration among academia, NIST, IoTSF, Forescout, and other industry partners.

Abstract

The increasing impacts of climate change necessitate adaptation-focused approaches in the design of urban open spaces. In this process, open parking lots are recognised as crucial urban spaces for enhancing resilience to climate change, beyond serving as mere vehicle storage areas. Elements such as the permeability of surface materials, rainwater management, shading opportunities, vegetative landscaping, and energy-efficient lighting systems directly impact the potential of these spaces to adapt to climate change. This study examines the design principles of urban open parking lots in the context of climate change adaptation, drawing on relevant literature. Sustainable design practices prominent in the literature are evaluated, focusing on the use of permeable pavement, rainwater harvesting, green infrastructure integration, and solutions for regulating the microclimate. Three existing open parking lots in Isparta's city centre—the Isparta Intercity Bus Terminal Parking Lot, the Iyaş Parking Lot, and the Delta Parking Lot—are presented as examples, and the opportunities and potential development opportunities of these areas in terms of climate-adapted urban design are highlighted. In conclusion, the evaluations conducted using the Isparta example demonstrate that open-air parking lots, when integrated with climate change adaptation strategies, can contribute to sustainable and climate-resilient urban planning processes.

Keywords: Urban open-air parking lots, climate change, parking lot design principles

1. Introduction

With the rapid increase in urbanisation, the pressure urban areas place on natural processes is becoming increasingly evident. As emphasised in the reports of the Intergovernmental Panel on Climate Change (IPCC, 2021), the increasing population density, energy consumption, transportation activities, and surface impermeability in cities worldwide are both accelerating climate change and making them more vulnerable to this change. Impacts such as heat waves, sudden rainfall, and increased surface runoff, in particular, directly impact the character of urban open spaces. This situation highlights the need to reconsider urban spaces not only in terms of use but also in terms of climate adaptation and environmental sustainability (UN-Habitat, 2022; EEA, 2023).

In this context, open parking areas, traditionally defined solely as vehicle storage, stand out as a significant space-consuming area within the urban fabric. Because parking surfaces are generally composed of impermeable materials such as asphalt or concrete, they prevent rainwater from seeping into the ground, which increases runoff and flooding (Hong & Lee, 2021). Furthermore, due to their high heat storage capacity, these surfaces exacerbate the urban heat island effect, negatively impacting environmental thermal comfort (Razzaghmanesh & Beecham, 2019). These effects necessitate considering parking lots not only as infrastructural elements but also as a type of open space with the potential to regulate urban microclimate (Graça, 2022).

In recent years, a notable trend has emerged in the international literature towards redefining parking areas within the framework of sustainable urban design (Figure 1). For example, Chen and Zhang (2023) stated that autonomous and shared vehicle systems will inevitably lead to the functional transformation of parking areas in the future, and these areas could transform into "green infrastructure-focused public spaces." Aldridge and Medina (2021) propose four principles for parking planning. These are: demand management, resource conservation, ecological integration, and linking it to urban systems. These principles advocate that parking lot designs should be considered as public open spaces integrated with ecological systems, rather than solely as technical requirements.

Figure 1. Example of sustainable parking compatible with green infrastructure (sustainabletechnologies.ca 2018)

The planning and design of urban parking spaces is a multifaceted process that encompasses not only vehicle storage but also environmental sustainability, user comfort, and adaptation to climate change. Today, parking lots are recognised as crucial open spaces for reducing cities' carbon footprints, supporting rainwater management, and balancing the microclimate (UN-Habitat, 2022; EEA, 2023). Therefore, modern parking design has evolved beyond technical efficiency to incorporate climate-compatible design approaches that integrate ecological, energy, and social considerations.

In international literature, prominent principles in parking design include the use of permeable surfaces, rainwater management, integration with green infrastructure, energy efficiency, and accessibility.

UN-Habitat (2022) recommends designing parking lots as "climate-resilient open space systems," emphasising that the combined use of permeable surfaces, rainwater storage, photovoltaic shading systems, and vegetative landscaping reduces the heat island effect in cities (Figure 2).

Figure 2. Example of a car park using photovoltaic shading systems (AmperaPark, 2025).

Similarly, the European Environment Agency (2023) states that increasing the permeable surface ratio and implementing design solutions that support the natural water cycle, together with tree shading, strengthen urban resilience (Figure 3).

Figure 3. Example of permeable paving system in parking lots (totallandscapecare.com, 2025).

In the United States, the U.S. Environmental Protection Agency (EPA, 2020) and Federal Highway Administration (FHWA, 2019) guidelines also consider sustainable parking design as an "extension of green infrastructure" and highlight the following criteria:

• Reducing impervious surfaces and using materials that allow water to infiltrate the ground;

• Integrating biofilters, rain gardens, and infiltration swales for stormwater management;

• Using sensor-controlled LED systems and solar-powered shading structures to ensure energy efficiency;

• Creating microclimatic balance with vegetative shading and green border elements;

• Developing inclusive solutions for people with disabilities, pedestrians, and cyclists within the framework of accessibility and safety principles.

These principles suggest that parking lots should not be viewed as merely static structural areas, but rather as active environmental components of the urban ecosystem (Aldridge & Medina, 2021; Zhang & Li, 2025).

The basic framework for parking lot planning in Türkiye is outlined in the Parking Regulation published by the Ministry of Environment, Urbanisation and Climate Change (2018). However, the current regulation primarily focuses on technical issues, such as capacity, area size, and location selection. It fails to include environmental indicators, including climate adaptation, the use of permeable surfaces, green infrastructure integration, and energy efficiency. This deficiency causes parking lots to remain environmentally unsustainable, even if they are physically functional.

In contrast, the TMMOB Chamber of Urban Planners Report (2021) and the TSE 12576 standards recommend incorporating green infrastructure as a mandatory design element in urban parking lots, enhancing the permeability of surface materials, and implementing energy-efficient systems. Furthermore, some local governments (e.g., Izmir, Konya, Eskişehir) have taken significant steps at the implementation level in recent years by preparing "climate-friendly parking guides." However, these initiatives have not yet been translated into a systematic standard at the national level. When global and national standards are considered together, it becomes clear that parking design should be based on a holistic approach shaped by the intersection of architecture, urban planning, landscape, and environmental engineering. Parking lots can play an active role in sustainable urban planning only by integrating climate-focused design principles, not just technical standards, into the planning scale. Such a transformation could transform parking lots into "urban micro-ecosystems" that reduce carbon emissions, generate energy, and contribute to the ecological cycle.

2-Materials and Methods

This study examines three open-air parking garages located in Isparta's city centre: the Delta Parking Garage, the İyaş Parking Garage, and the Isparta Intercity Parking Garages (Figures 4, 5, and 6) to discuss and illustrate climate change-adapted parking garage design principles. Isparta is a medium-sized city where environmental impacts can be observed in parking garage planning due to its topography, which includes limited flat areas, and increasing vehicle density. The parking garages were strategically located in different neighbourhoods within Isparta.

The Delta Parking Garage, with an area of approximately 1,722 m², is located in the Çelebiler neighbourhood of Isparta's central marketplace.

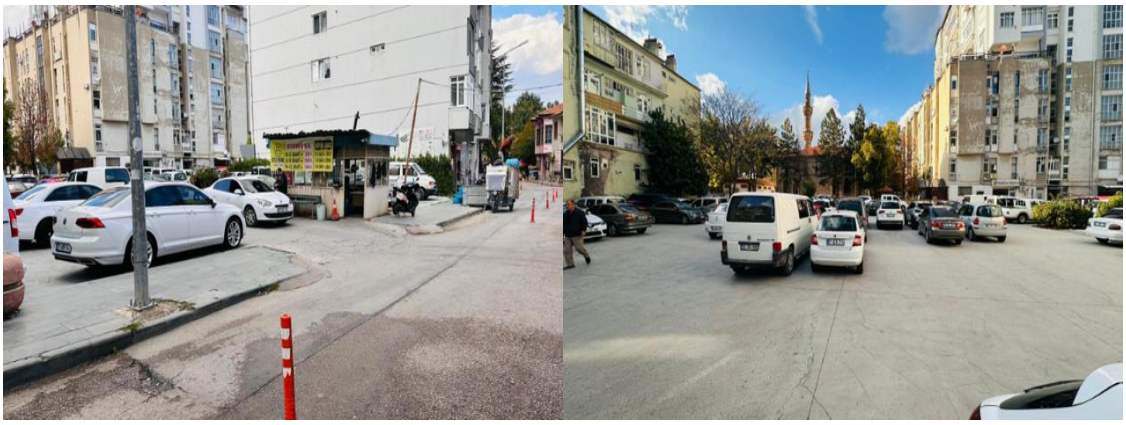

Figure 4. Delta Parking Lot

İyaş Car Park; This car park, approximately 9,211 m² in size, is an area formed after the demolition of the old bus terminal in the Bahçelievler neighbourhood of Isparta (Figure 5).

Figure 5. İyaş Parking Lot

Isparta Intercity Bus Terminal is located in the Çünür neighbourhood. The terminal opened for use on May 1, 2024. The terminal's parking lot is approximately 15,126 m² and is heavily used (Figure 6).

Figure 6. Isparta Intercity Bus Terminal Parking Lot

In this context, the study analyses the status of existing parking lots through the use of permeable surfaces, rainwater management, vegetative shading, and green infrastructure integration, as well as energy-efficient lighting systems and accessibility, which are fundamental design principles prominent in the literature. Thus, the evaluations conducted on these three existing and currently in use parking lots in Isparta will contribute to both local governments and sustainable urban design policies.

3. Findings and Discussion

In this study, three open-air parking lots located in Isparta's city centre—Delta Parking Lot, İyaş Parking Lot, and Isparta Intercity Bus Terminal Parking Lot—were evaluated within the context of climate change-adapted design principles. The findings were interpreted under the headings of permeability, rainwater management, vegetative landscaping and green infrastructure, energy efficiency and lighting, surface temperature and microclimatic conditions, accessibility, and user comfort. The urban context, physical conditions, and existing design features of all three areas differ significantly from one another. These differences also lead to a variation in the capacity to adapt to climate change (Graça, 2022; UN-Habitat, 2022). The surface materials of the three sample parking lots do not show significant differences in terms of climate adaptation potential. A private company operates the Delta Parking Lot as a paid parking lot. It has a capacity of approximately 90 to 95 vehicles. There are no plantings, vehicle boundaries, or accessible parking spaces (Figure 4). Its asphalt and concrete paving make the surface completely impermeable. This causes water to accumulate on the surface after precipitation, preventing natural infiltration. Furthermore, the dark surface absorbs high levels of sunlight, leading to increased heat accumulation and causing the area to experience thermal stress during the summer months.

İyaş Parking Lot has a capacity of approximately 300–310 vehicles and is a free parking area. Despite the large open spaces surrounding it, there are no green spaces. The ground impermeability rate is high, and there are no designated vehicle boundaries, designated parking areas for people with disabilities, or pedestrian accessways. However, the openness of the area on three sides provides a partial advantage in terms of air circulation. However, because there is no permeable ground or drainage infrastructure to direct water, surface runoff after rainfall is dispersed in an undirected manner.

The bus terminal parking lot has a capacity of approximately 500 to 510 vehicles. Thanks to its interlocking paving stone pavement, it exhibits a partially permeable surface. This feature allows water to naturally infiltrate, albeit slightly, without accumulating on the surface, especially during light to moderate rainfall. The literature indicates that similar systems reduce surface runoff, maintain groundwater balance, and mitigate the urban heat island effect (Cacciuttolo et al., 2023; Hong & Lee, 2021). However, observations indicate that the paving gaps in the bus terminal parking lot fill over time, and permeability decreases with usage. Overall, all three parking lots exemplify urban typologies with a high proportion of impermeable surfaces. This poses sustainability risks in terms of both the water cycle and thermal comfort in a city like Isparta, which experiences hot and dry summers, large daily temperature fluctuations, and cold and rainy winters.

Field observations revealed that none of the three parking lots has integrated rainwater harvesting, biofiltration, or directed drainage infrastructure. Because the ground level of the Delta Parking Lot is slightly lower than its surroundings, water accumulation after rainfall is typical. This accumulation does not seep through cracks in the ground, accelerating surface deterioration and reducing user safety. Rainwater runoff is more prevalent in the İyaş Parking Lot due to its large surface area; however, due to the lack of a drainage system, controlled removal of this water is impossible. Small cracks in concrete surfaces, in particular, lead to uneven water flow. In such areas, without the use of nature-based solutions such as rain gardens, surface gutters, or permeable drainage strips, water infiltration into the soil remains minimal (EEA, 2023). While the Bus Terminal Parking Lot appears to have an advantage over the other

two sites due to its interlocking stone paving surface, it also lacks a planned rainwater harvesting system or biofiltration system. In this context, all the parking lots in the Isparta example lack systems that contribute to the water cycle. Under their current conditions, they function as impermeable spaces that rapidly drain rainwater away from the surface.

Green infrastructure integration, one of the most effective tools for adaptation to climate change, is not present in any of the three parking lots. The Delta Parking Lot is physically unsuitable for the addition of green space due to the dense construction surrounding it. Although the İyaş Parking Lot is optimally located for potential green infrastructure applications due to its open three sides, the area lacks any vegetative landscaping. The large surface area reduces user comfort in the summer months due to the lack of shade, leading to increased interior temperatures. The Bus Terminal Parking Lot is similarly devoid of green spaces. Due to the lack of shaded walkways and planted borders, microclimatic comfort is limited. All these observations indicate that none of the "climate-resilient open space" criteria defined by UN-Habitat (2022) are met.

In terms of energy use, none of the three parking lots exhibits an energy-efficient design approach. The Delta Car Park has no lighting; nighttime use is provided by indirect light from surrounding commercial buildings and street lighting outside the parking area. Similarly, the Iyaş Car Park lacks a standalone lighting system; a few floodlights placed on the shopping mall facade provide limited light. This poses problems for both user safety and energy efficiency. In the Bus Terminal Car Park, lighting provided by high-mast floodlights covers the entire area but consumes a significant amount of energy. Such systems are not compatible with the low-carbon and sensor-based lighting strategies recommended by UN-Habitat (2022) and the EEA (2023). No area contains solar panels, motion sensors, LED-based lighting, or energy storage systems. Therefore, all three car parks offer significant opportunities for improvement in energy efficiency and reducing carbon emissions.

Field observations indicate that surface temperatures, particularly in the Delta and Iyaş parking lots, can be higher than the surrounding average. This difference is related to the absorption of solar radiation by dark-colored asphalt and concrete surfaces. The fact that such surfaces store heat during the day and release it slowly at night reinforces the urban heat island effect (Razzaghmanesh & Beecham, 2019). The Bus Terminal Parking Lot, thanks to its open location, offers relatively better air circulation. However, due to the lack of shade structures or tree cover, surface temperatures remain high. Microclimatic comfort cannot be achieved unless light-colored pavements or shaded transition areas are used in parking areas (Graça, 2022). In this context, all three areas lack heat-reducing strategies in terms of climate-adaptive design. Heat accumulation is thought to be particularly high around the Delta Parking Lot, particularly when combined with the reflective surfaces of surrounding structures.

None of the three parking lots has designated parking areas for people with disabilities. This is a significant shortcoming in terms of both accessibility standards and inclusive urban design principles. Additionally, elements that would increase user comfort, such as pedestrian paths, bicycle parking areas, or shaded pedestrian crossings, are absent. Despite being located in an area with heavy pedestrian traffic, the Iyaş Parking Lot lacks any designated pedestrian safety areas. This demonstrates that the parking lot is designed solely for vehicles and has strayed from its public function. Aldridge & Medina (2021) emphasise the importance of transforming parking lots into multifunctional public spaces for social sustainability. In this context, no trace of this transformation approach was found in any of the examples in Isparta.

The findings revealed that parking lots in Isparta are primarily composed of impermeable surfaces. This creates a critical vulnerability in terms of rainwater management. Hong and Lee (2021) demonstrated that permeable surfaces contribute to the prevention of urban floods by increasing rainwater infiltration capacity, while Cacciuttolo et al. (2023) demonstrated that permeable paving systems significantly reduce surface runoff. However, these systems were not found in the parking lots examined. In medium-sized cities like Isparta, rainwater management relies heavily on sewer infrastructure, resulting in the exclusion of nature-based solutions (such as rain gardens, biofilters, and surface gutters) from design processes. This not only increases surface runoff but also hinders groundwater recharge and weakens the water cycle balance of the urban ecology (EEA, 2023). Therefore, converting parking lots to permeable surface systems should be considered a priority action area in the city's climate adaptation strategies.

The lack of vegetative landscaping or green infrastructure in all three parking lots has a direct negative impact on microclimatic conditions. Graça (2022) emphasises that planting trees in urban open spaces is one of the most effective ways to reduce surface temperatures and improve thermal comfort. The primary reason for the lack of green infrastructure in Isparta's examples is that parking lot designs are solely focused on "vehicle capacity."

The Delta Parking Lot in the city centre, with its surrounding high-rise buildings, blocks microclimatic air circulation, leading to heat accumulation and deterioration of air quality. Despite its enormous open space potential, the Iyaş Parking Lot lacks vegetative shading. While the Bus Terminal Parking Lot offers better airflow due to its open surroundings, it falls short in terms of "heat island reduction" due to its lack of green infrastructure. These conditions clearly contradict UN-Habitat's (2022) principles of "landscape-based solutions to urban heat risk."

Energy efficiency is an often-overlooked yet critical element in the adaptation of parking areas to climate change. None of the three parking lots examined has LED lighting, solar panels, or intelligent energy management systems. This increases both carbon emissions and energy costs. UN-Habitat (2022) states that solar-powered lighting systems in urban open spaces are effective in reducing carbon emissions. Furthermore, Aldridge and Medina (2021) emphasise that photovoltaic shading structures in parking lot designs provide dual benefits in terms of both energy production and heat reduction. Therefore, parking lots in Isparta are classified as "passive energy-consuming spaces" in this respect. Even simple interventions for energy efficiency (e.g. LED conversion or solar panel pergola systems) can both reduce carbon emissions and become part of sustainable urban infrastructure.

Accessibility assessments indicate that parking lots in Isparta are designed with a focus on vehicles. Accessible parking spaces, pedestrian paths, and bicycle parking are not available in any area. This situation is inconsistent with the "inclusive and multifunctional open space" principles recommended by UN-Habitat (2022). Aldridge and Medina (2021) emphasise that transforming parking lots into multifunctional urban spaces is crucial for social sustainability. In this context, the Iyaş Parking Lot, thanks to its connection to the shopping mall, may have potential as an urban meeting space in the future. However, all three parking lots currently lack user comfort and social accessibility.

The Parking Regulation (2018), the fundamental legislation for parking lot planning in Türkiye, focuses on capacity and site selection criteria but does not include climate change adaptation or environmental performance criteria. This situation is clearly observed in the Isparta example. The lack of nature-based solutions, energy-efficient systems, or green infrastructure integration

in the parking lots examined is related to the legislation's failure to define physical environmental performance. In Isparta, parking areas have mainly been planned to meet short-term urban needs without considering long-term climate resilience. However, the city's topography, open space potential, and climate conditions provide a suitable foundation for implementing nature-based designs. In this context, the Bus Terminal Parking Lot, with its partially permeable surface structure, is a good starting example.

This study's evaluation of three open-air parking lots in Isparta's city centre within the context of climate change-adaptive design principles is crucial for revealing the current status and potential for improvement of open-air parking areas in Türkiye. The findings demonstrate that the risks stemming from climate change, clearly emphasised in the literature, are clearly observed in open-air parking lots in cities (IPCC, 2021; EEA, 2023). When the strengths and weaknesses of the current situation are evaluated, it is clear that parking lots are in dire need of transformation in terms of both their physical infrastructure and environmental performance. Firstly, the predominance of impermeable surfaces creates serious problems, such as rising surface temperatures and a decrease in in-situ water infiltration capacity in Isparta's arid-semi-continental climate. Particularly in the Delta and Iyaş parking lots, the heat stored by asphalt and concrete surfaces during the day and released at night hurts the microclimate. This is identified in the literature as one of the main factors contributing to the urban heat island effect (Razzaghmanesh & Beecham, 2019). While the partially permeable structure of the Bus Terminal Parking Lot is a positive example, the joint gaps that fill over time reduce permeability and limit the system's effectiveness. This finding is consistent with studies demonstrating that permeable pavement systems require regular maintenance (Hong & Lee, 2021; Cacciuttolo et al., 2023). One of the most critical shortcomings in adapting to climate change is stormwater management. None of the three parking lots features nature-based infrastructure solutions, such as rain gardens, biofilters, infiltration trenches, or storage systems, which can increase surface runoff and lead to water accumulation after sudden rainfall. UN-Habitat (2022) and EPA (2020) guidelines identify the integration of parking areas with rainwater management systems as a fundamental requirement for climate-resilient design. In this context, the current approach, as illustrated by the Isparta example, is insufficient to mitigate the risks associated with extreme precipitation resulting from climate change. The lack of green infrastructure is the most significant environmental vulnerability revealed by the findings. The lack of afforestation, green border elements, and shade both exacerbates the heat island effect and reduces user comfort. Extremely high vehicle interior temperatures, thermal stress on surfaces, and unshaded pedestrian crossings, particularly in summer, are factors that negatively impact microclimate. The literature indicates that green infrastructure can reduce surface temperatures in parking lots by 3–8°C (Graça, 2022). Nevertheless, the absence of green infrastructure in all three parking lots examined indicates a significant loss of opportunity for climate adaptation in urban open spaces.

When evaluated from an energy efficiency perspective, the absence of LED systems, sensor-activated lighting, or solar panels in parking lots exacerbates their negative impact on the carbon footprint. However, numerous studies have demonstrated the benefits of photovoltaic shading structures in terms of both energy production and thermal control (Aldridge & Medina, 2021). The fact that all existing parking lots in Isparta are passive energy-consuming spaces leaves a picture far behind modern parking standards in the context of climate change. Findings regarding accessibility and social sustainability, however, indicate that parking designs in the city are entirely vehicle-focused. The lack of accessible parking spaces, pedestrian paths, and

bicycle lanes, as well as the absence of user-centred design elements in any area, indicates that parking lots are deviating from their role as urban public spaces. However, the current approach recommends transforming parking lots into multifunctional, inclusive public spaces integrated with green infrastructure (UN-Habitat, 2022; Aldridge & Medina, 2021).

Furthermore, the study findings reveal not only shortcomings but also potential opportunities. The Iyaş Parking Lot's large surface area offers substantial potential for rainwater management and shading applications. The partially permeable structure of the Bus Terminal Parking Lot provides an important starting point for climate-adapted transformation. With these features, existing parking lots in Isparta can be transformed into sustainable microecosystems that adapt to climate change with the right interventions.

4. Conclusion and Recommendations

Analysis of three parking lot examples reveals that open-air parking lots in Isparta have not yet been integrated into climate change adaptation strategies.

These findings indicate that open-air parking lots continue to increase environmental impacts unless they are integrated with climate change-adapted urban infrastructure systems. The results explicitly obtained for Isparta suggest that open-air parking areas in similar medium-sized cities in Türkiye also pose similar environmental risks.

The findings align with the international literature, which emphasises the transformative potential of open-air parking lots in combating climate change (Graça, 2022; UN-Habitat, 2022; EEA, 2023). However, limited studies conducted in Türkiye suggest that this issue remains a voluntary environmental choice, rather than an infrastructural necessity.

The Isparta example provides a typical example for cities in the early stages of this transformation process. It demonstrates that local governments should integrate climate adaptation criteria into zoning plan decisions in parking lot designs. This research was conducted using field observations and existing physical data. Future studies are recommended to be supported by numerical modelling and simulation-based approaches, such as:

- Surface temperature measurements,
- Water permeability analysis,
- Modelling the microclimatic effects of plant species,
- Energy efficiency analyses of photovoltaic shading systems. Furthermore, conducting similar analyses in cities in different climatic zones will contribute to the classification of climate-adapted parking typologies on a national scale.

The use of permeable paving systems (permeable interlocking paving, grass flooring, permeable concrete) in parking lot surfaces will reduce surface runoff and encourage groundwater infiltration. Integrating afforestation, green strips, and shaded walking areas will reduce surface temperatures and increase microclimatic comfort. Solar panel-supported pergola systems can provide both energy generation and shading. On-site water management, including biofilters, rain gardens, and water storage systems, will help control sudden surface runoff in the city. The widespread adoption of LED-based, sensor-controlled, or solar-powered lighting systems will reduce energy consumption and lower carbon emissions. Parking lots should be repurposed as user-centred public spaces, not just vehicle-centred ones, through the provision of accessible parking spaces, bicycle racks, and shaded pedestrian crossings. A "climate-

compatible parking design guide" should be prepared for municipal parking projects, and performance indicators such as permeable surface area, percentage of green space, and energy efficiency should be made mandatory for projects.

- Quantitative microclimate measurements: In future research, in situ measurements of microclimatic parameters such as surface temperatures, humidity, wind speed, and the heat island effect will contribute to the scientific validation of climate-adaptive parking designs.
- Simulation-based analyses: The thermal impacts of different surface material scenarios can be modelled using geographic information systems (GIS) and energy modelling software (e.g., ENVI-met, i-Tree, and Rhino-Grasshopper plugins).
- Comparative regional studies: Comparing parking lot examples located in different climate zones in Türkiye (e.g., Mediterranean, Central Anatolia, and Black Sea) will reveal the impact of regional climate differences on design criteria.
- User behaviour and comfort perception: Social studies assessing parking lot users' perceptions of temperature, shading, accessibility, and safety can help develop user-based adaptation strategies.
- Nature-based infrastructure solutions: Rain gardens, biofiltration swales, and permeable soil combinations can play an important role in stormwater management and microclimate balance.
- Photovoltaic shading systems: Solar panel-supported shading structures can both reduce surface temperatures and reduce the carbon footprint of parking lots through energy production.
- New material research: Engineering studies on light-colored, permeable surface materials with high heat reflection coefficients (e.g., "cool pavement" technologies) should be increased.
- Smart lighting systems: Energy consumption can be reduced by integrating solar-powered LED lighting with motion sensors and timers.
- Municipal-level climate adaptation guidelines: A "Climate-Compatible Open Space Design Guide" should be prepared for parking lot projects; indicators of permeable surface area, percentage of green space, energy efficiency, and social inclusion should be made mandatory in this guide.
- Strengthening the legal framework: The current Parking Regulation (2018) focuses only on capacity and location selection. Future revisions should include climate adaptation criteria, green infrastructure requirements, and energy efficiency criteria.
- Planning based on local climate data: Parking lot design standards supported by microclimatic data should be developed in every city. These standards should be integrated into zoning plans and made applicable to ensure consistency. • Education and awareness campaigns: In-service training programs on climate-compatible design should be organised for architects, engineers, and urban planners; this content should be incorporated into university architecture and urban planning curricula.

In the future, parking lots should not only serve as vehicle storage areas but also be multifunctional open spaces that are integral to the urban ecology. Successfully achieving this

transformation requires a holistic approach that encompasses not only engineering or architecture but also urban policy, management, and community engagement.

Abstract

In recent years, the rapid increase in urbanisation and the parallel rise in the number of motor vehicles have created a significant demand for parking in cities, often leading to the shrinkage of green spaces and disruption of the ecological balance. Therefore, current urban planning approaches reveal that parking lots are not only functional spaces but also areas that must be evaluated in terms of sustainability and ecological integrity. This study is a compilation that examines how AI-supported planning approaches can contribute to the protection of green spaces. Literature reviews demonstrate that AI is a crucial tool for analysing spatial data to determine optimal parking locations and making design decisions that minimise environmental impacts. Furthermore, AI applications integrated with nature-based solutions strengthen environmental sustainability. Consequently, AI-based parking planning approaches have strategic potential for protecting green spaces, reducing carbon emissions, and creating cities adaptable to climate change. This study provides a comprehensive perspective that will contribute to the development of sustainable urban planning policies.

Keywords: Artificial Intelligence, parking planning, urban green spaces, sustainability.

1. Introduction

Rapid urbanisation observed worldwide since the beginning of the 21st century has led to significant increases in energy consumption, transportation demand, and spatial pressures. According to the United Nations' World Cities Report 2024, approximately 68% of the world's population is projected to live in cities by 2050, with the rate of urbanisation expected to double, particularly in developing countries (UN-Habitat, 2024). This process creates significant pressure on existing infrastructure capacity and threatens the sustainability of urban systems. The increase in the number of motor vehicles, in particular, has become a significant problem in terms of both energy consumption and urban land use.

Car ownership in cities has increased dramatically over the last three decades, and the resulting demand for parking has become one of the most critical elements of urban spatial planning (Shoup, 2021). While traditional transportation planning aims to facilitate vehicle mobility, this approach has inevitably led to adverse outcomes, including the shrinking of green spaces, the expansion of impervious surfaces, and the disruption of the ecological balance (Cheng et al.,

2022; Zhang et al., 2023). The increasingly concretised urban fabric strengthens the urban heat island effect, accelerates surface runoff, increases flood risk, and reduces carbon sequestration capacity (Wang et al., 2022). Therefore, parking planning is not only a functional necessity but also an area that requires re-evaluation in terms of ecological sustainability, climate adaptation, and the integration of green infrastructure (Qiao & Zhou, 2023).

In this context, artificial intelligence (AI) technologies offer revolutionary opportunities in urban planning. Thanks to the integration of advanced data analytics, deep learning, geographic information systems (GIS), and remote sensing data, complex spatial relationships can be analysed with higher accuracy (Kandt & Batty, 2021). AI stands out not only for its ability to interpret past data but also for its capacity to generate future scenarios. This enables the development of predictive and adaptive models in urban planning, allowing for multidimensional balances among transportation demand, land use, energy efficiency, and environmental impacts (Li et al., 2024).

Parking lot planning is one area where these technologies can be directly applied, as site selection is not only about spatial suitability but also involves the combined evaluation of environmental, social, and economic indicators. Machine learning-based systems can determine the most appropriate parking locations by analysing variables such as topography, population density, traffic flows, green space density, and carbon emissions (Saha et al., 2023). Thus, AI not only optimises the site selection process but also functions as a decision support mechanism that increases environmental awareness.

Current literature clearly demonstrates the potential of AI-supported urban planning to contribute to environmental sustainability. Vinuesa et al. (2020) stated that artificial intelligence is directly related to at least 134 targets of the Sustainable Development Goals, and that this technology has a transformative impact, particularly in climate action, clean energy, intelligent transportation, and sustainable cities. Similarly, the European Commission's 2023 AI for the Green Deal report emphasised the need to develop artificial intelligence in line with environmentally friendly policies and green transformation goals (European Commission, 2023).

The use of artificial intelligence in urban planning is not only a technical innovation but also enables transparency, accuracy, and the strengthening of data-driven decision-making processes. Thanks to big data infrastructures and sensor-based systems, dynamic indicators such as parking demand, traffic density, and air quality can be monitored in real time, and this information can be integrated into planning policies (Kitchin, 2020; Zhang et al., 2023). This transforms parking planning from a static engineering problem into a holistic systems approach encompassing environmental, social, and technological dimensions. On the other hand, increasing vehicle use impacts not only spatial sustainability but also economic and social sustainability. The time vehicles spend in traffic searching for parking can account for approximately 8–10% of total carbon emissions in cities (Shoup, 2021). Therefore, the integration of intelligent parking systems and green space protection policies is strategically important for cities' goal of becoming carbon neutral (Tan et al., 2021). AI-powered sensor networks can monitor parking lot occupancy rates and guide vehicles, thereby reducing fuel consumption, emissions, and traffic congestion.

In Türkiye, innovative urban planning applications have gained significant momentum in recent years. The National Smart Cities Strategy and Action Plan (2020–2025) report emphasises that AI-supported data analytics can be integrated with urban planning, parking management,

energy efficiency, and green space protection policies (Republic of Türkiye Ministry of Environment, Urbanisation and Climate Change, 2021). However, most applications in Türkiye are still at the operational level; the use of AI-supported decision systems at the spatial planning scale appears to be limited (Yılmaz & Aydınoğlu, 2023). This creates a significant gap in academic research and local government policies.

Integrating parking planning with green space management is important not only for environmental reasons but also for social well-being. Urban green spaces offer a range of multifaceted ecosystem services, including microclimate regulation, recreation, and public health benefits (Haase et al., 2021). Therefore, combining nature-based solutions with AI analyses in parking planning is a critical strategy for achieving sustainable urban planning goals.

Existing research demonstrates that AI is not only a technological tool in urban planning but also a new paradigm that supports environmental awareness, spatial efficiency, and social sustainability (Batty, 2021; Li et al., 2024). This study examines this paradigm shift in parking lot planning, specifically examining how AI-based models can contribute to the preservation of green spaces. Through a literature review, it is demonstrated that the integrated use of AI in spatial decision-making processes, combined with nature-based approaches, is a strategic direction for ecologically resilient cities of the future.

2. Materials and Methods

This study is a qualitative review examining the contributions of artificial intelligence technologies to parking lot planning and the protection of green spaces. The research aimed to develop a conceptual framework by integrating current scientific trends, theoretical approaches, and application examples from the literature. The study was designed with an interdisciplinary approach, encompassing publications in the fields of urban planning, environmental engineering, computer science, and sustainability studies.

During the research process, a systematic search was conducted for published academic studies on the intersection of artificial intelligence and sustainable planning. National and international databases, including Scopus, Web of Science (WoS), ScienceDirect, Google Scholar, and TR Index, were utilised for data collection. International policy documents and reports (e.g., United Nations-Habitat, European Commission, World Bank, OECD, and IPCC) were also included as reference sources.

The main keywords used in the search process were: “artificial intelligence,” “urban parking planning,” “green space,” “sustainability,” “machine learning,” “spatial analysis,” “ecological urbanism,” and “nature-based solutions.” In the Turkish literature review, the terms “artificial intelligence,” “parking lot planning,” “green space management,” “sustainable urbanisation,” and “smart cities” were used.

These keywords ensured that the scope of the research remained within the intersection of parking lot planning, green infrastructure, and artificial intelligence technologies. The DOI, journal impact factor, and citation counts of the selected publications were checked against the Web of Science database. For ethical reasons, the study was conducted using only open-access and publicly available data. No participant or personal data was used, and all sources were cited. Consequently, the study was structured as a literature-based qualitative analysis, and the obtained information was synthesised within a conceptual framework.

3. Findings and Discussion

3.1. The Role of Artificial Intelligence in Urban Planning Processes

In recent years, artificial intelligence (AI) has evolved from a data analysis tool to a predictive and transformative decision support mechanism in urban planning. By integrating big data analytics, remote sensing, and geographic information systems (GIS), AI algorithms can assess the spatial dynamics of cities in a multidimensional manner and establish complex relationships between population density, land use, transportation flows, and environmental indicators (Batty, 2021; Li et al., 2024). In this context, AI has transformed the traditional planning approach from a static analysis into a learning and continuously updating system. For example, convolutional neural networks (CNNs) can identify the distribution of green spaces, surface temperature differences, and urban heat island (UHI) density from high-resolution satellite imagery and integrate this data into spatial decision models (Wang et al., 2022). Such analyses enable the quantitative measurement of environmental impacts in parking lot planning and the selection of alternatives that will cause minimal ecological damage.

The most significant contribution of AI-based models is their ability to incorporate ecological planning criteria into spatial optimisation processes. This enables the development of planning approaches compatible with the carrying capacity of urban ecosystems and is of great importance for environmental sustainability (Kandt & Batty, 2021).

3.2. Artificial Intelligence Applications in Parking Lot Planning

Parking lot planning is a critical component that directly impacts both transportation efficiency and environmental quality in urban systems. Four main application areas of AI-based parking lot planning stand out in the literature:

(1) Location selection optimisation,

(2) Real-time occupancy prediction,

(3) Dynamic pricing and traffic routing,

(4) Environmental impact modelling (Saha et al., 2023; Cheng et al., 2022).

For example, in the "Smart Green Parking System" model developed in Singapore, deep learning algorithms reduced parking time by 28% by monitoring parking lot occupancy rates in real-time (Tan et al., 2021). This not only increased energy efficiency but also significantly reduced exhaust emissions.

Similarly, AI-powered parking management systems in European cities (especially in Amsterdam and Copenhagen) have developed spatial decision models to maintain connectivity with green spaces. These systems feature integrated parking spaces with permeable surfaces and planted lanes, which support both rainwater drainage and contribute to microclimate regulation (Jensen & Löfström, 2020).

Similar trends are emerging in Turkish examples. Metropolitan municipalities, in particular, aim to identify parking locations with ecological sensitivity by analysing the relationship between parking demand and green space density in their "smart city data platforms" (Yılmaz & Aydınoğlu, 2023).

3.3. Strategic Contributions of Artificial Intelligence in the Protection of Green Spaces

Green spaces are vital components that form the ecological backbone of cities. These spaces reduce greenhouse gas emissions by acting as carbon sinks, mitigate the urban heat island effect, provide habitats for biodiversity, and support urban health by regulating microclimates (Haase et al., 2021). However, the expansion of parking and transportation infrastructure, particularly in regions with high urbanisation rates, poses a threat to the sustainability of these spaces (Zhang et al., 2023). Artificial intelligence technologies offer revolutionary tools for creating early warning and monitoring mechanisms to prevent this loss. Deep learning models developed using satellite imagery, LiDAR data, and multispectral analysis can accurately classify the spatial distribution of green spaces and monitor their changes over time (Gao et al., 2022). For example, analysing "Normalised Difference Vegetation Index (NDVI)" data with AI algorithms can identify the decrease in green space due to parking lot expansion at the pixel level, providing planners with a scientific decision basis for spatial interventions.

Another strategic contribution of AI in this area is the quantification and spatialisation of ecosystem services. In traditional planning processes, indicators such as carbon sequestration, air quality improvement, or contribution to the water cycle are assessed qualitatively. However, AI-based models can analyse these impacts quantitatively, for example, estimating the potential carbon loss or surface temperature increase of a parking lot project (Qiao & Zhou, 2023). Thus, the planning process transforms from a physical location selection into a holistic decision-making mechanism that includes ecological cost analysis. With this method, ecosystem continuity can be preserved by recommending multi-story or underground alternatives instead of constructing new parking lots in areas with low green space density (Li et al., 2024). AI also enhances the performance of green infrastructure systems by integrating with nature-based solutions. Sensor-based monitoring networks transform green space management into a dynamic process by collecting real-time data on plant health, soil moisture, and surface temperature (Song et al., 2020). Thus, maintenance, irrigation, and restoration decisions for green belts surrounding parking lots can be optimised in a data-driven manner.

In the Turkish context, AI-supported green space monitoring systems have begun to be developed, particularly in major cities such as Istanbul and Ankara. The Istanbul Metropolitan Municipality's 2022 "Smart City Strategy" report states that green infrastructure mapping projects supported by satellite data strengthen the urban ecosystem and provide guidance for maintaining green connectivity in parking lot projects (IMM, 2022).

Consequently, AI-based analyses support the protection of green spaces at three levels:

1. Predictive monitoring—Pre-detection of green space loss,
2. Quantitative assessment—Measurability of ecosystem services,
3. Adaptive management—Planning decisions based on real-time environmental data.

When these three levels are considered together, it becomes clear that AI is not merely a technical tool for preserving the integrity of urban ecology but a strategic sustainability tool.

Nature-based solutions (NBS) are planning approaches that mimic ecological processes or draw direct inspiration from nature. When integrated with AI, these solutions become much more measurable, manageable, and scalable. AI-supported NBS approaches aim to increase ecosystem resilience in cities by analysing indicators such as permeable surface ratio, vegetation density, and water retention capacity (Raymond et al., 2017; Bhaduri et al., 2021).

For example, the "AI-Green Parking" system developed in China combines NDVI data, city temperature maps, and rainwater runoff models to reduce the environmental impact of parking lots (Liu et al., 2023). Similarly, the European Union's Nature for Cities project optimises the compatibility of parking lots, green roofs, and vertical gardens with carbon neutrality targets through AI-supported multi-criteria analyses (European Commission, 2021).

Such hybrid systems transform parking areas from passive infrastructure elements into active ecological components. In this transformation, AI adds a new dimension to nature-based planning by enabling continuous monitoring of environmental performance and automatically recommending necessary corrective measures.

Such hybrid systems transform parking areas from passive infrastructure elements into active ecological components. In this transformation, AI adds a new dimension to nature-based planning by enabling continuous monitoring of environmental performance and automatically recommending necessary corrective measures.

Artificial intelligence (AI)-supported parking planning is an innovative approach that has the potential to protect the integrity of green spaces while meeting the increasing demand for vehicles in cities. However, this approach represents not only a technical transformation but also a multi-layered change that presents new opportunities and challenges at the spatial, ecological, and governance levels (Batty, 2021; Qiao & Zhou, 2023).

The most significant contribution of AI is its ability to analyse complex spatial relationships with high accuracy and make ecological sustainability measurable. Deep learning and remote sensing-based systems can quantitatively assess the environmental impacts of parking areas, addressing variables such as impervious surface ratio, plant density, carbon emissions, and surface temperature within the same model (Gao et al., 2022; Liu et al., 2023). Another strength of AI-based systems is their ability to integrate with nature-based solutions. Raymond et al. (2017) and Bhaduri et al. (2021) emphasise that AI offers the possibility of "measurable nature-based planning" by modelling the impact of applications such as permeable pavement, rain gardens, vertical gardens, and green roofs. This approach moves design decisions from intuitive to data-driven and predictive.

Furthermore, AI stands out as a tool that facilitates multi-criteria decision-making processes for designers. Optimal parking locations can be determined by simultaneously evaluating various factors, including topography, traffic density, land use, green space distribution, and social access (Saha et al., 2023). This reduces human error and offers significant advantages in terms of time and cost.

However, the success of these models is highly dependent on the quality and accessibility of the data. In developing countries like Türkiye, the lack of high-resolution spatial data limits the accuracy of AI systems (Yılmaz & Aydınoğlu, 2023). It is also worth noting that AI models inherently consume large amounts of energy and have a significant carbon footprint. This could reverse some of the environmental gains (Vinuesa et al., 2020). Therefore, it is necessary to adopt the principles of "green AI" and design models with energy efficiency in mind.

AI-assisted planning creates both new opportunities and new challenges for designers. The most significant advantage is the increased speed and accuracy of spatial analysis processes. AI tools integrated with geographic information systems can process multi-layered data to determine the most suitable parking locations in seconds, thus significantly accelerating the design process (Li et al., 2024). However, to use this technology effectively, designers must possess digital

literacy and data analytics skills. The limited availability of these competencies in traditional planning education poses a significant obstacle to implementation (Kitchin, 2020).

Furthermore, there is uncertainty about how to integrate the results produced by algorithmic systems into planning decisions. While AI proposals often offer the most technically efficient option, they may not sufficiently account for qualitative factors such as social justice, aesthetics, or local identity (Floridi & Cowls, 2019). This requires designers to possess not only data but also the ability to provide contextual interpretation. Another challenge of AI-assisted planning is the ethical and governance dimension. According to the European Commission's "Trustworthy AI" framework, algorithms used in urban planning must be transparent, accountable, and subject to human oversight (European Commission, 2021). However, many local governments lack the institutional capacity to implement these standards. This could lead to the risk of algorithmic biases creating spatial injustices without being noticed (Haase et al., 2021). Therefore, for AI-based parking planning to succeed, technological innovations must be supported by ecological ethics, participatory planning, and multidisciplinary design principles. Once this integration is achieved, AI will not only be a tool for optimising planning processes but also a key to urban transformation in harmony with nature.

4. Conclusion and Recommendations

Generally, AI-assisted parking planning is an innovative approach that strengthens the environmental sustainability of cities, preserves the continuity of green spaces, and improves the quality of social life. This method surpasses traditional planning processes by developing a data-driven, ecologically sensitive, and human-centred approach to urban management. Examples from Türkiye and around the world demonstrate the practical applicability and measurability of this approach. Therefore, future policy and research agendas must focus on holistic planning models that incorporate the ethical, ecological, and social dimensions of AI. Consequently, when combined with nature-based solutions, AI-assisted planning processes will enable cities to transform into not only sustainable but also livable and resilient ecosystems.

The study's results offer multifaceted implications for urban planning and environmental policies. First, municipalities and planning authorities should redefine parking areas not simply as spaces for vehicle storage, but as urban components with ecological functions and social benefits (Grimmond, 2018; Mullaney et al., 2015). Secondly, sustainable parking policies should be integrated with the parameters of carbon emission, green space integrity, and water management. AI systems are powerful decision-support tools that enable this integration, providing planning authorities with digitally based environmental analysis (Kabisch et al., 2016; Johnson et al., 2022). Thirdly, local governments need to develop their data collection, sensor networks, and spatial analysis capacities. AI-based planning applications in Türkiye are still in their early stages; therefore, joint data sharing and research networks should be established among universities, public institutions, and the private sector (IMM, 2022; T.C. ÇŞİDB, 2021). Fourthly, ethical principles and transparency standards should be integrated into planning processes. The principles of data security, accountability, and public scrutiny in AI-based decision systems should be implemented in line with the European Union's "Trustworthy Artificial Intelligence" framework (Floridi & Cowls, 2019; European Commission, 2021). Finally, parking planning should be considered an integral element of the transportation system, integrated with sustainable mobility policies by being planned alongside public transportation, bicycle paths, and pedestrian-focused areas (Newman & Kenworthy, 2015; Tan et al., 2021).

While the protection of green spaces has long been a goal emphasised in sustainable urbanism literature, in practice, it has often been relegated to the background due to spatial pressures. AI has the transformative potential to re-establish this balance. AI enables the development of adaptive planning models that preserve the continuity of green spaces. Thus, AI dynamically processes environmental data, becoming a "living" part of urban ecosystems. Furthermore, AI enables ecological criteria to be measurable in planning decisions by transforming ecosystem services (e.g., carbon sequestration, air quality, microclimate regulation) into numerical planning variables. This encourages the evaluation of green spaces not only as an aesthetic but also as a functional planning component (Haase et al., 2021). AI-supported parking planning also has strong parallels with climate adaptation policies. In this context, parking lots no longer merely serve as vehicle storage; they have also become an integral part of the urban ecosystem.

Although AI-assisted urban planning applications in Türkiye are still in their infancy, the National Smart Cities Strategy (2020–2025) and various metropolitan projects developed over the past few years have created a strong trend in this area (Republic of Türkiye, ÇŞİDB, 2021). However, the biggest obstacle to protecting green spaces in Türkiye is the integrity of data and limited access to open data. For AI models to function effectively, high-resolution spatial data must be regularly updated and shared among local governments. Furthermore, it is crucial that planning institutions possess the necessary institutional capacity to integrate AI-based analyses into their decision-making processes.

This study contributes to the literature on the relationship between AI and sustainable planning, suggesting some directions for future research. Long-term impact analyses: Studies that monitor the environmental, social, and economic impacts of AI-assisted parking and green space integration using long-term datasets are necessary. This will enable us to evaluate the performance of AI models over time.

- Multi-scale modelling: AI-based planning models developed at the neighbourhood, city centre, and regional levels will provide decision-makers with more comprehensive scenario analysis capabilities.
- Increasing public participation: Developing participatory planning approaches that measure social acceptance of AI-based decisions is crucial. Public environmental awareness and local knowledge should be incorporated into the process (Gulsrud et al., 2020).
- Integrated data management: Open data platforms and standardised spatial databases should be created for AI models; this will facilitate international comparability.
- Integration with sustainable mobility: Parking planning should contribute to carbon footprint reduction by integrating with bicycle, pedestrian, and public transportation systems (Qiao & Zhou, 2023).

Abstract

Utopias envision ideal urban orders and visions of urban life and urban structure grounded in equality, sustainability, and collective welfare, while dystopias expose the social and environmental contradictions that arise when these ideals are distorted by power, capital, or inequality. The tension between these two paradigms provides a critical framework for interpreting the evolution of contemporary cities and their prospective futures. The concepts of utopia and dystopia have become increasingly central to theoretical debates in contemporary urban planning. Nevertheless, the ways in which these notions shape contemporary urbanization, urbanism, and visions of future cities remain insufficiently explored. Based on this problem, this study aims to analyze how utopian and dystopian perspectives are reflected in urban planning discourse and how they influence the conceptualization of urban futures. Based on the perspective Eren (2023) has presented for the future of cities and futuristic cities, this paper targets to illustrate how utopian urban ideals often lead to dystopian urban realities. Methodologically, this study adopts a qualitative research design that employs thematic content analysis of scholarly literature indexed in the Web of Science and Scopus databases between 1980-2025, using key terms such as utopia, dystopia, city planning, and sustainability. The analysis of 15 selected key publications identifies three recurring themes: Utopia as a design ideal, dystopia as a critical mirror of modern urbanism, and the need for a dialectical synthesis toward resilient and just urban futures. The paper concludes that utopian imagination and dystopian awareness should be viewed as complementary frameworks guiding city planning toward balance, responsibility, and inclusivity for the future of cities.

Keywords: Utopia, Dystopia, city planning, sustainability, future cities

1. Introduction

Cities have always represented far more than physical agglomerations of buildings, streets, and infrastructure. They are living manifestations of humanity's collective imagination, anxieties, and moral aspirations. Since the earliest settlements, the city has functioned as both a habitat and a projection of how societies imagine the good life. As Mumford (1962) observed, "the city is a product of nature, a symbol of society, and a projection of human values," embodying "the theater of social action" in which technological progress, cultural identity, and ethical order converge. Urban planning has historically mediated between these tangible and intangible dimensions, negotiating the relationship between material realities, political power, and idealized visions of the future of cities. Up to date, utopia and dystopia concepts have profoundly shaped the theory and practice of city planning. Contemporary urban theory views the city not merely as a physical space but as a historical arena where capitalist accumulation, class relations, and power structures are materially expressed (Turut & Özgür, 2018). Within this continuous negotiation, the concepts of utopia and dystopia have profoundly shaped the

theory and practice of city planning (e.g., star-shaped cities such as Palmanova (1593) and Scamozzi's polygonal models (1615), and Renaissance ideal city plans including Filarete's Sforzinda (1972) and Alberti's schemes (1485)).

The notion of utopia, originating in Plato's *Republic* and later articulated in Thomas More's *Utopia* (1516), occupies a foundational place in Western political and urban imagination. Plato's *Republic* is a philosophical inquiry into the nature of the ideal city. Deriving from the Greek ou-topos ("no place") and eu-topos ("good place"), the term denotes both an ideal society and the impossibility of its full realization. More's utopia was not merely a literary experiment, but an early critique of social inequality and moral corruption, using spatial order as a metaphor for justice and harmony. Utopian thinking thus provided a framework for envisioning cities as instruments of moral and social reform (Mumford, 1962; Levitas, 1990). Building on More's ideas, Leon Battista Alberti developed ideal urban schemes that later influenced the Renaissance ideal city plans of Albrecht Dürer, Cataneo, Maggi, and Filarete.

From Ebenezer Howard's Garden City (1902) to Le Corbusier's Ville Radieuse (1924) or the Walking City of Ron Herron (1964) modern urbanism has been profoundly shaped by the belief that spatial design could regenerate society through order, rationality, and aesthetic coherence (Fishman, 1982). Utopian plans promised balance between nature and industry, community and individuality, and progress and morality (Harvey, 2000; Hall, 2002). As Schubert (2004) argues, the tension between utopian design and social reality became increasingly evident in late-modern urbanism, where visionary spatial ideals often collided with everyday social complexities.

Howeve r, utopian imagination inherently carries the risk of control and exclusion when visions of order become totalizing. In this sense, dystopia emerges not as the opposite of utopia but as its critical counterpart. The term dystopia, coined by John Stuart Mill in the nineteenth century to describe "a place where everything has gone wrong," reflects the recognition that the pursuit of perfection can generate new forms of domination. Within urban planning, this critique resonates with the concept of "total design," in which architecture, landscape, transportation, and social life are subsumed under a single, centralized vision (Banham, 1960; Choay, 1997). When such comprehensive rationality suppresses diversity or spontaneity, the utopian project risks becoming dystopian.

Figure 1. Team Disney Building (Michael Graves, 1991), Burbank, California.

As Harvey (2000) and Soja (2010) emphasize, cities simultaneously embody progress and inequality, creativity and control. The commodification of space, social fragmentation, and the erosion of public life illustrate how ideals of efficiency and order can inadvertently reproduce alienation and exclusion. These dual narratives—utopia as vision and dystopia as warning—

are not opposites but dialectically intertwined (Jameson, 2005; Baeten, 2002). Each concept both defines and critiques the other, shaping the theoretical and practical possibilities of urban planning.

The twentieth century's grand experiments in modernist planning, such as Le Corbusier's Radiant City, Brasília, and numerous postwar new towns, exemplify this dialectic. Animated by utopian ideals of order and efficiency, they often resulted in socially fragmented, environmentally destructive, or authoritarian urban forms. Fainstein (2010) argues that the central challenge for contemporary planning is to sustain normative ideals—justice, equality, and sustainability—without succumbing to technocratic control or aesthetic abstraction.

In the contemporary era, the dialectic between utopia and dystopia has become more complex. Neoliberal restructuring, digitalization, and the global climate crisis have transformed how cities are imagined and produced (Brenner & Schmid, 2015). Contemporary utopian visions, epitomized by smart city and sustainability paradigms, promise efficiency, innovation, and ecological responsibility. Yet, as Kitchin (2014) and Greenfield (2013) observe, such frameworks often reproduce existing hierarchies, consolidate power within corporate and governmental domains, and marginalize citizens' voices. Similarly, sustainability agendas may inadvertently depoliticize inequality or commodify ecological values. In this sense, dystopian critique remains vital, revealing how contemporary "good city" narratives may conceal exclusion, surveillance, and environmental degradation (Baba, 2020; Eren, 2023).

City planning today operates within a paradox: It must harness utopia's creative vision while remaining vigilant to dystopia's ethical warnings. Bridging these modes of thought is not merely theoretical. This is a practical gap. When planning abandons imagination, it risks cynicism; when it abandons critique, it risks authoritarian optimism. Marcuse (2009) 's concept of "critical utopianism" offers a path forward, advocating for a planning approach that is simultaneously visionary and self-reflexive. City planners are thus called to design not for perfection, but for adaptability, inclusiveness, and ethical awareness (Gehl, 2010).

There is a need to study the influence of utopian and dystopian imaginaries and their role in redefining urban planning thought. This study argues that the dialectical relationship between utopia and dystopia constitutes an underexplored foundation for reimagining the city in the twenty-first century. It aims to understand the dialectical relationship between utopia as a design ideal and dystopia as a critical mirror of modern urbanism.

By synthesizing insights from urban theory, political philosophy, and environmental ethics, it examines how these paradigms shape planning discourse and practice. The goal is not to abandon utopian dreaming, but to ground it in pluralism, participation, and care (Eren, 2023). This synthesis transforms city planning into an act of dreaming and an act of responsibility — bridging ideals with the realities of urban life. A future-oriented city would prioritize equity over spectacle, participation over control, and ecological balance over profit (Lefebvre, 1991; Fainstein, 2010). According to Eren, the planning institution mediates between aspiration and constraint, imagination and responsibility. Ultimately, the critical question for scholars and practitioners is not only what kind of city is built, but what kind of society is cultivated (Harvey, 2008). In this evolving dialectic, utopia and dystopia remain essential coordinates guiding humanity's ongoing project of reimagining the city. Within this perspective, the study investigates how utopian and dystopian perspectives are reflected in urban planning discourse and how they influence the conceptualization of urban futures.

2. Materials and Method

This study employs a qualitative content analysis method to examine the theoretical and historical evolution of utopian and dystopian thought within the discipline of urban planning. The literature review was conducted through a systematic search of Web of Science and Scopus databases between January 1980 and November 2025, covering the period in which contemporary planning theory began to engage with critical urbanism and neoliberal restructuring. Table 1.

Table 1. Frequency of Utopia and Dystopia in Academic Literature

Concept / Years	Total	1980-1990	1991-2000	2001-2010	2011-2025
Dystopia	1026	14	12	71	929
Utopia	3107	29	75	393	2610
Utopia and Urban Planning	51	1	0	9	41
Dystopia and Urban Planning	9	0	0	2	7
Dystopia, Utopia, and Urban Planning	2	0	0	0	2

The analysis comprises fifteen core publications selected for their direct relevance to utopia, dystopia, and contemporary urban planning. These works were chosen because they make substantial theoretical contributions, are frequently cited within the field, and clearly articulate the conceptual foundations of the debate. In addition to these main sources, broader literature was reviewed to clarify key concepts, frame the research problem, and provide contextual support. The study employs a qualitative content analysis approach, focusing on identifying major themes and conceptual patterns across the literature, ensuring both depth in the selected works and a comprehensive understanding of the wider academic discourse. The selection criteria included peer-reviewed journal articles, book chapters, and theoretical works addressing the intersection of utopia, dystopia, and city/urban planning. The inclusion of authors such as David Harvey (2000; 2008), Henri Lefebvre (1991), Peter Marcuse (2009), Susan Fainstein (2010), and Dirk Schubert (2004) was guided by their foundational contributions to the dialectical relationship between space, power, and ideology in urban thought.

The reading list was further refined based on citation frequency, relevance to urban theory, and representation across different paradigms—classical utopian models (Howard, Le Corbusier, Mumford), critical urban theory (Lefebvre(1991), Harvey(2000), Soja(2010)), and integrative justice-oriented planning (Fainstein, Eren). Each text was coded thematically to identify recurring concepts such as spatial justice, participatory governance, technological utopia, environmental dystopia, and critical urbanism.

This methodological framework ensures a balanced evaluation of both utopian (visionary) and dystopian (cautionary) narratives, situating the paper within the broader intellectual tradition of

urban theory while maintaining methodological rigor and transparency in source selection. How visionary and critical approaches jointly inform contemporary urban planning is examined. Through qualitative content analysis, recurring patterns, thematic convergences, and critical tensions within the academic discourse on the future of cities are identified. The study examines how utopian ideals—such as justice, inclusivity, and sustainability—interact with dystopian critiques, highlighting the implications for contemporary urban planning practices.

By integrating theoretical contributions across disciplines such as urban studies, political philosophy, and environmental design, this methodological framework enables a comprehensive understanding of how idealized visions of the city, alongside their dystopian critiques, inform contemporary debates and contribute to reimagining more inclusive, resilient, and sustainable urban futures.

This methodological framework, based on qualitative content analysis of selected sources, enabled the identification of key themes across utopian and dystopian perspectives. In doing so, it clarified how these approaches are addressed within contemporary urban debates and provided the analytical basis for the evaluations and recommendations presented in the conclusion.

3. Findings and Discussion

The reviewed literature spans classical utopian models, modernist planning experiments, and contemporary dystopian critiques (Table 2). This corpus reveals a highly nuanced and evolving discourse in urban studies, highlighting how utopian and dystopian perspectives shape both conceptual and practical understandings of city planning. Table 2 presents a structured overview of these sources, summarizing their main focus, approach, and the parallel or contrasting insights they offer regarding urban utopian and dystopian frameworks.

Table 2. Structural summary of key articles

#	author(s) & year	focus / theme	approach / perspective	parallel & contrasting insights
1	howard, 1902	garden city, spatial order, social harmony	utopian	inspires modern city planners; limited empirical grounding contrasts with dystopian critiques (harvey, 2000)
2	le corbusier, 1933	radiant city, rational urban design	utopian	similar to howard in idealism; criticized by mumford (1962) for ignoring social realities
3	mumford, 1962	historical and social context of cities	critical-utopian	supports normative ideals but emphasizes social complexity; parallels fainstein (2010) on justice-oriented planning
4	harvey, 2000	neoliberal urbanism, privatization	dystopian	contrasts howard/le corbusier; parallels soja (2010) on spatial injustice

5	soja, 2010	spatial justice, critical geography	dystopian	aligns with harvey on inequality; challenges utopian notions of rational city planning
6	fainstein, 2010	justice-oriented urban planning	integrative	bridges utopian aspiration and dystopian critique; parallels eren (2023) on participatory governance
7	hall, 2014	intellectual history of urban planning	utopian / analytical	supports howard/le corbusier for historical context; highlights limits of idealism
8	baba, 2020	dystopian urbanism, gated communities	dystopian	aligns with harvey and soja; contrasts utopian ideals of openness and equality
9	eren, 2023	participatory governance, resilience	integrative	supports fainstein; contrasts technocratic utopias that ignore social feedback
10	marcuse, 2009	right to the city, social justice	dystopian / critical	challenges idealized spatial order; parallels integrative approaches advocating equity
11	brenner & schmid, 2015	urban theory, city as socio-spatial process	integrative / analytical	bridges theoretical debates; supports dystopian critique but acknowledges utopian imagination
12	lefebvre, 1991*	production of space, urban social relations	dystopian / critical	contrasts idealized utopias; aligns with harvey on socio-spatial inequalities
13	foucault, 1977*	discipline and spatial control in cities	dystopian / critical	provides analytical lens for exclusionary urban structures; contrasts participatory utopias
14	gehl, 2010	human-scale urbanism, livability	utopian / practical	supports utopian ideals with empirical focus; contrasts technocratic dystopian mega-projects
15	smith, 2018	smart cities, technological governance	dystopian / analytical	critiques tech-driven smart-city models for their risks of surveillance, inequality, and centralized control.

Table 2 summarizes the main themes emerging from the analysis, showing how utopian studies focus on desirable values, while dystopian works highlight structural risks and contradictions. After presenting these findings, the following section discusses how the literature conceptually frames these two approaches. In this way, the discussion connects the empirical patterns in Table 2 with the broader theoretical debates on utopian and dystopian thinking.

Utopian thinking gives direction it fuels creativity, sets ethical ideals, and keeps alive the belief that cities can embody justice and collective well-being. Dystopian critique, on the other hand,

grounds that imagination — it exposes inequality, exclusion, and the unintended consequences of unchecked idealism.

Figure 2. Moore house (Charles Moore, 1991), Orinda, California.

Classical utopian studies largely concentrate on spatial order, rationality, and the ethical or aesthetic ideals of city form (Howard, 1902; Le Corbusier, 1933). In addition, Gürel Üçer and Yılmaz (2004) show how utopian housing typologies function as spatial expressions of idealized social structures, reinforcing the link between built form and normative visions of urban life. In the field of city planning, other than star shaped cities and ideal city plans, Ebenezer Howard's Garden City (Welwyn and Letchworth) model proposes an integrated urban-rural design emphasizing social equality and environmental coherence, while Le Corbusier's Radiant City focuses on geometric order, functional segregation, and rational spatial planning. These models operate as imaginative and normative tools, guiding city planners to view cities as embodiments of societal ideals, where order, rationality, and aesthetic harmony were believed to lead to social progress (Le Corbusier, 1933). These utopian models offered a sense of hope and direction, emphasizing order, rationality, and aesthetic harmony as pathways to social progress (Le Corbusier, 1933; Howard, 1902). However, as Mumford (1962) and Fainstein (2010) observe, such idealized frameworks often neglected participation, social diversity, and the everyday realities of urban life. As a result, utopia functions not simply as a blueprint but as a conceptual lens—one that inspires creativity and normative aspiration while simultaneously revealing its own limitations. This is precisely where dystopian thought gains relevance: it questions the limits of perfection by exposing how visions of order or efficiency can, under certain conditions, drift toward control, inequality, or exclusion. In urban planning, dystopian moments emerge when ideal visions harden into rigid systems, surveillance-oriented environments, or profit-driven spatial arrangements. However, as Mumford (1962) and Hall (2014) argue, classical utopias often remain theoretical constructs, prioritizing moral and spatial perfection over socio-political complexities. Fainstein (2010) critiques these frameworks for insufficiently addressing social justice and participatory governance, highlighting the normative gaps that dystopian thought later addresses. Collectively, these studies demonstrate that utopia functions as a dynamic conceptual lens that balances visionary creativity with normative aspiration (Mumford, 1962).

Contemporary literature increasingly emphasizes dystopian critiques under neoliberal urbanization, identifying different mechanisms through separate lines of scholarship:

privatization as a driver of spatial inequity (Eren, 2007), gentrification as a form of dispossession linked to market-led restructuring (Harvey, 2000), and social segregation as a manifestation of uneven spatial justice (Soja, 2010). Although smart cities (e.g., Hollands, 2008; Batty et al., 2012; Kitchin, 2014) are often promoted through utopian narratives of innovation and sustainability, a growing body of research highlights that these visions can obscure underlying risks related to surveillance, data governance, and socio-spatial inequality. They risk reproducing neoliberal forms of inequality and social exclusion (Kemeç, 2023). Baba (2020) illustrates how gated communities and speculative mega-projects reproduce socio-spatial inequality, a pattern also emphasized in broader scholarship on fortified and exclusionary urbanism (Blakely & Snyder, 1997; Caldeira, 2000; Low, 2003). This body of research shows that such developments, while often justified through narratives of order, security, and efficiency, tend to deepen segregation and limit equitable access to urban resources, revealing the tensions between utopian promises and their unequal real-world outcomes. Similarly, Smith (2018) critiques smart cities, demonstrating that technology-driven efficiency can exacerbate social inequities and marginalize vulnerable populations. Marcuse (2009) underscores the political nature of urban space, warning that utopian visions may unintentionally reproduce structural injustices.

Lefebvre (1991) and Foucault (1977) provide frameworks to understand how spatial control and power relations transform idealized visions into lived dystopian realities. These analyses collectively demonstrate that dystopian perspectives act as corrective mechanisms. This grounds urban imaginaries in socio-political and environmental realities.

A growing body of research proposes integrative frameworks that reconcile utopian creativity with dystopian caution, aiming to develop more just, resilient, and participatory urban models. Recent thinkers such as David Harvey (2000) and Susan Fainstein (2010) argue that these perspectives are not opposites but complementary tools for understanding and improving contemporary cities. Fainstein (2010) advocates justice-oriented planning, incorporating social equity, participatory governance, and ethical accountability to mitigate the limitations of classical utopias and dystopian critiques.

Figure 3. Niban-kan Building (Kazuo Shinohara, 1970), Osaka.

Eren (2023) extends this by analyzing contemporary participatory governance models, demonstrating how community engagement can counter exclusionary dynamics highlighted by neoliberal urban processes. Brenner and Schmid (2015) situate these integrative approaches within broader urban theory, framing cities as socio-spatial processes where utopian and

dystopian dynamics intersect. Gehl (2010) operationalizes utopian ideals through human-scale design and livability principles, contrasting with technocratic mega-projects that often generate dystopian effects. Collectively, instead of treating utopia and dystopia as opposing categories, several scholars discuss them as interrelated analytical perspectives that illuminate different dimensions of urban transformation (Harvey, 2000; Fainstein, 2010; Schubert, 2004). These works argue that imaginative aspirations and critical evaluations function together in understanding how cities negotiate ideals, inequalities, and lived realities.Empirical insights reveal that urban conceptualization has shifted from prioritizing aesthetic order and formal coherence toward reflexive, justice-oriented paradigms (Marcuse, 2009; Brenner & Schmid, 2015; Lefebvre, 1991). Utopian and dystopian perspectives together provide a lens to bridge imaginative vision and grounded practice, guiding planners toward inclusive, resilient, and sustainable urban futures. For example, Fainstein's (2010) justice-oriented planning framework resonates with Howard's egalitarian ideals while extending them through explicit commitments to participation and equity, thereby addressing some of the limitations that dystopian critiques highlight under contemporary urban conditions (Harvey, 2000; Baba, 2020).

This combined utopian and dystopian perspective emphasizes that meaningful urban transformation depends on ethically informed, socially responsive, and environmentally conscious planning practices, fostering inclusive, resilient, and forward-looking urban environments.

Conclusion and Recommendations

This study examined how utopian and dystopian perspectives have shaped urban planning over time. The findings indicate that these perspectives function as complementary lenses that inform both the imaginative and critical dimensions of city planning. Utopian visions inspire creativity, normative ideals, and aspirational thinking, while dystopian perspectives provide critical reflection, highlighting potential unintended consequences and ethical considerations.

When combined, they form a dynamic dialogue between aspiration and realism. This dialogue helps city planners design cities that are visionary yet responsible, innovative yet inclusive, and imaginative and aware of their social limits. Looking ahead, planning education and practice should embrace both perspectives: To dream boldly like utopians, but to question critically like dystopian.

Only by holding these two ways of thinking together we can build cities that are not only smarter or more efficient, but truly humane, just, and resilient.

The analysis revealed several key insights: First, utopian frameworks continue to serve as generative tools, offering city planners models that foreground equity, environmental integration, and participatory values. Historical examples such as Howard's Garden City and Le Corbusier's Radiant City illustrate this imaginative function, although contemporary literature note that these models often abstract from socio-political realities. The second insight is that dystopian analyses function as corrective mechanisms, identifying risks such as social exclusion, inequality, and environmental vulnerability that arise when planning prioritizes order or efficiency over social and ecological considerations.

A third insight is the emergence of integrative approaches that combine utopian aspiration with dystopian caution. In line with Schubert's (2004) observation that urban design must continually negotiate between visionary ideals and socio-political realities, contemporary integrative approaches aim to balance creativity with ethical vigilance. These studies emphasize

resilience, participatory governance, and social justice, providing practical strategies for balancing creativity with critical vigilance. The reviewed literature shows that planning approaches which adopt this integrative perspective are better equipped to address contemporary urban challenges. Several studies (Arnstein, 1969; Kitchin, 2014; Soja, 2010) including those examining participatory governance, smart city interventions, and socio-spatial equity demonstrate that such frameworks can mitigate the risks highlighted by dystopian critiques while maintaining aspirational goals (Fainstein, 2010; Eren, 2023).

Based on the findings, the following recommendations are proposed:

- Education and capacity-building: City planners should be encouraged to consider both aspirational and cautionary perspectives in training and professional development.
- Participatory governance: Urban interventions should involve communities and stakeholders to ensure inclusivity and social accountability.
- Ethical and socially grounded technology use: Technological tools should be deployed in ways that balance efficiency with equity and cultural considerations.
- Integrated resilience strategies: Planning should address environmental, social, and infrastructural resilience simultaneously.
- Continuous reflexivity: Policies and urban designs should be regularly evaluated and adapted based on emerging social, ecological, and technological developments.

Conclusively, this study suggests that meaningful urban transformation requires combining imaginative aspiration with critical awareness. By blending the creative optimism of utopia with the critical awareness of dystopia, city planners can shape cities that are visionary yet inclusive, innovative and humane. The analysis conducted in this study indicates that utopian and dystopian perspectives are not strict opposites but function as complementary guides for understanding urban futures. This combined utopian and dystopian perspective emphasizes that meaningful urban transformation depends on planning practices that balance imaginative aspiration with critical awareness, enabling cities to become innovative, socially responsive, and environmentally conscious. This conclusion aligns with historical and contemporary examples in the literature, which increasingly recognize integrative approaches as effective strategies for addressing contemporary urban challenges.

The urban future depends on our capacity to sustain a dialogue between imagination and responsibility-between the desire to transcend the present and the obligation to confront its realities.

Thanks and Information Note

This article complies with national and international research and publication ethics standards. No ethical committee approval was required for this theoretical study. Both authors contributed equally to the manuscript. The authors declare that there is no conflict of interest.

Abstract

This study investigated the integration of green job principles into architectural carpentry and joinery practices in Gombe State, Nigeria. The objectives were to identify existing practices, assess the level of awareness and application of green job principles among practitioners, and determine the relationship between existing practices and sustainable approaches. A descriptive survey and correlational design were employed, consisted of 117 carpentry and joinery practitioners selected from workshops, construction firms, and technical colleges. Data were collected using a validated questionnaire titled Integration of Green Jobs in Carpentry and Joinery Practices Questionnaire (IGJCJPQ), which recorded a reliability coefficient of 0.81. Results indicated that most existing practices remain conventional and environmentally unsustainable, with limited adoption of renewable materials and energy-efficient tools. Awareness of green principles was moderate, but practical application was hindered by inadequate training and institutional support. A weak relationship was found between existing practices and the application of green job principles. The study recommends curriculum reform in TVET programs, continuous professional training, and strengthened institutional collaboration to enhance sustainable carpentry and joinery practices in Nigeria.

Keywords: Green jobs, carpentry and joinery, sustainability, TVET, Gombe State

Introduction

Architectural joinery and carpentry are woodwork trades consisting of designing, creating, and assembling wooden artifact and fittings that contribute to functionality and building appearance. The trades cover various aspects of work from cutting, shaping, joining, and finishing wooden members for furniture, fittings, doors, windows, and other architectural components. As Sigha, Adewumi, and Ibitoye (2025) and Isemede (2024) noted, carpentry and joinery are imperative in today's construction because they ensure firm and accurate woodwork needed for today's architectural structures. The trade efficiency relies significantly on the technical ability of artisans and craftsmen, on knowledge of materials, and attitude, which all have an impact on the quality, safety, and sustainability of construction methods. A pivotal feature of the successful carpentry and joinery skill is access and use of right materials. Folorunso (2021) emphasized that the selection of working material either hardwood, softwood, plywood, or Medium Density Fiberboard (MDF) should be informed by durability, strength, grain direction, and resistance to moisture. Proper knowledge of wood properties is equivalent to optimal use of wood materials and its longevity in building structure. But traditional carpentry and joinery have placed functionality, cost-effectiveness, and productivity over environmental issues such as waste management, use of renewable materials, and carbon efficiency (Adewolu, Ademilua, & Imomoh, 2024). This failure is an indictment on the imperative to redirect carpentry and joinery practice to greener and more sustainable options.

Carpentry and Joinery is a skilled trade offered in Nigerian technical colleges under the Technical and Vocational Education and Training (TVET) system. The subject is skill-oriented to equip students with employable skills for self-employment and paid employment in the building industry. The curriculum is centered on gaining skills in designing, cutting, constructing, setting out, and finishing various permanent and temporary wooden structures (Oviawe & Anaele, 2020). It involves both theoretical and practical aspects with the motive of preparing trainees for skilled craftsmanship, entrepreneurship, and sustainable construction. Deba, Saulawa, and Hasan (2022), stated that the program goals of Carpentry and Joinery are to expose students to expertise and competence in designing, constructing, and preserving timber for architectural building structures; to develop competencies in the construction of joinery, and to transfer skills for furniture and fitting assembling for domestic and public structures. These objectives aimed to develop craftsmen who are capable of being able to contribute meaningfully towards national development through the delivery of competent manpower in Nigeria's construction sector. However, the integration, sustainability and green competence into the training modules of carpentry and joinery is limited, resulting in educational mismatch with future environmental demands in the industry (Munif, 2024).

Despite these objectives, Nigeria continues to experience unemployment, environmental degradation, and unsustainable construction practices. The traditional carpentry and joinery trade remains dominated by non-renewable products and processes that contribute to waste generation, deforestation, and energy inefficiency. As the world continues to demand attention towards sustainability, more green jobs that assist in environment restoration or conservation which are now required (Jacob & Umoh, 2025). The trend is a call for balance between carpentry and joinery activities and environmentally friendly employment strategies that promote environmental conservation as well as socio-economic resilience.

Green jobs represent a paradigm shift methodology which employ generation of idears that balances economic growth and sustainable environmental management. They encompass woodwork operations like cutting, planing, and the use of energy-efficient powered tools and machines that reduce the environmental impact, promote energy saving, and increase the sustainable consumption of building materials (Lawal, Jimoh, Abdullah, Bello, & Awoyemi, 2024). According to Oboro (2024), green jobs directly contribute to the preservation of ecosystems, enhancing the effectiveness of use of resources, and reducing carbon emissions in industries such as construction, manufacturing, and agriculture. In the built environment, green jobs involve the utilization of eco-friendly materials; hardwood, softwood, plywood, or medium Density Fiber (MDF) in construction practice. The implementation of green job principles to architectural carpentry and joinery works offers a window of opportunity to sustainable development by enhancing wood-based construction works to be environmentally sustainable as well as economically feasible. From this, the blending of carpentry and joinery with the green job offers a strategic opportunity to drive traditional craftsmanship to a sustainable industrial development in Nigeria.

The incorporation of green jobs into joinery and carpentry activities involves reorientation at training institutions and industrial sectors. Craftsmen, artisans, and technicians must be equipped with knowledge, attitude and technical proficiency required for sustainable material selection, low energy-efficient construction processes, and application of renewable technologies. Soji, Usman, Abdullahi, and Adaji (2024) noted that green building practices thrive where craftsmen are highly aware of environmental management and are able to utilize green innovations. Chukwu, Omeje, Ojo, Okekpa, Vershima, and Kechere (2024) further

contended that technical and vocational training holds the central position to facilitate the transition to green through the development of skilled manpower capable of integrating sustainability concepts into traditional carpentry and joinery trades. Hence, inclusion of green competencies in the Nigerian TVET curriculum for joinery and carpentry is essential in ensuring that graduates are capable of performing in the evolving green economy. Success in this trend is, however, dependent on the extent to which industry stakeholders adopt sustainability-driven reforms that harmonize technical competence with environmental mindset.

Sustainable carpentry and joinery architecture emphasizes the responsible use of construction materials, efficient energy equipment, and economic sustainability in building operations. Adeniran and Omoniyi (2024) emphasized utilizing production methods with reduced waste, recycling, and wood reuse, as well as reducing the carbon footprint of wood conversion and preparation. In carpentry and joinery, sustainability involves the judicious selection of sustainably grown timber, using non-toxic adhesives and finishes, and incorporating energy-efficient strategies in structural building and furniture design. Sustainable practices promote life-cycle evaluation of products to ensure each production phase from logging to end product leaves a beneficial impact on environmental quality, as pointed out by Sadar Din and Ishak (2024). Therefore, carpentry and joinery sustainability extends beyond the choice of material; it includes occupational safety, skill development, and ethical craftsmanship. Amasuomo (2021) highlighted that Education for Sustainable Development (ESD) is central in empowering craftsmen with the needed knowledge, values, and skills to promote environmental sustainability in architectural carpentry and joinery practices. The integration of green practices into training and in-the-work activity ensures that the carpentry and joinery craft aligns with international standards of green building requirements, hence contributing to Nigeria's environmental and economic sustainability goals. Similarly, wood waste recycling, support the reuse of sawdust and offcuts to relieves forest pressure and promotes circular economy (Udokpoh & Nnaji, 2023). As a result, the incorporation of green jobs in architectural carpentry and joinery activities in Gombe State offers a strategic path towards fulfilling sustainable development through ecological preservation, economic empowerment, and technological advancement.

Statement of the problem

Carpentry and joinery work need to embrace green building principles that emphasize environmental responsibility, material efficiency, and economic viability. Such practice involves promoting efficient use of timber and other materials used in construction, employing energy-efficient renewable tools and production techniques with minimal impact on the environment. Within the scope of a green economy, joinery and carpentry are not merely technical professions but key factors for sustainable development. They are also committed to integrating environmentally friendly design principles, employing low-emission adhesives and finishes, and incorporating mechanisms for recycling and waste recovery in the production process. Integrating sustainability in every stage of production can reduce deforestation and loss of materials. Moreover, they can produce decent and inclusive jobs through the creation of green jobs that enable environmental protection while enhancing productivity and innovation in the construction sector.

But notwithstanding this, the vast majority of Nigerian carpentry and joinery operations are still dominated by conventional practices that value production and cost over sustainability. Most

carpentry and joinery artisans still rely on unsustainably harvested timber, inefficient and antiquated tools, and poor waste disposal methods. In addition, the integration of green skills into vocational training is also inadequate, rendering the graduate's incapable of adopting environmentally friendly practices. Institutional and policy gap impose additional limitations on industry progression toward green innovation.

Therefore, this study seeks to examine existing carpentry and joinery practices, assess awareness and application of green job principles, into architectural carpentry and joinery for a sustainable environment in Gombe State.

Purpose of the Study

The purpose of this study is to examine the integration of green job principles in architectural carpentry and joinery practices for a sustainable environment in Gombe State. Specifically, the study seeks to:

1. Identify existing carpentry and joinery practices in Gombe State.
2. Examine the level of awareness and application of green job principles among carpentry and joinery practitioners in Gombe State.
3. Examine the relationship between existing carpentry and joinery practices and the application of green job principles in the industry in Gombe State.

Research Questions

1. What are the existing carpentry and joinery practices in Gombe State?
2. What is the level of awareness and application of green job principles among carpentry and joinery practitioners in Gombe State?
3. What is the relationship between existing carpentry and joinery practices and the application of green job principles in Gombe State?

Hypothesis

H_{o1}: There is no significant relationship between existing carpentry and joinery practices and the application of green job principles in Gombe State.

Methodology

This study adopted the descriptive survey and correlational research design. This design was considered appropriate because it enabled the researchers to collect existing conditions, opinions, and practices regarding the integration of green jobs in architectural carpentry and joinery for a sustainable environment in Gombe State. The population of the study comprised of 117 carpentry and joinery practitioners in Gombe State, including master craftsmen, artisans, and technical instructors working in construction firms, private workshops, and technical colleges. Given the manageable population size, all 117 practitioners were considered for inclusion in the study; hence, no sampling was required. However, respondents were purposively selected to ensure adequate representation of practitioners across Gombe Metropolis, Billiri, Kaltungo, and Deba. The instrument for data collection was a structured questionnaire using a four-pointLikert-scale and tagged "Integration of Green Jobs in Carpentry and Joinery Practices Questionnaire" (IGJCJPQ). The questionnaire was divided into three sections. Section A consisted of bio-data of the respondents while Section B contained 10 items to elicit information relating to existing carpentry and joinery practices and Section C also contained 10 items to elicit information on the level of awareness and application of green job principles. Items in Sections B to C were structured on a four-point Likert scale ranging from

Strongly Disagree (1) to Strongly Agree (4). To ensure the validity of the instrument, the draft questionnaire was subjected to face validation by three experts; two from the Department of Technical Education, Federal College of Education (Technical), Gombe and one from the Department of Environmental Science Gombe State University. The reliability of the (IGJCJPQ) was tested by administering the questionnaire on 20 carpentry/joinery practitioners in Bauchi state who were not included in the main study. The obtained data were processed using Cronbach Alpha, which resulted 0.81. Personal administration and return of copies of the questionnaire were done by the researchers themselves and collected the questionnaire on the spot. Mean, and standard deviation and correlation, were employed to answer the research questions. The criterion mean value of 2.50 and above were accepted while mean values below 2.50 were rejected.

Results

The result of the analysis of the data is presented below:

Research Question 1

What are the existing carpentry and joinery practices in Gombe State?

Table 1. Mean and Standard Deviation of Existing Carpentry and Joinery Practices

S/N	Items statement	Mean	SD	Remarks
1	Carpentry/joinery in my region is basically involved in meeting the customer's requirements rather than considering factors related to the environment.	1.97	.73	Rejected
2	Most artisans and craftsmen prefer traditional tools and methods over modern, energy-efficient equipment.	3.28	1.04	Accepted
3	Timber for construction purposes is commonly harvested without concerns for sustainability in forestry practices.	2.48	.84	Rejected
4	Sawdust, scraps, and other waste materials are just disposed of rather than being reused or even recycled.	2.40	1.01	Rejected
5	Carpentry/joinery skills teach more concern for efficiency rather than sustainability in construction.	3.29	.63	Accepted
6	Projects generally emphasize near-term function over long-term ecological concerns.	3.57	.59	Accepted
7	Application of chemically treated or toxic finishing materials is also prevalent in carpentry/joinery operations.	3.44	.49	Accepted
8	Very few carpenters/joiners undergo any kind of professional training in eco-friendly carpentry/joinery practices.	3.45	.60	Accepted
9	Most carpentry and joinery work is reliant on non-renewable forms of energy.	3.52	.57	Accepted
10	Safety standards in occupational health can be overlooked in the course of carpentry and joinery production practices.	2.45	.43	Rejected

Table 1 indicated that six items were accepted and four rejected. The accepted items (2, 5, 6, 7, 8, and 9) indicate that carpentry and joinery activities in Gombe State area still dominated by conventional methods and practice, with limited adoption of modern and sustainable approaches. Conversely, items 1, 3, 4, and 10 Meeting the customer's requirements rather than

considering factors related to the environment, timber for construction purposes is commonly harvested without concerns for sustainability in forestry practices, sawdust, scraps, and other waste materials are just disposed of rather than being reused or even recycled., and poor conformity with safety standards were rejected. This suggests that, while traditional practices persist, there is an emerging awareness and gradual shift among practitioners toward more responsible and environmentally carpentry and joinery practices.

Research Question 2

What is the level of awareness and application of green job principles among carpentry and joinery practitioners in Gombe State?

Table 2. Mean and Standard Deviation of Awareness and Application of Green Job Principles

S/N	Items statement	Mean	SD	Remarks
1	I am aware that carpentry practices can affect the environment in a significant manner.	3.59	.49	Accepted
2	I understand the concept of Green Jobs in relation to the construction industry.	3.44	.67	Accepted
3	I work with wood that is certified to be ecologically sustainable.	3.37	.60	Accepted
4	I consciously minimize wood waste through reuse or recycling during my work.	3.38	.48	Accepted
5	I consider energy efficiency when choosing tools and equipment for woodwork tasks.	3.48	.50	Accepted
6	I use eco-friendly finishes, adhesives, and paint to avoid polluting the environment.	3.06	1.00	Accepted
7	I have undergone training/sensitization in relation to sustainable construction practices.	2.29	.90	Rejected
8	I design furniture, fittings with durability, recyclability in mind.	2.89	.95	Accepted
9	I agree with the suggestion that principles from the green industry should be incorporated into carpentry courses.	3.09	.99	Accepted
10	I believe adopting green job principles enhances both environmental protection and business profitability.	2.87	.99	Accepted

Table 2 revealed that nine of the ten items were accepted, while only one was rejected. Accepted items (1, 2, 3, 4, 5, 6, 8, 9, and 10) indicate moderate level of awareness and modest application of green job principles among the carpentry and joinery practitioners. Respondents demonstrated awareness of the environmental effects of their operations, showed interest in sustainable materials use, and acknowledgment of energy efficiency and eco-friendly production. However, item 7 relates to training and sensitization in sustainable construction techniques was negated. This suggests that despite growing awareness, the lack of formal training and institutional support continues to hinder full integration of green job practices in carpentry and joinery operations.

Research Question 3

What is the relationship between existing carpentry and joinery practices and the application of green job principles in Gombe State?

Hypothesis 1

There is no significant relationship between existing carpentry and joinery practices and the application of green job principles in Gombe State.

Table 3. Pearson Product Moment Correlation of Existing Carpentry and Joinery Practices and the Application of Green Job Principles

Variables	Mean	SD	N	rppmc	Remarks	Sig.	Decision
existing C&J practices	31.20	2.37	177	.236	Weak Relationship	.002	S
Aw & Ap of Green Job	30.00	3.05					

Table 3 reveals a weak but statistically significant positive correlation ($r = 0.236$, $p = 0.002$) between existing carpentry and joinery practices and the application of green job principles in Gombe State. Since $p < 0.05$, the null hypothesis is rejected. This indicates that although the relationship is weak, improvements in carpentry and joinery practices are associated with increased application of green job principles among practitioners

Discussion of Findings

The findings revealed that carpentry and joinery practices in Gombe State remain largely dominated by conventional methods with limited sustainability awareness. This result is consistent with the finding of Sigha, Adewumi, and Ibitoye (2025), who observed that traditional craftsmanship techniques, though valuable for architectural identity, often neglect sustainable design considerations. Similarly, Oviawe and Anaele (2020) found that most technical college graduates in carpentry and joinery lacked the competencies required for sustainable development, confirming the continued prevalence of non-green practices in the field. In the same vein, Adeniran and Omoniyi (2024) reported low adoption of cleaner production practices among wood processing facilities in Nigeria, which aligns with the weak integration of sustainability seen in this study. To this end, the current study confirms that carpentry and joinery activities in Gombe State still follow conventional methods, emphasizing productivity over environmental protection.

The results also indicated that the level of awareness and application of green jobs among the practitioners was moderate. This result was consistent with that of Munif (2024), who stated that the integration of green competences into higher education programs was a key imperative for cultivating sustainability skills. Hasan et al. (2022) have also introduced a standard tool for assessing the actual skills of Carpentry and Joinery Students that highlighted the steady rise of environmental awareness due to institutional changes. Further studying by Oboro (2024) indicated that there was a steady rise in awareness of green jobs opportunities for workers at Delta State, Nigeria. Therefore, the current study further asserted the pre-existing evidence that while awareness of environmental issues was on a steady increase for artisans, the actualized level of green job training was still inadequate.

The result of the hypothesis test revealed a weak but significant relationship between existing carpentry and joinery practices and the application of green job principles. Although the correlation is weak, its significance indicates a gradual transition from conventional to more sustainable practices. This agrees with Jacob and Umoh (2025), who identified that the

integration of blue, green, and grey economic models in Nigeria requires incremental adaptation rather than immediate transformation. Likewise, Soji, Usman, Abdullahi, and Adaji (2024) noted that green innovation competencies in construction are emerging slowly due to barriers such as limited resources and inadequate institutional frameworks. Lawal et al. (2024) also stressed that while energy efficiency awareness is growing, its adoption among Nigerian households and small industries remains weak, mirroring the situation observed among carpenters and joiners in this study. To this end, it can be inferred that the weak correlation recorded signifies the beginning of behavioral change towards green practices, even though full integration has not yet been achieved. This finding can be likened to the discovery made by Udokpoh and Nnaji (2023), which found that the reuse and recycling of sawdust have received little recognition by artisans despite its significant contribution to sustainable development. Chukwu et al. (2024) can further clarify that many institutions offering TVET in Nigeria continue to place more value on conventional craftsmanship rather than green skills, contributing to a huge skills mismatch between industry requirements and the outcome of technical education. This could be the reasons that respondents received less exposure to environmentally friendly training. Adewolu et al. (2024) pointed out that while awareness of sustainable construction requirements prevails in the southwest of Nigeria, there remains a barrier against actual implementation that was impeded by expensive and technical limitations. This study may add credence to the information that sustainability integration of another conventional trade including but not limited to carpentry and joinery remains current but developing.

Conclusion

In conclusion, the findings from this research have provided a crucial area linking the practices of carpentry and joinery to the application of green job principles in Gombe State. The research showed that despite practitioners possessing moderate knowledge of sustainable construction practice, the complete integration of green principles remains limited due to inadequate training and institutional support. This implies that sustainability promotion in carpentry and joinery must be strengthened through industry-technical education partnership, green modules in vocational training, and capacity-building initiatives.

Recommendations

1. There should be periodic workshops, seminars, and certification programs for carpentry and joinery practitioners
2. There should be strong collaboration between technical institutions and industry to enable innovation, research, and adoption of sustainable technologies within the woodwork sector.
3. The TVET program curriculum needs to be examined in order to incorporate environmental sustainability, use of renewable material, and waste management modules in the practice of carpentry and joinery.

salaheddine.ma.7@gmail.com

Abstract

In order to assess the quality of groundwater used for irrigation in the Sahara aquifer in Algeria, this research used irrigation water quality indices (IWQI), to assess and predict the quality of groundwater used for irrigation. The physicochemical parameters obtained for the collected groundwater samples showed that Ca_2+ > Mg_2+ > Na+ > K+ and Cl- > $SO_4$2- > HCO_3- > NO_3-, due to the predominance of limestone, sandstone and clay minerals under the action of human activity. To assess the quality of irrigation water, IWQIs values such as irrigation water quality index (IWQI), sodium adsorption rate (SAR), Kelly index (KI), sodium percentage (Na%), permeability index (PI) and magnesium risk. (MH) showed mean values of 47.17, 1.88, 0.25, 19.96, 41.18, and 27.87, respectively. For example, IWQI values revealed that 33% of samples were severely restricted for irrigation, while 67% of samples ranged from moderate to high restriction for irrigation, indicating that moderately to highly salt-sensitive crops should be irrigated in loose soils without all compressed layers. Finally, the application of physicochemical parameters and water quality indices constitutes a useful and practical strategy for assessing groundwater quality and development.

Keywords: Geographic Information System (GIS), multivariate analysis, Sahara Aquifer, Algeria

1. Introduction

In recent years, the deterioration of groundwater quality has been exacerbated by uncontrolled leaching of leachate from landfills, excessive use of fertilizers, and other human activities that are significantly dangerous to human health (Egbueri et al.,2021; Noori et al., 2019; Maghrebi et al., 2021). Many studies have evaluated groundwater quality in the world (Ghodbane et al., 2022; Chorfi et al., 2022). Nevertheless, the majority of these studies primarily concentrated on single-parameter evaluation, in which the governing elements were assessed individually, and the most compromised factor had a significant influence on water quality (Sener et al., 2017). Hence, there is an increasing need for techniques that allow for better water quality interpretation to ensure effective groundwater quality control and management. Owing to their statistical ease of use and adaptability. Irrigation water quality indices (IWQIs) are among the best methods for monitoring groundwater quality for agricultural activities. IWQIs can help to interpret complex water quality data in simple terms (Elsayed et al., 2020; El Osta et al., 2022; Masoud et al., 2022). Several indices have been used to categorize groundwater quality for agricultural purposes. These indices include the irrigation water quality index (IWQI), permeability index (PI), sodium adsorption ratio (SAR), Kelly index (KI), magnesium hazard (MH), and sodium percentage (Na%).

• This study aims to:

(i) Identify the groundwater characteristics and geochemical controlling mechanisms using physicochemical parameters and multivariate statistical analysis.

(ii) Assessment and classify the groundwater quality for irrigation using IWQIs.

2. Materials and Methods

2.1. Geographic Location

- The region of Doucen is located in the Northwestern city of Ouled Djelal. For the area-wise, it's 247 km^2.
- It has administrative borders with the communes of Chaiba to the west, El-Ghrouss to the east and north, the town of Ouled Djalel to the south (Figure 1).

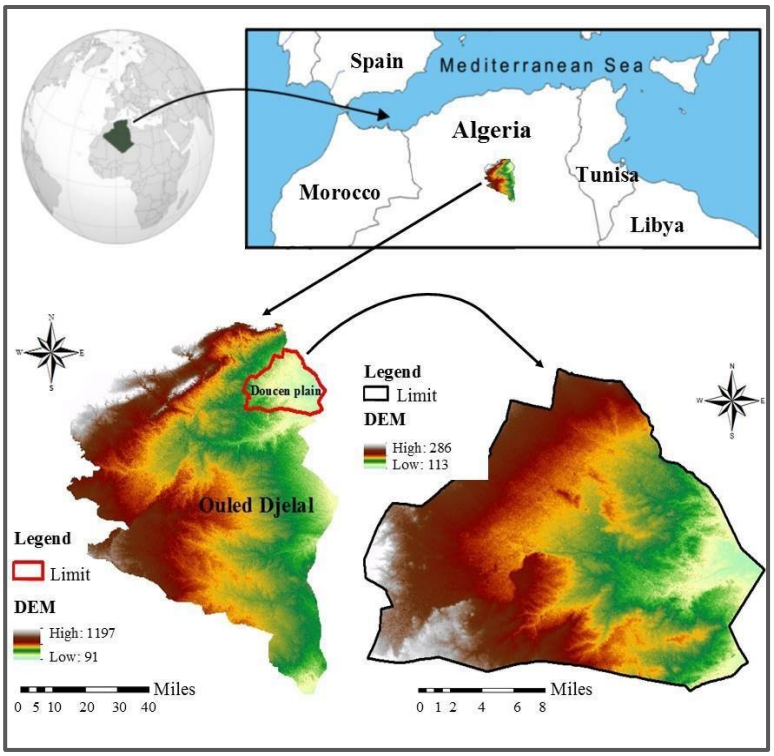

Figure 1. Map of the study area

Geologically, the formations ranging from the Secondary to the Quaternary periods are as follows:

i. Secondary formations (Cretaceous): consist of limestone, crystalline limestone, dolomite, sandstone, gypsum, anhydrite, clay, and marl.

ii. Tertiary formations (Paleogene and Neogene): consist of limestone, marls, gypsum, clays, gravel, and red sand.

iii. Quaternary Formations: These are made up of scree, pebbles, gravel, sand, gypsum, limestone, sandy alluvium, and clay alluvium (Figure 2).

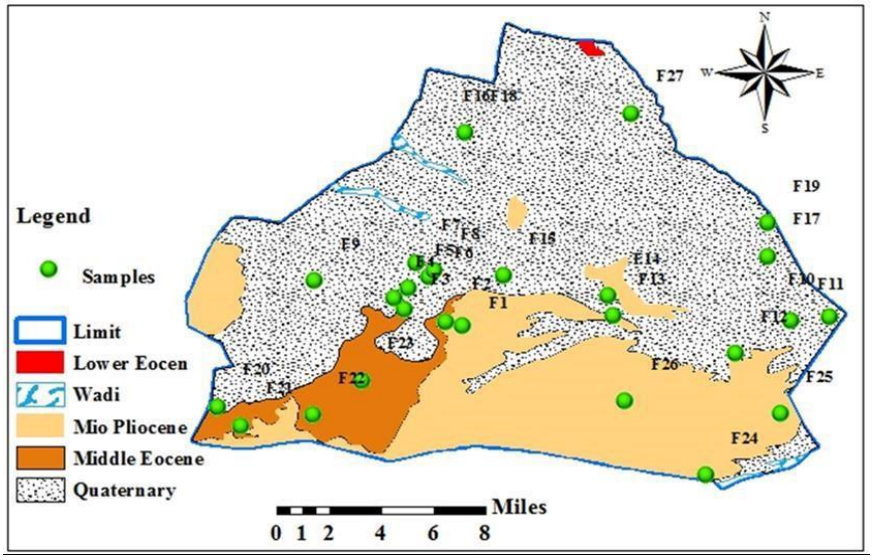

Figure 2. Geological map of the Doucen plain, Algeria

2.2. Methodology

1. Multivariate Statistical Analysis: two methods used:

• (i) Cluster analysis: The present study, Ward's clustering method and the Euclidean distance was used to apply CA.

• (ii) PCA method to extract the major elements related to the various causes of variance in hydrochemical data collected from the Doucen plain.

2. Irrigation Water Quality Indices (IWQIs)

• The IWQI, SAR, KI, Na%, MH, and PI% were all determined depended on the physicochemical parameters of the samples (Table1).

Table 1. The IWQIs, related formula

WQIs	Formula
IWQI	$\sum_{i=1}^{n} Q_i W_i$
SAR	$\frac{Na^+}{\sqrt{(Ca^{2+}+Mg^{2+})/2}}$
KI	$\frac{Na^+}{Ca^{2+}+Mg^{2+}}$
Na%	$\frac{(Na^+ + K^+)}{(Ca^{2+}+Mg^{2+})+(Na^+ + K^+)} \times 100$
MH	$\left[Mg^{2+} / \left(Ca^{2+} + Mg^{2+}\right)\right] \times 100$
PI	$\left(\frac{Na^+ + \sqrt{HCO_3^-}}{(Ca^{2+}+Mg^{2+}+Na^+)}\right) \times 100$

Note(s): All IWQIs are calculated in meq/L.

Spatial Distribution Pattern

- Using ArcGIS software, to produce maps presenting the geographical distribution of groundwater quality indicators,
- Such as IWQI, SAR, KI, Na%, MH, and PI%, that are useful for irrigation.

3. Findings and Discussion

3.1. Analysis of Multivariate Statistics

Three groups has been determined.

- The (G1) revealed a close association between HCO3, SO4, Mg, and Ca due to the presence of the sulphates or anhydride and calcium sulphates.
- The (G2) revealed a close association between the Na, K, Cl, and TDS, indicating the participation of chlorides and salts in the EC.
- Both G1 and G2 demonstrated that the lithological component dominated the mineralization of the Plio-Quaternary aquifer's waters in Doucen.
- G3 showed the dissociation of nitrates from other chemical elements present in groundwater, which indicating an anthropogenic source (Figure 3).

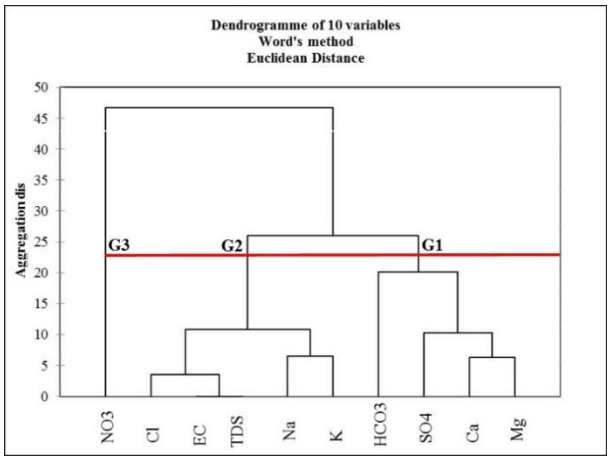

Figure 3. Cluster dendrogram for variables: G1 (group 1), G2 (group 2), G3 (group 3) and the groupscould be distinguished in terms of their hydrochemical variable at the red line.

3.2. Principal Component Analysis (PCA)

Three factors (F) were retained from the PCA analysis.

- F1 explained 59.86% of the dataset variability, while F2 and F3 explained respectively 11.35% and 10.35%.
- F1 has a robust positive relationship with TDS, Cl, Ca, Mg, K, and SO_4.
- The source of SO_4 may be coming from fertilizer and sulfur compounds.

- The Ca, Mg, and K could be due to anthropogenic sources, anhydride, and calcium sulphates.
- The presence of chloride could be due to weathering of soils.
- While F3 was highly correlated with NO_3 and moderate correlation with HCO_3, which indicating alkaline water passing through rocks and soil (Figure 4).

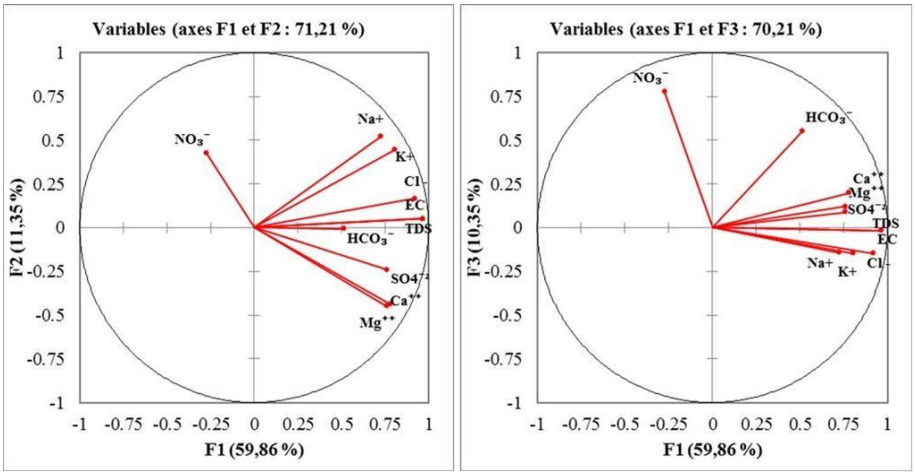

Figure 4. Plots of PCA scores for F2 vs. F1 (a) and F3 vs. F1 (b).

3.3. Irrigation water quality indices

3.3.1 Irrigation water quality index (IWQI)

✓ The resulting IWQI value ranging from 19 to 73 mg/L.

✓ The IWQI falls into three categories (moderate, high and severe restriction) with an equal 33.33%.

✓ According to IWQI values, the central of the region has a water quality degradation by the rock weathering, and the ion exchange process (Figure 5).

3.3.2. Sodium adsorption ratio (SAR)

- The calculated percent of SAR varied from 0.63% to 4.1%.
- 4 classes to identify the irrigation water, Unsuitable (>26%), Fair Poor (19-26%), good (10-18%), and excellent (<10%).
- The value of SAR indicated that all of the study site's water samples belongs to excellent category, which indicating its suitability for irrigation (Figure 5).

3.3.3. Kelley Index (KI)

- 02 classes here: If the KI value > 1, there is too much sodium. KI < 1 water is suitable for irrigation.

- In this study, the KI value diverse from 0.08 to 0.62. As regards the KI outcomes, the all samples were deemed irrigation-ready.
- The results indicated an overabundance of sodium ions in the water (Figure 5).

3.3.4. Sodium percentage (Na%)

✓ Na% ranged from 7.88% to 39.31%.

✓ There are 05 classes: excellent (< 20%), acceptable (20-40%), allowed (40-60%), dubious (60-80%), and inappropriate (> 80%).

✓ About 59.26% of the samples are in the excellent class, and these are positioned in the north, south east, and south west.

✓ However, about 40.74% of the samples are in the acceptable category for irrigation and are located in the geographic center of the region (Figure 5).

3.3.5. Magnesium Hazards (MH)

✓ The groundwater samples showed MH value varies from 25.38 to 56.22.

✓ Less than 50%, groundwater was appropriate for irrigation in 25 samples.

✓ More than 50%, it was not.

✓ These inappropriate samples are situated in the northern region (Figure 5).

3.3.6. Permeability index (PI)

- Three classes for PI were defined: unsuitable (PI<25), good (PI=25-75), and excellent (PI>75).
- The PI value was ranging from 13.95 to 46.68.
- Approximately 55.55% of the samples found in moderate class and the rest (44.44%) were unsuitable for irrigation, which located in the north, south east and south west of area (Figure 5).

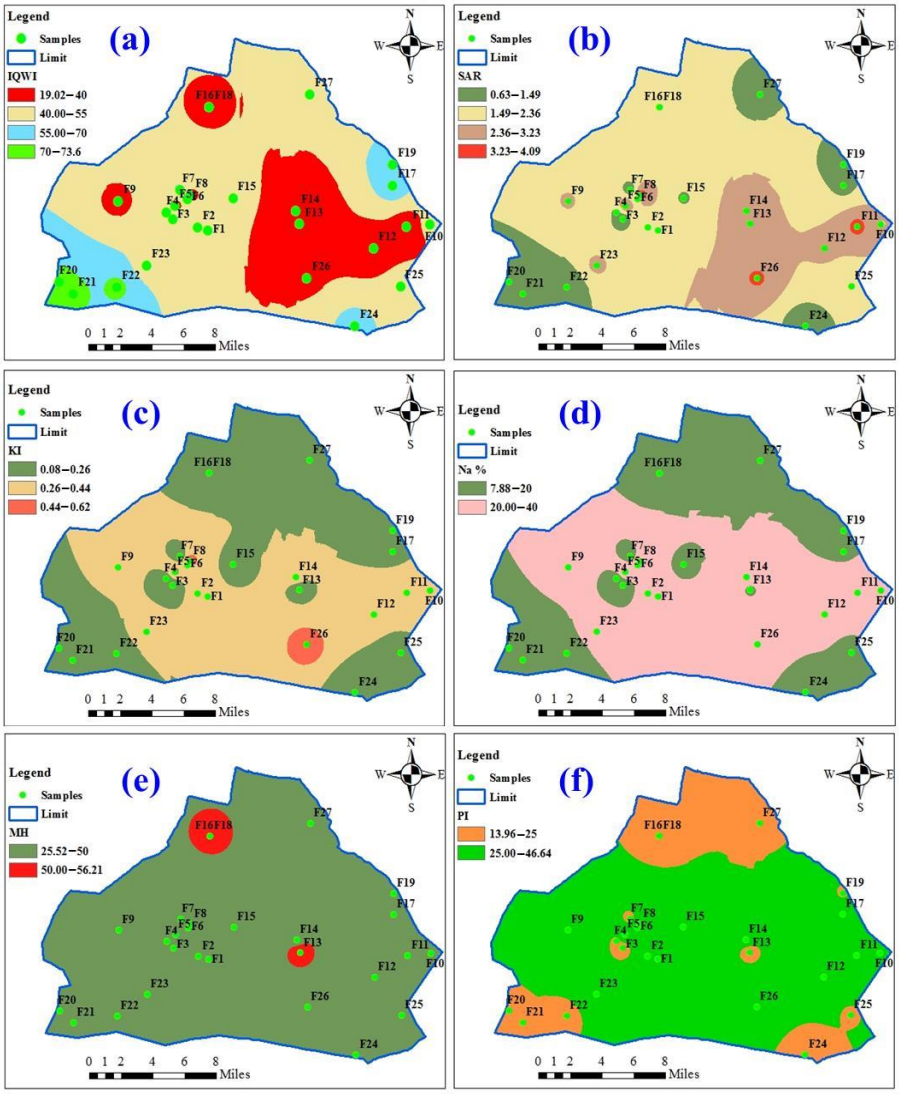

Figure 5. The spatial variation map of the Doucen plain: Irrigation water quality indices (IWQIs). (a) IQWI, (b) SAR, (c) KI, (d) Na%, (e) MH, (f) PI.

4. Conclusion and Recommendations

In this study, IWQIs, multivariate statistical analyses, were applied to determine groundwater quality for irrigation in the Doucen Plain.

- According to the physicochemical results, groundwater in the study area indicating Ca-Cl water type due to the dominance of sandstone, limestone, and clay minerals under the influence of anthropogenic activities, rock weathering, ion dissolution and exchange processes.
- The IWQI values revealed that 33% of our samples were severely restricted for irrigation, while 67% of the them diverse from moderate to high constraints for irrigation.

Abstract

The analysis of the Babar dam failure on Oued el Arab was carried out to show the impact of the flood wave and its speed on the four villages located downstream of the dam such as Hella, Kherenne, Chebla and El Oueldj. This model is dedicated to the description of floods during the dam failure following the formation of a breach in the dike. The main factors taken into account in this simulation are: the flood water level and the flood hydrograph. This flood risk analysis showed that the maximum flow of the flood wave recorded at the breach is 9253 m³/s), and that it begins to attenuate downstream of the dam along Oued El Arab where it arrives at the last village with a lower flow, of the order of 1110 m3/s. This simulation made it possible to create a risk map showing the areas threatened by the flood wave that would result from a complete failure of the structure. Consequently, a safety plan can be developed to mitigate the consequences of these floods as much as possible. A sensitivity analysis was conducted to determine the impact of the breach parameters on the "dam failure" scenario.

Keywords: Modeling, failure, sensitivity analysis, HEC-RAS.

1. Introduction

Many cities have been built alongside rivers all over the world, typically downstream of various hydraulic constructions like reservoirs and dams. As demonstrated in Japan (Swanson *et al*., 1986), canada (Clague *et al*., 1994), Malczyce (poland) (Chalfen *et al*., 2005), and algeria (Berghout *et al*., 2016; Bouchehed *et al*., 2017; Boussekıne *et al*., 2016; Derdous *et al*., 2015), such localization puts people and property at higher risk of flooding.

• This study was developed to address the impact of an earth dam failure on the downstream of the dam, as in the case of the Babar Dam.

• The failure simulation was performed using the one-dimensional HEC-RAS hydrodynamic model.

• This model can simulate the failure of a structure such as a dam or a lateral structure.

• In this work, we are looking for understand the impact of flood propagation downstream of the dam in the event of a failure using the HEC-RAS model.

2. Materials and Methods

Geographic Location

• The Babar Dam is located in southeastern Algeria in the eastern part of the Saharan Atlas in the Nememcha Mountains (Fig. 1).

• The lower part of the valley is situated between two mountain ranges, where the citys such as Hella, Kheranne, Chebla, and Ouelga are located.

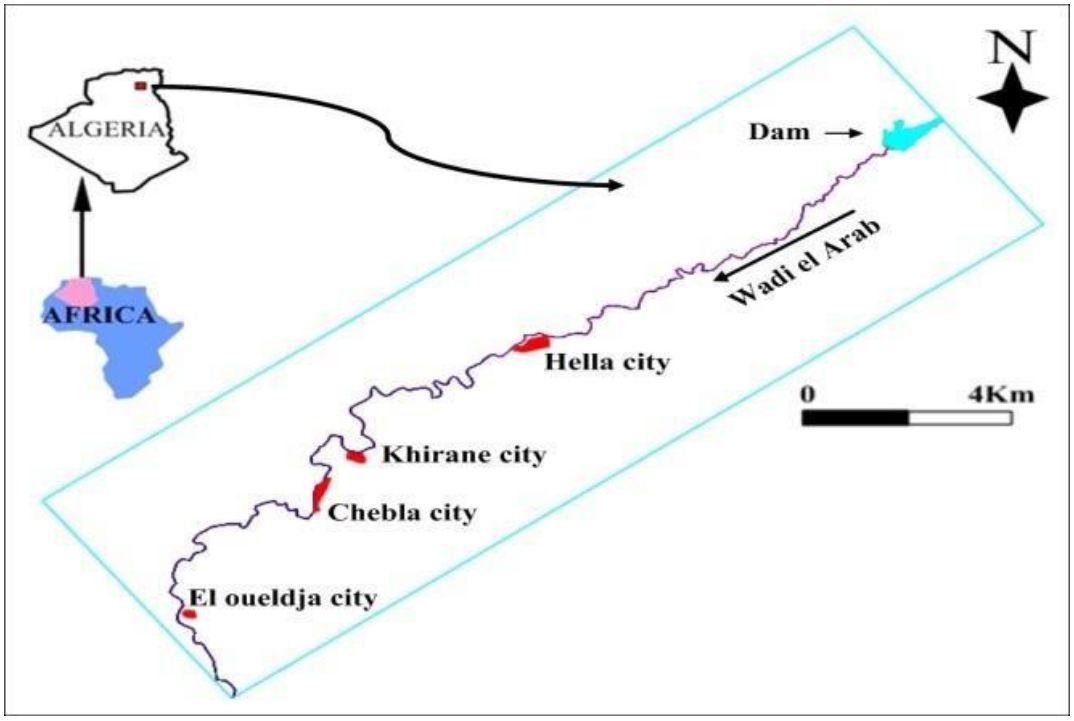

Figure 1. Map of the study area

3.1. HEC-RAS Model 4.1

HEC-RAS is a software program that allows simulations to be performed on four axes:

1- Calculations of the steady and unsteady flow of a river,
2- determination of sediment transport capacity,
3- analysis of water temperature.

3.2. Evaluation of Breach Parameters

In this case study, we chose two breach design formulas: 1- that of the (Trieste, D. J., 1988) 2- and that of (Froehlich, 1995) (Figure 2).

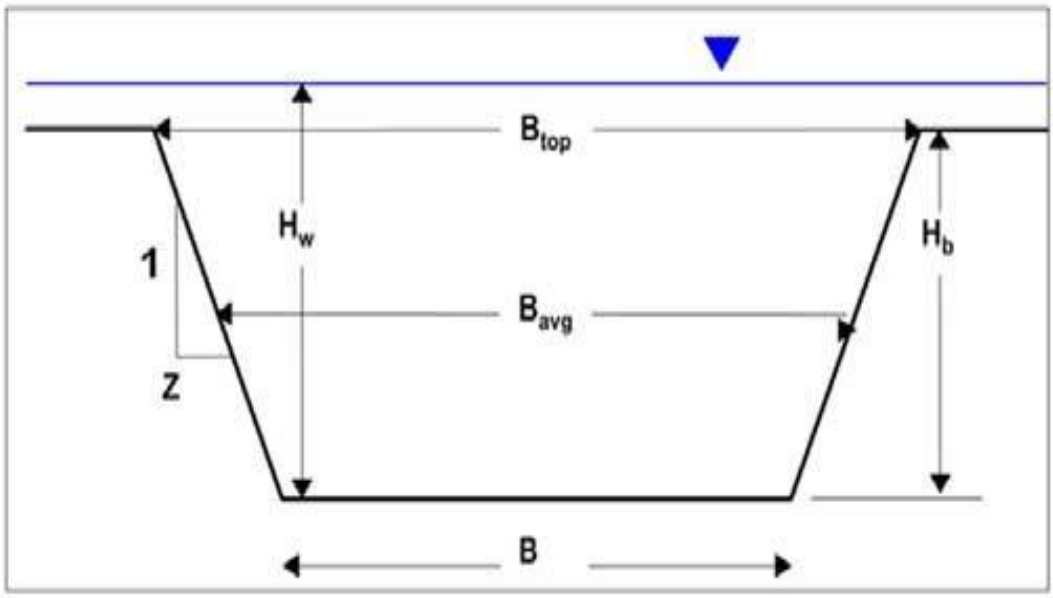

Figure 2. Breach profile type; source: own elaboration

3. Findings and Discussion

3.1. Dam Failure Scenario

The calculations of the breach parameters using the two methods are very similar, with the exception of the peak flow rate:

1- For Froehlich, D. C.: the peak flow rate is 9423.64 m³/s.

2- For Trieste, D. J., the peak flow rate is 8527.61 m³/s.

- The results of the Froehlich, D. C. method were considered the best estimate of the gap parameters,
- However, it can be adopted because the Froehlich, D. C. formula is:

1. The most suitable for earth dams,

2. The most recent

3. It is identified based on the study of real cases (63 cases).

3.2. Flood Wave Simulation (Discharge-Velocity)

Based on the results obtained by the HEC-RAS model using two parameters:

1- Qmax = 9423.64 m³/s,

2- The time taken to deplete the dam reservoir (t = 2:15 h) it can be concluded that dam failure can pose a real danger to all infrastructure as well as to the populations located downstream of the dam (Table 1).

Table 1. Simulated propagation of flood waves downstream of the dam

Station	station	Profile	Qtotal (m3/s)	Time (hour e)	Depth (m)	Min Ch El(m)	W.S. Elev(m)	E.G. Elev(m)	E.G. slope (m/m)	velosity (m/s)	flow Area (m2)	width(m)	Froude
Bredg 1	138	Max WS	9181,03	05 :00	11.14	900	911,16	913,36	0,00806	12,07	2507,77	402,35	1,17
Bredg 2	91	Max WS	1845,05	06 :40	5.8	760,71	766,81	767,33	0,004349	5,43	1029,37	325,18	0,75
village hella	90	Max WS	1844,2	06 :45	7.7	757	762,12	762,71	0,007299	5,71	957,03	400,19	0,93
village Khérenne	26	Max WS	1252,28	07 :45	7.7	392,73	401,75	402,21	0,001407	3,96	745,11	155,38	0,45
village Chebla	20	Max WS	1356,99	08 :00	5.5	357,22	363,53	363,84	0,002039	3,54	918,05	262,11	0,51
Village Oueldja	10	Max WS	1217,47	08 :45	5	305,23	310,53	311,75	0,010047	6,13	574,44	480,23	1,06

3.3. Flood Risk Analysis

- This analysis revealed that the first three villages (Hella, Khérenne, and Chebla) are the most exposed to this flood.
- This requires us to provide the authorities with a series of measures to attempt to mitigate the risk of flooding in the villages in the event of a dam failure.
- It will be essential to maintain the proper functioning of the dam and provide a warning system, as well as establish a population evacuation plan before the flood wave reaches them.
- This flood risk analysis using this model helps us determine the time it will take for this flood wave to reach these villages.
- Seen at the time of breach formation (1:054 h), the first village will be hit by the flood after 6:45 h and the last village at 8:45 h, which makes it easier to execute the alert plan.
- According to the risk map, we can implement:
- an integrated flood management strategy for the river downstream of the dam in the event of a dam failure that can save as many villages located on the riverbed as possible (Figure 3).

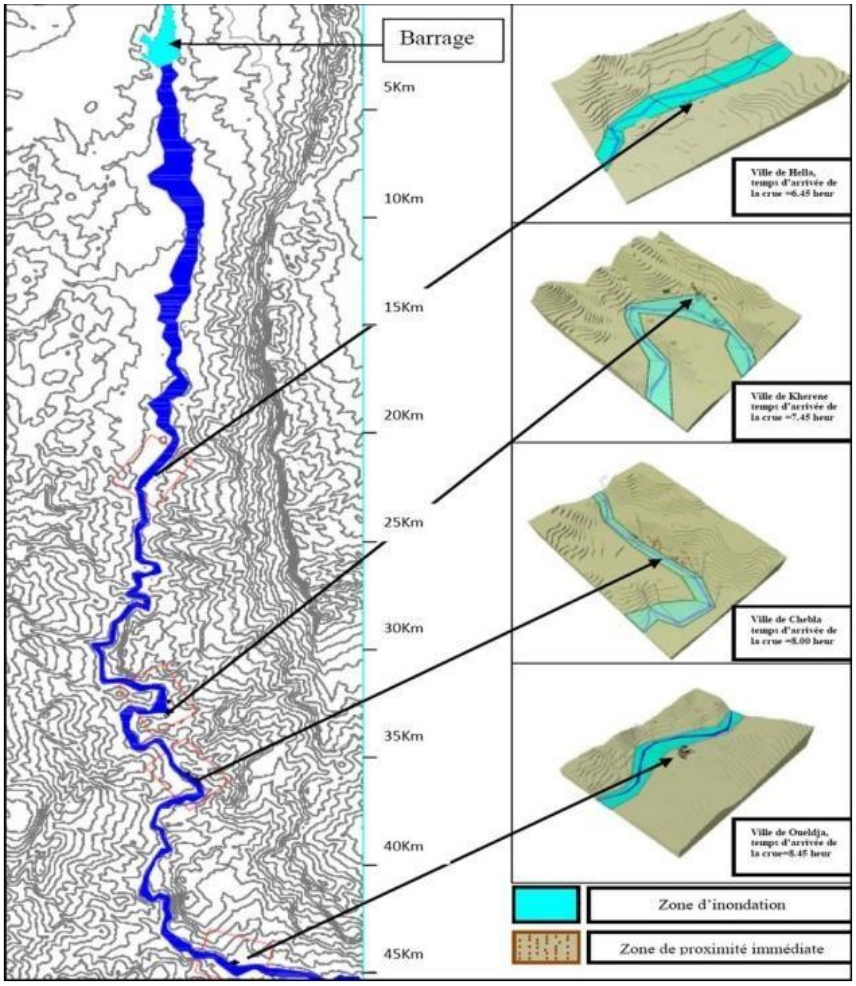

Figure 3. Babar Dam Break Flood Map

i. Conclusion and Recommendations

- The HEC-RAS model is well-suited to facilitate dam failure analysis.
- Proper analysis of dam failure risks will help in the development of contingency plans to mitigate the increased loss of life and property.
- Model stability issues are also addressed, and solutions have been provided to some typical problems.
- Using the HEC-RAS model, users can perform dam failure analyses and breach investigations.

Xülasə

Maliyyə infrastrukturu maliyyə sisteminin fəaliyyətini təmin edən və sahibkarlıq fəaliyyətinin inkişafı üçün əlverişli şərait yaradan institutlar, mexanizmlər və alətlər toplusudur. "Azərbaycan Respublikasında maliyyə infrastrukturunun sahibkarlığa təsiri formaları" məqaləsində bank sektoru, kapital bazarı, mikromaliyyə institutları, zəmanət sistemləri və dövlət dəstək proqramları kimi maliyyə infrastrukturunun əsas elementlərinin sahibkarlıq fəaliyyətinə təsiri araşdırılmışdır. Təhlillər göstərir ki, ölkəmizdə maliyyə mənbələrinin mövcudluğu, maliyyə əməliyyatlarının şəffaflığı, kredit və investisiya institutlarının inkişaf səviyyəsi kiçik və orta sahibkarlığın yaradılması və davamlılığı dinamikası ilə birbaşa əlaqəlidir. Əməliyyat xərclərini azaldan və sahibkarların maliyyə məhsullarına çıxışını genişləndirən maliyyə xidmətlərinin rəqəmsallaşdırılmasının roluna xüsusi diqqət yetirilməlidir. Həmçinin məqalədə: sahibkarlıq subyektlərinin maliyyə vasitəçiləri ilə səmərəli qarşılıqlı əlaqəsini məhdudlaşdıran institusional, struktur maneələr müəyyən edilmişdir; sahibkarlığın stimullaşdırılmasında, davamlı iqtisadi artımda əsas amil kimi balanslaşdırılmış maliyyə infrastrukturunun formalaşdırılmasının zəruriliyi barədə nəticə çıxarılmışdı; ədəbiyyat təhlili, müqayisəli və institutsional yanaşma, empirik təhlil (kəmiyyət metodları), keyfiyyət metodları, zəif və güclü tərəflərin diqanostikası aparılmışdır.

Açar sözlər: Maliyyə infrastrukturu; sahibkarlıq fəaliyyəti; mikro, kiçik və orta sahibkarlıq subyektləri

Forms of Influence of Financial Infrastructure on Entrepreneurship in the Republic of Azerbaijan

Abstract

Financial infrastructure is a set of institutions, mechanisms and tools that ensure the functioning of the financial system and create favorable conditions for the development of entrepreneurial activity. The article "Forms of influence of financial infrastructure on entrepreneurship in the Republic of Azerbaijan" examines the impact of key elements of financial infrastructure on entrepreneurial activity, such as banking sector, capital market, microfinance institutions, guarantee systems and state support programs. The analysis shows that the availability of financial resources in our country, the transparency of financial transactions, the level of development of credit and investment institutions are directly related to the dynamics of the creation and sustainability of small and medium-sized businesses. Particular attention should be paid to the role of digitalization of financial services, which reduces operating costs and expands entrepreneurs ' access to financial products. Also in the article: institutional, structural barriers have been identified that limit the effective interaction of business entities with financial intermediaries; it was concluded that it is necessary to form a balanced financial infrastructure as a key factor in the stimulation of entrepreneurship and sustainable economic growth; literature analysis, comparative and institutional approach, empirical analysis (quantitative methods), qualitative methods, diganostics of weaknesses and strengths were carried out.

Keywords: Financial infrastructure; entrepreneurial activity; Micro, small and medium-sized businesses

1. Introduction

Sahibkarlıq iqtisadi artımın, innovasiyaların və sosial dayanıqlığın əsas "mühərriklərindən" biri hesab edilir. Sahibkarlıq təşəbbüslərinin uğurlu fəaliyyət göstərməsi və inkişafı üçün maliyyə mənbələrinə çıxış, etibarlı hesablaşma mexanizmləri, mülkiyyət hüquqlarının qorunması və qərar qəbul etmək üçün məlumat verən maliyyə infrastrukturu mühüm rol oynayır. Dövlət, regional və yerli qurumlar - banklar, bank olmayan maliyyə-kredit təşkilatları, kapital bazarları, sığorta və zəmanət sistemləri - maliyyə infrastrukturunun əsasını təşkil edir.

Qloballaşma, maliyyə bazarlarının qeyri-sabitliyi, sürətlə dəyişən texnoloji şərait şəraitində maliyyə infrastrukturu təkcə dəstək elementi deyil, həm də rəqabətqabiliyyətlilik amilinə çevrilir. Sahibkarlar, xüsusən də kiçik və orta sahibkarlar birbaşa borc kapitalının alınma imkanlarından, maliyyə institutlarının şəffaflığından, risklərin qiymətləndirilməsi və idarə edilməsi mexanizmlərinin mövcudluğundan, maliyyə əməliyyatlarının əməliyyat xərclərindən asılıdır.

İnkişaf etməmiş maliyyə infrastrukturu ilə sahibkarlıq müxtəlif problemlərlə üzləşir və bunlara aşağıdakıları aid edə bilərik:

- maliyyələşmə prosesinə məhdud giriş;

- kreditlərin yüksək dəyəri;

- investisiyaların zəif səviyyədə qorunması;

- zəmanət sistemlərinin beynəlxalq standartlara cavab verməməsi;

- investorların etibarının olmaması və s.

Bu məqalənin məqsədi maliyyə infrastrukturunun sahibkarlığa necə təsir etdiyini, bu cür təsiri qiymətləndirmək üçün hansı metodlardan istifadə edilə biləcəyini araşdırmaq, habelə sahibkarlıq fəaliyyətini stimullaşdırmaq istiqamətində maliyyə infrastrukturunun yaxşılaşdırılması üçün təkliflər hazırlamaqdır. Bundan əlavə, maliyyə infrastrukturunun sahibkarlığa təsirinin əsas formalarını sistemləşdirmək və təhlil etmək, həm müsbət, həm də məhdudlaşdırıcı təsirləri müəyyənləşdirmək və ən təsirli olduğu şərtləri göstərmək lazımdır.

Azərbaycanda maliyyə infrastrukturunun tətbiqi və inkişafının təhlili göstərir ki, bu, sahibkarlıq fəaliyyətinin stimullaşdırılmasında, xüsusilə kiçik və orta sahibkarlığın seqmentlərində, eləcə də qeyri-neft sektorunda getdikcə daha əhəmiyyətli rol oynayır. Azərbaycan iqtisadiyyatı şaxələndirmək, rəqabət qabiliyyətini artırmaq, neft sənayesindən kənarda iş yerləri yaratmaq vəzifəsi ilə üzləşir və maliyyə infrastrukturu bu prosesdə zəruri vasitə kimi çıxış edir.

2. Tədqiqat Metodları

Azərbaycan Respublikasında maliyyə infrastrukturunun sahibkarliğa təsiri formalarını araşdırarkən müxtəlif tədqiqat metodlarının istifadəsi məqsədəuyğundur. Bunların bəzilərini nəzərdən keçirək.

Ədəbiyyat üzrə təhlil maliyyə infrastrukturu və sahibkarlıq mövzusunda yerli və xarici işlərin, o cümlədən məqalələr, beynəlxalq təşkilatların hesabatları, dövlət və regional tədqiqatların öyrənilməsini nəzərdə tutur. Bu, anlayışları sistemləşdirməyə, maliyyə infrastrukturunun əsas

komponentlərini müəyyən etməyə və maliyyə institutları ilə sahibkarlıq arasında qarşılıqlı əlaqənin mövcud nəzəri modellərini müəyyən etməyə imkan verir. Məsələn, innovativ sahibkarlığın maliyyə infrastrukturunun tədqiqi vençur və büdcə fondlarının, sığorta mexanizmlərinin və zəmanət institutlarının innovativ fəaliyyətə necə töhfə verdiyini göstərir.

Müqayisəli və institutsional yanaşma maliyyə institutlarının inkişaf səviyyəsinə, qanunvericilik bazasına, sahibkarlığa dəstək mexanizmlərinə (zəmanət institutları, mikromaliyyə, investisiya vasitəçiləri) görə müxtəlif ölkələrin və bölgələrin müqayisəsini əhtə edir. Hüquqi və institutsional amillərin maliyyə infrastrukturunun səmərəliliyinə təsirinin təhlili olduqca vacib məsələdir. Məsələn, kiçik və orta sahibkarlığın inkişafına həsr olunmuş əsərlərdə institusional yanaşma hüquqi tənzimləmə, maliyyə institutlarının şəffaflıq dərəcəsi və etimad səviyyəsindəki fərqlərin sahibkarların maliyyə imkanlarına necə təsir etdiyini müəyyənləşdirməyə imkan verir.

Keyfiyyət metodları sahibkarlarla, maliyyə institutlarının, dövlət orqanlarının mütəxəssisləri ilə müsahibələri; maliyyə infrastrukturunun əhəmiyyətli dərəcədə yaxşılaşdırıldığı və sahibkarlığın artdığını göstərdiyi uğurlu bölgələrin/ölkələrin işlərinin təhlilini nəzərdə tutur. Bu, yalnız kəmiyyət nöqteyi-nəzərdən əlaqələrini deyil, həm də infrastrukturun sahibkarlıq fəaliyyətinə təsir etdiyi mexanizmləri müəyyənləşdirməyə kömək edir.

Güclü və zəif tərəflərin diaqnostikası toplanan məlumatlar əsasında maliyyə infrastrukturunun aşağıdakı istiqamətlərdə təhlilinin aparılmasını nəzərdə tutur:

*** güclü tərəflər** (məsələn, inkişaf etmiş bankların olması, hüquqi cəhətdən müdafiə, zəmanət sistemləri);

*** zəif tərəflər** (tənzimləmə problemləri, yüksək əməliyyat (tranzaksiya xərcləri), kiçik sahibkarlar üçün maliyyələşdirmə mənbələrinin əlçatmazlığı);

*** imkanlar** (rəqəmsallaşma, sistemə daxi olmanın genişləndirilməsi, dövlət dəstəyi);

*** təhdidlər** (maliyyə cəhətdən qeyri-sabitlik, inamsızlıq riski, korrupsiya və s.).

Empirik təhlil/kəmiyyət metodları ölkəmizdə maliyyə infrastrukturu və sahibkarlıq arasında qarşılıqlı əlaqələri daha geniş, aydın şəkildə izah etməyə şərait yaradır. İlk öncə Azərbaycan Respublikasında sahibkarlıq fəaliyyətini nəzərdən keçirək.

Cədvəl 1. 2019-2023-cü illərdə Azərbaycan Respublikasında fəaliyyətdə olan mikro, kiçik və orta sahibkarlıq subyektlərinin sayı **[7]**

Cədvəl 1-də 2019-2023-cü illərdə Azərbaycan Respublikasında fəaliyyətdə olan mikro, kiçik və orta sahibkarlıq subyektlərinin sayı təqdim olunub. Bu cədvəldən belə nəticəyə gələ bilərik ki,

2019-cu il ilə müqayisədə 2023-cü ildə sahibkarlıq subyektlərinin ümumi sayı 129845 vahid, yaxud 47.9% artmışdır. Müqayisə olunan dövrdə həm mikro, həm kiçik və orta sahibkarlıq subyektləri üzrə artım müşahidə edilirdi [7].

Cədvəl 2. 2019-2023-cü illərdə Azərbaycan Respublikasında mikro, kiçik və orta sahibkarlıq subyektlərinin əsas makroiqtisadi gostəricilər **[7]**

Cədvəl 2-də 2019-2023-cü illərdə Azərbaycan Respublikasında mikro, kiçik və orta sahibkarlıq subyektlərinin əsas makroiqtisadi gostəricilər təqdim olunub. Bu cədvəl əsasında qeyd etmək lazımdır ki, 2019-cu il ilə müqayisədə 2023-cü ildə ölkəmizdə yaradılmış əlavə dəyər, işçilərin

sayı və orta aylıq nominal əmək haqqı artmışdır. Lakin 2019-cu il ilə müqayisədə 2023-cü ildə əsas kapitala investisiyalar 1056.1 mln. manat, yaxud 30.9 azalmışdır [7].

Cədvəl 3-də 2019-2023-cü illərdə ölkə iqtisadiyyatında mikro, kiçik və orta sahibkarlıq subyektlərinin payı təqdim olunub. Bu cədəvldən belə nəticəyə gəlmək olar ki, 2019-cu il ilə müqayisədə 2023-cü ildə ölkə iqtisadiyyatında yaradılmış əlavə dəyərdə (həmçinin qeyri neft-qaz sektoru üzrə) artım; müəssisələrdə muzdla işləyənlərin ümumi sayında cüzi artım, lakin həmin göstəricidə qeyri neft-qaz sektoru üzrə azalma; sahibkarlıq subyektləri tərəfindən əsas kapitala yönəldilmiş investisiyalarda (həmçinin qeyri neft-qaz sektoru üzrə) azalma müşahidə edilirdi [7].

Cədvəl 4. 2019-2024-cü illərdə Azərbaycan Respublikasında bankların kredit portfelinin strukturu barədə məlumat, mln. manat **[8]**

Cədvəl 4-də 2019-2024-cü illərdə Azərbaycan Respublikasında bankların kredit portfelinin strukturu barədə məlumat təqdim olunub. Bu cədvəldən aşağıdakı vacib məqamları xüsusi qeyd etməliyik:

* 2019-cu il ilə müqayisədə 2024-cü ildə Azərbaycan Respublikasında bankların kredit portfelində canlanma müşahidə edilir, belə ki, təhlil olunan dövrdə kredit portfeli 12576.8 mln. manat, yaxud 84.4% artmışdır;

* kredit portfelində ən böyük artım ipoteka kreditlərin payına düşür:

- 2019-cu il ilə müqayisədə 2024-cü ildə kredit portfelində biznes kreditləri 5755.6 mln. manat, yaxud 63.7% artmışdır;

- 2019-cu il ilə müqayisədə 2024-cü ildə kredit portfelində istehlak kreditləri 4369.7 mln. manat, yaxud 107.2% artmışdır;

- 2019-cu il ilə müqayisədə 2024-cü ildə kredit portfelində ipoteka kreditləri 2451.5 mln. manat, yaxud 136.6% artmışdır.

İllər	**2021**	**2022**	**2023**	**2024**

Cədvəl 5. Bankların qeyri-işlək kreditlərinin strukturu barədə məlumat (mln. manat) **[8]**

Cədvəl 5-də 2021-2024-cü illərdə Azərbaycan Respublikasında bankların qeyri-işlək kreditlərinin strukturu barədə məlumat təqdim olunub. Sevindirici hal ondan ibarətdir ki, 2021-ci il ilə müqayisədə 2024-cü ildə bankların qeyri-işlək kreditlərinin məbləği 92.9 mln. manat, yaxud 12.4% azalmışdır. Kredit portfelində növləri üzrə qeyri-işlək kreditlərin payında vəziyyət aşağıdakı kimidir:

- 2021-ci il ilə müqayisədə 2024-cü ildə biznes kreditləri üzrə qeyri-işlək kreditlərin məbləği 2.6% azalmışdır;

- 2021-ci il ilə müqayisədə 2024-cü ildə istehlak kreditləri üzrə qeyri-işlək kreditlərin məbləği 1.2% azalmışdır;

- 2021-ci il ilə müqayisədə 2024-cü ildə ipoteka kreditləri üzrə qeyri-işlək kreditlərin məbləği 2.0% azalmışdır.

Maliyyə ifrastrukturunun sahibkarlığa təsiri formaları arasında dövlət dəstək mexanizmləri xüsusi qeyd olunmalıdır. "Sahibkarlığın inkişafı fondu" güzəştli kredit mexanizmlərini, subsidiyaları, kredit zəmanətlərini fəal şəkildə tətbiq edir. 2024-cü ildə bu fond vasitəsilə güzəştli kredit alan sahibkarlıq subyektlərinin sayı əvvəlki ilə nisbətən 74.7% artmışdır və belə kreditlərin məbləği təxminən 248.1 milyon manat təşkil etmişdir. Dövlət zəmanəti və subsidiya mexanizmi də fəaliyyət göstərir: 2024-cü ildə 12 layihə üçün 19.2 milyon manat kredit üzrə 23.4 milyon manat məbləğində dövlət zəmanəti verilmişdir ki, bunun da bir hissəsi subsidiyalaşdırılmışdır (təxminən 6.2 milyon manat) [13].

Cədvəl 6, 7 və 8-də maliyyə ifrastrukturunun sahibkarlığa təsiri forması kimi maliyyə texnologiyaların istifadəsi dərəcəsi təqdim olunub.

Cədvəl 9. 2022-2024-cü illərdə Azərbaycan Respublikasında elektron bankçılıq **[8, 9, 10, 11, 12]**

Cədvəl 9-dan aşağıdakı məqamların qeyd olunması vacibdir:

- 2022-ci il ilə müqayisədə 2024-cü ildə internet bankçılıq üzrə əməliyyatların sayı 3600 min əməliyyat, yaxud 14.5% azalmışdır;

- 2022-ci il ilə müqayisədə 2024-cü ildə internet bankçılıq üzrə əməliyyatların həcmi 71375 mln. manat, yaxud 35.1% artmışdır;

- 2022-ci il ilə müqayisədə 2024-cü ildə mobil bankçılıq üzrə əməliyyatların sayı 506417 min əməliyyat, yaxud 416.8% artmışdır;

- 2022-ci il ilə müqayisədə 2024-cü ildə mobil bankçılıq üzrə əməliyyatların həcmi 41218 mln. manat, yaxud 181.7% artmışdır.

3. Nəticə və Təkliflər

Azərbaycanda maliyyə infrastrukturu sahibkarlıq mühitinə əhəmiyyətli və müxtəlif təsir göstərir: kiçik və orta müəssisələrinin kreditləşməsinin artırılmasından tutmuş rəqəmsal ödənişlərin genişləndirilməsinə və dövlət elektron sistemlərinin tətbiqinə qədər. Bu təsiri gücləndirmək üçün aşağıdakı nəticə və təklifləri qeyd etmək lazımdır:

Nəticələr:

1. Maliyyə infrastrukturu sahibkarlığa çoxölçülü təsir göstərir. Əsas komponentlər-kredit resurslarına giriş, investisiyaların cəlb etmək bacarığı, zəmanət sistemləri, sığorta və maliyyə cəhətdən qorunma - biznesin artımı və davamlılığı üçün zəmin yaradır. Adekvat infrastruktur olmadan sahibkarlar yeniliyə və miqyaslanmaya qarşı maneələrlə üzləşirlər.

2. İnstitutsional amillər vacibdir. Qanunvericilik, mülkiyyət hüquqlarının qorunması, maliyyə qurumlarının şəffaflığı, məhkəmə sistemi və hüquqi məsələlərin tətbiqi sahibkarlar, investorlar və maliyyə vasitəçiləri arasındakı etimada əhəmiyyətli dərəcədə təsir göstərir.

3. Mikromaliyyələşdirmə kiçik sahibkarlığa dəstək mexanizmi kimi önəmli təsir göstərir. Bir çox kiçik sahibkarlar və startaplar üçün ənənəvi bank kreditləri ya mövcud deyil, ya da çox bahalıdır. Mikromaliyyə təşkilatları bu boşluğu doldurur, lakin onlar tez-tez miqyas, tənzimləmə mühiti və davamlılıq problemləri ilə qarşılaşırlar.

4. Maliyyə xidmətlərinin rəqəmsallaşdırılması vacib drayverdir. Elektron ödənişlər, məsafədən xidmət, maliyyə texnologiyaları (FinTech) əməliyyat xərclərini azaldır, onun sürətini artırır, uzaq bölgələrə girişi yaxşılaşdırır və sahibkarların giriş maneələrini azaldır.

5. Regional fərqlər və zəif infrastruktur bağlantısı sahibkarlığın ümumi artımını məhdudlaşdıra bilər. Nisbətən inkişaf etmiş maliyyə sistemi olan ölkələrdə belə, maliyyə infrastrukturunun zəif olduğu bölgələr və ya sektorlar mövcuddur - məsələn, zəif kapital bazarı, zəmanət sisteminin və maliyyə vasitəçiləri arasında kifayət qədər rəqabətin olmaması.

Təkliflər:

1. Qanunvericilik və institutsional bazanın təkmilləşdirilməsi:

* Mülkiyyət hüququnu, maliyyə institutlarının şəffaflığını, investorların qorunmasını təmin edən standartların hazırlanması və tətbiqi;

* Mikromaliyyə təşkilatları, startaplar və kiçik müəssisələr üçün tənzimləmə prosedurlarının sadələşdirilməsi.

2. Zəmanət və sığorta institutlarının inkişafı:

* Kiçik müəssisələr və fəaliyyətə başlayan sahibkarlar üçün dövlət və ya yarı dövlət zəmanət fondlarının yaradılması;

* İnnovativ və aşağı riskli layihələrdə maliyyə risklərini əhatə edən sığorta məhsullarının inkişafı.

3. Mikromaliyyələşdirmə və alternativ maliyyə mənbələrinə dəstək:

* Mikromaliyyə təşkilatlarının kapitallaşmasını və dayanıqlığını artırılması, onların maliyyə bazarlarına və investisiyalarına çıxışının təmin olunması;

* Vençur kapitalı, kraudfandinq, biznes-mələklər kimi maliyyə mənbələrinin inkişaf etdirilməsi.

4. Maliyyə infrastrukturunun rəqəmsal transformasiyasının stimullaşdırılması:

* Uyğun olduğu yerlərdə elektron ödəmələr, mobil bankçılıq, blok-çeyn-həlləri infrastrukturlarının inkişaf etdirilməsi;

* Əməliyyat və tranzaksiya xərclərinin azaldılmasını, kreditlərin təsdiqlənməsi prosedurlarının sürətləndirilməsini, daha çox şəffaflığı təmin edən texnologiyaların tətbiqi.

5. Maliyyə savadlılığının və informasiya infrastrukturunun inkişafı:

* Sahibkarlara maliyyə uçotunun aparılması, pul vəsaitlərinin hərəkətinin idarə edilməsi, maliyyə alətlərinin anlaşılması bacarıqlarının öyrədilməsi;

* Maliyyə məhsulları, hüquq və vəzifələr, müxtəlif maliyyə mənbələrinin riskləri və faydaları haqqında məlumatların əldə olunması.

6. Regional siyasət və infrastrukturun yerli şəraitə uyğunlaşdırılması:

* Bölgələrin xüsusiyyətlərinin nəzərə alınması: urbanizasiyanın səviyyəsi, iqtisadi ixtisaslaşma, texnologiyaların mövcudluğu, nəqliyyat infrastrukturu;

* Dəstək tədbirlərinin sınağı, yerli ehtiyaclara uyğunlaşdırılması üçün daha az inkişaf etmiş bölgələrdə pilot layihələrin həyata keçirilməsi.

Abstract

The escalating farmer-herder conflicts in Benue State, Nigeria, have triggered widespread rural displacement, disrupted agricultural activities, and destabilized local economies. Drawing from Focus Group Discussions and Key Informant Interviews across selected conflict-affected communities, the study investigates the socio-economic consequences of displacement and the broader implications for food production and rural resilience. The research employed a qualitative methodology, using random, purposive and snowball sampling techniques to select participants with direct experience of displacement. Data analysis reveals that sudden violent attacks often characterized by burning of properties, bloodshed and rape led to widespread displacement of rural farmers. Displaced farmers face significant livelihood disruptions, including loss of farmland, reduced income, food insecurity, family separation and social disintegration. Despite adopting coping strategies such as informal labour and temporal migration, they remain economically vulnerable and socially marginalized depending on stipends from family members and donations from individuals and organizations for those in IDPs camps. The findings underscore the long-term threat that rural displacement poses to agricultural development in Nigeria's north central, particularly in regions central to national food security. The study calls for multi-level policy responses, including improved land governance, community-based peacebuilding, livelihood rehabilitation programs, and early warning systems to prevent further displacement.

Keywords: Farmer-Herder Conflict, Rural Displacement, Livelihood Disruption, Agricultural Development, Climate-Induced Conflict, Benue State.

1. Introduction

1.1. Background and Context

In Nigeria's Middle Belt, farmer–herder conflicts have increasingly become a pervasive and destructive phenomenon, especially in states like Benue that are agriculturally rich yet socially vulnerable. Historically, pastoral mobility and settled farming coexisted through negotiated access to grazing and farmland, but mounting pressures have eroded this balance. These pressures include demographic growth, land conversion, agricultural expansion, and environmental stress; particularly those associated with climate change, variability and resource depletion (Adoga, Umeh & Idris, 2024; Ogunbode, Ajayi & Omisore., 2020). More recently, violent clashes, cattle

intrusion, crop destruction, and retaliatory attacks have led to displacement, livelihood loss, and food insecurity in affected rural zones (Nwankwo, Onuigbo & Chukwuma 2024; ACCORD, 2022).

Benue State is especially significant in this discourse because it is often referred to as Nigeria's "food basket." Its fertile soils and favorable agro-ecological conditions support diverse cropping systems and livestock production. However, the escalation of conflicts over land, water, and grazing access has disrupted agricultural timelines, displaced farm families, and undermined local food systems. The conflict in Benue is not merely local in scale but carries broader implications for national agricultural development and stability (Ijirshar, Udaah, Mile, Vershima, & Adaudu 2025). Indeed, recent studies show that insecurity in Benue state correlates with reductions in crop and livestock outputs (Ijirshar *et al*., 2025).

1.2. Problem Statement

While much of the existing scholars addresses the causes, nature, and security dimensions of farmer–herder conflicts, less attention has been given to the processes and consequences of rural displacement triggered by those conflicts; and how displacement, in turn, affects agricultural development. Rural populations forced to abandon farmland often lose critical assets, face social disintegration, and struggle to re-establish livelihoods under challenging conditions. In Benue State, where agricultural productivity is key to rural incomes and food security, such disruptions may have deeply negative ripple effects on local economies and communal stability.

Hence, a focused inquiry is needed to understand how conflict-induced displacement reshapes agricultural landscapes, constrains rural livelihood options, and potentially stunts growth in agrarian sectors. Without such knowledge, policies designed to reduce conflict or rehabilitate displaced populations may fail to address the structural economic consequences.

1.3. Research Questions and Objectives

In response, this study is guided by the following research questions:

a. How does farmer–herder conflicts in Benue State contribute to rural displacement?
b. What challenges do they face in rebuilding their livelihoods?
c. What are the short-term and long-term impacts of rural displacement on agricultural development in Benue State?

The objectives of this study are thus: To interrogate how the farmer–herder conflicts in Benue State precipitate rural displacement, to characterize the obstacles they encounter in re-establishing their livelihoods and to assess both immediate and enduring impacts of displacement on agricultural productivity, land use, and rural economies.

1.4. Significance of the Study

This research contributes in multiple ways. First, by centering displacement as a focal outcome of conflict, it opens a lens on livelihood disruptions that is less represented in existing studies. Second, by paying particular attention to agricultural development, it bridges peace/security research with agrarian economics and rural development discourse. Third, by combining lived

experiences from conflict-affected communities with policy-oriented inquiry, the study offers grounded insights to policymakers, development agencies, and local stakeholders striving to design interventions with real impacts. Finally, in the context of climate change and growing resource stress across West Africa, the findings from Benue may serve as a case from which lessons can be drawn for other conflict-prone agrarian regions.

1.5. Scope and Limitations

This study is geographically focused on selected rural communities in Benue State that have recently experienced farmer–herder conflicts and consequent displacement. Data is drawn through Focus Group Discussions and Key Informant Interviews with displaced farmers, host community members, and local leaders. The temporal scope centers on conflict and displacement events occurring approximately between 2018 and 2025, aligning with heightened conflict waves in the north central Nigeria. While the qualitative methodology limits broad generalizability, the depth of insight gained will illuminate displacement dynamics and agricultural consequences that may resonate in comparable agrarian settings.

1.6. Literature Review

1.6.1. Theoretical perspectives on displacement

Displacement, whether due to conflict, disaster, or development; has been studied through multiple theoretical lenses. A promising conceptual framework is offered by Hirsch, Eizenberg, & Jabareen (2020), who defines key dimensions of displacement: power, positionality, eligibility, temporality, and resistance. These concepts emphasize that displacement is not merely physical relocation but involves shifts in rights, identities, and agency. Hirsch's framework helps in analyzing how rural households displaced by conflict transform their social and economic interactions.

In the domain of resilience and sustainability, Kochskämper, Glass, Haupt, Malekpour. & Grainger-Brown (2025) explore the interplay between resilience-building and advancing the SDGs. They argue that resilience interventions tailored for cities and communities can accelerate SDG progress, but only when they consider local vulnerabilities and equity (Kochskämper *et al*., 2025). This work suggests that in contexts of displacement, resilience frameworks must be integrated with SDG objectives to ensure displaced populations are not left further behind.

Other theoretical perspectives include structural violence theory, which views displacement as an outcome of entrenched inequalities and systemic exclusion (Galtung, 1969 cited in broader conflict literatures such as Henderson, 2019; Disabil, 2017). Also relevant is political ecology, which emphasizes how resource access, power relations, and environmental stressors intersect to force relocation and livelihood change. These theories help situate displacement within broader structural forces rather than treating it as isolated crises.

From a development planning vantage, rights-based theory of development frames displacement as a violation of human rights, demanding redress in terms of restitution, compensation, and participation in rebuilding (often invoked in UN and humanitarian literature). This aligns with the ethos of SDG principles of "leaving no one behind."

1.6.2. Displacement and the sustainable development goals

Since the adoption of the 2030 Agenda, scholars have interrogated how displaced populations are integrated into or excluded from SDG monitoring and implementation. Le Voir (2023) critically examines how displaced persons are often invisible in key SDG indicators, especially those related to sexual and reproductive health, showing that data systems rarely disaggregate by displacement status. This invisibility undermines accountability and equity under the SDG framework.

More broadly, Le Voir (2023) links forced displacement as a barrier to SDG attainment. The paper highlights how conflict-driven internal displacement directly affects goals related to poverty (SDG 1), food security and hunger (SDG 2), and decent work (SDG 8) by disrupting productivity, access to resources, and labor markets. The argument is that displacement both results from unsustainable development paths and inhibits progress toward sustainable outcomes.

1.6.3. Empirical studies: displacement, conflict, and rural livelihoods

Empirical studies from Nigeria and Sub-Saharan Africa reveal rich insights into displacement caused by agrarian conflict. A case study in the Middle Belt of Nigeria found that herder incursions forced farm families to migrate seasonally or permanently, losing land capital and community support systems (e.g. Mbah, Jiriko, & Amah, 2020). Those displaced often adopt secondary occupations, wage labor, or petty trade, though with significantly reduced income stability.

In the Sahel, forced migration due to conflict and environmental stress is well documented. For instance, scholars show that displaced farming households suffer lower food consumption, reduced crop diversity, and loss of social capital (Su & Amrit, 2024; Olanrewaju & Balana, 2023). Even after resettlement, returnees often struggle with reclaimed land, poor fertility, or conflict over new plots.

In Nigeria's Niger Delta, conflict-induced displacement from oil pollution and resource contests has been linked with declines in agricultural output and increased poverty. Some of studies showed that displaced rural producers had lower access to credit, inputs, and extension services, reducing yields relative to non-displaced communities (Odozi & Uwaifo, 2021; Ofuoko & Evwierhurhoma, 2018; Obi, 2010).

Another study in Northern Nigeria examined the displacement from Boko Haram conflict and found that displaced farmers had truncated crop cycles, limited market access, and adoption of short-term survival farming strategies (Tafida *et al*., 2023; George, & Adelaja, 2022). The authors argued that displacement contributes to a downward spiral in agrarian productivity, reinforcing economic fragility. Figure 1 shows some of the effects of displacement on communities and the people.

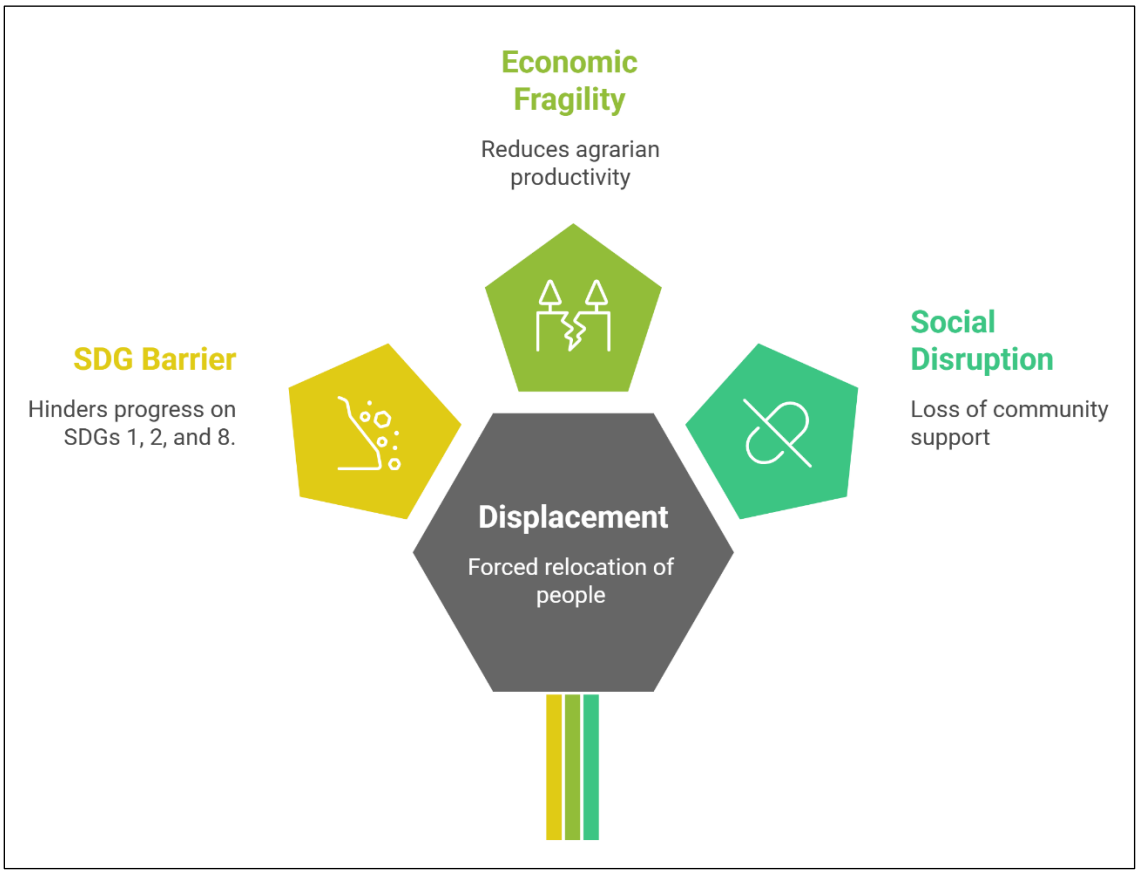

Figure 1. Effects of displacement

2. Materials and Methods

2.1. Study Area

Benue State lies in Nigeria's north central, occupying a landmass of about 34,059 km². It is geographically bounded between latitudes 6° 25′ and 8° 08′ N and longitudes 7° 47′ and 10° 00′ E, and shares boundaries with Nasarawa (north), Taraba (east), Cross River, Ebonyi and Enugu (south), and Kogi (west) (Figure 2). The name is derived from River Benue which runs through.

Benue is characterized by a tropical savanna climate (Köppen's AW), with distinct rainy (April–October) and dry (November–March) seasons. Annual rainfall typically ranges from 1,000 mm to about 2,000 mm in many parts; the state also experiences a mono-peak rainfall pattern in some areas. Mean temperatures range from 23 °C to 37 °C, with relative humidity averaging 70 % (Ologunorisa, Obioma & Eludoyin, 2021). Vegetation & Soils

Vegetation transitions across the state from forest to savanna in the south to woodland/Guinea savanna in the north; reflecting soil fertility gradients and rainfall differences. Much of the land is cultivated, and natural vegetation has been altered by agricultural expansion. Soils are predominantly loamy, alluvial in floodplains, and basement complex-derived in upland areas,

forming a basis for mixed agriculture and suitability for many cash and food crops (Ujoh, Igbawua, Ogidi, 2019).

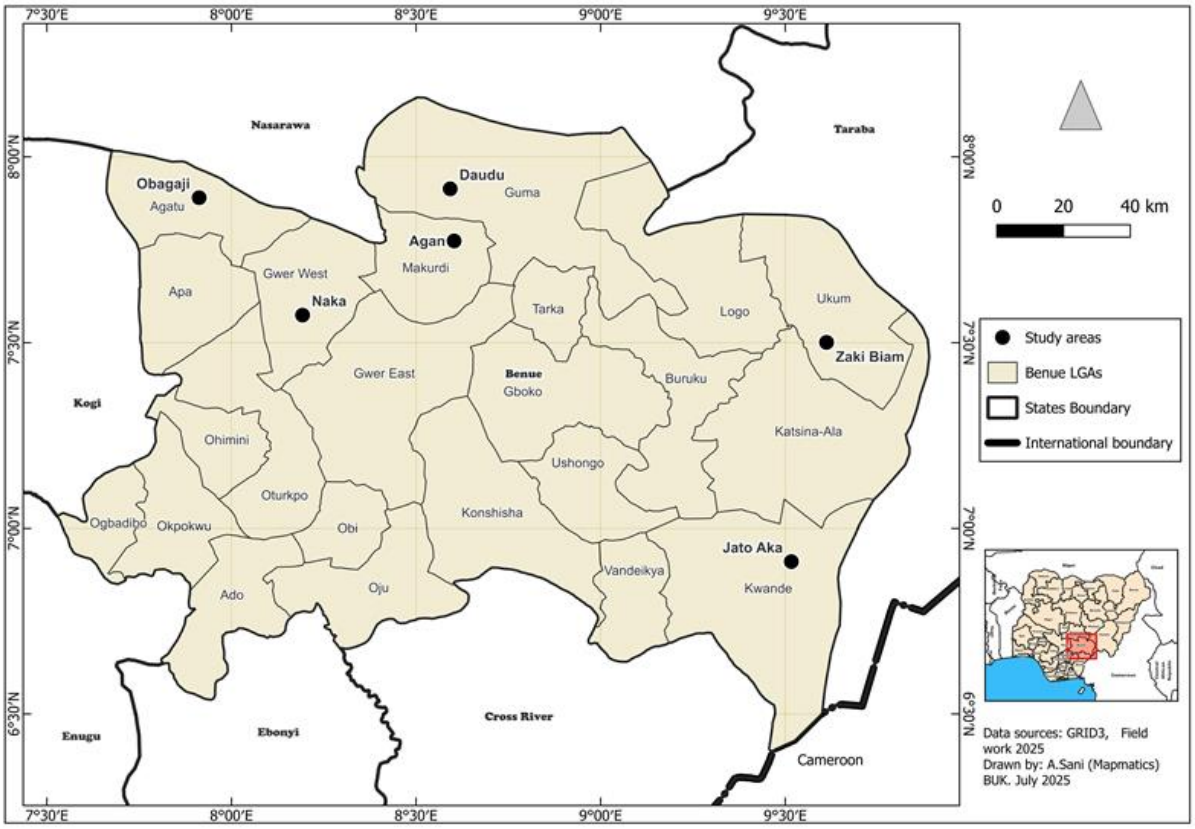

Figure 2. Map of Benue State showing the Six Sample Area

Agriculture is the mainstay of Benue's economy: over 70 % of the population is engaged in farming. Prominent crops include yam, maize, cassava, rice, soybeans, beans, sorghum, millet, and others. Livestock rearing (cattle, goats, sheep) is widespread, especially in fringe zones. Fishing is also important along water bodies like the River Benue. The state is often dubbed Nigeria's "Food Basket" because of its significant contribution to national staples (Ukpoju & Oue, 2024).

2.2. Research Design

This study adopted a qualitative research design, focusing exclusively on the experiences and perspectives of farmers who have been directly affected by the perennial violent farmer–herder conflict and displacement. Focus Group Discussions (FGD's) and Key Informant Interviews (KII) were used as tools for data collections. The aim is to elicit rich, contextually grounded data rather than produce large-scale statistical generalizations.

2.3. Sampling Methods

Simple random, purposive and snowball sampling were used, simple random sampling was used to select six local government areas of Agatu, Guma, Gwer West, Kwande, Makurdi and Ukum out of the 23 in the state; purposive sampling approach was used to select six rural communities within each of the local government known for recurrent farmer–herder conflicts and the resultant rural displacement. The six communities are: Obagaji in Agatu LGA, Daudu in Guma LGA, Naka in Gwer West LGA, Jato Aka in Kwande LGA, Agan in Makurdi LGA and Zaki Biam in Ukum LGA

Within each community, farmers who had experienced displacement or disruption of their farmland were selected via snowball sampling (to reach those affected) and random sampling (among the eligible pool) to diversify voices.

2.4. Data Collection Methods

2.4.1. Focus Group Discussions (FGDs)

12 Focus Group Discussions (FGDs) were conducted with two (male and female) FGDs in each community, as the focus is on agricultural impacts and livelihood disruption. Each FGD had 10 participants in attendance making a total of 120 participants.

The FGDs were semi-structured and guided by a discussion protocol focusing on: Drivers of conflict and how its effects on displacement, experiences of displacement and livelihood disruption, adaptation or recovery strategies, perceived impacts on agriculture and future prospects. Each FGD lasted between 60 and 90 minutes, audio-recorded (with permission), and transcribed verbatim.

2.4.2. Key Informant Interviews (KIIs)

Additionally, 12 Key Informant Interviews (KIIs) were conducted across the communities (2 per community), with local agricultural extension workers and community leaders.

Semi-structured interviews were used with the local experts, extension agents, or community leaders to complement and triangulate FGD data; especially regarding institutional responses, historical trends, and policy perspectives.

All interviews and FGDs were conducted in local languages (e.g., Tiv, Idoma) where necessary, with translation to English during transcription.

2.5. Data Analysis

Benue has often been a hotspot of contestation over land and grazing rights, because of its central location and agricultural potential, making it a relevant site for studying farmer-herder conflicts and displacement. Data was analyzed using thematic content analysis, transcripts were read repeatedly and coded into thematic nodes (e.g., “violent attacks,” “family separation,” “temporary shelter” “land abandonment”). Codes were grouped into broader themes following an inductive-deductive approach; inductive to capture emergent themes and deductive based on research questions.

NVivo was used to manage and organize codes and transcripts, facilitating pattern identification, cross-community comparison, and theme interrelations. Findings from FGDs and KIIs were triangulated to validate consistency.

2.6. Limitations

Because the study relies on qualitative data from farmers only, the perspectives of herders, non-farmers, or government actors are excluded. The purposive and snowball sampling limit statistical generalizability; the results however, provide depth and insight rather than population-wide representativeness. Recall bias may affect participants' estimates of losses or timelines in displacement and agricultural impacts.

3. Findings and Discussions

3.1 Findings

The data were organized into three major themes, reflecting the core research questions:

3.1.1. Conflict induced displacement

Participants across all six communities identified key reasons why the conflict led to widespread displacements:

A female FGD participant in Obagaji expressed that:

"The attacks are extremely violent and led to the deaths of many people, several missing even years after attacks. When you do not hear or see someone again after such an attack, you assume they died in the attack, with such magnitude of bloodshed, fleeing to new locations is the safer option"

Another female FGD participant in Naka added that:

"One terrible evil these herdsmen have been doing is the raping of women and young girls on the farms; sometimes they will kill them after raping them and sometimes, they will leave them to go. These trauma is difficult to live with; this is why we fled our own land"

A male FGD participant in Daudu further stated that:

"We are sedentary and have permanent residences while the herders are migrants with temporary makeshift structures, when they attacked our community, they burnt many houses and farms, even if we are to return back there, we will be rebuilding everything afresh"

A KII participant in Zaki Ibiam collaborating these statements stated that:

"These herdsmen attacks are sudden, persistent and can happen at any time of the day; whether while people are asleep in the night or in places of worship on Sunday. Given the magnitude of the violence and the fear of being killed by these heartless men, the displacement we are seeing the option for the farmers".

Plate 1. Part of Yelewata community in Guma local government area after armed herdsmen attack on June 14, 2025 that claimed over 100 lives and displaced over 3000 people.

3.1.2. Displacement experiences and adaptation challenges

Participants expressed their displacement experiences which were both sudden and prolonged:

A male FGD participant in Daudu narrated that:

"My entire village had to flee overnight due to violent attack that happened that night, it was when we got to Daudu that we actually knew all those that were killed, we could not go back until after a week only to meet decomposing bodies of our loved ones and our burnt properties. I personally lost all my credentials because I could not carry it as I ran for my life".

A female FGD participant in Makurdi stated that:

"as we fled our community, I got separated with my eldest son who is 12 years old. I thought he was with my husband who was much more behind us but when we got to Agan and he caught up with us, he was not with him. We kept searching for him and did not see him for over three months before he was brought to us from another IDP camp in Guma. In our case, we were very lucky, some people here are still looking for their loved ones. The sad thing is that, it is sometimes better to know that someone is dead than to just keep searching endlessly without ever finding them yet hoping you will see them one day. When fleeing, the most difficult people to carry are the elderly, some of them are sick, some blind even the children are easier because we can back them and others can run".

A KII participant in Jato Aka said that:

"there are several people in this place that have not gone back home since they fled during the time Fulani herdsmen attacked their communities, some have been here for 5 to 6 years, staying in temporal makeshift shelters"

Another KII participant in Obagaji added that:

"one painful angle to the effect of displacement is the increase in dependency burden, many of those displaced have lost their means of livelihoods and have no choice but run to either IDP camps

or to their relatives. In such conditions, they depend on the relatives for food and other stipends. So you can imagine, how pathetic for an able bodied man becoming dependent".

3.1.3. Rural displacement and agricultural decline

An FGD participant in Zaki Ibiam reported that:

"The displacement has cost us severely in terms of crop productivity and yield, those who are to cultivate are displaced resulting in low production of crops, either due to conflict-time abandonment or loss of access to farms".

Another FGD participant in Naka expressed that:

"displacement has led to farmland abandonment; some formerly productive areas remain uncultivated due to insecurity. The farmers are afraid of getting killed if they attempt to cultivate some areas"

"Apart from crops, we also lost farming tools, stored grains, and livestock during attacks. Before the crisis, I had six hectares of rice, five hectares of maize, three hectares of cassava. Now, I am squatting with my brother, some of our people are in IDP camps depending on donations from well-meaning individuals and non-governmental organizations" added another FGD participant in Makurdi.

A KII participant in Makurdi while collaborating the effects of rural displacement on agricultural development in the state stated that:

"as a result of the displacement, some of those displaced survive by becoming hired helps to cultivate farmlands for others, some shifting to peri-urban agriculture by growing short-cycle crops on rented lands near towns. However, this has not really boosted agricultural productivity in the state because many of them are still working below their normal capacity".

3.2. Discussion

The thematic results presented earlier illuminate how farmers in conflict-affected communities in Benue State experience displacement and agricultural disruption. In this discussion, we interpret those findings in light of existing literature and theory, reflecting on their broader meaning for policy and sustainability.

3.2.1. Displacement, livelihood losses, and agricultural decline

The experiences of displaced persons such as dependency on relatives, living in temporary makeshift shelters are consistent with Adoga, Akumaga & Mohammed (2025) who reported that most displaced persons stay in Internally Displaced Persons (IDPs) camps which are either schools or makeshift structures, exposed to poverty and hunger; depending largely on donations from non-governmental organizations and wealthy individuals. The more fortunate ones stay with their relatives as dependents.

The scale of yield loss, land abandonment, and asset depletion recorded in this study echoes findings from Nnaji, Ratna, Renwick & Ma (2022) who established that the incidence and severity of farmer-herder conflict increase food insecurity for rural households. In their survey, the severity

of conflict had a larger negative effect than mere incidence; paralleling your observations that more intense or repeated displacements lead to deeper and more lasting agricultural disruption.

The finding that farmland is left uncultivated under insecurity is consistent with broader patterns in conflict zones: Omotayo et al. (2025) documents declines in farm investment in conflict-affected areas, and participant reports of asset loss and abandonment substantiate the qualitative dimension of that trend. In sum, displacement becomes not only a geopolitical issue but a structural drain on agricultural productivity.

3.2.2. Implications for food security and sustainable development

The results underscore that rural displacement in Benue State is not simply a local social or security issue; it has profound implications for food security, agricultural development, and the realization of sustainable development goals (SDGs). The reduction in cultivated land, loss of crop yield, and displacement-induced failure to invest in agriculture directly undermine SDG 2 (Zero Hunger) and SDG 1 (No Poverty).

Moreover, as conflicts intensify and farmers abandon farmland, national food baskets shrink and supply chains tighten, compounding vulnerabilities. The linkage between insecurity and declining productivity observed in the recent study on insecurity in Benue (Ijirshar et al., 2025) reinforces that conflict-related displacement has quantifiable negative impacts on agricultural output locally.

3.2.3. Contributions and future directions

This study's qualitative depth, centering on farmers' voices, contributes to a more grounded understanding of how conflict-driven displacement impacts agriculture at community scale; complementing macro-level quantitative studies.

Future work should incorporate mixed methods: combining FGDs with household surveys and remote sensing of land use change; to triangulate qualitative reports with observable environmental and yield data. Also, exploring displacement from the perspective of herders, host communities, and institutional actors would enrich the multi-actor dynamics of conflict and displacement.

4. Conclusion, Policy Implications, and Recommendations

This study has explored the complex relationship between farmer-herder conflicts, rural displacement, and agricultural development in Benue State, Nigeria. Drawing on 12 focus group discussions and twelve key informant interviews, the findings reveal that conflict-driven displacement is both a humanitarian and developmental crisis. Farmers face recurring violence, land abandonment, loss of livelihoods, and disruptions to food production systems. Displacement not only weakens rural resilience but also undermines Nigeria's broader food security goals. The findings reaffirm that beyond ethnic or cultural tensions, the root causes lie in resource competition, land governance failures, climate stress, and weak institutional responses. Resolving this crisis requires multi-dimensional interventions that address both immediate relief and long-term agricultural recovery.

The study has implication for food security risk; displacement from farming communities reduces cultivated land and threatens local and national food production; challenging Nigeria's progress

toward SDG 2 (Zero Hunger) and SDG 1 (No Poverty). Institutional gaps through inadequate enforcement of land-use policies, poor coordination among security agencies, and lack of effective early warning systems worsen the cycle of violence and displacement. In addition, weak conflict resolution systems between traditional and state mechanisms remain fragmented or reactive, failing to address systemic grievances and recurring clashes.

Recommendations

The following are recommended:

1. The federal government should establish clear, participatory land tenure systems that reduce overlapping claims between farmers and pastoralists.

2. The government should invest in agricultural recovery and support by providing displaced farmers with access to inputs, extension services, and climate-smart technologies to rebuild their livelihoods.

3. The government should also support the resource users with climate-resilient infrastructure such as expansion of irrigation systems, water points, and storage facilities in conflict-prone areas to reduce dependence on rain-fed agriculture and seasonal migrations.

4. The government should establish a national conflict-monitoring system that integrates satellite data, community reporting, and socio-economic indicators for proactive interventions.

By translating findings into action, this study calls on policymakers, development actors, and local stakeholders to treat conflict-induced displacement as both a development emergency and an opportunity to rebuild more resilient agricultural systems in Benue State.

Thanks and Information Note

The article complies with national and international research and publication ethics. Ethical Approval from the state Ministry of Agriculture as well as the farmers' association was gotten before heading to the field. Additionally, community leaders were consulted to facilitate access and ensure culturally appropriate engagement. Before each FGD or interview, participants were briefed about the study's purpose, assured of confidentiality, and asked for voluntary informed consent. Anonymity was preserved by using anonymized identifiers. Participants could decline to answer questions or withdraw at any time without penalty.

Author 1 conceived the idea, collected the data and wrote the initial manuscript, author 2 also helped with data collection and edited the manuscript. There is no conflict of interest.

Abstract

This study investigates the stress-strain state of a thin-walled cylindrical shell containing a small circular hole surrounded by several elliptical inclusions of different materials. Three configurations of inclusion arrangement relative to the hole are considered: vertical, horizontal, and diagonal. A finite element analysis was performed to evaluate the influence of the distance between the hole and the inclusions, their spatial arrangement, and material properties on the stress concentration factor (SCF). The results were compared with corresponding data for plates. The analysis of the conducted studies shows that for inclusions harder than the shell material, a horizontal arrangement reduces the SCF by approximately 36%, while for softer inclusions, a vertical arrangement reduces the SCF by approximately 20%. Furthermore, decreasing the distance between the hole and the inclusions leads to a decrease in stress concentration, with the most favorable configuration observed at the closest distance for horizontally positioned hard inclusions.

Keywords: Cylindrical shell, circular hole, elliptical inclusions, stress concentration factor, finite element method.

1. Introduction

Thin-walled structural elements such as shells and plates are widely used in aerospace, aviation, energy and civil engineering, architecture, and construction. Structural and technological requirements often result in structural inhomogeneities in the form of holes and inclusions, which inevitably disrupt the material's continuity (Avdonin, 1969). Such inhomogeneities lead to stress concentrations and influence the deformation and failure processes of the system (Savin, 1968). Therefore, accounting for the influence of local stress concentrators and finding ways to reduce stress concentrations in thin-walled structures remain important problems in solid mechanics and architectural sciences (Gudramovich et al., 2017). Numerical methods, particularly the finite element method, provide effective tools for solving such problems (Zienkiewicz et al., 2014).

Numerous studies have been devoted to the study of the stress-strain state of thin-walled shells with openings, among which the seminal work (Guz et al., 1980) deserves special mention. The problem of reducing stress concentration is extremely pressing. Among modern studies in this area, we note the work (Hart & Hudramovich, 2021), which proposes an effective scheme of variational-grid methods for solving a wide class of problems with structural inhomogeneities.

This scheme makes it possible to significantly accelerate the convergence of the numerical finite element method. In the work (Hudramovich et al., 2024), the possibility of using a radially inhomogeneous inclusion made of a functionally graded material around a hole is considered, which significantly (by 56%) reduces the local stress concentration. In the work of the authors (Hart & Shebanov, 2024), the idea of using hard elliptical inclusions at a certain distance from the hole was proposed, which led to the effect of reducing the stress concentration. This work is a continuation of the authors' research on the selection of rational parameters of inclusions in a thin-walled cylindrical shell with a small hole.

2. Materials and Methods

Let us consider the stress-strain state of thin-walled elastic homogeneous cylindrical shells of thickness h, radius R, and length H. The shells contain a small through circular hole of radius r, around which two (or four) identical elliptical inclusions are symmetrically located, each with a major semiaxis a and a minor semiaxis b. The centers of the inclusions are located at a distance l from the center of the hole ((Figure 1). The shell is subjected to a uniaxial uniform tensile load p.

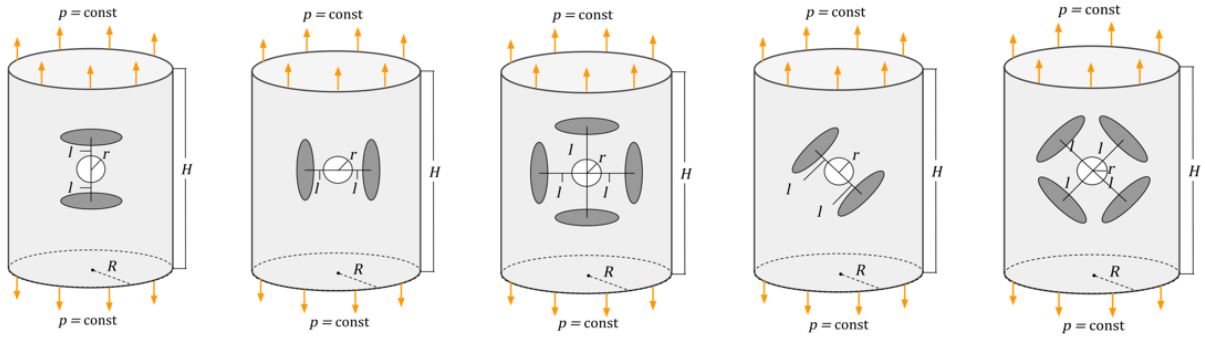

Figure 1. Geometry and loading schemas

The proposed configurations allow us to study the influence of the orientation and number of inclusions on the stress distribution around a circular hole in the shell.

In the variational formulation, the problem of studying the stress-strain state of a thin-walled, non-uniform cylindrical shell is reduced to minimizing the functional of the system's total potential energy. In the current study, this problem will be solved using the finite element method.

The results are obtained for the cylindrical shell with the following parameters: R=0.3m, H=0.8m, h=0.005m, r=0.02m. The half-axes of the elliptical inclusions are a=0.04m, b=0.02m. Two types of the materials with such moduli of elasticity E_i and Poisson's ratio μ_i were used: E_1=70 GPa, μ_1=0.3, E_2=210 GPa, and μ_2=0.33 with corresponding strength limit and offset yield limit: σ_u=470 MPa, $\sigma_{0.2}$=415 MPa and σ_u=720 MPa, $\sigma_{0.2}$=620 MPa. The choice of materials is conditional. The external tensile load at the ends of the shell is p=10 MPa.

To simplify the analysis, the relative inclusion stiffness factor is introduced: $k = E_{inc} / E_{shell}$, where E_{inc} is the modulus of elasticity of the inclusion and E_{shell} is the modulus of elasticity of the shell material. We consider the cases when $k > 1$ ("hard" inclusion) and $k < 1$ ("soft" inclusion).

The calculations were carried out for a shell containing two and four identical inclusions, symmetrically located at different distances l from the center of the circular hole to the geometric center of the elliptical inclusion (l = 8r; 5r; 3r; 2.5r).

3. Findings and Discussion

For all studied inclusion arrangements (Figure 1), stress and strain intensity fields were found, and the magnitude of the SCF was determined. Figures 2–6 show the results of the studies for hard and soft inclusions.

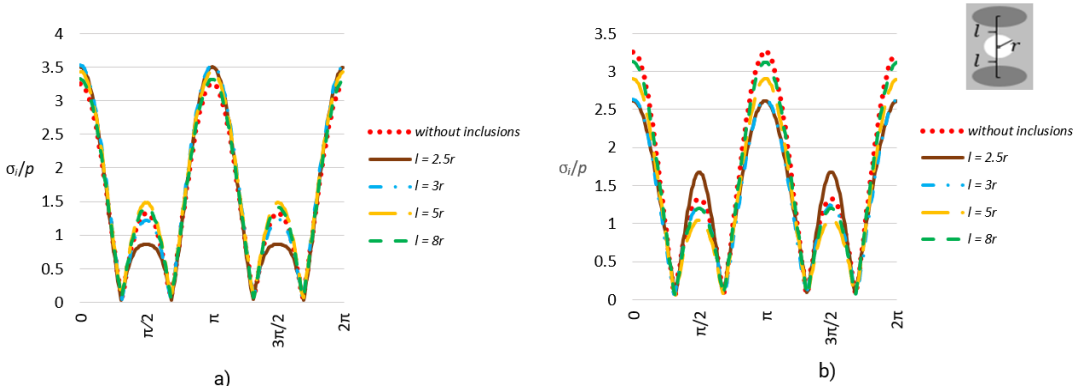

Figure 2. Distribution of the relative stress intensity σ_i/p along the contour of the hole for the case of two vertically located elliptical inclusions: k > 1 (a); k < 1 (b)

Figure 2 shows the variation of the normalized circumferential stress σ_i/p along the contour of a circular hole. Figure 2a corresponds to the case with two hard, vertically positioned inclusions (k > 1), while Figure 2b corresponds to the case with softer inclusions (k < 1). According to the figure, the use of hard inclusions does not reduce the stress concentration factor (SCF), but in the case of soft inclusions, it decreases when the inclusions are located sufficiently close to the hole.

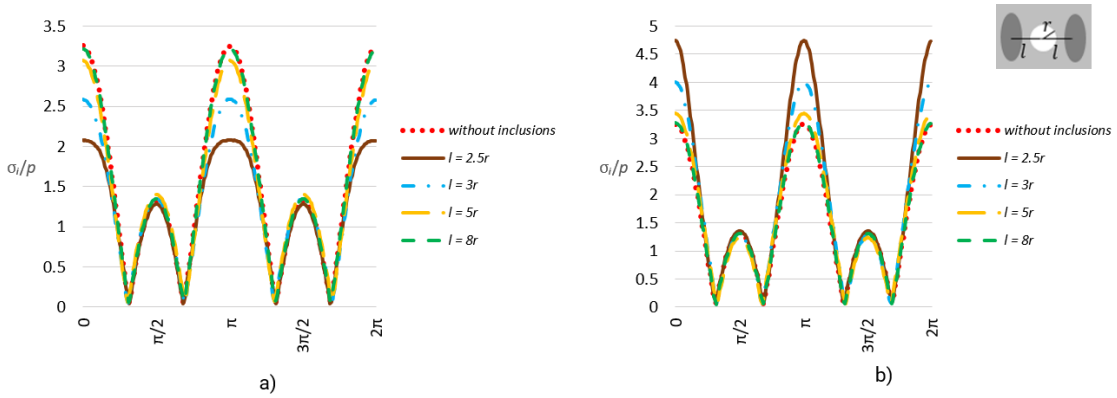

Figure 3. Distribution of the relative stress intensity σ_i/p along the contour of the hole for the case of two horizontally located elliptical inclusions: k > 1 (a); k < 1 (b)

Figure 3 presents the σ_i/p distribution in the circumferential direction along the hole contour for two horizontal inclusions. In the case of hard inclusions, the SCF decreases significantly at relatively close distances from the hole, whereas the use of soft inclusions does not lead to a decrease in the SCF.

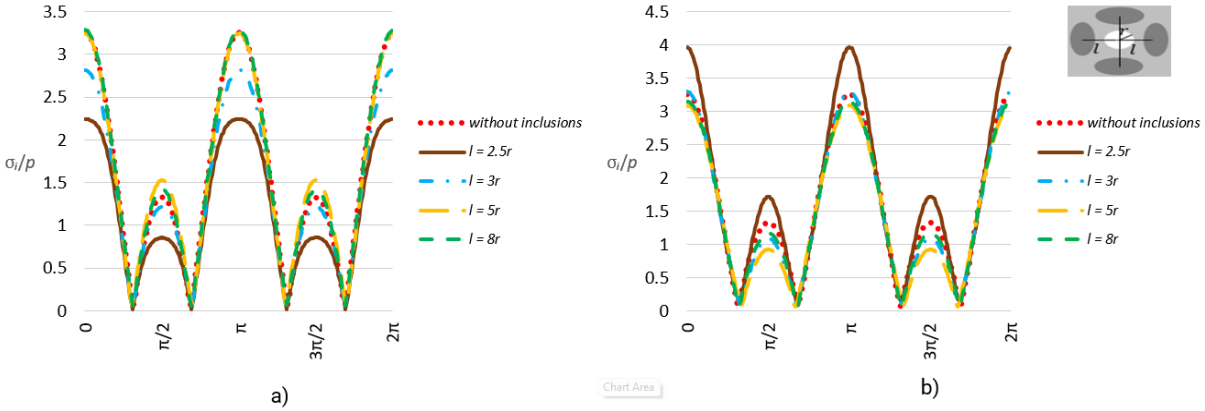

Figure 4. Distribution of the relative stress intensity σ_i/p along the contour of the hole for the case of four inclusions located along *Ox* and *Oy* axes: k > 1 (a); k < 1 (b)

Figure 4 presents stress distribution σ_i/p along the hole contour for the case of four inclusions positioned around the hole, symmetrically relative to the x- and y-coordinate axes. As in the previous configuration, placing hard inclusions closer to the hole significantly reduces the stress concentration. Using soft inclusions, however, does not significantly reduce the SCF.

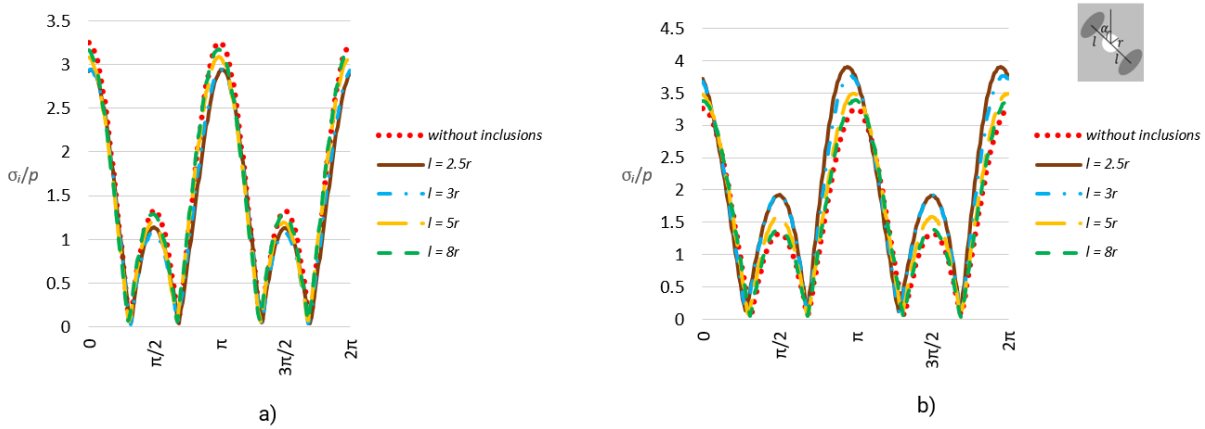

Figure 5. Distribution of the relative stress intensity σ_i/p along the contour of the hole for the case of two diagonally located elliptical inclusions: k > 1 (a); k < 1 (b)

Figure 5 shows the stress distribution σ_i/p along the hole contour for two diagonal inclusions. Here, too, a decrease in SCF is observed for hard inclusions and an increase for soft inclusions. However, a mechanical effect is also observed: as two hard diagonal inclusions approach the hole, the stress concentration zones shift in the direction opposite to the inclusion's location (to the right in the

figure). When using soft inclusions, a mechanical "shear effect" is also observed, but the stress concentration zones shift in the opposite direction (to the left in the figure).

Figure 6 shows the stress distribution σ_i/p along the hole contour for four diagonal inclusions. In this case, it is also observed that the use of hard inclusions reduces the SCF, while the use of soft inclusions increases the SCF.

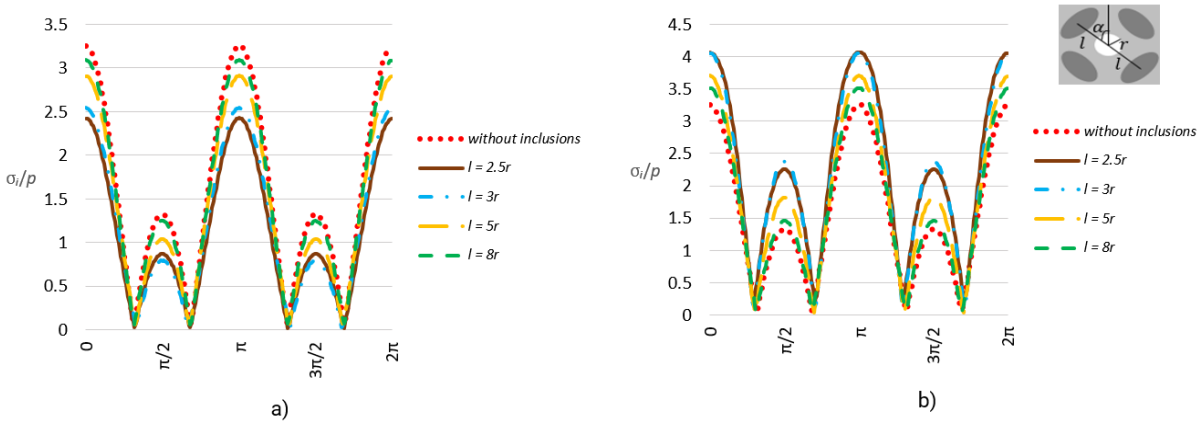

Figure 6. Distribution of the relative stress intensity σ_i/p along the contour of the hole for the case of four diagonally inclusions : k > 1 (a); k < 1 (b)

As an illustration of the best result from the options considered, we present the data in the Table 1.

Table 1. Stress concentration factor in a cylindrical shell with two horizontally located "hard" and "soft" inclusions

Problem / Distance, *l*	*k* > 1		*k* < 1	
	SCF	**δ, %**	**SCF**	**δ, %**
8*r*	3,22	-1,1	3,28	+0,8
5*r*	3,07	-5,5	3,45	+6,1
3*r*	2,59	-20,4	4,01	+23,2
2,5*r*	**2,08**	-36,1	4,74	+45,8

Here, δ is the deviation of the SCF from the corresponding value for the shell without inclusions (SCF=3.25 (Guz et al., 1980)).

The best result here is observed in the case of two "hard" inclusions at l=2.5r. The reduction in SCF the compared to the shell without inclusions is observed here by 36%.

ii. Conclusion and Recommendations

Among the studied configurations of elliptical inclusions surrounding a circular hole in a cylindrical shell, the horizontal arrangement of "hard" inclusions (k > 1) proved to be the most effective in reducing the stress concentration factor (SCF), resulting in a reduction of approximately 36% compared to a shell without inclusions. For "soft" inclusions, the vertical arrangement proved to be the most effective, providing a SCF reduction of approximately 20%. The analysis revealed a pronounced mechanical effect: as two "hard" diagonal inclusions approach the hole, the stress concentration zones shift in the direction opposite to the inclusion position (i.e., clockwise). A similar "shear effect" was also observed when using "soft" inclusions; however, in this case, the shift in the stress concentration zones occurs in the opposite direction (counterclockwise). This mechanical effect is qualitatively consistent with a similar phenomenon observed for a plate.

A promising direction for further research is to determine rational inclusion parameters for other hole configurations, taking into account their impact on reducing the SCF. This approach has significant practical implications for improving the design processes and optimizing components of modern engineering structures, ensuring increased strength, durability, and operational efficiency.

Thanks and Information Note

The article complies with national and international research and publication ethics. Ethics Committee approval was not required for the study. This work was supported by ongoing institutional funding. No additional grants to carry out or direct this particular research were obtained. All authors contributed equally to the article. Abstract

Filmmaking is rapidly transforming by Artificial Intelligence (AI) across the globe, with Nigeria's vibrant film industry (i.e. Nollywood) emerging as an adopter and a contested site for technological experimentation. How technological, institutional, and regulatory frameworks as emerging AI regimes are reforming creative practices and industry structures in Nigeria is examined in this paper. Also, the integration of AI tools was explored in this paper across pre-production, production, post-production, and distribution by situating Nollywood within global discourses of platform capitalism and algorithmic governance. The paper highlights several case studies such as AI-enabled editing, subtitling, visual effects, and distribution on digital platforms. It addresses the challenges in governance related to intellectual property, labour, and cultural representation. The paper, by drawing on a multi-level framework of AI regimes, emphasizes that in time to come, Nigerian filmmaking will depend on innovation that is balanced with protections for creative labour and cultural integrity. The paper concludes by recommending policies and practices for building a comprehensive, sustainable AI-enabled film ecosystem in Nigeria and Africa in general.

Keywords: Artificial intelligence, filmmaking**,** Nigeria, Nollywood, regime

1. Introduction

Nollywood, as condensed in global discourse is a contemporary filmmaking industry in Nigeria, and the second largest film industry in the world by output, contributing to the world film industry with over 2,000 films produced annually [1, 2]. Known for its resourcefulness, cultural vibrancy, and speed, Nollywood operation for a long time has been within informal economies and decentralized production networks [3, 4]. Be that as it may, in the past decade, film industry in Nigeria has gradually embroiled with global digital infrastructures, particularly as international streaming platforms, such as Netflix, Showmax, Amazon Prime, and regional operators, such as iROKOtv, and Africa Magic incorporate Nigerian content into global circuits [5-7].

Artificial Intelligence (AI) plays vital roles in this transformation [8]. AI encompasses a wide range of technologies that enable automated or semi-automated decision-making, creative augmentation, and pattern recognition [9]. Recommendation algorithms are now underpinned by AI on streaming platforms, moreover, post-production tools (noise reduction and automated rotoscoping) are powered by AI, and multilingual subtitling is supported by AI for linguistically diverse Nigerian audiences [10]. Beyond tools, AI is gradually building business models and audience engagement strategies.

This study explores emerging AI regime in Nigerian filmmaking. By AI regime, we refer not only to the technologies but also to the market logics, social practices, and governance structures that mediate the means for deploying AI. This framing underscores AI as not only a neutral tool but also as part of a sociotechnical assemblage that redistributes labor, power, and cultural expression. We based the study on three interrelated research questions:

(1) What method is used for integration of AI tools into filmmaking practices in Nigeria?
(2) What governance challenges, labor dynamics, and power relations accompany these integrations?
(3) What industry, community, and policy strategies could allow inclusive and culture-driven AI adoption in Nigerian film?

The study combines conceptual frameworks and analysis, literature review, methodology, and empirical illustrations drawn from trade publications, industry reports, and case studies. The study further situates experience of Nigerians within global shifts, while foregrounding the local dynamics of multilingualism, informality, and regulatory uncertainty. The bone of contention is the advantages and the disadvantages in adopting AI, where advantages bring creative opportunities, and disadvantages bring serious risks. The trajectory of AI adoption by Nollywood will depend on context-specific practices and proactive governance.

1.1. Conceptual Framework: AI Regimes and Film Ecologies

The work in science and technology studies, and political economy were extended by the notion of AI regimes, this is because they both view technologies as tools embedded in several aspects of governance, labor, and purpose driven, and not as isolated tools [11-13]. According to [14], components of the AI Regimes in Film are (1) Technological affordances, which are the actual AI capabilities, such as script generation, automated subtitling, and GAN-based visual effects. (2)

Institutional actors, which include filmmakers, professional associations, post-production companies, global platforms, and government regulators. (3) Regulatory frameworks, which involve film policy initiatives, data protection regimes, and copyright law. (4) Market logics, which also involve subscription-driven models, recommendation systems, and monetization incentives that influence storytelling choices. (5) Cultural contexts, which include the multilingual, multicultural, and diasporic nature of Nigerian audiences.

Filmmaking in Nigeria can be referred to as an ecology, where there is an intertwinement of production, distribution, and reception [15]. The interventions of AI ripple across this ecology, in that, linguistic representation is affected by the automated subtitling; distribution visibility is shaped by recommendation algorithms; and labor hierarchies are altered by AI-driven editing. The application of AI regime lens enables people to see the adoption of AI as not only about technical efficiency but also about governance, who decides the way and manner the tools are deployed, who benefits, and who do not benefit [16].

1.2. Strands of Literature on Film and AI

There are three strands into which literature on film and AI can be grouped; they are (1) Global perspectives on AI in creative industries. (2) AI in film and media. (3) African and Nigerian contexts.

(1) Global perspectives on AI in creative industries: These include (a) automation versus augmentation, which involves the debate among scholars whether creative labor is displaced by AI or human creativity is enhanced, (b) platform capitalism, this is evident in the work of researchers like Srnicek [17], where it was showed the influence of platforms on centralizing control and monetizing data, thereby raising concerns about cultural homogenization, (c) algorithmic governance, which is evident in studies that underscore the importance of recommendation systems in shaping cultural consumption and audience exposure.

(2) AI in Film and Media: How AI is used in audience analytics, script analysis, editing, dubbing, and CGI is documented by research [18]. Hollywood has used AI for box office performance prediction and trailer generation [19]. Asians are taking advantage of AI-assisted dubbing and translation for cross-border circulation [20].

(3) African and Nigerian Contexts: Informality, rapid production, and local-global dynamics are emphasized by literature on Nollywood [21]. AI in Nigeria is directly addressed by few studies; however, emerging reports such as UNESCO and local press show that AI-based editing, automated subtitling, and low-cost VFX are gradually adopted by filmmakers. A gap is showed through policy analyses that film and tech policies in Nigeria rarely address AI explicitly, leaving regulation ad hoc [22, 23].

Global optimism is revealed by the literature about potential of AI and concerns about cultural homogenization and labor precarity [24]. For Nollywood, there is an intersection of these debates and longstanding issues of linguistic diversity, resource constraints, and global marginalization.

2. Methodology

To analyze the intersection of emerging AI regimes and contemporary filmmaking in Nigeria, a designed qualitative review and interpretive methodology are adopted by this study. To capture both governance perspectives and creative practices, the framework of the study combines systematic literature analysis, industry mapping, and case study evaluation. Fig. 1 shows a conceptual framework diagram illustrating governance, practice, and creative futures.

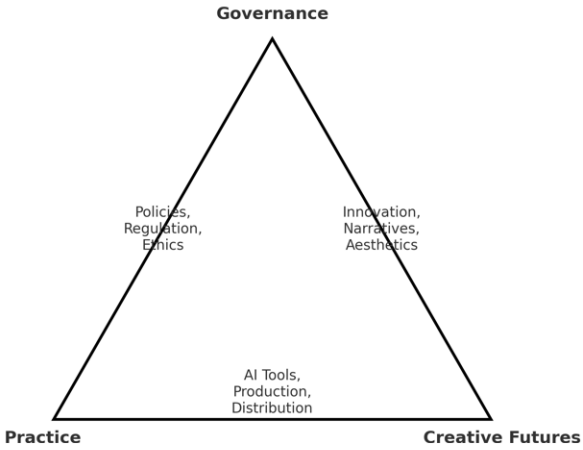

Figure 1. A conceptual framework diagram showing governance, practice, and creative futures

2.1. Research Design

The research employs a multi-layered qualitative approach founded upon policy and governance analysis, such as government policy analysis, regulatory discourse analysis, and institutional document analysis shaping AI adoption in Nigeria. Industry practice analysis, such as examining how AI is incorporated into filmmaking practice by creative practitioners, studios, and filmmakers, forms part of the research design. Furthermore, the research design takes a future orientation, which is by combining insights on how stories, aesthetics, and future practice are redrawn by AI in Nollywood and surrounding creative industries.

2.2. Data Sources

The data used in this study is got from the following sources:

(a) Academic literature on AI in African film studies, creative industries, and digital governance in peer-reviewed journal articles and conference papers.
(b) Policy and institutional reports like National Film and Video Censors Board (NFVCB) guidelines, Nigerian National Artificial Intelligence Policy (2023 draft), and UNESCO/UNCTAD digital economies reports.
(c) Industry journalism and newspaper coverage, including interviews with Nigerian producers, trade publications (Variety, The Africa Report), and press releases from Nollywood production companies adopting AI technology.

(d) Case studies, a number of which are selected films and production processes in which AI tools, including deepfake technology, Computer-Generated Imagery (CGI), scriptwriting, and AI-driven editing have been utilized or discussed within the Nigerian context.

2.3. Sampling and Selection

Key texts and cases most relevant to AI and filmmaking in Nigeria were selected by using purposive sampling. Selection criteria included evidence of Nigerian or African contextual relevance, direct focus on creative technologies enabled by AI, and representation of both practitioner voices and governance frameworks.

2.4. Analytical Framework

A comparative thematic analysis structured around three dimensions was employed by the study:

(a) Governance, including ethics, regulation, intellectual property, and labor implications of AI in Nigeria.
(b) Practice, including actual use of AI in Nollywood for production, distribution, and audience engagement.
(c) Creative futures, including speculative and innovative scenarios for cinema in Nigeria, considering global AI transformations.

2.5. Validity and Limitations

For enhancing validity, results were compared across practitioner interviews, policy documents, and secondary texts. Nevertheless, there had been certain limitations which the research was aware of, specifically lack or shortage of peer-reviewed Nigerian case studies on AI filmmaking. Promotional discourses, as potentially witnessed through dependence on media accounts and industry reports. The currency of published sources may be outpaced by rapid technological change. By combining creative foresight, industry practice mapping, and governance analysis, a comprehensive lens was offered by this methodology for understanding how contemporary filmmaking in Nigeria is being reshaped by emerging AI regimes.

3. Case Studies

In this section, four case studies were conducted, including Case A: AI in post-production and VFX workflows, Case B: Algorithmic distribution and platform economies, Case C: AI-assisted subtitling and localization, and Case D: AI in scriptwriting and pre-production.

3.1. Case A: AI in Post-Production and VFX Workflows

Post-production houses in Nigeria are exploring AI-based tools such as Topaz Video Enhance AI (for upscaling) and DaVinci Resolve's AI-driven noise reduction. Both time and labor costs are reduced by these tools, allowing more refined visuals at lower budgets. However, the need for entry-level assistants (who once handled manual frame cleaning) is also reduced by these tools. Fig. 2 shows AI in post-production and VFX workflows.

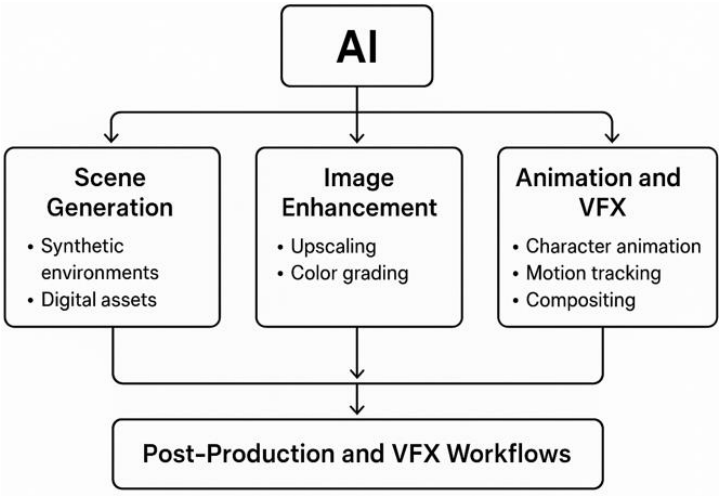

Figure 2. AI in post-production and VFX workflows

3.2 Case B: Algorithmic Distribution and Platform Economies

AI-driven recommendation systems are used by streaming platforms like Showmax and Netflix. This raises visibility challenges for Nigerian films, such as local films being relegated behind global blockbuster by algorithmic bias. Moreover, diasporic audiences who are seeking African content are depending on AI for targeted recommendations. While some voices are amplified by the platform regime, others are marginalized. Fig. 3 shows algorithmic distribution and platform economies.

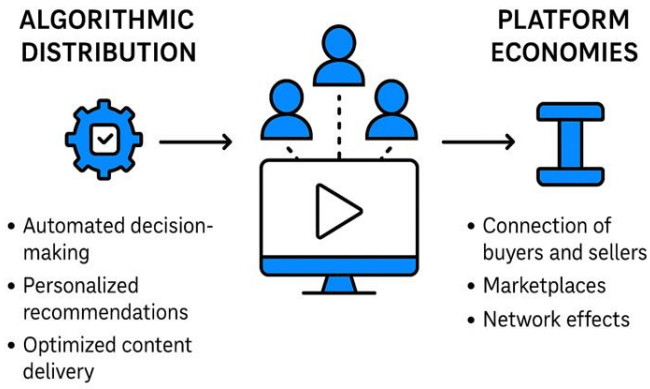

Figure 3. Algorithmic distribution and platform economies

3.3 Case C: AI-Assisted Subtitling and Localization

Multilingual reality in Nigeria, which include English, Pidgin, Hausa, Yoruba, and Igbo makes subtitling important. Multilingual versions are generated by increasingly use of AI-based speech-to-text and translation tools, such as Google AutoML, and YouTube subtitles. While the use of AI for subtitling expands reach, reception is undermined by quality issues, such as mistranslation, and loss of cultural nuance. This limitation makes traditional, human-in-the-loop subtitling essential. Fig. 4 shows AI-assisted subtitling and localization.

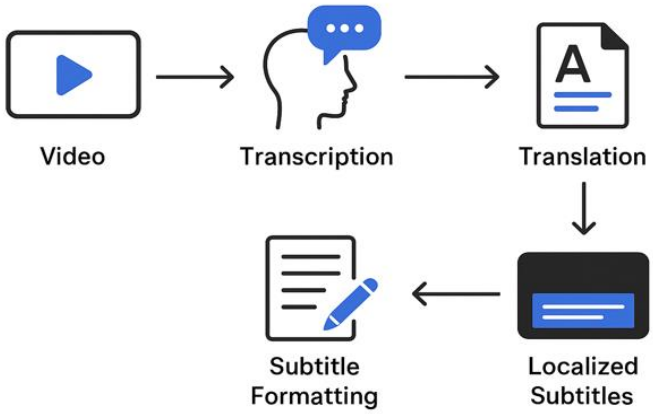

Figure 4. AI-assisted subtitling and localization

3.4. Case D: AI in Scriptwriting and Pre-production

AI text generators, such as ChatGPT-like tools are beginning to be explored by some Nigerian writers for various assignments such as brainstorming dialogue or story arcs. This practice raises questions about authorship, novelty, and intellectual property. While homogenization is an issue to writers, they acknowledge utility of AI for speeding up drafts. Fig. 5 shows AI in scriptwriting and pre-production.

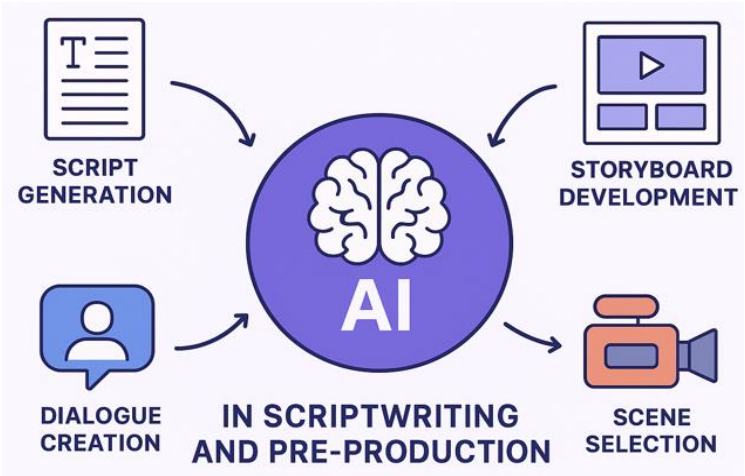

Figure 5. AI in scriptwriting and pre-production

4. Analysis: Themes and Tensions

4.1. Labor Reconfiguration

While certain manual roles such as assistant editors, and translators are displaced by AI tools, new oversight roles such as quality controllers, and AI tool specialists are also created. The risk is that new opportunities are outpaced by job losses, especially for young entrants.

4.2. Creative Affordances

Ambitious projects like CGI, and high-quality editing are attempted by resource-constrained filmmakers using AI. Aesthetic horizons may be expanded by this, but also risk overreliance on pre-trained, globally oriented models that may not reflect local textures.

4.3. Platform Power and Algorithmic Gatekeeping

Visibility is controlled by streaming platforms through algorithms, privileging content optimized for engagement. The pressure faced by filmmakers in Nigeria to adapt to global genres, thumbnails, and metadata strategies undermines experimental or culturally specific storytelling.

4.4. Governance Gaps

There are no clear policies on AI in Nigerian creative industries. There is silence on AI generated content by the intellectual property laws. Filmmakers are exposed to exploitation by global tech firms due to weakness of data protection.

4.5. Cultural Integrity vs. Marketization

Globally, Nigerian cinema is expanded through localization enabled by AI but risks flattening linguistic and cultural subtlety. Hybrid workflows that combine AI speed with human oversight are required by cultural pluralism.

5. Recommendations

For policymakers, it is recommended that AI is explicitly integrated into film policy frameworks in Nigeria. Developing guidelines for copyright and IP attribution in works assisted by AI is also recommended. Moreover, it is recommended to the policymakers to support training programs and capacity building for AI in creative industries. For industry, adoption of hybrid workflows such as AI + human oversight is recommended to balance efficiency with quality. In addition, negotiation of the contracts underpinning the platforms to provide fair visibility for Nigerian films is recommended. In addition, establishment of collective bargaining instruments for safeguarding creative labor is recommended. For practitioners, testing of AI as an augmentative tool, but not a replacement, is recommended. In addition, practitioners are encouraged to establish provenance and lock in intellectual rights by documenting workflows. Finally, for ethical AI adoption, they should share communal knowledge about best practices.

6. Conclusion

The governance, practice, and creative futures of emerging AI regimes and contemporary filmmaking in Nigeria have been presented in this study. AI integration into filmmaking in Nigeria

is inevitable but uneven. While creative possibilities are opened by AI, it also puts labor, cultural nuance, and sovereignty at risk. By AI regime concept, it is obvious that adoption of AI is not only a technical issue but a governance challenge that requires coordinated action from those who make policies, industry leaders, and practitioners (creative communities). For Nollywood, the task is to harness the potential of AI while preserving cultural identity and equitable labor practices. If handled effectively, AI could help cinema in Nigeria expand its global influence while deepening its cultural roots. However, if left unregulated, it risks aggravating inequalities and cultural homogenization. Governance as much as innovation will determine the future of Nigerian film in the era of AI.

Abstract

The growing demand for sustainable practices in the built environment has led to the need for energy-efficient, environmentally responsive, and socially inclusive designs in commercial developments. Thereto, this study explores sustainable design features in shopping malls through a qualitative case study approach, examining four malls across diverse climatic zones: Noke Mall (Taipei, Taiwan – Humid subtropical climate), Sarit Centre (Nairobi, Kenya – Subtropical highlands climate), SPAR Port Harcourt Mall (Rivers State, Nigeria – Tropical wet climate), and Palms Shopping Mall (Lagos State, Nigeria - Tropical wet and dry climate). Data were collected through physical observations, existing architectural documentations, and synthesized based on the following themes; sustainable sites, water efficiency, energy and atmosphere, materials and resources, indoor environmental quality, innovation in design process, and regional priority as adopted from Leadership in Energy and Environmental Design [LEED] green building rating categories. Hence, the study findings reveal a range of sustainability practices, including natural ventilation, daylighting, and flexible circulation spaces, as well as gaps such as high dependency on mechanical systems and limited water reuse strategies. The study provides evidence-based recommendations for architects, developers, and built environment professionals to enhance sustainability in mall design, balancing user experience with environmental responsibility.

Keywords: Building systems, Design features, green building, shopping malls, sustainability

1. Introduction

Shopping malls are central to modern urban life, serving as hubs for commerce, social interaction, and leisure. Beyond their commercial function, malls increasingly reflect broader societal

priorities, including sustainability, user experience, and architectural innovation. In recent years, urbanization, climate change, and environmental degradation have underscored the need for malls to integrate sustainable building systems that minimize energy and water consumption, promote waste management, and optimize indoor and outdoor environmental quality. Mall design has evolved from simple retail clusters to complex mixed-use developments that combine shopping, leisure, office, and sometimes residential spaces. These multifunctional centres aim to attract diverse users while optimizing space, energy use, and operational efficiency. The sustainability of shoping malls is influenced not only by materials and technologies but also by planning strategies, circulation design, and climate-responsive features. For instance, building orientation, natural ventilation, and daylighting strategies can reduce energy demand for lighting, heating, and cooling, while green spaces enhance the aesthetic and ecological quality of the environment (Han et al., 2019; Aktas, 2012). Despite the theoretical understanding of sustainable mall design, there remains a lack of empirical studies documenting real-life implementations across different geographic and climatic contexts. Most existing studies rely heavily on secondary data, and historical descriptions, leaving uncertainty about how sustainability principles translate into practice.

1.1. Aim of the study

This study examines four shopping malls in distinct regions — Humid subtropical climate, Subtropical highlands climate, Tropical wet, and dry climates in view to extrapolate sustainable design features.

1.2. Objectives of the study

The objectives of this study are to:

i. Identify sustainable features of each case study.

ii. Explore the design and operational features of selected shopping malls with respect to key sustainable systems.

iii. Provide recommendations for future malls that balance environmental responsibility with user experience and commercial viability.

Thus, this study contributes to the innovative sustainable solutions in the built environment sub-theme, offering practical insights for architects, developers, engineers, and urban planners.

2. Literature Review

2.1. Mall patterns and functional design

Shopping malls have historically followed several functional patterns, including dumbbell, strip, high-rise, and cluster types (Ali, 2015; Tiwari & Abraham, 2010). Cluster-type layouts are particularly suited to community-centered malls, where multiple units are organized around a shared open space. Contemporary design trends often combine these patterns to maximize circulation, accessibility, and multifunctionality. For example, modern malls integrate retail, leisure, food courts, and office spaces, creating mixed-use environments that enhance visitor experience and generate diversified revenue streams (Heffner & Twardzik, 2015).

2.2. Sustainability in Mall Design

Sustainability has emerged as a key consideration in mall designs with strategies such as:

i. Energy-efficient systems: LED lighting, automated lighting controls, and HVAC systems optimized for local climate conditions (Aktas, 2012; Han et al., 2019).

ii. Passive environmental strategies: Natural ventilation through atria, wide corridors, and large fenestrations; daylighting via skylights and roof openings; and strategic building orientation to reduce solar gain.

iii. Water and waste management: Water-efficient plumbing, rainwater harvesting, greywater reuse, and proper waste segregation and recycling.

iv. Materials selection: Use of locally sourced, recycled, or low-embodied-energy materials to reduce carbon footprint and enhance indoor environmental quality.

Despite these recommendations in literature, empirical studies evaluating actual implementation in operational malls remain limited. Most previous work has focused on design guidelines or theoretical modeling rather than assessing real-life performance (Lorek & Spangenberg, 2014; El-Hedhli et al., 2013).

2.3. User experience and functional planning

The architectural and operational design of malls influences both shopper behavior and satisfaction. Elements such as spacious atria, clear circulation, landscape integration, and accessible amenities contribute to a positive shopping experience (Farrag et al., 2010; Teik et al., 2015). In addition, mixed-use layouts can improve dwell time and enhance commercial viability. However, emerging digital retail trends and e-commerce have challenged traditional mall formats, requiring innovative responses such as integrated entertainment zones, interactive displays, and adaptive reuse of spaces (Çakmak, 2012; Kumar & Thakur, 2014).

2.4. Green Building Certification

For buildings to be certified sustainable there are key criteria they must meet. Hence, green building certifications are used to ascertain a project's ability to showcase commitment in being environmentally responsible. Notably, Leadership in Energy and Environmental Design [LEED], and Building Research Establishment Environmental Assessment Method [BREEAM] are predominant certification systems in the world.

2.4.1. Leadership in Energy and Environmental Design (LEED)

LEED is a global sustainable building certification program developed by the non-profit U.S. Green Building Council (USGBC). It covers rating systems for the design, construction, operation, and maintenance of green buildings, homes, and neighborhoods, which is tailored towards helping building owners / operators be environmentally responsible, and ensure efficient use of resources, thereof (Green Building Facts, Retrieved 24 November 2015).

However, this study adopts LEED green buildings rating categories (themes) to explore the sustainable development of selected malls which include; sustainable sites, water efficiency,

energy and atmosphere, materials and resources, indoor environmental quality, locations and linkages, awareness and education, innovation in design, and regional priority (Green Building Facts, Retrieved 24 November 2015).

2.4.2. Categories for earning LEED credits

i. Sustainable Sites: This category takes cognizance of site selection deliverables, site analysis, development density, heat island effects, drainage systems, and efforts in managing run-offs.

ii. Water Efficiency: Keen on reducing potable water use within the building, through low-flow fixtures, water-efficient landscaping, and systems.

iii. *Energy & Atmosphere:* Awards credits for energy efficiency, use of renewable energy, and clean commissioning systems.

iv. *Materials & Resources:* Examines the use of recycled building materials / elements, green building materials, and waste management during construction and operation of buildings.

v. *Indoor Environmental Quality:* Focuses on occupant health and comfort by addressing ventilation, air quality, daylighting, views, and the use of thermal efficient materials.

vi. *Innovation:* Highlights innovative strategies and exemplary performance in existing credits.

vii. *Regional Priority:* Adds extra credit for projects that considers local environmental priorities selected by regional chapters (Green Building Facts, Retrieved 24 November 2015).

2.5. Research Gap

This study adopts a case study approach, will current observations, and photographic documentation to provide a more accurate and relatable understanding of sustainable shopping mall design. By bridging the gap between theory and practice, this research enables context-sensitive design recommendations, ensuring that future shopping malls are environmentally sustainable, commercially viable, and user-friendly.

3. Research Methods

3.1. Research design

This study adopts a qualitative research method to explore sustainable practices in shopping malls across different geographic and climatic contexts. The approach allows for in-depth, contextual analysis of architectural, operational, and environmental strategies implemented in existing malls. Thus, emphasis is placed on observation, photographic documentation, and architectural assessment.

3.1.1. Selection criteria

Four shopping malls were selected based on these criteria:

i. Accessibility for data collection
ii. Ability to meet basic functional and architectural standards of a shopping mall.
iii. Observable sustainability features – such as energy-efficient lighting, passive ventilation systems, green spaces, and climate-responsive design strategies.
iv. Different climatic and geographic contexts to allow comparative analysis of architectural features.

The selected cases include:

i. Noke Mall, Taipei, Taiwan (Humid subtropical climate)
ii. Sarit Centre, Nairobi, Kenya (Subtropical highlands climate)
iii. SPAR Port Harcourt Mall, Rivers State, Nigeria (Tropical wet climate)
iv. Palms Shopping Mall, Lagos State, Nigeria (Tropical wet and dry climate)

3.1.2. Data collection, analysis, and synthesis

The qualitative data for this study was obtained from primary and secondary sources. The primary data were obtained via physical observation for SPAR Port Harcourt Mall (Rivers State, Nigeria, and Palms Shopping Mall, Lagos, Nigeria while the secondary data were obtained from publication (websites) for Noke Mall, Taipei, Taiwan (Archidaily, 2025) and Sarit Centre, Nairobi, Kenya (Sarit centre, 2025). To synthesize the data from the selected shopping malls in view to explore how sustainable they are, the categories (themes) used by LEED was utilized viz: *Sustainable Sites, Water Efficiency, Energy & Atmosphere, Materials & Resources, Indoor Environmental Quality, Innovation, and Regional Priority.*

Each case study is presented by describing the design, construction, and current operational status to avoid ambiguities about future versus completed features. More so, a narrative approach was adopted to synthesize the data encapsulated in the use of visual documentation, descriptive observation, and secondary information. Thereto, this study ensures that recommendations are evidence-based and grounded in the current state of each mall, rather than abstract theoretical expectations.

3.1.3. Ethical considerations

Permission was obtained from the mall management of the local case studies for observation, and photography. All data collection adhered to privacy and security protocols, ensuring ethical research practices.

3.2. Case Study 1 (Noke Mall, Taipei, Taiwan)

i. Mall description

Location	No. 200, Lequn 3rd Road, Zhongshan District, Taipei City, Taiwan 10491
Coordinates	$25^{0}4^{1}56^{11}$N; $121^{0}33^{1}26^{11}$E
Architect	Behet Bondzio Lin Architekten
Lead Architect	Yu-Hanv Michael Lin

Contractor	Taiwan Kumagai CO. LTD
Area	22415sqm
Stores	100
Type of Mall	Regional Mall
Category	Mixed use Architecture, Sports Architecture, and Retail
Access	Jiannan Road metro station, Wenhu line of Taipei Metro
Website	https://retail.jut.com.tw

ii. Background

Noke is a mall in the Dazhi area of Zhongshan District, Taipei, Taiwan that commenced operations on the 29th day of April, 2023. It has a total floor area of 36,300m^2 [391,000 sq ft] layered in 10 floors with 7 floors above, and 3 floors below the ground. The mall is characterized by 5 core units viz; Tsutaya Bookstore, Michelin restaurant La Vie, Apu Jan, Onibus, and Aurora Ice Rink. It is composed of 48% retail units, 34% for catering, and 18% for entertainment.

iii. Structure

The mall's structural system consists of reinforced, and pre-stressed concrete members forming the main framework, with steel trusses supporting the roof covering. Glazing and light metal cladding cover the building envelope, while tensile fabric is used for the mall canopy. Images show fenestrations allowing for daylighting.

iv. Key Materials

Concrete, steel, glass, light metal cladding, and tensile fabric

Figure 1. Exterior perspectives of Noke Mall, Taipei, Taiwan

3.3. Case Study 2: Sarit Centre, Nairobi, Kenya

i. Mall description

Location	Westlands suburbs of Nairobi, Kenya
Coordinates	$1^{0}15^{1}35^{11}$S; $36^{0}48^{1}5^{11}$E
Architect	T.S. Nandra & Associates
Lead Architect	James Kennedy
Area	46,450 sqm
Anchor Store	Uchumi Supermarket
Type of Mall	Community Mall (multi-purpose)
Category	Mixed use Architecture
Website	www.sarit.com; www.saritexpo.com

ii. Background

The centre is features a 300 seat cinema, a 140 m^2 food court and a 280 m^2 expo centre with the propensity to host over 50 stands (Sarit centre, 2025). At the time of its opening, it was the first shopping mall in East Africa and remains one of the largest in the region, hitherto.

The mall nicknamed: “A city within a city” changed shopping mall concepts in East Africa. According to the mall’s management, approximately 25,000 visitors are served daily with an approximately 5,500 car traffic frequenting daily both in the mall’s parking facilities and neighboring streets (Sarit centre, 2025).

The centre’s form is orthogonal characterized by right angles with no curves in its layout plan. This can be traced to Brent Cross Shopping Mall in London, where the inspiration to build the the local shopping mall originated. Wide walkways and aisles are provided throughout the shopping mall, giving shoppers and visitors sufficient space for movement and passing to observe things without being obstructed. The main walkways that connect the entrances to the two atriums at the centre of the mall are 4500mm to 6000mm in width, according to their positions with regard to traffic flow. This is because these are the regions that receive the highest number of traffic flow as patrons either exit from or enter into the mall before dispersing to their destinations of choice within the mall.

iii. Structure

The building is framed with reinforced and pre-stressed concrete, supported by steel roof trusses, with glazing and light metal cladding forming the façade envelope. Staircases, elevators and ramps are provided at the central area of the shopping mall. These serve as vertical circulation channels without causing congestion. The staircases and ramps are wide enough for such public spaces. Circulation is centralized in the mall such that, there are two atriums at the centre where all the main entrances lead, from whence patrons disperse to their destinations.

iv. Key Materials

Pre-stressed, and reinforced concrete, steel, glass, and light metal cladding

Figure 2. Exterior, and interior perspectives of the Sarit centre, Nairobi, Kenya

3.4. Case Study 3: SPAR Port Harcourt Mall, Rivers State, Nigeria

i. Mall description

Location	No. 1 Azikiwe road, Old GRA, next to Government House, Port Harcourt, 500101, Rivers State.
Coordinates	4.749^0N; 7.035^0E
Owner	Artee Group led by Haresh Keswani
Architect	Anthony Dornubari Enwin
Area	16,000 sqm
Anchor Store	SPAR
Type of Mall	Neighbourhood Mall
Category	Mixed use Architecture (Shopping and Entertainment)
Website	www.sparnigeria.com

ii. Background

The SPAR Port-Harcourt mall branch was built between 2013-2014 as redevelopment and expansion of the existing Supabod Store Structure. Its operational time is from 9:00 AM - 9:00 PM on working days and 11:00 AM - 9:00 PM on weekends. Between 12:00 noon - 5:00 PM daily, is usually very busy. It is known to be one the largest mall in Port Harcourt spreading over 16,000 sq.m (172, 223 sq.ft) of retail space with over 50 brands of Grocery, Fashion, Electronics, Food & Multiplex & many more. It is a renowned centre for shopping and entertainment. It features 3D, 2D and 9D cinema film house, restaurants, one Anchor store (Spar), etc. Some of the big brand tenants are: Dollar store, Sumptuous meals, Debonair Pizza, Levis, Swatch, Lifemate, FineBrothers, MTN, Airtel, Nike, Adidas, etc.

iii. Structure

The structural system consists of reinforced and pre-stressed concrete forming the main frame, with steel trusses supporting the roof. Glazing and aluminium cladding envelope portions of the mall. Observed images show that fenestrations are minimal, offering limited daylight penetration, and natural ventilation, hence, depends on active systems.

iv. Key Materials

Reinforced concrete, bricks, and steel-trussed roof structure

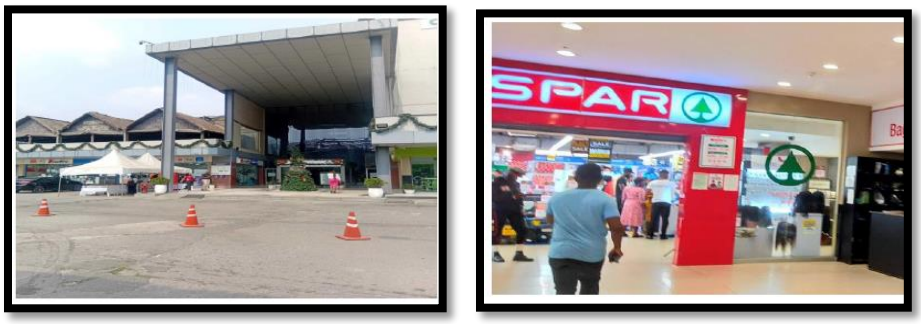

Figure 3. Main entrance to the Mall, and interior perspective of the Anchor store (Fieldwork, 2025)

3.5. Case Study 4: Palms Shopping Mall, Lagos State, Nigeria

i. Mall description

Location	1 Bisway St, Maroko, Lekki 106104, Lagos, Nigeria
Coordinates	$6^026^19^{11}$N; $3^027^14^{11}$E
Owner	Persianas Properties Ltd. led by Tayo Amusan
Developer	Persianas Group
Date commissioned	December, 2005 by Oba of Lagos, and President Obasanjo
Area	21,000 m^2 of lettable retail space
Anchor Tenants	Game, ShopRite, and Genesis Deluxe Cinemas
Type of Mall	Neighbourhood Mall
Category	Mixed use Architecture (Shopping and Entertainment)
No. of stores, and services	69 shops, 6 screen cinema, and 1000 parking spaces
Website	www.thepalmsmall.com

ii. Background

The Palms Shopping Mall, located on Lekki Peninsula, Lagos, covers approximately 40,000 m² with 20,000 m² of lettable retail space. Real-life images show a spacious single-story layout with wide corridors, multiple entrances, and clearly defined zones for retail, leisure, and cinema facilities. The mall is a one-story facility with off-road parking available for about 720 vehicles. It stands out as the first and largest mall of its kind in Nigeria, matching the quality of shopping malls globally. It also features art anchor tenants, a six-screen cinema, and open recreational areas. Observations highlight well-integrated parking areas and accessibility for pedestrians.

iii. Structure

The structure comprises reinforced and pre-stressed concrete forming the main skeleton, with steel trusses for the roof and aluminium cladding on the facade. Field studies reveal the mall depends extensively on active systems for ventilation and air-conditioning.

iv. Key Materials

Reinforced, and pre-stressed concrete frame, and steel roof trusses.

Figure 4. The exterior view of the Palms Shopping Mall, Lagos State, Nigeria

4. Main Discussion

The study outcomes are based on deductions from extant literature and the selected four case studies as highlighted below;

4.1. Deductions from Extant Literature

The literature on shopping malls emphasizes the interplay between functional design, user experience, and sustainability. Several patterns of mall development have been identified, including dumbbell, strip, high-rise, and cluster forms, with cluster patterns being particularly suitable for community-centered malls (Ali, 2015; Heffner & Twardzik, 2015). This shift addresses the evolving consumer behaviour, encourages extended visits, and contributes to economic and environmental sustainability (Amit & Kameshvari, 2012; El-Hedhli et al., 2013). Ancillary facilities such as basement storage, parking structures, and green spaces are incorporated to reduce urban congestion and environmental pollution, demonstrating the growing importance of sustainable infrastructure planning (Lorek & Spangenberg, 2014).

Sustainability considerations in mall design are multidimensional. Key components include:

i. ***Energy efficiency:*** Incorporation of passive design strategies, natural ventilation, and daylighting reduces reliance on artificial lighting and HVAC systems (Aktas, 2012; Han et al., 2019).
ii. ***Water management:*** Efficient plumbing systems, rainwater harvesting, and greywater reuse mitigate water consumption and promote resource sustainability (Farrag et al., 2010).
iii. ***Materials and construction:*** The choice of eco-friendly and locally sourced materials minimizes environmental impact and enhances lifecycle performance (Çakmak, 2012).
iv. ***Waste management:*** Integration of recycling and composting systems within operational protocols addresses solid waste challenges and supports environmental stewardship (Dubihlela & Dubihlela, 2014).
v. ***User-centric design:*** Spacious circulation, visually appealing interiors, and safe environments improve shopper comfort and satisfaction while aligning with sustainable goals (Tiwari & Abraham, 2010; Kusumowidagdoa et al., 2015).

Furthermore, the literature highlights the influence of technological advances and retail evolution on mall design. Online shopping, retail warehouse parks, and experiential consumer preferences have necessitated malls to adapt by enhancing aesthetic appeal, multifunctional spaces, and features (Teik et al., 2015; Köksal & Aydın, 2015).

4.2. Deductions from Case study 1 (Noke Mall, Taipei, Taiwan)

a. Findings

Thematic analysis of data collected from the mall reveals the following:

i. Sustainable Sites: The mall is strategically sorrounded by shrubs, and trees which aid in ehancing air quality, and reducing heat island effects.

ii. Water Efficiency: It features water efficient sanitory fittings which cut down water usage

iii. Energy & Atmosphere: Features some curtain walls / extensive glazing which allows for daylighting, natural ventilation, and visual comfort reducing dependence on active systems, in turn, energy consumption.

v. *Materials & Resources:* The mall is characterized by plants in the indoor spaces, and some wooden furniture.

vi. *Indoor Environmental Quality:* The back wall of the grand staircase serves as the framework for vertical greenery which enhances the indoor thermal comfort of the users, thereof. In sum, the open-plan layout allows for adaptive reuse of spaces for retail, enhances accessibility, and crowd flow.

vii. *Innovation:* Showcases the design of Ice rink that uses folded aluminum panels to lighten the roof members which permit sunlight from the north directions into the interior space.

viii. *Regional Priority:* It celebrates a traditional departmental store devoid of windows by creating large staircase that divides the mass, and connects upper and lower sections. Thereto, brings in users from the overpass directly to a vertical plaza (Archidaily, 2025).

b. Conclusion

Noke Mall demonstrates how a humid subtropical climate can inspire a sustainable design through strategic natural ventilation, and daylighting, and flexible interior spaces. In sum, the spatial arrangement of the mall promotes user experience.

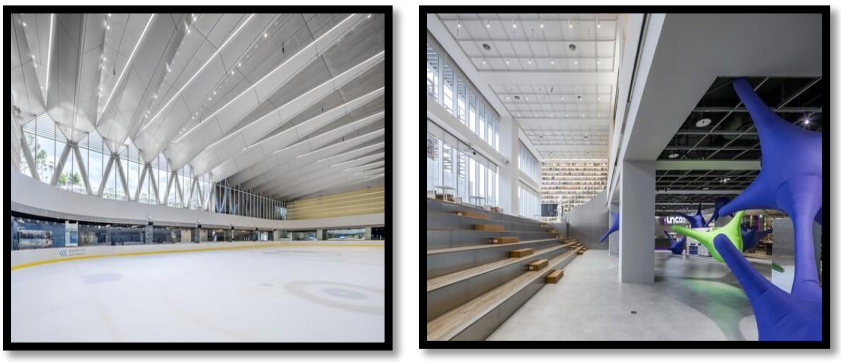

Figure 5. Interior views of the Noke Mall, Taiwan

4.3. Deductions from Case study 2 (Sarit Centre, Nairobi, Kenya)

a. Findings

i. Sustainable Sites: The parking spaces provided does not sufficiently meet the user density especially during peak shopping periods. More so, some parking lots were not properly arranged taking cognizance of all the vehicles, and users. However, patches of trees exist on site supported with drainage systems.

ii. Water Efficiency: Paucity in water reuse, harvesting, and water efficient landscaping strategies exists

iii.Energy & Atmosphere: There is no evidence of power generation relying on renewable energy sources. Despite passive features, the mall still relies significantly on air-conditioning systems for cooling the interior spaces.

iv.Resources: Dearth in the use of green building materials, and recycled building materials.

v. *Indoor Environmental Quality:* User comfort is maintained by large fenestrations / curtain walls fostering daylighting and ventilation as well as visual comfort. In addition, it features traditional building materials e.g., reinforced concrete, and bricks as well as open interior circulation areas.

vi. *Innovation:* No observed innovation

vii. *Regional Priority:* Sections of the bar / lounge are finished with stonework effects celebrating the natural endowment of the Kenya people (Sarit Centre, 2025).

b.Conclusion

Sarit Centre reveals how a Subtropical highlands climate mall design experiments with Climate-adaptive roof and façade design. Inclusively, studies on the mall shows integration of passive, and active design strategies to maintain user comfort and reduce energy use.

Figure 7. Interior views of the Sarit Centre's atrium and lounge

4.4. Deductions from Case study 3 (SPAR Port Harcourt Mall, Rivers State, Nigeria**)**

a. Findings

i. Sustainable Sites: The site has vehicles parking close the mall, and inadequate parking spaces. Also, the landscaping floor is concretized.

ii. Water Efficiency: Deficient in water harvesting, and reuse systems

iii. Energy & Atmosphere: Relies on standby generators to power its artificial lighting, ventilation, and air-conditioning systems

iv.Materials & Resources: Reinforced concrete and bricks are the key building materials observed, therein which are rendered, and painted.

v. *Indoor Environmental Quality:* The mall has limited fenestrations, and openings. Furthermore, interior circulation areas are usually flooded by users (shoppers) especially at peak shopping periods.

vi. *Innovation:* Not evident

vii. *Regional Priority:* Not observed

b. Conclusion

The mall illustrates a basic strip-type mall design adapted to a Tropical wet climate. Despite its spatial planning, there is need to incorporate user accessibility features (for the disabled). More so, sustainable water and energy management could significantly improve overall performance of the mall.

Figure 8. Exterior views of the SPAR Port Harcourt Mall

4.5. Deductions from Case study 4 (Palms Shopping Mall, Lagos)

a. Findings

i. Sustainable Sites: Few trees evidenced on the site, and the landscaping floor is concretized which contributes to urban island heat. Lit parking areas, visible entrances, and controlled access points enhance security, and safety. Additionally, stormwater drainage, and solid waste disposal system is observed.

ii. Water Efficiency: Paucity in water recycling or eco-friendly systems.

iii. Energy & Atmosphere: Air-conditioning and lighting systems account for significant energy use. The energy use relies on non-renewable sources viz; Standby generators.

iv. Materials & Resources: Reinforced concrete and bricks are the key building materials observed, therein which are rendered, and painted.

v. Indoor Environmental Quality: Depends on mechanical ventilation, and air-conditioning systems. Open spaces within the mall facilitate smooth movement, and air circulation. Therein, some ramps provide accessibility for users with disabilities.

vi. Innovation: Not evident

vii. Regional Priority: Not applicable

b. Conclusion

It exemplifies an adaptable mall with multiple retail configurations in a coastal environment of a tropical wet and dry climate, balancing functionality, accessibility, and user comfort. It showcases good circulation, adequate lighting, and inclusive access. However, improvements in efficient water use and energy reduction strategies could enhance its overall environmental performance.

Figure 9. Interior views of the Palms Shopping Mall

5. Conclusions And Recommendations

Comparative study of the four shopping malls across revealed critical insights into sustainable design practices and operational efficiency viz:

i. Planning and Layout

- Spacious atriums, wide circulation corridors, and clear zoning (retail, leisure, parking) enhance user experience and facilitate accessibility as evidenced in the case studies.
- Mixed-use integration (cinemas, restaurants, and leisure areas) supports community engagement, though implementation varies across malls.

ii. Building Materials and Structure

- Pre-stressed concrete is the dominate structural material, offering durability and adaptability for large open-plan retail spaces.
- Limited glazing and fenestrations promote natural lighting but are often paired with energy-intensive air-conditioning system across the malls.

iii. Sustainability and Environmental Strategies

- Sarit centre (mall) shows a better integration of passive ventilation and daylighting, reducing energy dependency.
- SPAR Port Harcourt Mall, and Palms Shopping Mall relies heavily on mechanical ventilation / air-conditioning systems, increasing operational energy requirements.
- Noke Shopping Mall shows partial adoption of passive design elements, with potential for improvement in water recycling, waste management, and energy-efficient systems.

iv. Safety, Security, and Accessibility

- All malls provide emergency exits and circulation routes, but the effectiveness varies with layout complexity.
- Varying degrees of accessible design features e.g., ramps, lifts are present in the malls supporting inclusivity for disabled users.

v. Energy and Water Efficiency

- Malls in the Subtropical climates demonstrated better energy efficiency relative to passive strategies amongst other factors.
- Tropical malls still rely heavily on artificial cooling, indicating need for climate-responsive development.
- Water-saving technologies and recycling systems are limited in Nigerian case studies.

vi. Circulation and User Experience

- Open, flexible layouts in the malls enhances shopping experience.
- This was an attempt to ensure smooth circulation in the malls, nevertheless, there is need to foster adaptability, and flexibility in modern mall planning, and design.

5.1. Recommendations

Based on the findings from the four case studies, the following evidence-based recommendations are proposed for developing sustainable shopping malls:

i. Lighting

- Maximize natural lighting through skylights, atriums, and well-placed fenestrations to reduce energy consumption.
- Interior lighting should enhance shopper comfort, while exterior lighting ensures safety and contributes to the aesthetic appeal.
- Emergency/escape lighting must comply with safety regulations, with HID lamps, T8 fluorescents, or LED options.

ii. Ventilation and Air-conditioning

- Combine passive ventilation (atriums, wide corridors, operable windows) with efficient mechanical systems to optimize energy use.
- Limit roof glazing to ≤30% of ceiling area to prevent excessive heat gain.
- Install CO_2 sensors to regulate airflow according to occupancy.

iii. Safety and Security

- Avoid layouts that encourage loitering or crime; provide visible entrances and monitored circulation spaces.
- Emergency exits should be well-marked and accessible, with multiple evacuation routes.
- Incorporate digital and physical security measures to safeguard users and assets.

iv. Water and Waste Management

- Implement water-saving fixtures: controlled flush toilets, faucet aerators, and rainwater harvesting where feasible.
- Adopt waste separation and recycling systems, including balers and compactors for efficient waste management.

v. Fire Protection

- Fire compartments must be strategically placed, with automatic detection, alarms, sprinklers, and fire-retardant treatments for vulnerable materials.
- Escalators and lifts must comply with fire safety codes, with automatic shut-off and metal shutters for fire containment.

vi. Circulation and Accessibility

- Ensure sufficient space for circulation, particularly in high-traffic zones.
- Design for inclusive access, with ramps, lifts, and accommodations for users with special needs (blind, deaf, mobility-impaired).

vii. Orientation and Site Planning

- Orient buildings to maximize natural ventilation and daylight.
- Consider local topography, prevailing winds, and surrounding land uses to enhance energy efficiency and user comfort.

viii. Parking and Traffic Organization

- Provide well-lit parking; pedestrian, vehicular, and service traffic paths.
- Multi-deck parking can be integrated above or below retail spaces to optimize land use.

ix. Architectural Character and Flexibility

- The design should integrate architecture with the urban context, creating an attractive, functional, and vibrant environment.
- Open-plan retail spaces allow flexibility to adapt to future innovations.
- Incorporate mechanical conveyors (escalators, lifts, travellators) for efficient vertical and horizontal circulation.

ahmedova.y99@gmail.com (Responsible Author)

Abstract

The planning of outdoor recreation has become an essential component of sustainable tourism development and environmental management in the 21st century. As societies become more urbanized and technologically advanced, the human need for direct contact with nature is increasing rapidly. Outdoor recreation planning therefore serves as a bridge between human well-being and environmental protection, ensuring that leisure activities in natural environments are designed, managed, and experienced in a sustainable way. It involves the systematic organization and management of natural areas to meet people's recreational needs while maintaining ecological balance and biodiversity. This process requires the integration of physical planning with environmental, social, and economic considerations. Rather than focusing solely on the spatial distribution of recreation sites, modern outdoor recreation planning emphasizes the harmonious coexistence of people and nature through policies that promote responsible use, conservation, and education. Recreational activities such as hiking, camping, wildlife observation, and eco-trails play a vital role in promoting physical health, mental relaxation, and ecological awareness. Well-designed outdoor recreation spaces help individuals reconnect with nature, cultivate respect for the environment, and develop a personal sense of ecological responsibility. As urban expansion and modern lifestyles intensify, the demand for nature-based recreation continues to grow. This makes sustainable planning even more crucial for reducing environmental pressure, preventing overuse of resources, and maintaining natural beauty for future generations. Effective outdoor recreation management thus requires assessing the carrying capacity of natural landscapes, identifying potential ecological risks, and applying long-term strategies that balance tourism development with conservation priorities.

Keywords: Outdoor tourism, recreation planning, sustainable development, ecotourism

1. Introduction

Günümüz turizm sektörü, sürdürülebilirlik kavramının güçlenmesi ve doğal alanlara yapılan seyahatlerin artmasıyla önemli bir dönüşüm yaşamaktadır. Artan kentleşme, çevre bilinci ve sağlıklı yaşam trendleri, bireyleri açık havada vakit geçirmeye ve doğa temelli aktivitelere katılmaya yönlendirmiştir. Bu bağlamda, açık hava turizmi yalnızca bir eğlence ve dinlenme alanı değil, aynı zamanda yerel ekonomik kalkınmayı, ekolojik farkındalığı ve toplum refahını destekleyen stratejik bir turizm türü haline gelmiştir (UNWTO, 2019). Bu nedenle, açık hava turizminin doğru bir şekilde organize edilmesi ve rekreasyon hizmetlerinin bilimsel olarak planlanması hem turizm hem de çevre yönetimi açısından kritik öneme sahiptir.

Açık hava turizmi, doğal ortamda rekreasyonel, macera, spor ve eğitim faaliyetlerini içeren geniş bir turizm türüdür. Trekking, kampçılık, dağcılık, kano, kuş gözlemciliği, yaban hayatı fotoğrafçılığı ve ekoturizm gibi aktiviteleri içerir. Bu turizm türünün ayırt edici özellikleri arasında doğayla doğrudan temas, düşük karbon ayak izi, çevresel duyarlılık, yerel kültürle etkileşim ve sosyal-mesleki sürdürülebilirlik yer alır (Newsome, Moore ve Dowling, 2013).

UNWTO (2019) raporuna göre, doğa temelli turizm faaliyetleri küresel seyahatin yaklaşık %20'sini oluşturmakta ve bu oran her yıl artmaktadır. Bu durum, açık hava turizminin hem ekonomik hem de sosyo-ekolojik açıdan stratejik önemini artırmaktadır.

Açık hava rekreasyonunun ve doğa temelli turizmin insan ve toplum refahı üzerindeki birçok olumlu etkisi son yıllarda giderek daha fazla kabul görmektedir. Açık havada seyahat etmek ve zaman geçirmek fiziksel ve psikolojik sağlığı iyileştirebilir, sosyal ilişkileri güçlendirebilir ve insanları doğal ve kültürel miraslarıyla bağlayabilir. Bu faaliyetler aynı zamanda doğa koruma için finansal kaynak yaratır, yerel ekonomileri canlandırır, yerel ve ulusal kimliklerin gelişimini destekler ve çevre koruma konusunda kamuoyunun farkındalığını artırır. Doğal ortamlardaki bu deneyimler, bireylerin ve toplulukların dayanıklılığını ve direncini güçlendirerek önemli bir sosyal ve ekolojik değer yaratır.

Açık hava ve doğa temelli turizmin yaygınlaşmasıyla birlikte, bu faydaların adil ve eşit bir şekilde paylaşılmasının sağlanması konusu, politika yapıcılar, yerel topluluklar ve faydalanıcı gruplar için bir endişe kaynağı olmaya devam etmektedir. Eşitlik ilkesi, yalnızca mevcut turizm faaliyetlerinin sürdürülebilir refahı için değil, aynı zamanda gelecek nesiller için de önemli kabul edilmektedir.

Turizm sektörü, yerel yönetimler ve kalkınma kuruluşları, doğal alanlara artan ilgi göz önüne alındığında, bu alanları popüler seyahat ve rekreasyon destinasyonlarına dönüştürmek için çeşitli girişimlerde bulunmuştur. Doğa temelli turizm, dünyanın en hızlı büyüyen turizm sektörlerinden biridir. Birçok kamu arazisi, rezerv ve milli park, uluslararası alanda tanınan turistik yerler haline gelmiştir. Turizm, birçok ülke için ekonomik kalkınmanın itici gücü olmakla kalmayıp, aynı zamanda korunan alanlardaki biyolojik çeşitliliğin ve doğal mirasın korunmasının finansmanında da önemli bir rol oynamaktadır. Ayrıca, açık hava rekreasyonu ve doğa turizmi, ziyaretçilerde çevresel sorumluluk duygusunu artırarak doğal çevreyi iyileştirme sürecine katılmalarını sağlar. Bu faaliyetler, sürdürülebilir turizm yönetiminin temel bileşenleri olarak kabul edilir.

Ancak, doğa temelli turizmin hızlı büyümesi bazı olumsuz etkilere de yol açabilir. Turist akışındaki hızlı artış, bazı bölgelerdeki yerel toplulukların yaşamlarında köklü değişikliklere yol açabilir; altyapının aşırı yüklenmesine, kaynak sıkıntısına, yerel ürün ve geleneklerin ticarileşmesine ve bölgenin yabancı işçiler ve yeni işletme sahipleri tarafından ele geçirilmesine neden olabilir. Tüm bu süreçler yerel halk için ekonomik getiri sağlamadığında, sosyal gerilimler ve çatışmaların artması muhtemeldir. Doğal alanlara dayalı turizm, biyolojik çeşitliliği ve koruma çalışmalarını destekleyebilirken, kontrolsüz ve aşırı ziyaretler ekosistemler ile sosyal çevre arasındaki hassas dengeyi bozabilir.

Kaynak yöneticilerinin karşılaştığı temel zorluklardan biri, doğal ve kültürel mirası korurken ve ekonomik fırsatları genişletirken aynı zamanda yüksek kaliteli ziyaretçi deneyimleri yaratmaktır. Yerel toplulukların bu sürece yakın katılımı, yönetim sonuçlarını önemli ölçüde iyileştirebilir. Ancak, işgücü sıkıntısı, finansal kısıtlamalar ve kurumsal kısıtlamalar, toplulukların tam ve sürdürülebilir bir şekilde katılımını zorlaştırmaktadır.

Sürdürülebilirlik, mevcut ve gelecekteki ekonomik, sosyal ve çevresel etkileri dikkate alarak ve ziyaretçilerin, endüstrinin, doğal çevrenin ve ev sahibi toplulukların ihtiyaçlarını dengeleyerek bilimsel turizmin gelişimini destekler. Temel hedefler, ekosistemlerin istikrarlı işleyişini

sürdürmek, biyolojik çeşitliliği ve doğal mirası korumak, yerel toplulukların kültürel kimliğini ve değerlerini muhafaza etmek ve nihayetinde sürdürülebilir ekonomik büyüme ve yoksulluğun azaltılmasını sağlamaktır. Bu hedeflere ulaşmak, farklı yönetim organları, ortaklar ve paydaşlar arasında koordinasyon, esnek yönetim yaklaşımları ve yaratıcı çözümler gerektirir.

Kara, su ve deniz ekosistemleri şu anda önemli bir antropojenik değişim altında olduğundan, sürdürülebilir turizm uygulamaları çevresel ve sosyal sürdürülebilirliğin sağlanması açısından her zamankinden daha önemlidir. Bu metnin temel amacı, sürdürülebilir turizm ve açık hava rekreasyonunun temel unsurlarını incelemek, parkların ve korunan alanların etkili yönetimini teşvik etmek ve bu alanların daha geniş sosyo-ekolojik sürdürülebilirliğe katkılarını bilimsel olarak değerlendirmektir.

2. Findings and Discussion

Açık hava rekreasyonu ve rekreasyon hizmet planlaması dinamik ve devam eden bir süreçtir. Rekreasyon talebindeki değişimler, mevcut tesislerin operasyonel durumu ve turist davranışlarında gözlemlenen yenilikler, bu alandaki planlamanın düzenli olarak güncellenmesini ve değerlendirilmesini gerektirmektedir. Açık hava rekreasyon planı, hem önerilen destinasyonun gelişim yönlerini belirlemeli hem de bölgede ve ötesinde gözlemlenen açık hava aktivitelerindeki eğilimleri yansıtarak uzun vadeli bir bakış açısı oluşturmalıdır. Bu bağlamda, destinasyon içindeki mevcut rekreasyon hizmetlerinin planlanması, yalnızca yerel fırsatların analizini değil, aynı zamanda çevre bölgelerde bulunan ve potansiyel gelişim fırsatları sunan açık hava rekreasyon alanlarının da incelenmesini gerektirir.

Açık Hava Destinasyon Ana Planı

Açık hava turizmi ana planı, sosyal, ekonomik, çevresel ve yasal faktörlere dayalı fiziksel bir planlama belgesidir ve destinasyon alanının büyümesi ve gelişmesi için yön sağlar. İnşaat Maliyeti Rekreasyon Planı, bu ana planı destekleyen ve onunla uyumlu bir alt plandır. Bu ana plan, rekreasyonel aktivitelerin yapılandırılması, planlama takviminin belirlenmesi ve gelecekteki yönetim mekanizmalarının oluşturulması için temel bir harita görevi görür.

Açık hava rekreasyon hizmetlerinin planlanmasının genel süreci üç ana aşamadan oluşur:

1) Tanımlama,

2) Değerlendirme,

3) Uygulama.

1. Tanımlama aşaması

Planlamanın ilk aşaması olan tanımlama, açık hava rekreasyon fırsatlarını etkileyen iç ve dış faktörler hakkında bilgi toplamayı içerir. Bu aşamada, destinasyon hakkında gerekli tüm bilgiler sistemleştirilir ve ana plana dahil edilir. Bu yaklaşımın temel nedeni, destinasyonun kullanımı boyunca planın periyodik olarak güncellenmesi ve mevcut bilgilerde eksiklikler ortaya çıkarsa, çeşitli kaynaklardan ek bilgilerin edinilerek plana entegre edilmesidir.

2. Değerlendirme aşaması

Açık hava rekreasyon hizmetlerinin planlanmasının ilk adımı, potansiyel etkilerin değerlendirilmesidir. Bu aşama, hem iç hem de dış koşulların açık hava etkinlikleri üzerindeki potansiyel etkilerini analiz eder. Potansiyel alanlar ve kısıtlamalar özetlenir ve turizm destinasyonunun ihtiyaç ve gereksinimleri belirlenir. Değerlendirme, hem iç hem de dış koşulların dışında rekreasyonel aktivite ve tesislerin mevcudiyetinin yanı sıra potansiyel kullanıcıların özellikleri ve ihtiyaçlarını da dikkate alır (Hammitt, Cole ve Monz, 2015).

Bu aşama, alanlardaki fırsatları ve kısıtlamaları belirlemenin yanı sıra turizm ve rekreasyon hizmetlerinin etkinliği için stratejik planlar geliştirmek için bir temel sağlar.

3. Uygulama Aşaması

Verilerin toplanması ve değerlendirilmesi, potansiyel alanların, kısıtlamaların, ihtiyaçların ve gereksinimlerin belirlenmesine yol açar. Bu süreç, açık hava rekreasyon hizmetlerinin planlanmasını ve destinasyon için bir ana kalkınma planının hazırlanmasını başlatır. Uygulama aşamasında, kavramsal alternatifler geliştirilir ve gelecekteki gelişim için en uygun plan seçilir. Bu seçim, uzun vadeli planlamanın temelini oluşturur (Manning, 2011).

Orman Alanlarında Açık Hava Rekreasyon Hizmetleri

Toplumsal değişimler, artan boş zaman ve orman alanlarının sağlık ve iyileştirici işlevlerine artan ilgi, ormanlarda açık hava rekreasyon hizmetlerine olan talebin sürekli artmasına neden olmaktadır. Açık hava rekreasyon faaliyetleri yalnızca eğlence ve macera amaçlı olmayıp, aynı zamanda sağlık ve çevrenin geliştirilmesi açısından da önemlidir (Newsome, Moore ve Dowling, 2013).

Orman alanlarındaki rekreasyon faaliyetleri, özellikle doğa temelli turizm ve ekoturizm şeklindedir. Bu faaliyetler sağlık, çevre ve eğitim açısından önemli faydalar sağlamakta ve birçok araştırmacı tarafından doğrulanmaktadır. Bu faydalar, modern toplumlarda ormanların ekonomik ve sosyal değerinin belirlenmesine yardımcı olur ve açık hava rekreasyon hizmetlerinin planlanmasında çok işlevli orman yönetiminde önemli bir rol oynar (Eagles, McCool ve Haynes, 2002).

Orman alanlarındaki rekreasyonel hizmetlerin planlanması, çevresel koşullara önemli ölçüde bağlıdır. Mekân ve rekreasyonel deneyimler arasındaki ilişkiyi inceleyen çoğu yaklaşımda mekânsal yönler yeterince dikkate alınmamıştır. Aynı zamanda, orman kaynakları rekreasyonel amaçlarla kullanılabilir, ancak doğal koruma değerleri çerçevesinde korunmalıdır. Bu iki faktörün -rekreasyon ve doğal koruma- nasıl dengeleneceği sorusu, modern araştırmalarda tartışmalı bir konu olmaya devam etmektedir (Hammitt, Cole ve Monz, 2015; Newsome, Moore ve Dowling, 2013).

Bu nedenle, orman alanlarındaki açık hava rekreasyonel hizmetlerinin planlanması, hem turist deneyimini en üst düzeye çıkarmayı hem de ekosistem hizmetlerini korumayı amaçlayan kapsamlı bir yönetim yaklaşımı gerektirir.

Planlama genellikle üç düzeyde ele alınabilir.

Birinci düzey – stratejik planlama: Bu aşamada, temel kararlar hükümet tarafından belirlenen politikalara dayanır ve ulusal, bölgesel veya yerel düzeyde makro ölçekte faaliyet gösteren demografik ve talep faktörleri dikkate alınarak alınır. Stratejik planlamayı etkileyen bilgiler, rekreasyon talebi modellerini, kentsel ve bölgesel kalkınma eğilimlerini, ulaşım altyapısını ve ekonomik faktörleri yansıtan ulusal anketleri içerir. Bu aşamada geliştirilen politikalar, destinasyon gelişimini yönlendirir ve geniş kapsamlı hedefler belirler.

İkinci düzey – arazi ve kaynak yönetimi düzeyinde planlama: Bu aşamada, stratejik politikalar ve stratejiler uygulamaya konur. Örneğin, rekreasyon sağlayıcısı ulusal ormancılıkla ilgilenen bir devlet kurumuysa, faaliyetleri ulusal politika ve stratejilerin çeşitli yönlerini yansıtacak ve hem kamu hem de özel sektörden finansal kaynak çekerek önemli girişimler gerçekleştirecektir. Böyle bir yaklaşım, Danimarka'da ormanların genişletilmesi gibi büyük projelerin uygulanmasında kilit rol oynar.

Üçüncü seviye - alan düzeyinde planlama: Bu seviyede, belirli faaliyetlerin gerçekleştirildiği alanlar (otoparklar, bilgi merkezleri, tuvaletler, yürüyüş yolları vb.) planlanır. Büyük bir rekreasyon alanında bu tür alanlar birden fazla olabilir. Genel plan ise bu alanları bölgelere ayırır ve geliştirilecek belirli alanları belirler. Üçüncü seviye planlama, rekreasyon planlayıcılarına ve tasarımcılarına alanın gelişimi, altyapının yerleşimi, detaylı tesisler, bilgi sağlama ve diğer gerekli unsurlar hakkında kesin bilgiler sağlar.

Açık Hava Rekreasyonuna Talep Eğilimleri:

Son yıllarda rekreasyon yönetimi alanında yapılan gözlemler iki önemli eğilimi ortaya koymuştur:

- Açık Hava Rekreasyonuna olan talep sürekli artıyor ve bu büyüme duracak gibi görünmüyor.
- İnsanların kullandığı rekreasyon türleri farklı faaliyet alanlarına yayılmış ve değişmiştir. Bu eğilim, mevcut alanların artan ziyaretçi sayısını karşılamakta zorlanabileceğini ve sağlanan tesislerin insanların beklentilerini tam olarak karşılayamayabileceğini göstermektedir.

Gelişmiş ülkelerde rekreasyon talebindeki değişimleri şekillendiren bir dizi ana eğilim bulunmaktadır. Bunlar, demografik, sosyal, politik, teknolojik ve ekonomik faktörlerin yanı sıra insanların yaşam tarzları ve davranış kalıpları tarafından belirlenir. Bu eğilimlerin analizi, planlama sürecinde kritik öneme sahiptir ve destinasyon geliştirme stratejilerinin oluşturulmasında doğrudan etkilidir.

3. Conclusion and Recommendations

Bu çalışma, açık hava turizmi ve rekreasyon hizmetlerinin sürdürülebilir planlanmasının önemini ve uygulanabilirliğini ortaya koymuştur. Araştırmalar ve gözlemler göstermektedir ki, açık hava rekreasyonu yalnız bireysel eğlence ve dinlenme olanağı sunmakla kalmayıp, aynı zamanda yerel ekonomiyi canlandıran, ekolojik farkındalığı artıran ve toplumsal refahı destekleyen stratejik bir turizm türüdür. Doğa temelli turizm faaliyetleri, fiziksel ve psikolojik sağlık üzerinde olumlu etkiler yaratmakta, sosyal ilişkileri güçlendirmekte ve ziyaretçilerin doğal ve kültürel mirasa olan bağlarını artırmaktadır.

Açık hava rekreasyon hizmetlerinin planlanması, tanımlama, değerlendirme ve uygulama aşamalarını içeren dinamik bir süreçtir. Bu süreç, mevcut tesislerin durumunu ve ziyaretçi taleplerini dikkate alarak düzenli güncellemeler gerektirir. Stratejik, arazi yönetimi ve saha düzeyinde yapılan planlama, destinasyonların hem kısa hem de uzun vadeli gelişimini güvence altına almakta; ekosistem hizmetlerinin korunmasını ve ziyaretçi deneyiminin optimize edilmesini sağlamaktadır.

Orman alanları gibi doğal ortamlarda rekreasyonel hizmetlerin planlanması, ekolojik koruma ile ziyaretçi memnuniyetini dengede tutmayı gerektiren çok işlevli bir yönetim yaklaşımı sunar. Bu alanlardaki hizmetlerin sürdürülebilirliği, doğru planlama, paydaş katılımı ve esnek yönetim stratejilerinin uygulanmasına bağlıdır. Ayrıca, açık hava turizmine yönelik talep sürekli artmakta ve rekreasyon türleri çeşitlenmektedir; bu durum planlamada esnek ve bütüncül yaklaşımların benimsenmesini zorunlu kılmaktadır.

Sonuç olarak, açık hava turizminin sürdürülebilir yönetimi; ekonomik, sosyal ve çevresel boyutların dengeli şekilde ele alınmasını, yerel toplulukların sürece dahil edilmesini ve kaynakların korunmasını gerektirir. Etkili planlama ve yönetim ile açık hava turizmi, hem ziyaretçilere kaliteli deneyimler sunabilir hem de yerel ve küresel düzeyde ekolojik ve sosyo-ekonomik değerler yaratabilir. Bu nedenle, politika yapıcılar, yöneticiler ve turizm profesyonelleri, sürdürülebilir açık hava rekreasyonunu destekleyecek stratejiler geliştirmeye devam etmelidir.

Abstract

This study examines the effectiveness of land use planning and zoning regulations in controlling urban development within Bauchi Metropolis, Nigeria. Rapid urbanization in the region has often resulted in haphazard growth, despite the existence of formal regulatory frameworks. The research adopted a quantitative descriptive survey design, administering structured questionnaires to 400 residents and property owners across three rapidly developing areas: Old Airport Area Bauchi, Gidan Gona (BSADP) and Tudun Salmanu. Data were analyzed using descriptive statistics via SPSS. Findings reveal a mixed result, first the planning process was perceived as most effective in ensuring sufficient utility provision for population density and in preventing incompatible land uses. However, the system was rated least effective in critical areas such as enforcing regulations, deterring violations, preserving property values and providing developmental certainty for residents. The study concludes that while the technical planning agenda shows strength in utility allocation and land-use segregation, significant institutional weaknesses undermine its regulatory authority and market-confidence functions. It is recommended that the Bauchi Urban Development Board should prioritize strengthening enforcement mechanisms, enhancing transparency in plan communication and building public trust to ensure the planning system fulfills its role in promoting orderly and sustainable urban development.

Keywords: Effectiveness, land use planning, zoning regulations, urban development

1. Introduction

Urbanization is a dominant global trend of the 21st century, presenting both opportunities for economic growth and profound challenges for sustainable development (United Nations Habitat, 2022). In the Global South, this urban expansion is often characterized by rapid, unplanned and informal growth that outpaces the capacity of municipal authorities to provide essential services and regulate physical development (Adewale, 2023). Effective land use planning and zoning regulations are universally recognized as critical tools for guiding urban growth, ensuring orderly development, promoting environmental sustainability and enhancing the quality of life for urban

residents (Olotuah & Adesiyan, 2022). These instruments are designed to segregate incompatible land uses, allocate space for public amenities, and create a functional and aesthetically pleasing urban form (Mabogunje, 2022). However, the chasm between the theoretical frameworks of planning and their practical implementation on the ground is a central concern in urban studies, particularly in developing nations like Nigeria (Ajayi & Ogunyemi, 2023). The Nigerian urban context exemplifies the intense pressures of rapid urbanization, where planning authorities grapple with institutional weaknesses, inadequate funding and complex socio-political dynamics (Fagbohun, 2023). At the national level, the challenge is not a lack of planning legislation with instruments like the Land Use Act of 1978 providing a foundational framework, but rather its ineffective enforcement and the proliferation of informal settlements that develop outside the purview of official regulations (Nwokoro & Onyebueke, 2022). This failure often results in chaotic urban landscapes, infrastructure deficits and heightened vulnerability to environmental hazards. A study by Eze et al. (2023) on urban sprawl and infrastructure decay in Nigerian cities found that in major Nigerian cities, over 60% of new developments occurred without official planning approval, leading to severe strain on water, road and sanitation infrastructure. This national context sets the stage for understanding the localized pressures within specific states and metropolises.

Within the study area Bauchi State, the capital metropolis serves as the primary political, economic and administrative hub, attracting significant rural-urban migration and driving demand for land and housing (Isah & Bello, 2024). This has triggered a rapid transformation of the city's periphery, converting agricultural and vacant land into residential and commercial uses, often in an uncoordinated manner (Sani & Dogo, 2023). The Bauchi State Urban Development Board (BUDB), tasked with preparing master plans and enforcing zoning regulations, operates within a constrained environment. A study by Bala and Mohammed (2024) on challenges of development control in Bauchi State, Nigeria identified political interference, corruption among land officials and insufficient technical capacity as the three most significant factors crippling the enforcement of zoning regulations in the state. The study further revealed that political pressure led to the overturning of 40% of enforcement actions in sampled cases, demonstrating a significant gap between policy and practice.

According to Garba and Shehu (2024), the city of Bauchi exhibits a patchwork of planned layouts existing alongside extensive, densely populated unplanned settlements where basic services are scarce. Zoning regulations, which are meant to separate residential areas from noisy and polluting industrial activities, are frequently violated, leading to land use conflicts and environmental degradation. The consequences of this regulatory failure are not merely spatial but have direct implications for public health and social equity. Dankoli and Gwary (2025) study on spatial analysis of land use compliance and public health risks in Bauchi Metropolis employed Geographic Information Systems (GIS) to map land use violations. The findings confirmed that neighborhoods with the highest density of zoning violations, particularly the encroachment of residential areas into industrial zones, correlated strongly with elevated reports of respiratory ailments and environmental pollution among residents. This direct link underscores the tangible human cost of ineffective planning controls. While these studies individually highlight aspects of non-compliance, institutional weakness, and informal processes, there is a need for a consolidated

and focused inquiry that directly measures the effectiveness of the entire land use planning and zoning system in Bauchi Metropolis. The problem, therefore, is that despite the existence of formal land use planning and zoning regulations intended to guide urban development in Bauchi Metropolis, the city continues to experience haphazard growth, significant non-compliance with land use plans, and deteriorating urban environmental conditions. This study seeks to critically investigate this disconnect, evaluating the specific factors such as institutional, political, economic or social that render these regulatory tools ineffective in controlling urban development, thereby contributing to the ongoing discourse on sustainable urban management in Nigeria.

1.1. Conceptual and Theoretical Perspective

Land use planning and zoning represent the primary legal and policy instruments through which governments seek to impose order, predictability and public welfare objectives onto the dynamic processes of urban development (Raparthi & Dewidar, 2024). Conceptually, their effectiveness is not a binary outcome but a spectrum, contingent upon the interplay of regulatory frameworks, institutional capacity, market forces and socio-political realities (Akah et al., 2024). Theoretically, planning systems are often analyzed through the lens of communicative rationality, which emphasizes collaborative decision making among stakeholders and political economy, which highlights how power relations and capital accumulation shape urban outcomes, often leading to deviations from formal plans (Mastop et al., 2023). The dynamics of land use control can be effectively understood through the lens of the following theoretical frameworks: The theory of planned behavior: this theory posits that behavior (e.g., complying with zoning laws) is determined by intention, which is influenced by attitudes, subjective norms, and perceived behavioral control (Yadav et al., 2023). For example Raparthi and Dewidar (2024) explained that in Bauchi Nigeria, developers' attitudes towards the planning system are negative (seen as a hurdle), the subjective norm is non-compliance (as it is widespread), and perceived behavioral control is high (as enforcement is weak). This theoretical combination powerfully predicts the high non-compliance rates observed.

Institutional theory: this perspective highlights the role of formal and informal rules of the game (Akah et al., 2024). The failure can be interpreted as an institutional clash where the imported, formal institutions of land use planning are not legitimized or embedded within the local socio-cultural context, which is governed by strong, informal institutions of traditional land ownership and kinship. The weaker institution (formal planning) is consistently subverted by the stronger one (informal traditions).

Political economy approach: this theory argues that urban space is a product of power relations and economic interests (Mastop et al., 2023). The development pattern is not merely a planning failure but an outcome of a political economy where land is a source of patronage. Powerful actors (politicians, elites) manipulate the planning system for personal gain, leading to selective enforcement and the allocation of land in contravention of the master plan, thereby rendering the regulations ineffective as a public interest tool.

1.2 Empirical Aspect

The effectiveness of zoning and land use planning varies dramatically across regions, as revealed by recent empirical studies. In much of Africa, formal land use planning exists in a parallel reality to the dominant mode of urban development, informality, with the key challenge being the limited reach and enforcement of regulations. Watson and Agbola (2023) investigated who is the plan for? the co-production of urban space in Accra and Lagos, Ethnographic action research within informal settlements, engaging residents and planning officials was adopted. The study concluded that formal zoning maps and land use regulations have minimal effectiveness in controlling development in rapidly growing African cities. Urban space is largely co-produced through a complex interplay of traditional land rights, informal land markets, and community self-organization. The authors advocate for a shift from rigid, master planning approaches to more flexible, participatory, and incremental planning that recognizes and integrates these existing processes. Njoh et al. (2022) studied urban planning, land use management and corruption in Sub-Saharan Africa. Systematic review of literature on planning and governance across multiple Sub-Saharan African countries was used. Findings identified corruption as a primary mechanism rendering land use planning ineffective. Pervasive practices like bribery for building permits, illegal rezoning, and non-enforcement of regulations against powerful actors mean that planning regulations often serve as a tool for rent-seeking rather than a mechanism for guiding development in the public interest. Nwokoro and Onyebueke (2024) studied the governance of urban sprawl: planning regulation and land commodification in the peri-urban fringe of Abuja. GIS-based land use change detection and surveys of landowners and developers in Abuja's peri-urban areas. The study found that despite the existence of a sophisticated Abuja Master Plan, peri-urban development is largely chaotic and unregulated. Zoning regulations are ineffective due to conflicting land tenure systems (statutory vs. customary), weak enforcement capacity of the development control department, and the rapid commodification of land by powerful traditional elites. The study found that over 70% of new developments in the study area violated zoning standards, demonstrating a profound failure of regulatory control. Adewumi & Ojo (2023) investigated digital technologies and land use planning: assessing the potential of GIS for development control in Lagos Metropolis. Action research pilot project deploying a GIS-based platform for monitoring building permits and compliance in selected Lagos Local Government Areas was used. The research highlighted that a significant part of ineffectiveness stems from archaic, paper based and non-transparent planning administration. Their pilot demonstrated that digitizing records and using GIS for monitoring could significantly improve compliance tracking and enforcement. However, the study also cautioned that technology alone is insufficient without addressing the underlying political will and corrupt practices that often override technical systems.

Shehu and Garba (2022) studied the role of informal land markets in subverting formal land use planning in Bauchi, Nigeria. Qualitative; In-depth interviews and focus group discussions with land administrators, community leaders, and residents in rapidly developing peri-urban wards was used. The research identified the vibrant informal land market as a major subverted of formal planning. Land is predominantly acquired through traditional means, bypassing official planning authorities. This process often disregards zoning regulations, leading to the development of

residential areas on land officially zoned for other uses. The study emphasizes the need for integrating traditional and formal land governance systems. Bashir and Umar (2023) studied compliance with land use zoning regulations in Bauchi Metropolis, Nigeria. GIS analysis of land use change and structured questionnaires administered to households and officials of the Urban Development Board was used. The study revealed a 68% non-compliance rate with official zoning regulations across the metropolis. GIS analysis showed significant encroachment of residential uses into designated green areas and institutional zones. The primary reasons cited were weak enforcement mechanisms, corruption among officials and public ignorance of the provisions of the master plan. The empirical evidence demonstrates that the effectiveness of land use planning and zoning is not merely a function of the technical quality of the plan itself. It is predominantly determined by the governance ecosystem in which it operates. Therefore, an understanding of zoning's effectiveness requires moving beyond the map and the ordinance to analyze the political, economic and social structures that determine whether a plan remains a symbolic document or becomes a genuine tool for shaping equitable and sustainable urban futures

2. Materials and Methods

The study adopts a quantitative research design, specifically a descriptive survey approach. This design is appropriate because it allows for the systematic collection of numerical data from a sample of a population to describe phenomena, attitudes, and opinions. The primary goal is to quantify the perceptions and experiences of residents and professionals regarding the effectiveness of land use planning and zoning regulations. This approach facilitates the generalization of findings from the sample to the broader population of the Bauchi Metropolis. The study population consists of the key stakeholders involved in, or affected by, land use planning and urban development in Bauchi Metropolis. This heterogeneous population is divided comprises residents/property owners involving adult residents and landowners specifically house hold heads of residential and commercial properties (Old airport area Bauchi, Gidan Gona (BSADP) and Tudun Salmanu). The areas were selected over others because they are hotspots of recent and rapid urban development, characterized by a high volume of new construction, conversion of land use and commercial/residential expansion, which makes them ideal case studies for investigating the practical challenges of regulatory compliance and ground level implementation of urban planning standards in Bauchi Metropolis.

Based on the data provided in Table 1, the sample frame for the study comprises 13,000 residents and property owners, who are distributed across three specific sub-categories. The sub-category of Tudun Salmanu represents the largest segment with a population of 5,500, followed by the Old Airport Area Bauchi with 4,500, and Gidan Gona (BSADP) with 3,000. From this overall frame, a total sample size of 400 individuals was selected for the study, with 169 participants from Tudun Salmanu, 138 from the Old Airport Area Bauchi, and 92 from Gidan Gona (BSADP).

Table 1. Sample frame for the study

Category	Sub-Category	(Sample Frame)	Sample size
Residents/Property owners (house hold/property heads)	Old Airport Area Bauchi	4,500	138
	Gidan Gona (BSADP)	3,000	92
	Tudun Salmanu	5,500	169
Total		**13,000**	**400**

Due to the diverse aspect of the population, a scientific sampling formula was used to determine a representative sample size. The Taro Yamane formula is appropriate for finite populations and will be applied:

$$n = \frac{N}{1+ N(e)^2}$$

Where e is the degree of accuracy or sampling error, which is ± 5%; n is the sample size; and N is the target population.

$$n = \frac{13{,}000}{1+ 13{,}000(0.05)2} = n = \frac{13{,}000}{1+ 32.5} = n = \frac{13{,}000}{33.5}$$

n = 388 rounded to 400

The main tool used to gather data was a structured questionnaire. Closed-ended questions on a 5-point Likert scale from (1) less effective to (5) highly effective were used in the questionnaire's design (Joshi *et al.*, 2023). The use of close-ended questions is preferable in such quantitative designs as they facilitate easier data aggregation and statistical analysis (Mutepfa & Tapera, 2019). The adoption of the 5-point Likert scale is justified as it ensures that questions are posed in a fair and balanced manner, effectively capturing the strength of respondents' attitudes and perceptions (Al Baghal et al., 2020). The quantitative data obtained from the questionnaires were analyzed using descriptive statistics. The analytical instrument was the Statistical Package for the Social Sciences (SPSS) program. In particular, the replies' mean and standard deviation were calculated. The average response or central tendency for each item, which represents the overall degree of agreement or disagreement, was calculated using the mean score. The degree of agreement among the respondents was shown by the standard deviation, which was used to quantify the variability or dispersion of the replies around the mean. Clear and succinct presentation of the results was made possible by this analytical method, which converted the raw data into an interpretable manner.

3. Findings and Discussion

Prior to result presentation, Demographic information of respondents was presented in Table 2, while result for effectiveness of land use planning and zoning regulations in controlling urban development in the study area was presented in Table 3

Table 2. Demographic information of respondents

S/N	Attributes	Options	Frequency	Percent %
1	Gender	Male	295	73.7
		Female	105	26.3
2	Age group	18 - 25 years	63	15.8
		26 - 35 years	96	24.0
		36 - 45 years	103	25.7
		46years and above	138	34.5
3	Highest educational qualification	Diploma	68	17.0
		Bachelor's degree	167	41.7
		Master's degree	122	30.5
		PhD	43	10.8
4	Length of residence in Bauchi Metropolis	Less than 2 years	96	24.0
		2 – 5 years	138	34.5
		6 – 10 years	103	27.8
		11years and above	63	15.7
5	Occupancy category	Tenant	148	37.0
		Property owner	252	

The demographic profile of the 400 respondents provides a crucial context for understanding the perspectives on land use planning and zoning regulations within Bauchi Metropolis. The survey captured a predominantly male sample, with 73.7% of respondents being male and 26.3% female, which may reflect gendered patterns of property ownership or head-of-household roles in the study area. In terms of age distribution, the largest cohort was respondents aged 46 years and above, constituting 34.5% of the sample, followed closely by the 36-45 year age group at 25.7%. This indicates that the majority of respondents (60.2%) are middle-aged and older adults, who are likely to have considerable experience and a long-term stake in the urban development of the metropolis.

Regarding educational attainment, the largest proportion of respondents, 41.7%, held a Bachelor's degree as their highest qualification, while 30.5% possessed a Master's degree. This shows that a significant majority of the study's participants (72.2% combined for Bachelor's, Master's, and PhD) have a tertiary education, which suggests a population generally capable of understanding the

technical and regulatory aspects of land use planning and zoning. The data on the length of residence reveals important insights into the respondents' familiarity with the city. The largest group, 34.5%, have lived in Bauchi Metropolis for 2 to 5 years, while 27.8% have resided there for 6 to 10 years. Crucially, only 15.7% have lived in the area for 11 years or more, indicating a population with a relatively recent connection to the city, which may influence their perceptions of long-term urban change. Finally, the occupancy category shows that property owners form the majority of respondents at 63.0%, compared to tenants at 37.0%. This high rate of property ownership is particularly significant for this study, as property owners are directly and financially impacted by land use and zoning regulations and their responses will be vital in assessing the effectiveness of these planning controls.

Table 3. Effectiveness of Land Use Planning and Zoning Regulations in Controlling Urban Development

Effectiveness	Mean	Std. Deviation	Ranking	Remark
Effectiveness of planning process in ensuring sufficient provision of utilities (e.g., water, electricity) for neighborhood's population density	3.519	0.930	1	Effective
Effectiveness of zoning regulations in preventing incompatible land uses in the neighborhood (e.g., a factory next to a home)	3.509	0.937	2	Effective
Official zoning plan at ensuring land uses on street are consistent with their designated purpose (e.g., residential area remains residential)	3.099	0.818	3	Moderate
Zoning regulations in contributing to a cleaner and healthier living environment in your community	3.060	0.862	4	Moderate
Public awareness efforts been in ensuring residents know the specific zoning category (e.g., residential, commercial) that applies to their property	2.980	0.905	5	Moderate
Effectiveness of the relevant planning authority in enforcing zoning regulations (e.g., stopping illegal construction or land use)	2.970	0.963	6	Moderate
Effectiveness of regulations in controlling urban sprawl and unplanned development in the metropolis	2.713	1.177	7	Moderate
Effectiveness of land use planning regulations in preserving or increasing property's value	2.173	1.068	8	Less effective

Effectiveness of the current systems and penalties at deterring people from violating land use and zoning rules in Bauchi Metropolis	2.164	1.080	9	Less effective
Land use planning provides security that surrounding plots will develop as intended (e.g., residential to remain residential)	2.054	1.068	10	Less effective

Based on the data presented in Table 3, the study on the effectiveness of land use planning and zoning regulations in Bauchi Metropolis yields a mixed but revealing picture. The analysis indicates that the planning process is perceived as most effective in ensuring the sufficient provision of utilities for the neighborhood's population density, ranking first with a mean score of 3.519. Closely following in second place, with a mean of 3.509, is the effectiveness of zoning regulations in preventing incompatible land uses, such as locating a factory next to a home. Both of these top ranked items are remarked as effective. The results further show that five aspects of the system are considered to have moderate effectiveness. These include the official zoning plan's role in ensuring land use consistency on streets with a mean of 3.099, the contribution of zoning regulations to a cleaner and healthier environment with a mean of 3.060, public awareness efforts regarding zoning categories with a mean of 2.980, the effectiveness of the planning authority in enforcing regulations with a mean of 2.970, and the role of regulations in controlling urban sprawl (mean 2.713).

Conversely, the system is perceived as least effective in three critical areas, all remarked as less effective. The data reveals that land use planning regulations are seen as ineffective in preserving or increasing property value, ranking eighth with a mean of 2.173. The current systems and penalties are also considered poor at deterring violations, ranking ninth with a mean of 2.164. Finally, land use planning provides the least sense of security that surrounding plots will develop as intended, ranking last with a mean of 2.054. In summary, while the regulatory framework shows strength in utility planning and preventing land use conflicts, its perceived effectiveness significantly diminishes in areas of enforcement, deterrence, property value assurance, and providing developmental certainty for residents.

3.1. Discussion of Result

The finding that the planning process is most effective in ensuring sufficient utilities for population density is supported by contemporary studies on integrated urban management. Research by Abubakar *et al.* (2024) on Nigerian cities concluded that structured planning frameworks significantly improve the allocation and extension of water and electrical infrastructure in high density settlements, directly aligning with Bauchi's experience. Furthermore, its success in preventing incompatible land uses, such as separating industrial zones from residential areas, is corroborated by a study of Mbanga and Dlamini (2023) in land use policy, which found that clear zoning regulations remain a primary tool for minimizing land use conflicts and mitigating environmental externalities in rapidly urbanizing African metropolises.

Conversely, the system's perceived ineffectiveness in preserving or increasing property value is a common challenge discussed in recent literature. For example, Chigbu *et al.* (2023) noted that property values are more strongly influenced by market forces, security, and direct infrastructure investment than by zoning ordinances alone, which explains the resident's perception in Bauchi. This is compounded by the system's failure to provide developmental certainty, a concept emphasized by Opawole *et al.* (2022), who argued that inconsistent application of plans and frequent ad-hoc amendments by planning authorities create uncertainty that discourages long-term private investment and undermines confidence in the system.

The ineffectiveness in deterring violations and enforcement is a widely acknowledged issue in planning studies across the Global South. A study focusing on enforcement mechanisms in Ghanaian cities by Asiama *et al.* (2024) found that limited institutional capacity, corruption, and political interference consistently cripple the ability of planning departments to enforce regulations, leading to widespread non-compliance that diminishes the system's authority. This lack of enforcement directly undermines the sense of security for surrounding plots, as the failure to penalize violations, such as illegal building extensions or commercial operations in residential zones, creates a landscape of unpredictability and risk for adjacent landowners. In conclusion, while the technical aspects of Bauchi's planning system in utility provision and land-use segregation align with supported best practices, its systemic failures in enforcement, value preservation, and creating certainty reflect well documented institutional and governance challenges prevalent in similar urban contexts.

4. Conclusion and Recommendations

The land use planning process in Bauchi Metropolis is most effective in its core function of ensuring sufficient utilities to support the current and planned population density and in successfully preventing incompatible land uses within designated zones. This success indicates a fundamentally sound planning framework at the initial stages of development and utility provision. Conversely, the system is perceived as least effective in critical areas related to post planning governance and market outcomes, specifically failing to adequately preserve or increase property value, struggling to deter violations of zoning regulations, and not providing a strong sense of security or developmental certainty for surrounding plots and residents. Consequently, the system’s overall effectiveness diminishes significantly when it comes to enforcement, deterrence of illegal development, assurance of property value, and providing developmental certainty for the residents of the metropolis.

To address the identified shortfalls, it is strongly recommended that the Bauchi planning authorities immediately shift focus and dedicate substantially greater resources toward strengthening the enforcement and monitoring mechanisms of the existing zoning regulations to effectively deter violations. Furthermore, the authorities should establish clearer, more transparent processes for communicating development plans and changes to the public, aiming to increase property value assurance and provide a greater sense of security and developmental certainty for property owners and surrounding communities. Finally, this study's contribution to knowledge is the identification of a specific disconnect within a land use planning system, where procedural and

infrastructural planning can be successful while it's regulatory and market-confidence functions fail, providing a nuanced case study for urban planners in similar developing contexts.

Abstract

The growing demand for energy-efficient buildings has intensified the search for innovative strategies in passive thermal regulation. This study presents a chemical engineering approach to optimizing microencapsulated Phase Change Materials (PCMs) for integration into architectural finishes and insulation systems. PCMs, typically based on paraffin waxes, absorb and release substantial latent heat during phase transitions, thereby stabilizing indoor temperature fluctuations. Our research focuses on the thermochemical optimization of both the PCM core and its polymeric shell. In particular, we examine the influence of nanoparticle additives (TiO_2 and carbon nanotubes) on the latent heat storage capacity and thermal conductivity of microcapsules. Experimental results indicate that doping the PCM with 0.5 wt% TiO_2 nanoparticles significantly reduces supercooling and enhances the effective thermal conductivity of PCM-infused plaster by approximately 15%, without altering the phase transition temperature. This chemically enhanced PCM formulation introduces a new class of "smart" building materials, offering superior thermal performance in regions with pronounced diurnal temperature variations, such as the Mediterranean climate of Demre.

Keywords: Phase Change Materials, PCMs, thermochemical, nanoparticles, heritage, thermal regulation

1. Introduction

The need for sustainable, energy-efficient buildings has become critical in light of increasing global energy demands and the environmental impact of conventional HVAC systems (Cabeza et al., 2011). Passive thermal regulation using materials and design strategies that naturally stabilize indoor temperatures presents a cost-effective alternative for both modern and heritage structures (Kasaeian et al., 2017). Phase Change Materials (PCMs) have emerged as one of the most promising passive thermal management technologies. They store and release latent heat during phase transitions, thereby smoothing temperature fluctuations within the human comfort range (20–28°C) (Zalba et al., 2003). However, large-scale integration of PCMs into building materials remains limited due to challenges such as leakage, chemical instability, and low thermal conductivity when embedded in matrices like plaster or concrete (Shilei et al., 2007). Microencapsulation, which encapsulates the PCM within a protective polymer shell, mitigates leakage and compatibility issues (Zhang *et. al.*, 2018). However, the fundamental challenge of low thermal conductivity persists.

This research addresses these limitations by focusing on the thermochemical optimization of microencapsulated PCMs. Through nanoparticle-enhanced encapsulation chemistry, we aim to

improve heat transfer efficiency and reliability, enabling broader application in architectural materials.

An ideal PCM for architectural applications should possess a melting temperature within the comfort range, high latent heat storage capacity, and long-term thermal reliability. Paraffin waxes, composed mainly of n-alkanes, are the most common choice owing to their high enthalpy of fusion (~200 kJ/kg), chemical stability, and non-corrosive nature (Shukla et al., 2009). In this study, *n*-tetradecane (melting point ≈ 25°C) was selected as the PCM core.

Microencapsulation involves enclosing the PCM within a thin polymeric shell to prevent leakage during the liquid phase and protect it from chemical interaction with the surrounding matrix. The encapsulation also enhances surface area, enabling faster heat transfer. We employed an in-situ polymerization technique using a melamine–formaldehyde (MF) resin shell, chosen for its mechanical durability, chemical inertness, and high encapsulation efficiency (Zhang et al., 2018).

A key limitation of organic PCMs is their low intrinsic thermal conductivity (~0.2 W/m·K). To overcome this, nanostructured dopants can be introduced to improve thermal transport pathways. Titanium dioxide (TiO_2) nanoparticles serve as effective nucleation agents that reduce supercooling and enhance phase transition kinetics (Tang et al., 2020), while carbon nanotubes (CNTs) provide a high-conductivity framework that facilitates rapid heat transfer (Huang et al., 2011).

2. Materials and Methods

2.1. Synthesis of Doped Microcapsules

Microcapsules containing n-tetradecane were synthesized via in-situ polymerization. Prior to encapsulation, predetermined amounts of TiO_2 and CNT nanoparticles (0.25%, 0.5%, and 1.0% by weight of the PCM) were dispersed into the liquid n-tetradecane using ultrasonic homogenization for 30 minutes to ensure a uniform suspension.

2.2. Characterization Techniques

The synthesized microcapsules were integrated into a standard gypsum plaster matrix at a concentration of 10 wt%. The resulting composite was cast into standardized discs for testing. The following characterization techniques were employed:

- Thermal Analysis: Differential Scanning Calorimetry (DSC) was used to determine the latent heat of fusion (ΔH), melting temperature (T_m), and solidification temperature (T_s). The degree of supercooling was calculated as $\Delta T = T_m - T_s$.
- Thermal Conductivity: The thermal conductivity (λ) of the plaster composites was measured using the transient plane source (TPS) method with a hot disk apparatus.
- Chemical Stability: Fourier-Transform Infrared Spectroscopy (FTIR) was conducted on samples before and after 100 accelerated thermal cycles to detect any chemical degradation or shell rupture.

3. Findings and Discussion

3.1. Effect on Latent Heat and Supercooling

The optimal performance was achieved at 0.5 wt% TiO_2 loading. The doped PCM exhibited only a 1.2% reduction in latent heat compared to the control, indicating minimal displacement of the active phase material. Supercooling was significantly reduced, with the temperature difference ($\Delta T = Tm - Ts$) decreasing from 2.1°C to 0.8°C. This improvement can be attributed to enhanced nucleation provided by TiO_2 particles, promoting more reliable solidification (Zhang et al., 2018).

3.2. Thermal Conductivity Enhancement

Thermal conductivity measurements of the plaster composites confirmed the positive impact of nanodoping. The baseline plaster with undoped PCM microcapsules had a conductivity (λ) of 0.56 W/m·K.

- The 0.5 wt% TiO_2-PCM composite showed a 15% enhancement, achieving $\lambda = 0.65$ W/m·K.
- In contrast, the CNT-doped composites showed a maximum improvement of only **7%** ($\lambda = 0.60$ W/m·K) at the same loading.

This disparity underscores the critical role of nanoparticle dispersion and interfacial compatibility. While CNTs have higher intrinsic conductivity, they are prone to agglomeration due to strong van der Waals forces, forming insulating clusters that hinder effective heat transfer (Liu et al., 2021). The TiO_2 nanoparticles, being smaller and more easily dispersed, created a more uniform and effective thermal network within the PCM-plaster matrix.

3.3. Architectural Implications

The thermochemically optimized PCM offers practical benefits for both modern and heritage architecture:

- Thinner Structural Layers: Improved λ values allow reduced PCM quantities for the same heat capacity, minimizing wall thickness, vital for historical building retrofits.
- Predictive Thermal Performance: Reduced supercooling ensures consistent phase-change behavior, enabling accurate simulation and integration within Building Information Modeling (BIM) frameworks (Pomianowski et al., 2013).

4. Conclusion and Recommendations

This study successfully demonstrates that the thermochemical optimization of microencapsulated PCMs via nanoparticle doping is a highly effective strategy for overcoming key material limitations. The incorporation of 0.5 wt% TiO_2 nanoparticles resulted in a composite material that exhibits a 15% higher thermal conductivity and a 62% reduction in supercooling, with minimal impact on its latent heat storage capacity.

The findings validate the use of TiO_2 as a superior additive compared to CNTs for this specific application, primarily due to its dual functionality as a nucleating agent and its more favorable

dispersion characteristics. This optimized PCM composite represents a significant advancement towards practical, high-performance "smart" building materials for passive climate control.

For future work, we recommend:

1. Long-Term Durability Studies: Investigating the performance over thousands of thermal cycles and under real-world weathering conditions.

2. Multi-Functional Shells: Exploring shell materials with inherent fire-retardant or self-healing properties to enhance safety and longevity.

3. Life-Cycle Assessment (LCA): Conducting a comprehensive LCA to evaluate the environmental and economic payback of using these enhanced materials in both new and retrofit construction projects.

Abstract

The architecture of extracurricular activities (EA) in foreign languages constitutes an essential strategic framework for developing the intercultural competence of university students. The study analyses the multidimensional structure of EA, highlighting its organizational, pedagogical, and intercultural functions, as well as how they integrate linguistic, sociocultural, and communicative skills. Events such as round tables, thematic panels, professional simulations, and collaborative projects demonstrate that EA stimulates active involvement, autonomy, intrinsic motivation, and critical reflection, providing authentic experiences of intercultural interaction and language practice. The educational strategies identified: project-based learning, professional simulations, international collaboration, intercultural debates, and guided reflection facilitate the development of empathy, cultural openness, cognitive flexibility, and adaptability of students in multicultural and multilingual contexts. The research results confirm the role of AE in internationalizing the educational process, strengthening multilingual and intercultural skills, and preparing students for the professional and social challenges of a globalized world. The study recommends the implementation of a coherent AE architecture that harmonises objectives, strategies and teaching methods to maximise the impact on the development of intercultural competence, language skills and lifelong learning.

Keywords: extracurricular activities architecture, intercultural competence, foreign languages, educational strategies, university environment

1. Introduction

"Knowledge, skills, and concepts are important components of success in all spheres of activity, but they do not guarantee it. Success also depends, and not to a small extent, on people's goals, values, feelings, hopes, motivation, independence, cooperation, perseverance, and intuition."

(V. Landsheer)

In a world marked by globalization, accelerating information flows, and ever-closer interdependence between economies and cultures, the role of higher education takes on a strategic dimension in training specialists capable of communicating and collaborating effectively in a multilingual and multicultural environment. Market liberalization intensified economic and technological exchanges, academic and professional mobility, and the diversification of intercultural contacts require a reassessment of traditional educational paradigms. In this context,

universities are called upon not only to impart knowledge, but also to develop transversal skills: linguistic, communicative, intercultural, and civic, which will enable graduates to integrate effectively into a knowledge-based society, both socially and professionally.

Globalization, a complex process of interconnecting the world through the rapid movement of goods, capital, information, and people, has created a "world without borders" in which linguistic and cultural plurality is becoming an everyday reality. In this sense, teaching and learning foreign languages takes on major significance: they are no longer just language learning objectives but means of building intercultural awareness and an open attitude towards diversity (Pîrlog, A. & Rusu, D., 2023).

In the European educational environment, the concepts of plurilingualism, multilingualism, and interculturalism are essential benchmarks of the language policies promoted by the Council of Europe (2018), advocating for an education in which foreign language learning develops not only communication skills but also the ability to understand and interpret the cultural realities of other peoples. The Common European Framework of Reference for Languages (CEFR) proposes an action-oriented approach to the teaching-learning process, focused on concrete tasks and the development of intercultural communication skills, a key concept in contemporary education.

Intercultural competence (IC) can be defined as a dynamic set of knowledge, attitudes, skills, and behaviours that enable effective and appropriate interaction with people from other cultures. IC involves empathy, openness, tolerance, cultural negotiation skills, but also critical reflection on one's own identity. Developing this competence in the university environment requires not only a cognitive act, but also an attitudinal and behavioural one, cultivated through authentic learning and interaction experiences.

In this regard, extracurricular activities (EA) in foreign languages constitute a privileged space for the formation and manifestation of intercultural competence. They complement the formal teaching-learning-assessment process through non-formal and informal educational experiences, stimulating active participation, reflection, cooperation, and intercultural dialogue. The various forms of EA: conferences, round tables, symposiums, debates, thematic workshops, student circles, competitions, exhibitions, or festivals, etc., promote direct contact with cultural and linguistic diversity, strengthening students' intrinsic motivation to learn foreign languages.

At the Academy of Economic Studies of Moldova (ASEM), extracurricular activities organized in French, English, and German are examples of good educational practices that contribute to the formation of an open and inclusive academic culture. They aim to strengthen linguistic and intercultural skills, stimulate critical thinking, and develop team spirit, responsibility, and the ability to adapt to diverse cultural contexts.

The architecture of extracurricular activities can be understood as a set of principles, structures, dimensions, and pedagogical strategies that define their design, planning, and implementation, constituting a fundamental element for the efficiency of the educational process. Thus, the coherent alignment of formative objectives with forms of extracurricular activity, teaching strategies, resources, and the learning context aims to develop students' intercultural skills.

Educational strategies can be defined as action plans, carried out systematically to achieve the expected objectives. They should promote experiential learning, critical reflection, and active student participation through methods such as role-playing, simulations, case studies, collaborative projects, thematic workshops, etc. In this way, cultural empathy, negotiation and adaptation skills are developed, and intercultural barriers related to stereotypes, prejudices, ethnocentrism or culture shock are reduced.

In a society characterised by pluralism and interdependence, EA in foreign languages become strategic tools for intercultural education, providing a favourable framework for the development of authentic communication and mutual understanding between young people from different cultures. Extracurricular activities prepare students not only for professional performance, but also for active participation in the social and cultural life of a world united in diversity.

Based on the assumption that extracurricular activities in foreign languages contribute greatly to the development of students' intercultural competence, this study aims to analyse their architecture from a pedagogical and methodological perspective, pursuing the following specific objectives:

1. Analysis of the architecture of extracurricular activities in foreign languages (dimensions, components, functions).

2. Exploration of theoretical and conceptual approaches to intercultural competence (IC).

3. Investigation of the role of extracurricular activities in the development of students' intercultural competence.

4. Identifying educational strategies, methods, and tools that promote the development of intercultural competence.

5. Illustrating good practices in the activities carried out (round tables, panels, etc.).

6. Highlighting the role of EA in preparing students for professional, social, and intercultural challenges in a global and multilingual context.

Therefore, this study aims to analyse how the architecture of extracurricular activities in foreign languages can be strategically designed to support the development of intercultural competence, which is essential for professional and social integration in a globalized world, while also providing. By identifying and describing the educational and methodological strategies used in this process, the study aims to provide examples and directions for practical application in the academic environment that will support teachers in designing activities capable of stimulating intercultural communication, tolerance, empathy, and openness to diversity.

2. Materials and Methods

This chapter aims to present the methodological framework of the research, highlighting the material used and the methods applied in the process of theoretical analysis and empirical observation. The study aims to provide a scientific basis for the analysis of the architecture of extracurricular activities in foreign languages as effective educational tools for the development of intercultural competence in the university environment. Our research focuses on identifying

educational strategies and forms of organization of extracurricular activities capable of contributing to the development of intercultural competence among students in higher education.
The theoretical basis of the research consists of contemporary approaches by specialists in the field of foreign language teaching and intercultural education, which offer current perspectives on key concepts such as intercultural competence, plurilingualism, multilingualism, strategy, extracurricular activity, and interculturality. These contributions provide a solid conceptual basis for understanding the relationship between linguistic and intercultural training, emphasizing the decisive role of the university environment in stimulating dialogue between cultures.
The empirical material consists of extracurricular activities (EA) organized within university foreign language programs, particularly at the Academy of Economic Studies of Moldova. These varied activities: conferences, round tables, workshops, competitions, cultural festivals, thematic campaigns, and collaborative projects aimed to directly involve students in authentic intercultural contexts and develop their communication, reflection, and collaboration skills. Observing these activities also highlighted their positive impact on the development of intercultural competence and motivation for foreign language learning, based on adaptability, critical reflection, and continuous feedback
To achieve the objectives set, the research used a set of complementary theoretical and empirical methods, which facilitated both conceptual analysis and interpretation of the data obtained through observation.

The research was based on a combination of theoretical and empirical research methods, designed to ensure an integrated and coherent approach to the phenomenon under investigation. In this context, we note that the methods of analysis and synthesis, induction and deduction were used to delimit the conceptual framework and critically interpret the relevant bibliographic sources. These methods allowed us to identify the major directions of research in the field of intercultural education, analyse the educational strategies proposed by specialists, and correlate them with current university practices.

Empirically, the research was based on direct observation, as a participant-observer, of extracurricular activities carried out in the university environment. This method provided the opportunity to document the organization, capture the dynamics of student interactions, the intercultural communication strategies adopted, and the ways in which cultural experiences are capitalized on in specific educational contexts. Systematic observation was complemented by the analysis of student feedback, which allowed for a qualitative assessment of perceptions regarding the relevance and effectiveness of these activities, as well as the identification of elements that contribute to the development of intercultural competence.

The combination of theoretical and empirical methods facilitated an integrated approach to the phenomenon, allowing the correlation of conceptual dimensions with observed educational realities. In this way, the research aimed not only to describe but also to interpret the architecture of extracurricular activities in foreign languages, with a view to identifying educational strategies that can support the development of intercultural competence in the contemporary university environment.

Following the analysis, a series of effective educational strategies that promote the development

of intercultural competence were identified:

• the use of interactive and collaborative activities;

• the promotion of practical experiences in various cultural contexts;

• the stimulation of critical reflection on one's own attitudes, values, and stereotypes;

• the integration of continuous feedback into the learning process.

Preliminary results showed a significant impact of extracurricular activities on the development of intercultural competence, confirmed by:

• improved foreign language communication skills;

• increased cultural openness and tolerance;

• motivation to participate in intercultural educational activities;

• positive perceptions of the relevance and practical applicability of extracurricular activities.

Thus, through a mixed theoretical and empirical approach, the research provided a comprehensive analysis of the relationship between linguistic and intercultural training in a university context. The methods used allowed not only for the description but also for the critical interpretation of the educational experiences observed, contributing to the identification of strategies that can optimize the development of intercultural competence through extracurricular activities.

3. Findings and Discussion

3.1. The architecture of Extracurricular Activities: Dimensions, Components, Functions

In the current context of globalization, university education can no longer be reduced to the transfer of knowledge in a formal setting. The development of linguistic and intercultural skills requires an integrated approach, in which extracurricular activities (EA) become a privileged space for experimentation, interaction, and reflection.

For the purposes of this research, *the concept of extracurricular activities architecture in foreign languages* reflects a systemic approach to pedagogical design, which integrates structural, functional, methodological, and value dimensions into a coherent construction oriented towards the overall development of the student. This approach is aligned with the principles of intercultural education and experiential learning (Byram, 1997; Deardorff, 2006; Kolb, 1984), as it values interaction, reflection, and action as essential ways of developing intercultural competence. Thus, extracurricular activities become components of an open and reflective educational ecosystem, capable of supporting students' attitudinal and behavioural transformation through authentic intercultural learning experiences.

Thus, the concept of *architecture* is used metaphorically to designate the internal structure, coherence, and dynamics of a set of activities oriented toward complex formative objectives. In an educational context, the architecture of extracurricular activities represents the totality of relationships, strategies, forms, and values that define how these activities are designed, implemented, and evaluated. An operational definition could be as follows: *The architecture of*

extracurricular activities in foreign languages represents a coherent and flexible system of non-formal educational interventions that articulate linguistic, cultural, and social dimensions in a participatory framework, promoting the development of communication and intercultural skills through direct experience, collaboration, and critical reflection. This approach is in line with the principles of intercultural and experiential education, as defined by Byram (1997), Deardorff (2006), and Kolb (1984), emphasizing learning through interaction, reflection, and active involvement in authentic cultural contexts. This architecture is not limited to a succession of isolated activities but involves strategic thinking and an educational vision oriented towards the formation of global citizens, capable of interacting competently and empathetically in diverse cultural contexts.

3.1.1. To understand the complexity of the concept, it is useful to analyse the architecture of EA through the lens of complementary dimensions that reflect its structure, purpose, methodology, and values

✓ *The structural dimension* refers to the organization and typology of extracurricular activities. Depending on the purpose and level of involvement, EA can include:

• linguistic and cultural workshops (thematic workshops, conversation sessions, intercultural laboratories);

• clubs and interest groups (Francophone film clubs, translation clubs, intercultural communication clubs);

• competitions and festivals (olympiads, public speaking competitions, multicultural fairs);

• interdisciplinary and collaborative projects, in partnership with other faculties or institutions;

• study visits, mobility programs, and international partnerships, which ensure direct contact with other cultures and languages.

The structural dimension therefore defines the surface architecture of activities—the concrete way in which they materialize in the educational and social space, as well as the forms of organization (individual, group, institutional, external partnerships).

✓ *The functional dimension* explains the educational goals and functions of EA. These are not only complementary to formal education but also become genuine tools for personal and professional development. Among the essential functions are:

• developing linguistic and intercultural communication skills;

• stimulating intrinsic motivation for language learning;

• promoting multilingualism and European awareness;

• strengthening social skills (cooperation, empathy, leadership, negotiation).

EA thus fulfil an educational, integrative, and transformative function, contributing to the formation of a flexible intercultural identity and the cultivation of openness to diversity.

✓ *The methodological dimension* concerns the pedagogical principles and strategies that underpin the architecture of EA. These are based on the constructivist paradigm and experiential approaches to learning (Kolb, 1984; Dewey, 1938). Frequently used methods include:

• project-based learning, which stimulates collaboration and the application of knowledge in real contexts;

• experiential education, based on direct experience and analysis;

• gamification, as a motivational and active engagement strategy;

• collaborative learning, which values interaction and negotiation of meaning between participants;

• intercultural storytelling, used as a means of expressing identity and developing cultural empathy.

Through these methods, EAs become authentic contexts for meaningful learning, where language is practised as a living tool for intercultural interaction and reflection.

✓ *The value and cultural dimension* is at the heart of EA architecture, giving meaning and purpose to the entire educational process. Extracurricular activities promote fundamental values such as tolerance, respect for diversity, solidarity, team spirit, civic responsibility, and the ethics of dialogue. Therefore, EA contribute not only to the development of intercultural competence, but also to the consolidation of a culture of peace and dialogue, which is essential in a world characterized by mobility and cultural plurality.

Thus, the structural and functional dimension of extracurricular activities highlights their typology and educational goals (Byram, 1997; Deardorff, 2006; Fantini, 2000), while the methodological dimension is based on the principles of experiential pedagogy (Kolb, 1984; Dewey, 1938). The value and cultural dimension gives meaning and purpose to the whole endeavour, promoting values such as tolerance, respect and solidarity (Deardorff, 2009; UNESCO, 2013).

3.1.2. The components of the extracurricular activities (EA) architecture are interdependent, giving coherence and efficiency to this system

✓ The educational vision, focused on the development of intercultural skills and values.

✓ The formative objectives, which aim to develop plurilingual and intercultural competence.

✓ The actors involved, representing the educational community (teachers, students, institutional partners, the socio-economic environment).

✓ Learning spaces, physical and virtual, formal and non-formal, which extend the traditional boundaries of the classroom.

✓ Educational resources, linguistic, digital, cultural, and community-based.

✓ Impact assessment, carried out through portfolios, individual reflection, participatory feedback, and critical self-assessment.

The components listed above function in a dynamic relationship, giving the EA architecture an open, adaptable, and participatory character.

3.1.3. Extracurricular activities essentially fulfil the following major functions

• *Complementary function*, whereby EAs complement the formal teaching-learning process, consolidating the skills acquired and creating contexts for the practical application of knowledge.

• *The integrative function*, which promotes interdisciplinary connections between fields such as tourism, communication, economics, the arts, or international relations.

• *The transformative function*, aimed at shaping intercultural identity, developing critical thinking, and global citizenship awareness.

• *The motivational function,* which stimulates interest in learning and the emotional involvement of students through relevant and authentic activities.

In conclusion, we note that the architecture of extracurricular activities in foreign languages is a complex pedagogical construct, in which the cognitive, affective, and axiological dimensions of education intersect. It reflects an innovative educational vision based on dialogue, partnership, and experience, designed to transform the learning process into a space for cultural co-creation.

Through the strategic integration of these dimensions and functions, extracurricular activities become an essential vector for the development of intercultural competence, a fundamental skill for young people's adaptation and success in today's globalized society. In this sense, the architecture of extracurricular activities represents an organizational and educational framework that promotes openness, empathy, and global responsibility.

3.2. Intercultural Competence (IC): Theoretical and Conceptual Aspects

In the context of globalization and intensified intercultural exchanges, academic and professional mobility, the development of intercultural competence (IC) has become a strategic priority in modern education, particularly in the field of training specialists capable of communicating effectively in foreign languages and interacting harmoniously in diverse cultural contexts, while supporting dialogue, cooperation, and intercultural cohesion.

Intercultural competence is an integrated set of knowledge, skills, attitudes, and behaviours that enable individuals to effectively manage situations of cultural interaction and adapt to multicultural environments.

This competence involves not only knowledge of other cultures, but also critical reflection on one's own cultural identity, empathetic openness, and the ability to negotiate common meanings in intercultural interactions.

3.2.1. The concept of intercultural competence, situated at the intersection of linguistics, pedagogy, psychology, and sociology, is often defined as a set of knowledge, skills, attitudes, and behaviours that enable individuals to effectively manage situations of communication and collaboration between different cultures.

According to researchers in the field Byram (1997), Deardorff (2006), Fantini (2000), intercultural competence (IC) represents a dynamic set of knowledge, attitudes, skills, and behaviours that facilitate effective and appropriate interaction between people from different cultures. In a broad

sense, this involves not only understanding cultural differences, but also developing an attitude of respect, empathy, and openness towards otherness, along with the ability to negotiate culturally and reflect critically on one's own identity.

In the literature, the term is approached from multiple perspectives: cognitive, affective, and behavioural, and is frequently associated with the processes of experiential learning, critical reflection, and cultural adaptation. Recent studies highlight the fact that IC is not a singular competence, but a multidimensional construct in which linguistic, cultural, and social elements combine in a complex structure oriented towards understanding and valuing diversity. In this context, we note that the theoretical analysis of intercultural competence provides the conceptual framework necessary for designing the architecture of extracurricular activities in foreign languages, which become privileged spaces for the formation of intercultural awareness, the development of empathy, reflective thinking, and the ability to adapt to otherness.

The field of interculturality has developed at the intersection of several sciences: pedagogy, linguistics, psychology, anthropology, and sociology. In recent decades, numerous theorists and practitioners (T. Cartaleanu, V. Goraș-Postică, T. Cozma, A. Nedelcu, D. Nicolescu, B. H. Spitzberg, W. R. Cupach, M. Barrett, G. Hofstede, S. F. Trompenaars, R. Hall, and others) have contributed to defining and interpreting the concept, proposing various theoretical and methodological models.

Although there is no universal consensus on a single definition, most authors agree that interculturality involves interaction between different cultures in a framework based on respect, dialogue, tolerance, and equality. In this sense, interculturality involves not only contact between cultures, but also the mutual transformation of participants, which implies an educational and reflective dimension.

Thus, intercultural education is understood as a process of continuous training in the ability to perceive, interpret, and evaluate cultural differences without prejudice, cultivating empathy, critical thinking, and openness to diversity.

3.2.2. Various models and theoretical studies propose structuring IC into several complementary dimensions. Among the most representative are:

1. *The model of B. H. Spitzberg and W. R. Cupach (1984)*

The authors identify several types of competencies that coexist in the structure of intercultural competence:

Knowledge - represents the theoretical and practical understanding of the norms, values, cultures, and social contexts in which communication takes place. It includes information about cultural differences, interaction styles, and accepted behavioural rules, which allow for appropriate adaptation in intercultural situations.

Skill - refers to the ability to apply knowledge in practice, i.e., to choose effective and appropriate communicative behaviours in various contexts. It involves skills such as negotiation, clarity of expression, active listening, empathy, and intercultural conflict management.

Motivation - represents the individual's desire and commitment to communicate effectively and appropriately, including an interest in understanding other cultures and openness to intercultural interaction. It includes positive attitudes such as curiosity, tolerance, openness, and perseverance in complex or ambiguous situations.

Therefore, interpersonal communication competence (which extends to an intercultural context) involves knowledge, motivation, and skills. (Spitzberg & Cupach, 1984)

In our opinion, the following types of skills can be considered a didactic adaptation of the above model, useful for the detailed analysis of intercultural competence in an educational context.

1. Fundamental skills – the ability to adapt and orient oneself effectively in a new cultural environment.

2. Social skills – empathy, the ability to compromise, collaboration, tolerance, and trust.

3. Interpersonal skills – style of interaction in intercultural contexts.

4. Linguistic skills – correct and appropriate use of a foreign language.

5. Communication skills – negotiation and clear expression of ideas in multicultural contexts.

6. Interpersonal skills – behavioural and relational adaptation to diversity.

2. Martyn Barrett's model (2013)

M. Barrett proposes a model based on four key categories that describe the attitudinal, cognitive, and behavioural aspects of intercultural competence:

• Attitudes – respect, curiosity, openness to other cultures.

• Skills – empathy, flexibility, effective communication, critical thinking.

• Knowledge – cultural, linguistic, and sociolinguistic, enabling understanding of one's own culture and that of others.

• Behaviours – appropriate and constructive expression in multicultural interactions.

Thus, in these works, Barrett describes intercultural competence as a set of "values, attitudes, knowledge, understandings, skills, and behaviours which are needed for ... interacting and communicating effectively and appropriately with such people" (Barrett, 2013).

According to a study by Bertelsmann Stiftung (2006), 22 elements were identified by experts in the field of intercultural competence as essential for effective intercultural interaction. This defines intercultural competence, from self-awareness and openness to critical analysis, empathy, cognitive flexibility, and social adaptation. The author emphasizes that no single competence is sufficient on its own. IC results from the complex interaction of several cognitive, affective, and behavioural factors.

A comparative analysis of the models and theoretical study outlined above allows us to identify some common defining elements of intercultural competence:

• Attitudes of respect, empathy, and openness to diversity.

• Knowledge of cultures, values, norms, and communication styles.

• Intercultural adaptation, negotiation, and interpretation skills.

• Cooperative behaviour and constructive dialogue.

• Critical reflection on one's own cultural identity.

At the same time, intercultural competence is formed at the intersection of the cognitive (knowledge), affective (attitude), and behavioural (action) levels, being a transversal competence that supports education for global citizenship and effective intercultural communication.

The development of intercultural competence is closely linked to multilingualism, a phenomenon that reflects the coexistence and use of several languages in a common geographical or institutional space. Multilingualism promotes the transfer of meanings and values between cultures, stimulating mutual understanding and social integration.

In this context, two major dimensions of the impact of intercultural competence can be identified:

1. *Economic dimension* – contributes to the improvement of professional qualifications, performance, and competitiveness in the global labour market;

2. *Socio-cultural dimension* – promotes social inclusion, intercultural dialogue, equal access to education, and respect for diversity.

Summarizing the information obtained, we could define intercultural competence as a complex, dynamic, and integrative capacity that brings together the cognitive, affective, and empathic knowledge, skills, attitudes, and behaviours necessary for effective communication and harmonious adaptation in diverse cultural contexts, by valuing differences and overcoming the limits of cultural diversity.

However, in our view, we insist that intercultural competence remains an operational, vast, complex, and controversial pedagogical concept that is difficult to define, as it encompasses various types, categories, and components, can be approached from multiple perspectives (pedagogical, sociological, psychological, anthropological) at the cognitive, affective, and behavioural levels, has direct connections with communication, language, culture, and values, and is applicable in multiple contexts (formal/curricular, informal/extracurricular, cultural, and, above all, intercultural).

Therefore, intercultural competence is an operational, broad, and multidimensional pedagogical concept, situated at the intersection of the educational, sociological, and communicative fields. The theoretical models analysed converge on the idea that the development of IC requires the integration of cognitive, affective, and behavioural dimensions. In university education, extracurricular activities provide a privileged setting for practising and applying intercultural competencies through direct experiences, collaboration, and reflection. In a world characterized by mobility and cultural pluralism, intercultural competence is an essential condition for active citizenship, social dialogue, and cultural inclusion.

3.3. The Role of Extracurricular Activities in Foreign Languages in Developing Students' Intercultural Competence (IC).

In the context of globalization and cultural diversity, intercultural competence (IC) stands out as an essential component of training specialists capable of interacting effectively in multicultural environments. Extracurricular activities (EA) in foreign languages are, in this context, strategic tools in the educational architecture, complementing the formal learning process and offering authentic, practical, and intercultural experiences. Through systematic organization, EA facilitate the simultaneous development of linguistic, intercultural, and social skills, contributing to the formation of a flexible and adaptable personality.

3.3.1. Classification of extracurricular activities

Extracurricular activities in foreign languages can be defined by a clear structure, in which each activity pursues specific objectives that are integrated into the IC development strategy. They can be classified as follows:

• Socio-cultural activities: student clubs, theatre groups, themed festivals;

• Academic and scientific activities: conferences, symposiums, round tables, debates, workshops, and interdisciplinary projects;

• International mobility programs: Erasmus+, training internships, intercultural projects, and academic exchanges.

The formats are varied and adapted to intercultural purposes: workshops, essay or poster competitions, poetry recitals, exhibitions, thematic trips, and visits to cultural institutions or professional organizations. This methodological diversity allows for the integration of linguistic, cultural, and social dimensions, stimulating the practical application of the knowledge and skills acquired.

3.3.2. Dimensions and roles in the development of intercultural competence

The architecture of foreign language EA integrates several dimensions of intercultural learning. In the specialized literature, cognitive-affective-behavioural are frequently found as a fundamental triad. (Al-Sumait et al., 2023; Huang, 2023). It should be noted that the experiential dimension can be described as an extension/didactic adaptation inspired by experiential learning theory (David A. Kolb, 1984).

• Cognitive: critical reflection on cultural differences and the integration of multiple perspectives;

• Affective: cultivating empathy, tolerance, and respect for diversity;

• Behavioural: practising intercultural communication and teamwork skills.

• Experiential: active involvement in cultural exchanges, interactive activities, and trips that require adaptation to diverse contexts;

Therefore, combining cognitive, affective, behavioural, and experiential dimensions in extracurricular activities in foreign languages contributes to the integrated development of

intercultural competence. Students acquire not only knowledge and skills, but also open attitudes and practical experiences that enable them to communicate, collaborate, and adapt effectively in diverse intercultural contexts. Thus, extracurricular activities prove to be essential tools in the formation of a flexible intercultural identity and a genuine openness to diversity.

3.3.3. Organization and implementation strategies

In our opinion, planning EA within the educational architecture involves clearly defined stages:

1. Defining the theme, purpose, and intercultural objectives.
2. Developing the scenario and content of the activity.
3. Choosing the appropriate forms, methods, means, and tools.
4. Distributing roles and responsibilities among participants.
5. Establishing the optimal time and period for implementation.
6. Identifying the targeted skills and assessment methods.
7. Analysing the results and providing feedback.

These stages ensure a coherent and efficient implementation, transforming EA into genuine spaces for learning, reflection, and personal development (Rusu D., 2023).

3.3.4. Benefits and strategic impact of extracurricular activities

Implementing EA as part of the educational architecture generates multiple benefits:

- Strengthening intercultural and multilingual skills;
- Stimulating curiosity, creativity, and critical thinking;
- Developing adaptability and cooperation;
- Cultivating empathy, tolerance, and respect for diversity;
- Facilitating academic mobility and authentic intercultural experiences;
- Promoting learning through interaction and discovery.

EA contributes to the formation of an open-minded student profile, capable of interacting effectively in multicultural contexts, strengthening both professional and transversal skills.

3.3.5. Determinants of success in acquiring intercultural competence

The success of intercultural competence training through EA depends on two key factors: the teacher/mentor who plans and organizes the activity, stimulates motivation and involvement, and the student/participant who accepts the challenge, gets actively involved, and applies the strategies learned.

Collaboration between the teacher and student, together with clear planning, adherence to the organizational stages, optimal time allocation, and the use of appropriate interactive methods and techniques, ensures that intercultural objectives are achieved and transforms extracurricular

activities into genuine spaces for learning, reflection, and personal development.

Therefore, the architecture of extracurricular activities in foreign languages represents a strategic and integrated framework for developing students' intercultural competence. Through rigorous planning, varied use of forms and techniques, active involvement of participants, and the guiding role of teachers, EA ensure authentic, collaborative, and reflective learning experiences. In this way, the integration of the intercultural dimension into extracurricular activities becomes an essential pedagogical tool for the development of the linguistic and intercultural skills necessary in a globalized professional and social environment.

In the context of academic training, extracurricular activities in foreign languages are the central pillar of the architecture of intercultural competence development. They offer concrete, collaborative, and reflective experiences through which students apply their linguistic and cultural knowledge in real communication situations.

The mechanism for developing linguistic and intercultural skills, as described in the university curriculum for foreign language courses, depends on a number of factors: the quality of teacher-student and student-student interactions, motivation, active involvement, practical and extracurricular activities. Extracurricular academic activities thus become an effective tool and a factor of success in foreign language learning and in strengthening professional and transversal skills.

By their very nature, extracurricular activities reflect multiple goals: intellectual, educational, moral, emotional, aesthetic, linguistic, and cultural, and contribute to the formation of an open personality capable of intercultural dialogue, adaptation, and cooperation. In this sense, the architecture of extracurricular activities becomes a functional model for integrating the intercultural dimension into modern education.

3.4. Strategies for Developing Intercultural Competence (IC) within the Framework of Extracurricular Activities

The architecture of extracurricular activities (EA) in foreign languages provides a strategic and integrated framework for developing students' intercultural competence (IC). It combines practical activities, intercultural experiences, and guided reflection, offering authentic contexts for learning and multicultural interaction beyond the classroom. Within this framework, educational strategies, methods, and tools are selected and structured to facilitate the achievement of the central objective of IC development.

3.4.1. *Practical activities* form the applied foundation of EA architecture. They enable students to transform cultural and linguistic knowledge into concrete communication and collaboration skills. Relevant examples include:

• International collaborative projects, in which students cooperate with colleagues from partner universities;

• Interactive workshops and thematic clubs (e.g., English Club, La Francophilie), which explore culture through traditions, gastronomy, music, and art;

• Simulations and role-playing games designed to reproduce real intercultural situations;

• Case studies analysing intercultural conflicts and dilemmas.

Skills developed: effective intercultural communication, working in multicultural teams, cultural empathy. These activities develop students' ability to adapt their language, behaviours, and collaboration strategies in diverse cultural contexts.

***3.4.2. Intercultural experiences* complement the practical dimension and allow the consolidation of skills through immersion and interaction, offering direct contact with cultural diversity.**
Examples of practices:
• **Academic exchanges and short-term mobilities** (e.g., Erasmus+, summer programs) that facilitate learning through immersion;
• **International virtual meetings and debates**, which support interaction with native speakers and peers from different cultures;
• **Volunteering and service-learning in multicultural communities**, which provide opportunities to apply the foreign language and to understand real cultural contexts.

Skills developed: cultural adaptability, openness to diversity, management of intercultural conflicts. These experiences contribute to strengthening resilience, flexibility, and the ability to navigate effectively in complex cultural contexts.

3.4.3. *Intercultural experience*s complement the practical dimension and allow the consolidation of skills through immersion and interaction, offering direct contact with cultural diversity.
Examples of practices:
• **Academic exchanges and short-term mobilities** (e.g., Erasmus+, summer programs) that facilitate learning through immersion;
• **International virtual meetings and debates**, which support interaction with native speakers and peers from different cultures;
• **Volunteering and service-learning in multicultural communities**, which provide opportunities to apply the foreign language and to understand real cultural contexts.

Skills developed: cultural adaptability, openness to diversity, management of intercultural conflicts. These experiences contribute to strengthening resilience, flexibility, and the ability to navigate effectively in complex cultural contexts.

3.4.4. *Guided reflections* allow students to become aware of their own values, stereotypes, and cultural attitudes, and enable the adjustment of intercultural behaviours.
Examples of practices:
• **Reflection journals** on intercultural experiences;
• **Guided discussions and debriefing** after activities or simulations;
• **Critical analysis of cultural environments and situations**, in order to identify barriers and learning opportunities.

Skills developed: self-cultural awareness, intercultural critical thinking, self-assessment, and

continuous intercultural learning. These processes enable students to value diversity, adjust their behaviours, and improve their intercultural communication strategies.

3.4.5. Integrated educational strategies, methods, and tools
Within the AE architecture, educational strategies are implemented through a combination of specific methods and tools:
• **Cultural exchange projects and international collaboration** – fostering authentic dialogue and intercultural cooperation.
• **Thematic clubs, film and literature circles** – exploring cultural traditions, arts, and media.
• **Simulations and case studies** – developing skills for adaptation and solving intercultural problems.
• **Volunteering and service-learning** – practical experiences in multicultural contexts.
• **Workshops and intercultural competence trainings** – developing empathy, awareness, and critical thinking.

Here is the English translation:

3.4.6. Intercultural competences strengthened through EA

1. **Cultural adaptability** – flexibility and resilience in unfamiliar situations.

2. **Effective intercultural communication** – appropriate use of verbal and non-verbal language, empathy, and active listening.

3. **Cultural openness and empathy** – genuine interest in other cultures, respect, and appreciation of differences.

4. **Intercultural critical thinking** – analysing situations from multiple perspectives and identifying appropriate solutions.

Thus, the architecture of extracurricular activities provides a coherent and structured framework for identifying and implementing educational strategies, methods, and tools that support the development of intercultural competence. The combination of practical activities, intercultural experiences, and guided reflections ensures the acquisition of the linguistic, cognitive, social, and affective competences necessary for effective intercultural interaction, highlighting the active role of students and the support of mentors in shaping IC.

3.5. The Architecture of Extracurricular Activities in Foreign Languages in the Development of Intercultural Competence

The academic environment must be stimulating and diverse, offering each student sustained motivation for personal and professional development. In this context, extracurricular activities (EA) in foreign languages represent strategic tools for enhancing interdisciplinary and cross-curricular connections, as well as for engaging the intellectual-cognitive and emotional-affective resources specific to a holistic education.

3.5.1. The main objectives of EA at the level of the Department of Modern Languages (DML) **include:** increasing motivation for learning foreign languages, encouraging openness to other

cultural values, developing personality and critical thinking, stimulating creativity in group activities, promoting both individual and team work, integrating postmodern educational technologies, promoting ethical-moral and spiritual values, enriching vocabulary, and achieving the objectives in national and institutional development strategies (ASEM).

The architecture of extracurricular activities aims at integrating a coherent set of objectives, strategies, and tools that enable the development of:

- **Intercultural and plurilingual competence;**
- **Critical, reflective, and creative thinking;**
- **Oral and written communication skills;**
- **Cooperation and teamwork skills;**
- **Ethical-moral, cultural, and European values;**
- **Autonomy in learning and the use of postmodern educational technologies.**

3.5.2. Components of the EA architecture at the level of the DML

1. Practical activities – allow the application of linguistic and cultural knowledge in real or simulated contexts:
• collaborative projects and debate competitions;
• thematic clubs and interactive workshops;
• simulations, round tables, and case studies;
• brain-ring contests and presentation sessions.
Competences developed: effective intercultural communication, work in multicultural teams, cultural empathy.

2. *Intercultural experiences* – offer direct contact with cultural diversity and the use of foreign languages in authentic contexts:
• academic exchanges and short-term mobilities (Erasmus+, summer programs);
• international meetings, debates, and workshops;
• volunteering and service-learning in multicultural communities;
• participation in festivals, thematic recitals, exhibitions, poster and essay competitions.
Competences developed: cultural adaptability, openness to diversity, managing intercultural conflicts.

3. *Guided reflections* – enable awareness of personal values and stereotypes, stimulating continuous learning:

• reflection journals and debriefing discussions after activities;
• critical analysis of cultural situations;

• evaluations and feedback from mentors and peers.
Competences developed: self-cultural awareness, intercultural critical thinking, self-assessment, and continuous learning.

Integration of EA into the architecture of the Department of Modern Languages

Over time, the Department of Modern Languages has developed a coherent framework for organizing EA, combining practical activities, intercultural experiences, and guided reflections. This includes:

- student conferences and symposia;
- presentation sessions, round tables, and thematic panels;
- intercultural workshops and applied training sessions;
- national and international events and celebrations;
- essay competitions, poster contests, and cultural festivals, etc.

Active participation in these EA is monitored and academically recognized, motivating students and encouraging their continuous involvement. Through this architecture, EA at the DML level provide an integrated and diversified framework that facilitates the acquisition of the linguistic, intercultural, cognitive, social, and affective competences necessary for effective interactions in a multicultural environment.

3.6. Examples of Good Practices in Developing Intercultural Competence through Extracurricular Activities

In the context of the internationalization of education and the demands of the global labour market, the Department of Modern Languages (DML) within the Academy of Economic Studies of Moldova has developed a coherent and application-oriented architecture of extracurricular activities (EA) in foreign languages, aimed at shaping students' intercultural and linguistic competences. The purpose of this chapter is to highlight examples of good practices implemented within the DML, adapted to the needs of contemporary education and capable of meeting the requirements for training specialists in a multilingual and multicultural environment.

The actors involved in organizing and implementing EA include: the AUF-Moldova National Office, ASEM, the International Relations Service, the Faculty of International Economic Relations, the Francophone University Branches (IER and Tourism), the Francophone Employability Centre (CEF), the ASEM Scientific Library, DLM teaching staff (French, English, and German sections), students, local and international institutional partners.

The joint actions of these actors ensure an integrated dimension in which the cultural, linguistic, professional, and ethical components are combined into a complex educational approach with profound formative impact. For clarity, the examples are structured into categories: thematic socio-cultural activities, academic and scientific activities, international mobility programs, continuing education programs, and international educational partnerships.

1. Thematic socio-cultural activities

This category of EA promotes intercultural dialogue, stimulates interest in culture, reading, and values and traditions—both local and international. These activities are essential for familiarizing students with different intercultural contexts and for strengthening social and linguistic competences, contributing to the development of empathy, critical thinking, and openness to diversity.

1.1. Activities promoting books and reading

These activities highlight reading as a form of intercultural connection, strengthening critical thinking, cultural *expression*, and aesthetic sensibility. They expose students to world literature and culture, offering practical contexts for intercultural reflection: reading clubs, literary salons, round tables, and book exhibitions. Examples include:

- ✓ "Generation Next" Reading Club;
- ✓ Literary Salon "Reading Means Living";
- ✓ Round Table "Books Teach You How to Live";
- ✓ Literary-Artistic Tribute "Ion Hadârcă – A Knight of Metaphor";
- ✓ National Campaign "We Read Aloud Together";
- ✓ Campaign "BiblioASEMia: The Library – Attracts, Satisfies, Educates, Motivates";
- ✓ Project "Book of the Week";
- ✓ Book Exhibition "ACADEMICA".

1.2. Activities promoting national and European values

These activities foster understanding of cultural differences, universal values, and axiological similarities among nations. Events held on commemorative or thematic days (Eminescu, Vieru, Francophonie, Europe Day, Human Rights Day, etc.) facilitate intercultural dialogue. Through active involvement in recitals, panels, debates, or artistic activities, students observe and compare cultural perspectives, strengthening their intercultural competences. Examples include:

✓ Mihai Eminescu's Birthday (15 January) – Poetry Recital *"We Read Eminescu"*, cultural activity *"Reading Aloud from Eminescu's Journalism"*;

✓ Grigore Vieru's Birthday/National Reading Day (14 February) – Round Tables *"A Good Book Is a Good Friend"*, *"One Book, One Voice, Many Ears"*, *"The Joy of Reading"*, Online Questionnaire *"Reading Practices"*;

✓ St Valentinés Day (February 14) / 'Dragobete' (February 24) - Cultural and artistic activities: "St. Valentine Party", "Dragobete - the feast of love", " Le véritable amour est une langue que le sourd peut entendre et l'aveugle peut voi".

✓ International Women's Day (March 8) - Literary café: "Merci, Mesdames!".

✓ Europe Day (May 9) - Discussion panels: "L'Europe à la une!", " OUI à l'Europe!", "European Kaleidoscope", Film club: "À la découverte du Parlement Européen".

✓ International Students' Day (November 17) - Discussion panels: "Etudier pour évoluer ", "I am proud to be a student", " La jeunesse c'est le printemps de la vie ", " Est-il facile d'être jeune?",

✓ European Day Against Human Trafficking (October 18) - Round tables: "Human trafficking is inhumane. Sois libre! Les trafiquants vendent des rêves ".

✓ International Human Rights Day (December 10) - Discussion panel: "Protecting fundamental human rights in the EU".

1.3. Activities for developing professional competence

These activities help students build professional and intercultural skills by engaging them in real or simulated contexts of international communication and cooperation:

✓ Training Workshop *"*Étudiants visionnaires: naviguer dans l'Intrapreneuriat et l'Entrepreneuriat;

✓ Panels: *"*Entrepreneurs français qui ont changé le monde*", "Market Leader in Education", "Encouraging Leadership for 30 Years"*;

✓ Student Contest *"*La puissance économique des villes française*"*;

✓ Essay Contest *"*Le rôle du facteur linguistique dans la formation des futurs économistes*."*

1.4. Activities dedicated to multilingualism and plurilingualism

Organized on occasions such as International Francophonie Day, European Day of Languages, English Language Day, etc., these activities stimulate linguistic awareness and cultural sensitivity: debates, festivals, contests, exhibitions. Examples include:

✓ Interuniversity Contest *"Francophonie – Tradition and Innovation at ASEM"*;

✓ Brain-ring competitions: "À travers l'économie", "Business ethics", "Connaissez-vous la France?"

✓ Debates: "Enjeux des jeux", "Multilingualism - an asset for the new generation?!", "Towards a business culture: mindsets, behaviours, ethics"

✓ Festivals: "Kaléidoscope francophone", "Mosaïque francophone"

✓ Discussion panels: "Qui langue a, à Rome va", "Languages - the treasure of Europe", "A virtual round trip in England", "Eine virtuelle Reise nach Deutschland"

✓ Essay competitions: " Mon idée pour le français", "Le rôle du professeur dans l'enseignement supérieur"

✓ Poster competitions/exhibitions: "J'aime la francophonie ", "Dimensions francophones ", "La francophonie en Moldavie"

✓ Themed exhibitions, flash mobs, etc. constitute authentic experiences of cultural-linguistic interaction and creative expression (Rusu D., 2023)

2. Academic and scientific activities

These activities complement the socio-cultural dimension by offering opportunities for theoretical

and practical enrichment in intercultural and professional contexts. Round tables, workshops, student scientific conferences, and international symposia encourage dialogue among students, faculty, and specialists from diverse cultures. By actively participating in these events, students acquire skills in academic and professional communication, the ability to conduct intercultural analysis, and a collaborative spirit in international contexts, becoming familiar with international academic practices.

2.1. Activities to promote multi- and plurilingualism. EA in an academic context offers opportunities for research, collaboration, and intercultural reflection. Among the most representative activities of this kind are:

✓ Round tables: "Europe Connected Through Linguistic Diversity, Intercultural Dialogue and Economic Cohesion," "Global Visions on Business: Exploring the Future from the Perspective of Economic Resilience in a Multilingual World," "Nous sommes Francos!," "Advertising - a Form of Brainwashing," "Landeskunde - Kompetenz durch aktuelles Wissen. Tatsachen über Deutschland."

✓ Interdisciplinary workshops on the Internet, the metaverse, and global trends;

✓ Student Scientific Conference *"Current Economic, Social, and Political Issues in the Vision of Young People"*;

✓ Youth Researchers' Symposium – panels on culture, economy, linguistic diversity, and intercultural negotiation;

✓ National Scientific Conference *"Multilingualism and Interculturality in the Context of Globalization"*.

3. Academic mobility programs

International mobility programs are an essential component of higher education for the development of intercultural skills. They provide economics students with direct intercultural and linguistic learning experiences at partner universities across Europe, facilitating adaptability, empathy, and intercultural communication. In this context, we note that participation in the Erasmus+ program at the University of Liechtenstein, the Konrad Adenauer Foundation's Sur-Place program, internships, and academic exchanges allow students to experience various educational and cultural systems, strengthening linguistic and intercultural skills in a real-world setting.

4. Continuing education programs

In parallel, the workshops and continuing education programs implemented by the Francophone Employability Centre in collaboration with other partner entities provide students with practical tools for integration into a multicultural professional environment and for the development of creativity, leadership, and communication skills. In this regard, we mention:

✓ Trainings: "Aide à l'intégration dans l'entreprise: des astuces francophones dans un environnement économique multiculturel," " La créativité au service de l'entrepreneuriat et de

l'innovation," " Communication du projet professionnel personnalisé et premiers pas en techniques de créativité".

✓ Workshops: "Campus France: Study Opportunities in France," "Intercultural Exchange: From Understanding to Friendship."

5. International educational partnerships

Projects and collaboration programs with institutions from France, Morocco, Lebanon, or other countries allow the involvement of visiting lecturers and international trainers in both teaching and extracurricular activities, providing students with authentic examples of good intercultural practices. Overall, mobility programs and international partnerships strengthen intercultural knowledge and skills through direct experience and global collaboration. An example of good practice in international educational partnership is:

✓ The project "Development of Sciences in French in the Republic of Moldova" / Développement des sciences en français en République de Moldavie, implemented in collaboration with the AUF-Moldova National Office, involved trainee lecturers from Morocco and France in scientific, teaching, and extracurricular activities (2022–2024).

✓ The program "Formation de formateurs à l'accompagnement entrepreneurial" strengthened the practical dimension of extracurricular activities, ensuring the transfer of expertise and pedagogical innovation with the participation of experts and trainers from France, Lebanon, and Morocco.

Thus, the examples of good practices presented confirm that EA in foreign languages represent a key pillar of the educational architecture of the Department of Modern Languages, contributing to:

1. the formation of integrated intercultural, linguistic, and professional competences;
2. the stimulation of empathy, adaptability, and critical thinking;
3. the strengthening of collaboration among institutional actors and the academic community;
4. the promotion of an education oriented toward action, reflection, and international cooperation.

Consequently, the architecture of EA becomes an open and dynamic educational ecosystem in which intercultural learning experiences are cultivated through thematic socio-cultural activities, academic and scientific events, international mobility programs, continuing education initiatives, and international partnerships. EA implemented through collaboration with institutional actors highlight the formative potential of foreign languages in building intercultural competence at the university level.

3.7. Round Table and Panel Discussion – Extracurricular Activities with an Impact on Intercultural Competence and Language Communication Skills

Within institutional strategies for developing intercultural competence and language communication skills, extracurricular activities are planned and implemented according to a

coherent architecture that combines cognitive, affective, and socio-cultural objectives with modern teaching-learning methods, techniques, and tools. Two relevant examples carried out at ASEM with Francophone and Francophile students illustrate how the round table and panel discussion can leverage extracurricular activities to develop intercultural competence (IC) and language skills.

3.7.1. Round Table "The Book Teaches You How to Live" / "Le livre fait vivre" – Activity for Promoting Reading and Universal Culture. The extracurricular activity dedicated to the National Reading Day (February 14) was organized in collaboration with the European Union Information Centre within the ASEM Scientific Library.

***Target audience*:** Francophone and Francophile students from various ASEM faculties, special guests, professors, library staff, and two student-moderators from each faculty.

Purpose: Encouraging reading in the native language and in foreign languages, cultivating a love for books and beauty, and stimulating activity in reading rooms.

Main objectives:

1. Developing intercultural competence and language communication skills (reading, listening, oral and written expression).
2. Strengthening multicultural competence and interest in world literature and authors' biographies.
3. Stimulating heuristic skills, raising general cultural awareness, and enriching vocabulary.
4. Developing existential competence and sociocultural knowledge; promoting European and Francophone values.
5. Raising intercultural awareness and sensitivity toward universal culture.
6. Developing practical skills, creativity, and teamwork.
7. Utilizing the playful and imaginative dimensions of language through aesthetic activities.

Strategies and tools used: PowerPoint presentations on relevant literary works, thematic posters, interactive activities (crosswords, aphorism commentary, identifying authors), video and audio sequences, poetry reading, musical and entertainment breaks.

Learning outcomes: Students were able to carry out communicative and mediation activities, interpret and synthesize information from authentic texts, use vocabulary and linguistic expressions correctly, cooperate effectively in groups, utilize the artistic and playful dimension of language, and recognize the role of the book as a source of information, emotion, and reflection.

Recognition of participants: Certificates of participation, diplomas for organizers, small gifts from the EU Delegation in Moldova.

3.7.2. Panel Discussion "YES! to Europe" / "OUI! à l'Europe" – Activity for Promoting Intercultural Dialogue and European Values. The event was organized on the occasion of Europe Day (May 9), in collaboration with the European Union Information Centre within the ASEM

Scientific Library.

Target audience: Francophone and Francophile students from ASEM faculties, special guests, professors, library staff, and two student-moderators from each faculty.

Purpose: Promoting intercultural dialogue and common European values (democracy, human rights, rule of law) in the context of cultural and linguistic diversity.

Main objectives:

1. Developing intercultural competence and language communication skills (reading, listening, oral discourse, and written expression).
2. Strengthening multilingual and multicultural competences, cultivating interest in European and Francophone values.
3. Familiarizing students with EU history, symbols, founding personalities, and the benefits of European integration.
4. Stimulating learning capacity and critical thinking, developing general culture and vocabulary.
5. Developing existential competence and sociocultural knowledge; promoting European and Francophone values.
6. Raising intercultural awareness and sensitivity toward European traditions, gastronomy, and languages.
7. Developing practical skills and intercultural abilities through creative, reflective, and group activities.
8. Utilizing the playful, artistic, and imaginative dimensions of language.
9. Identifying opportunities offered by multilingualism, interculturality, and European integration.
10. Training in the use of the EU Electronic Library website.

Strategies and tools used: PowerPoint presentations, virtual tours of Europe, interactive and cognitive activities (crosswords, games, quizzes), opinion polls, video and audio sequences, thematic posters, and interactive discussions.

Learning outcomes: Students were able to read and interpret authentic texts, use vocabulary correctly, communicate coherently and fluently, analyse and synthesize information, creatively utilize digital resources and ICT, cooperate in teams, and demonstrate an open and empathetic attitude toward European and intercultural values.

Recognition of participants: Certificates of participation, appreciation diplomas for organizers, small gifts from the EU Delegation in Moldova (Rusu D. & Amorțitu A., 2024).

3.7.3. Conclusions and applied reflections

The analysis of the above extracurricular activities confirms that they provide an effective framework for developing intercultural competence and language communication skills.

The architecture of these activities was designed to integrate multiple components:

1. Structure and planning:

The events—the round table "The Book Teaches You How to Live" / "Le livre fait vivre" and the panel discussion "YES! to Europe" / "OUI! à l'Europe"—were meticulously planned, with scenarios, materials, and clearly assigned tasks, ensuring coherence and efficient execution. Preparations began after the winter session, and the activities were conducted during optimal periods without overlapping with exams.

2. Teaching strategies:

The activities combined interactive, communicative-action, and heuristic methods: PowerPoint presentations, cognitive and playful games, thematic discussions and debates, audio-video sequences, posters, flashmobs, workshops, and virtual tours. These strategies enabled a multidimensional approach to developing linguistic, intercultural, cognitive, and social competences.

3. Integration of key competences (IC and language skills):

Each activity aimed at simultaneous development of:

- **Savoirs (knowledge):** literary culture, European and universal values, sociocultural elements.
- **Savoir-faire (practical skills):** oral and written expression, presentations, group communication, intercultural cooperation.
- **Savoir-être (existential competence):** open attitude, empathy, tolerance, social responsibility.
- **Savoir-apprendre (autonomous learning):** identifying sources, using ICT tools, critical evaluation of information.

4. Learning outcomes and practical impact:
Participating students demonstrated:

- Ability to interpret and synthesize information in foreign languages.
- Active participation in intercultural dialogue and debates.
- Creative use of language through posters, cognitive games, and audio-video sequences.
- Awareness of the value of reading, European culture, and linguistic diversity.
- Strengthened inter-faculty cooperation and reduced fear of public speaking.

***5. Constructive feedback and overcoming obstacles*:** Prompt interventions for individual problems (excessive emotions, lack of confidence, inexperience) and linguistic challenges (pronunciation, oral/written expression) ensured engagement and motivation of all participants, maintaining a positive and stimulating atmosphere.

Thus, these activities not only complement curricular learning but also represent a model of applied extracurricular architecture: connecting linguistic, intercultural, and socio-professional objectives, leveraging institutional resources, and stimulating personal and professional development of students.

Active participation in institutional extracurricular activities in foreign languages confirms:

- The essential role of extracurricular activities in shaping intercultural competence and language communication skills.
- The efficiency of integrating teaching strategies, interactive methods, and ICT tools.
- The positive impact on student autonomy, creativity, and collaboration.
- The contribution to developing an open, inclusive, and European academic culture.

The experience gained through these activities constitutes a model of good practice for designing future extracurricular activities in foreign languages, aimed at strengthening intercultural and linguistic competences necessary for young people in a global and European context.

4. Conclusions and Recommendations

1. The architecture of extracurricular activities (EA) is shaped as a complex, multidimensional system, integrating organizational, pedagogical, and intercultural components with formative, motivational, and integrative functions. It facilitates the organization of round tables, panel discussions, workshops, festivals, and collaborative projects.

2. Intercultural competence (IC) is a dynamic and integrative construct, resulting from the interaction of linguistic, sociocultural, and communicative-action competencies. It develops effectively in both formal contexts and through extracurricular activities, providing students with the ability to interact successfully in multicultural and multilingual environments.

3. Extracurricular activities in foreign languages allow the transfer of theoretical knowledge into real communication situations, strengthening empathy, cultural openness, cognitive flexibility, and intercultural mediation skills—essential elements for shaping a professional profile suitable for a globalized society.

4. Integrated educational strategies: project-based learning, professional simulations, intercultural debates, international collaboration, and guided reflection stimulate critical

thinking, autonomy, creativity, negotiation skills, and active student engagement, facilitating the transfer of competencies into complex professional and social contexts.

5. Thematic events and active student involvement provide a practical framework for developing intercultural and multilingual competence, reducing language anxiety, increasing motivation and responsibility, and promoting values such as empathy, tolerance, and cooperation.

6. Cooperation among faculty, institutions, and international partners maximizes the impact of extracurricular activities, supporting the internationalization of education, intercultural exchanges, and the consolidation of communication and intercultural adaptability skills.

7. Systematic integration of extracurricular activities into the educational architecture ensures coherence between formal learning and practical experiences, creating a favourable environment for lifelong learning and the consolidation of intercultural competence.

8. Multilingualism and cultural diversity are foundations of European identity and modern education; extracurricular activities enable students to leverage cultural differences without losing their own identity, developing communication, mediation, and intercultural interaction skills.

9. Identified best practices confirm that extracurricular activities contribute to the internationalization of the educational process and the formation of an academic identity open to pluralism, preparing students for the challenges of globalization and European integration.

10. Sustainable implementation of extracurricular strategies requires an integrated institutional vision, continued organization of thematic activities, creation of student clubs and circles, recognition of student involvement, and assessment of impact, in order to consolidate a durable architecture for intercultural competence and language skills.

Recommendations

1. **Develop a structured model of extracurricular activities (EA)** tailored to the needs of higher education and aligned with intercultural and linguistic training objectives, integrating thematic activities, intercultural projects, and international collaborative experiences.

2. **Evaluate the impact of EA on intercultural competence development** using tools that measure linguistic, sociocultural, and behavioural progress, to optimize teaching and organizational strategies.

3. **Continue and diversify extracurricular activities**, including debate clubs and thematic circles, to reinforce lifelong learning, student autonomy, and the interdisciplinary integration of intercultural competencies.

4. **Provide ongoing professional development for faculty** in interactive and action-oriented methods to support the development of students' critical thinking, negotiation skills, and intercultural competencies.

5. **Promote internationalization and leverage multilingual experiences** through institutional collaborations, academic mobility, and joint projects, contributing to the formation of students' European and global identities.

Mapping Albania's Cultural Heritage: A Spatial and Typological Analysis of Tangible and Intangible Assets

Mishela RAPO [1*]

ORCID 1: 0009-0000-9263-0146
[1]MSc. Mishela Rapo, European University of Tirana, Faculty of Economics, Business, and Development, Department of Management and Marketing
mishelarapo@gmail.com (Responsible Author)

Abstract

This study analyzes the spatial distribution and typological composition of Albania's cultural heritage, drawing on data from the national inventory of tangible and intangible assets. Using a descriptive-analytical approach supported by Excel-based data processing, the research provides a comparative overview of heritage representation across the country. Findings reveal that tangible heritage constitutes the most comprehensively documented component of Albania's cultural landscape. Monuments, archaeological sites, historical architecture, and religious structures collectively account for more than two-thirds of all recorded elements. These assets are widely represented across regions, with the highest concentrations in Gjirokastër, Berat, Vlorë, Tirana, and Korçë, reflecting their enduring historical and architectural significance and their potential for heritage-based tourism development. In contrast, intangible heritage appears significantly underrepresented in the national register. The recorded data include only three regions, Gjirokastër, Korçë, and Shkodër, where traditional crafts, polyphonic music, rituals, and gastronomy are officially recognized as cultural assets. This limited spatial scope highlights major gaps in the systematic documentation and territorial integration of living heritage. The resulting imbalance between tangible and intangible heritage underscores the need for a more comprehensive and geographically inclusive inventorying framework. The study recommends the development of an integrated geo-information system that would enable more accurate mapping, monitoring, and policy coordination of cultural assets. Such an approach would strengthen Albania's capacity to preserve, promote, and manage its diverse heritage, ensuring that both material monuments and living traditions contribute to sustainable regional development and cultural identity preservation.

Keywords: *Albania; cultural heritage; cultural categories; spatial distribution; geo-information system; heritage documentation*

1. Introduction

Cultural heritage constitutes one of Albania's most valuable national resources, shaping collective identity while offering significant opportunities for sustainable tourism and local development (Rapo & Kruja, 2024). In recent years, the growing recognition of culture as a development driver has elevated the importance of documenting and understanding heritage assets not only for preservation but also for their potential contribution to economic growth and place branding (Perry, 2023; Rapo & Zenelaj, 2025). Despite the increasing emphasis on heritage in national and international strategies, comprehensive analyses of Albania's cultural inventory remain scarce. Most existing studies address individual heritage categories or local case studies, while systematic, data-based evaluations of both tangible and intangible assets are limited (Brokaj, 2024; Kruja & Berberi, 2019; Bashi, 2015). This gap restricts the ability of policymakers and tourism planners to understand how cultural resources are spatially distributed, legally protected, and thematically classified across the country. Moreover, integrating cultural heritage into tourism strategies requires a clear understanding of its quantitative structure and regional dynamics. This study

addresses an empirical, methodological, and contextual research gap in Albania's cultural heritage analysis. It offers the first nationwide, data-based examination of both tangible and intangible assets, highlighting regional disparities and documentation gaps. By applying a descriptive-analytical approach and recommending GIS integration, the study contributes to more effective heritage mapping, policy planning, and sustainable cultural management.

Literature Review

Albania's Cultural Potential

Albania possesses one of the most diverse cultural landscapes in Southeast Europe, shaped by millennia of human habitation and intercultural exchange. Scholars have emphasized that the country's geographic position, between East and West, has produced a unique synthesis of Illyrian, Byzantine, Ottoman, and Mediterranean influences (Doempke, 2016; Vietti, 2019; Sawicka, 2013). This cultural hybridity has endowed Albania with an exceptional wealth of both tangible and intangible heritage resources that extend across its urban centers, coastal zones, and rural territories (Rapo & Zenelaj, 2025). The national and international academic literature increasingly links this cultural diversity to sustainable economic and social development. As Bellos et al. (2022) argue, heritage-based tourism has emerged as one of Albania's strongest comparative advantages, providing a bridge between cultural preservation and market-oriented growth. However, despite its potential, the sector remains under-researched and under-utilized due to fragmented data systems, insufficient documentation, and limited community participation in heritage management (Dollma, 2010 Dollani et al., 2016; Dobjani et al., 2025). Strengthening heritage governance and integrating local communities are thus essential for transforming cultural assets into sustainable tourism resources (Seidl, 2014; Bashi, 2015).

Tangible Cultural Heritage

Albania's tangible cultural heritage reflects millennia of artistic, architectural, and religious development. The country's earliest UNESCO recognition dates to 1992, when the archaeological site of Butrint was inscribed on the World Heritage List. Situated in southern Albania, Butrint contains remains from the Hellenistic, Roman, Byzantine, and Venetian periods, including a Greek theater, Roman baths, and a medieval fortress-an exceptional testimony to the continuity of Mediterranean civilizations (Doempke, 2016; Wilkes, 2008). In 2005, Gjirokastër, known as the "city of stone," was added to the World Heritage List for its well-preserved Ottoman-era houses, two-story stone dwellings, and bazaar architecture. Three years later, in 2008, the historic center of Berat-the "city of a thousand windows"-was incorporated, forming the joint inscription "Historic Centres of Berat and Gjirokastër." Together, these cities illustrate the coexistence of Christian and Muslim communities and the synthesis of Byzantine, Ottoman, and vernacular design (Vietti, 2019). In 2017, Albania's participation in the multinational property Ancient and Primeval Beech Forests of the Carpathians and Other Regions of Europe expanded its recognition to include natural heritage. Two years later, in 2019, the Albanian section of the Natural and Cultural Heritage of the Ohrid Region-shared with North Macedonia-was also inscribed on the World Heritage List. This site encompasses archaeological remains and the early Christian church of Lin near Pogradec, reflecting the region's enduring sacred landscape (UNESCO World Heritage

Centre, n.d.). Beyond the UNESCO-listed monuments, Albania's national register records 3,381 tangible assets, including urban ensembles, monasteries, mosques, bridges, and water mills (Ministry of Tourism and Environment, nd). More than 60 percent of these are designated as first- or second-category protected monuments, underscoring their cultural and geographic breadth (Bellos et al., 2022). Religious structures such as the Church of St. Mary in Apollonia, the Lead Mosque in Shkodër, and the Ardenica Monastery in Fier demonstrate Albania's historic interfaith coexistence (Murzaku, 2015). Despite this wealth, several studies note persistent challenges in conservation management, including maintenance deficiencies and incomplete documentation (Bashi, 2015; Dollani et al., 2016). Effective preservation requires integrated strategies among public institutions, local governments, and the private sector to ensure systematic care and sustainable reuse. When properly managed, Albania's tangible heritage serves as both a foundation of national identity and a driver of cultural tourism (Seidl, 2014).

Intangible Cultural Heritage

Parallel to its material monuments, Albania possesses a vibrant intangible cultural heritage that continues to shape community life through music, ritual, craft, and gastronomy. The country's earliest recognition in this field came in 2005, when Albanian Folk Iso-Polyphony was proclaimed by UNESCO World Heritage Centre (n.d.) as a Masterpiece of the Oral and Intangible Heritage of Humanity. This multipart vocal tradition, centered in southern Albania, represents one of Europe's oldest surviving polyphonic systems and is performed at weddings, funerals, and local festivals (Wheeler, 2018; Lici, 2023). In 2022, UNESCO World Heritage Centre (n.d.) inscribed the Xhubleta-the traditional bell-shaped skirt and its associated artisanal techniques from the Northern Albanian Alps-on the List of Intangible Cultural Heritage in Need of Urgent Safeguarding. This recognition highlights both the craftsmanship and the symbolic role of the Xhubleta as an expression of female identity and cultural continuity. One year later, in 2023, UNESCO World Heritage Centre (n.d.) added the Kcimi dance of Tropojë, a northern folk performance emphasizing rhythm and group coordination, to the Representative List of the Intangible Cultural Heritage of Humanity. This was followed by Albania's participation in multinational nominations such as Transhumance, the traditional seasonal migration of livestock across Mediterranean mountain routes, emphasizing ecological and pastoral knowledge shared across regions. According to national records, Albania lists 99 intangible elements, nearly half of which pertain to traditional craftsmanship (Bushati, 2017; Kruja & Berberi, 2019). Music and performing arts form another central pillar, encompassing civic songs of Shkodër, Serenata Korçare, and Sazet e Vlorës, each representing unique local soundscapes. Seasonal festivals such as Dita e Verës (Summer Day) in Elbasan and culinary practices like Lakror me Saç continue to sustain local identity through collective celebration and shared knowledge (Laurìa et al., 2020). As Novik (2020) and Rapo and Zenelaj (2025) argue, safeguarding intangible heritage requires not only preservation but activation-through festivals, craft fairs, educational workshops, and experiential tourism. Promoting these living traditions alongside architectural monuments enhances Albania's cultural diversity, economic sustainability, and national identity, ensuring that heritage remains a dynamic force connecting past and present.

2. Materials and Methods

This study used a descriptive-analytical approach based on secondary data from Albania's National Cultural Heritage Inventory, the official register documenting both tangible and intangible assets. The dataset, updated to 2025, included 3,381 tangible and 99 intangible elements. Tangible heritage data were first organized by category (architecture, archaeology, religion, nature, etc.), legal protection status (Cultural Monument I, II, Protected Area, etc.), and geographical distribution (region and municipality). This allowed for comparison of heritage density and typology across regions. Intangible heritage data were then separated and grouped by domain, such as crafts, music, rituals, gastronomy, professions, and oral expressions. Each element was coded thematically to identify patterns and enable comparison between regions. Quantitative analysis was conducted in Microsoft Excel, using frequencies and percentages to calculate the distribution of heritage types and their spatial concentration. Tables were created to illustrate these results clearly. Finally, an interpretive synthesis helped connect the numerical findings with broader cultural and regional contexts. This step-by-step process, from data collection and classification to analysis and interpretation, ensured accurate, comparable, and meaningful insights for improving heritage documentation, management, and sustainable tourism planning.

3. Findings and Discussion

The analysis of Albania's national heritage inventory provides a comprehensive overview of the country's tangible and intangible cultural resources, revealing their typological diversity, geographical distribution, and protection status. The results demonstrate that cultural heritage constitutes the dominant component of Albania's tourism and identity assets, both in terms of quantity and spatial representation.

The national inventory includes 3,381 tangible elements, encompassing monuments, archaeological sites, traditional architecture, natural assets, and other protected areas. This large dataset illustrates the remarkable density of heritage resources across the Albanian territory. The data reveal that cultural heritage forms the majority of the inventory, reflecting the deep interconnection between history, identity, and landscape. The analysis by region shows that heritage assets are widely dispersed, though a clear concentration exists in southern Albania. The Gjirokastër region leads with 697 elements (20.6%), followed by Berat (16.8%), Vlorë (10.9%), Tirana (10.5%), and Korçë (9.0%). These regions correspond to major historical centers with rich urban architecture and strong cultural identity. Gjirokastër and Berat stand out as UNESCO-listed cities with preserved urban cores, while Vlorë and the surrounding southern area include important coastal, archaeological, and religious sites, such as the ancient city of Butrint. Tirana's high representation reflects its dense concentration of urban monuments, museums, and Ottoman-modern heritage layers. The regional pattern highlights a clear southern and central dominance, with heritage often clustered in cities historically linked to trade, religion, and culture. In terms of classification, cultural tourism resources dominate with 73.7% of all elements, confirming that heritage-related assets are the backbone of Albania's tourism potential. Nature tourism represents 21.5%, encompassing landscapes, lakes, and natural parks, while smaller shares belong to special interest (3.4%), coastal (1.2%), and event tourism (0.2%). This structure indicates that while Albania's natural beauty is substantial, it is the cultural layer that provides the greatest thematic

depth and distinctiveness for visitors. The subcategory analysis offers further insight into the composition of the national inventory. Heritage and architecture account for 50% of all recorded elements, representing castles, museum towns, and traditional houses. Natural resources follow with 18.7%, while archaeological sites make up 11.4%. Religious heritage comprises 9.4%, confirming the importance of sacred architecture in Albania's cultural landscape. Smaller yet significant portions belong to speleological sites (3.4%), museums and memorials (3%), and mountain or coastal assets (under 2% each). This typological diversity illustrates how Albania's cultural heritage extends beyond monumental structures to include everyday expressions of human interaction with the landscape. The protection framework of heritage assets is relatively robust. Cultural Monuments of Category I-those of national importance-represent 36.9% of all recorded elements, while Category II-regional or local significance-comprises 28.9%. Natural Monuments account for 20.5%, and Protected Areas for 5.9%. When aggregated, Cultural Monuments (I+II) constitute 65.8% of the entire inventory, underscoring the dominance of cultural over natural heritage within Albania's protected landscape. This structure shows a mature legal recognition of built heritage, though it also indicates a relative underrepresentation of natural sites in formal protection schemes. At the municipal level, the most represented areas include Berat (14%), Gjirokastër (13.4%), Tirana (8.7%), Shkodër (5.4%), and Elbasan (3.4%). These cities form the backbone of Albania's heritage network, containing key examples of urban fortifications, civic architecture, and religious landmarks. UNESCO recognition further enhances their international significance: Butrint (1992), Berat (2005), and Gjirokastër (2005) are designated as World Heritage Sites, forming the cornerstones of Albania's global cultural identity (Table 1).

Table 1. Summary of Albania's tangible cultural heritage (N=3,381) (Ministry of Tourism and Environment, n.d.)

Main dimension	Core values	Number	Percentage (%)	Observations / Examples
Total elements	–	3,381	100.0	Registered in the national database
Distribution by regions (Top 5)	Gjirokaster	697	20.6	High concentration of monuments and traditional architecture
	Berat	569	16.8	The museum city of Berat (UNESCO) dominates the register
	Vlore	369	10.9	Butrint (UNESCO), archaeological and coastal sites
	Tirana	354	10.5	Urban monuments, museums, Ottoman & modern heritage
	Korce	305	9.0	Museum city, Byzantine church, serenade and architecture
Main categories	Cultural Tourism	2,492	73.7	Dominates over 2/3 of the register

	Nature Tourism	726	21.5	Includes landscapes, natural resources, highlands
	Special interest tourism	114	3.4	Caves, unique practices
	Coastal Tourism	42	1.2	Beaches, marine attractions
	Event Tourism	6	0.2	Rare events related to inheritance
Main subcategories	Heritage/Architecture	1,690	50.0	Castles, museum towns, traditional houses
	Natural resources	633	18.7	Lakes, water sources, natural parks
	Historical/Archaeological	384	11.4	Butrint, Apollonia, ancient sites
	Religious	317	9.4	Churches, mosques, tekkes, monasteries
	Speleology	115	3.4	Protected caves (Pëllumbas, etc.)
	Other cultural sources	101	3.0	Museums, memorials, ethnographic centers
	Mountain	50	1.5	Traditional roads, iconic mountains
	Coast/Beach	44	1.3	Protected coves, bays and beaches
Legal protection statuses	Cultural Monument I	1,248	36.9	Monuments of high national value
	Cultural Monument II	977	28.9	Monuments of regional/local value
	Natural Monument (MN III)	694	20.5	Many caves, natural springs
	Protected area	198	5.9	National parks, protected areas
	Cultural Monuments (I+II)	2,225	65.8	Two-thirds of the register is related to cultural heritage
Most represented municipalities (Top 5)	Berat	474	14.0	Historical and religious monuments of the museum city
	Gjirokaster	453	13.4	Museum city, castles and characteristic neighborhoods
	Tirana	294	8.7	Urban monuments, national museums
	Shkoder	181	5.4	Rozafa Castle, religious and civic heritage
	Elbasan	116	3.4	Elbasan Castle, archaeological ruins
UNESCO key elements	Butrint (1992); Berat & Gjirokastra (2005)	–	–	UNESCO World Heritage, major potential for international cultural tourism

The recorded data on intangible cultural heritage attributes cover just three regions, Gjirokastër, Korçë, and Shkodër, with a total of only 99 registered items. Two Albanian traditions inscribed on the UNESCO Representative List of the Intangible Cultural Heritage of Humanity, Isopolyphony

(Iso-polyphonic folk singing of southern Albania, inscribed 2008) and the Xhubleta (Artisanal skills and women's traditional dress from the Northern Albanian Alps, inscribed 2022), anchor the regional identity of Gjirokastër and Shkodër respectively. Together, these elements illustrate Albania's north–south cultural polarity-one musical and communal, the other artisanal and symbolic-demonstrating how regional specificity contributes to the nation's broader cultural narrative (Table 2).

Table 2. Distribution of Intangible Cultural Heritage Attributes by Region (Register - Intangible Cultural Heritage, n.d.)

Region	Number of Attributes	Percentage of Total (%)	Dominant Heritage Domains
Korçë	37	37.4%	Cuisine, Crafts, Music
Shkodër	32	32.3%	Music, Oral Traditions, Craftsmanship
Gjirokastër	39	39.4%	Rituals, Music, Domestic Heritage
Total	99	100%	-

With 37 recorded attributes (37.4%), Korçë demonstrates a balance between culinary, artisanal, and musical traditions. Culinary practices such as Festa e Lakrorit (Pie Festival), Tava e Koranit (Trout Casserole), and Buka me Qiqra (Chickpea Bread) highlight domestic creativity rooted in agrarian life. Artisanal craftsmanship remains vital, represented by trades such as copperware (kujunjxhiu), pottery, and textile work. Meanwhile, musical traditions like Serenata Korçare and Sazet e Korçës reflect the city's urban refinement and long-standing artistic sensibility. The convergence of craft, cuisine, and song positions Korçë as a hub of cultural synthesis in southeastern Albania. Shkodër's 32 attributes (32.3%) reveal a distinct northern character emphasizing music, oral expression, and craftsmanship. The Xhubleta stands as the region's emblematic heritage element, symbolizing female artistry and ancestral continuity. Musical forms such as Ahengu Shkodran, Kënga Qytetare Shkodrane, and Vallet e Pukës demonstrate a vibrant interplay between folk and urban musical traditions. Handicrafts-including filigree work, Venetian masks, and textile weaving-reflect cross-Mediterranean influences that have historically shaped Shkodër's cultural landscape. Additionally, oral traditions, such as the Gjama e Burrave (Men's Lament) and Proverbat e Dukagjinit (Proverbs of Dukagjin), preserve a strong moral and philosophical ethos rooted in northern customary law and community solidarity. Gjirokastër records 39 attributes (39.4%), marking it as the most diverse region in the dataset. Its heritage is defined by music, ritual, and domestic traditions. Isopolyphony remains a cornerstone of regional identity, performed both in local settings and during the National Folklore Festival of Gjirokastër. Culinary practices such as Trahanaja (fermented grain soup), Gliko e Arrës (walnut preserve), and Llokume me Bajame (almond sweets) reflect household continuity and intergenerational transmission. Rituals like Riti i Llazarëve (Lazarus Day rite) and Paja e Nuses (bride's dowry preparation) express themes of fertility, transition, and social cohesion. Collectively, these practices underscore Gjirokastër's role as a southern stronghold of Albanian musical, ritual, and domestic heritage. The classification of Albania's intangible cultural heritage reveals a diversified structure dominated by traditional crafts and artisanal skills, which account for 30.3% of all

registered elements. This category underscores the enduring importance of manual expertise in practices such as weaving, wood carving, embroidery, and musical instrument making, reflecting both economic and aesthetic dimensions of cultural transmission. Traditional knowledge and practices represent 20.1% of the total, encompassing activities tied to everyday life, seasonal cycles, and material culture, such as food preservation, and wood decoration. Traditional music, song, and dance (17.2%) illustrate the regional distinctiveness of Albania's performing arts, including iso-polyphony and saze ensembles, which have attained international recognition. Gastronomy and food preparation (15.2%) further highlight the role of culinary heritage in social cohesion and identity expression, while rituals, ceremonies, and customs (12.1%) preserve symbolic and spiritual meanings embedded in local traditions. Oral traditions and expressions constitute the smallest proportion (5.1%), suggesting a potential underrepresentation of verbal heritage and narrative forms within the current documentation framework (Table 3). Overall, the data reveal a predominance of tangible, skill-based heritage domains, while knowledge systems and oral expressions appear less documented, indicating the need for more systematic recording and safeguarding of these vulnerable cultural forms.

Table 3. Distribution of Intangible Cultural Heritage Attributes by Category (Register - Intangible Cultural Heritage n.d.)

Category	Examples	Count	Percentage (%)
Traditional Music, Song, and Dance	Iso-polyphony, Saze ensemble of Korça, Saze of Përmet, Shkodra urban song, Aheng of Shkodra, Vlach song of Drenova, Devoll folk song, Serenades of Korça, Singing dances of Ersekë, Dances of Puka, Dances of Dropull, Women's song of Selo, "Majë krahit" song	17	17.2%
Rituals, Ceremonies, and Customs	Korça wedding ceremony, Shkodra wedding ceremony, Childbirth ritual, Lazarus ritual, Spring bracelet ritual, Bride's water ritual, Coffee stone ritual, Funerary ritual, "Poganiqe" ritual, Men's mourning lament (Gjama e burrave)	12	12.1%
Traditional Crafts and Artisanal Skills	Traditional costume making, Weaving on looms, Embroidery, Wool processing, Wood carving, Filigree work, Pottery, Blacksmithing, Saddlery, Tinsmithing, Stone carving, Mask making, Tobacco processing (Sheldia), Musical instrument making (çifteli, sharkia)	30	30.3%
Gastronomy and Food Preparation	"Lakror" pie festival, "Lakrori with corn", "Tava e koranit" (carp dish), "Supa pasha qofte" (meatball soup), Preparation of walnut preserves, Rosewater distillation, Baking under "saç", "Trahana" preparation, Almond Turkish delight, Winter preserves (zahiretë e dimrit)	15	15.2%
Oral Traditions and Expressions	Philosophical proverbs of Dukagjin, Monophonic recitation (Logatja), "Rusticat" of Polena, "Rosicat" of Boboshtica, "Arapët" of Polena" folk narrative	5	5.1%
Traditional Knowledge and Practices	Preparation of dowry (Paja e nuses), Meat drying, Washing in "dërstilë" (wooden washing trough), Grain milling in water mills, Decorative wood carving, Application of motifs in wood, Traditional ceiling carving, Hand knitting and crocheting, Production of salted gherkins	20	20.1%
Total		**99**	**100%**

The analysis highlights a pronounced imbalance between the documentation of tangible and intangible cultural heritage in Albania. While tangible assets-such as monuments, archaeological sites, and historical architecture-are comprehensively recorded and spatially well represented, intangible heritage remains significantly under documented. The national inventory includes only 99 intangible elements, concentrated in three regions: Gjirokastër, Korçë, and Shkodër. This narrow geographical scope fails to reflect the country's rich diversity of living traditions, which extend far beyond these administrative areas. The limited representation points to structural and methodological shortcomings. The absence of systematic field research and irregular data updates have hindered the continuous documentation of non-material practices. Moreover, intangible heritage often depends on oral transmission and community participation-factors that are difficult to capture within conventional bureaucratic recording systems. A comparison with UNESCO's Intangible Cultural Heritage Lists reveals further gaps. While some internationally recognized elements, such as iso-polyphony, are included in the national register, several others are missing. For example, transhumance practices, which are recognized and protected by UNESCO, are not documented in the national inventory. Addressing this disparity requires not only improved data management but also a conceptual shift in heritage governance-from a monument-centered perspective toward an inclusive model that values living traditions equally. Developing a geo-referenced inventory and establishing stronger collaboration with local communities would help integrate intangible heritage into Albania's broader cultural policy and development strategies.

4. Conclusion and Recommendations

Albania's heritage management framework demonstrates clear strengths in the documentation and protection of tangible assets but remains limited in its ability to capture the full scope of intangible cultural heritage. The imbalance between material and living heritage reflects institutional priorities that have historically favored monuments and architecture over community-based cultural expressions. Bridging this gap requires a more integrated and participatory approach to heritage governance. Developing a geo-referenced cultural heritage information system (GIS) would provide a unified platform for documenting, comparing, and monitoring both tangible and intangible assets. Equally important is the establishment of systematic field research programs and stronger collaboration among state institutions, academic bodies, and local communities to ensure the authenticity and continuity of living traditions. Embedding intangible heritage within national cultural policy would enhance regional representation, support identity preservation, and stimulate sustainable cultural tourism. Such an inclusive approach would not only strengthen Albania's alignment with UNESCO principles but also secure sustainable tourism.

Abstract

The colonial period in Bengal (1757–1947) profoundly transformed the architectural landscape, introducing hybrid typologies that reflected a dialogue between European grandeur and indigenous spatial sensibilities. This study explores the form, space, and spatial organization of three exemplary colonial-era houses in Narayanganj, a prominent river port and industrial hub during British rule. Through architectural documentation, spatial mapping, and morphological analysis, the paper examines how colonial domestic architecture in this region negotiated climatic adaptation, social hierarchy, and cultural identity. The selected houses—representing distinct socio-economic and stylistic backgrounds—illustrate variations in planning concepts, façade articulation, and functional zoning. While the external expressions reveal neoclassical and Indo-Saracenic influences, the internal arrangements reflect a nuanced response to Bengali lifestyle and environmental demands, such as cross-ventilation, verandah transitions, and courtyard-centric planning. The study identifies a spatial duality—the coexistence of formality and intimacy, where the imported ideals of order and symmetry were localized through vernacular materiality and living patterns. By analyzing these architectural configurations, the paper contributes to understanding the colonial negotiation between power, culture, and space, offering insight into the evolution of domestic architecture in Bengal. The findings not only emphasize the architectural significance of Narayanganj's colonial heritage but also underscore the urgent need for heritage conservation and adaptive reuse to safeguard these endangered cultural assets for future generations.

Keywords: Colonial architecture, Narayanganj, spatial organization, domestic heritage, form and space

1. Introduction

The built-environment of the Bengal region during the British colonial era presents a compelling terrain for architectural history and spatial analysis. Within the period of British rule, the architecture of Bengal became not merely a technical or aesthetic exercise but a marker of power, identity, and cultural negotiation. As one commentary succinctly puts it, "colonial architecture …

evolved when colonists created a fusion by blending the architectural vocabulary of their country of origin with the design principles of the region they colonized" (The Daily Star, 2018). In the provincial towns of Bengal, domestic residences of landed elites and colonial officials emerged as particularly rich sites for study. Living in the Periphery: Provinciality and Domestic Space in Colonial Bengal investigates the architectural transformations of such houses in nineteenth-century Bengal, observing that new forms of rural-urban mobility, shifting social relations, and colonial governance produced hybrid domestic spatial arrangements (Sengupta, 2007). Against this backdrop, this paper examines three colonial-era houses located in the district of Narayanganj to explore how loftiness—understood here as architectural grandeur, elevated status, and spatial prominence—is expressed through Form (façade, massing, materials), Space (rooms, volumes, circulation), and Spatial Organization (layout, hierarchy, internal/external relationships).

These houses illustrate how colonial domestic architecture in Bengal did not simply replicate European prototypes but negotiated local climate, construction traditions, and sociocultural needs. As studies of vernacular Bengal architecture observe, the region's domestic built-form has deep roots in climatic adaptation, social Organization, and local materiality (Hasan, 2010; Ahmed, 1984). At the same time, the colonial mansions and zamindar houses incorporated European classical detailing, large verandas, tall columns, and elevated foundations to express status and command—a phenomenon examined in the context of Dhaka's zamindar houses (Alam, 2019; Khan, 2006). Focusing on three specific houses in Narayanganj, this research adopts a comparative case-study approach to answer the following questions:

- In what manner do the houses express "loftiness" in their form and façade treatment?
- How are internal spatial volumes and circulation arranged to reflect colonial-era notions of hierarchy and representation?
- How is spatial organization between interior and exterior, private and public zones configured to manifest the social and power dynamics of the period?

In doing so, the paper contributes to the broader discourse on colonial domestic architecture in Bengal by emphasizing the lesser-studied provincial towns rather than the metropolitan capitals. Methodologically, the study is grounded in field surveys, measured drawings, photographic documentation, and archival research. The analysis draws on architectural theory of form and space (Ching, 2014), as well as postcolonial spatial studies, to interpret how built form becomes a vehicle of colonial ideology and local agency. As Sengupta argues, domestic house-forms in colonial Bengal are "typological models of colonial modernity" that reflect multiple overlapping spatial cultures (Sengupta, 2007). In sum, by interrogating the three colonial houses of Narayanganj through the lens of loftiness in form, space, and spatial Organisation, this paper seeks to uncover how architecture served as both a marker and mediator of colonial power and local adaptation. The findings aim to advance understanding of colonial domestic architecture in Bengal and have implications for heritage conservation and the adaptive reuse of such built assets.

1.1. Background / Context

The city of Narayanganj evolved into a prominent colonial river-port and industrial hub during British rule, shaping its architectural identity through the interplay of trade, power, and urban

expansion. The emergence of colonial residential architecture in Bengal reflected a unique synthesis between European stylistic ambition and local climatic, material, and cultural realities (Afzal, 2019). In particular, domestic buildings in colonial towns such as Narayanganj became physical expressions of social hierarchy and adaptation, embedding the grandeur of empire within vernacular construction logic. As *The Daily Star* (2018) notes, colonial architecture in Bengal "was charged with the explicit purpose of representing the empire itself," revealing how built form operated as a marker of both aesthetic and political dominance. The houses constructed by elite families thus provide an architectural lens through which colonial ideology and local agency may be examined in tandem.

1.2. Problem Statement

Despite extensive research on monumental colonial edifices such as courts, churches, and administrative buildings, comparatively little scholarly attention has been devoted to the domestic scale—particularly the lofty colonial residences that communicated both prestige and adaptation. In Narayanganj, a city historically shaped by European commercial activity, these houses remain under-documented and under-analyzed (Bengal Institute for Architecture, Landscapes & Settlements, n.d.). While a few regional studies have traced heritage houses in Barodi and surrounding areas (Tracing Colonial Footprints, 2024), a focused investigation into the form, space, and spatial organization of three representative colonial houses in Narayanganj has yet to be undertaken. This absence limits our understanding of how colonial spatial ideologies were translated into the intimate scale of domestic architecture.

1.3. Motivation / Significance

Investigating these colonial houses is vital for several reasons. First, they provide insights into how colonial culture negotiated with Bengali spatial traditions, producing hybrid typologies that reflect both aspiration and adaptation (Afzal, 2019). Second, given the rapid urban transformation of Narayanganj, such documentation supports the preservation of its fading architectural heritage (Bengal Institute for Architecture, Landscapes & Settlements, n.d.). Third, this study contributes to the discourse on colonial loftiness a concept that encapsulates both physical elevation and social superiority—as expressed through form, hierarchy, and circulation. Understanding these dynamics enriches broader theories of colonial domesticity and spatial hybridity (The Daily Star, 2018).

1.4. Research Objective / Aim

The primary aim of this paper is to analyze how colonial loftiness was manifested in the form, spatial organization, and hierarchy of three selected colonial houses in Narayanganj. Specifically, the research investigates (a) the geometric configuration of the houses, (b) the relationships between public, semi-private, and private zones, and (c) the adaptation of these spatial logics to climatic and cultural contexts. By mapping and diagramming the internal layouts, the paper seeks to reveal how colonial design principles interacted with local construction practices to produce a distinctive architectural identity.

1.5. Contribution / Novelty Statement

This research provides a comparative spatial analysis that moves beyond stylistic description, positioning these three houses as microcosms of colonial hybridity in Bengal. Unlike prior works that focus primarily on public institutions, this paper foregrounds the residential dimension of colonial architecture its negotiation between European order and Bengali domesticity (Tracing Colonial Footprints, 2024). The study introduces a typology of colonial house form specific to Narayanganj, expanding the architectural historiography of Bengal's provincial towns. Furthermore, the paper contributes a methodological framework combining field documentation, archival review, and spatial diagramming—offering replicable tools for heritage studies elsewhere.

1.6. Scope and Limitations

The scope of this study is limited to three accessible houses within Narayanganj that retain substantial elements of their original design. The analysis focuses on plan geometry, volumetric articulation, and spatial relationships rather than detailed conservation or sociological study of occupants. While the findings may illuminate broader patterns in Bengal's colonial domestic architecture, generalizations are made cautiously. Contemporary renovations are noted but not central to the analysis.

1.7. Paper Structure

The paper is organized as follows: Section 2 reviews relevant literature on colonial domestic architecture and theories of spatial hybridity. Section 3 describes the research methods, including documentation and spatial mapping. Section 4 presents the case studies and their comparative analysis. Section 5 discusses the findings in relation to the concept of colonial loftiness. Section 6 concludes with implications for heritage conservation and future research.

2. Materials and Methods:

This study used a combined field survey and archival research approach to document and analyze colonial-era domestic buildings. Fieldwork involved measuring dimensions, assessing building condition, taking photographs, and preparing quick sketches of important architectural elements. Archival materials such as municipal records, historic maps, old photographs, and jute-era directories were reviewed to understand historical context. The collected information was examined through typo-morphological analysis to identify common building types like courtyard houses, colonnaded villas, and bungalows. Qualitative spatial-syntax tools, including convex maps and justified graphs, were used to study integration, hierarchy, and social boundaries within the layouts. Climatic analysis assessed sun-path, wind flow, verandah depth, ceiling height, and ventilation strategies to evaluate environmental responsiveness. Finally, a comparative matrix was created to summarize recurring patterns in form, space, and organization across the studied buildings.

3. Case Study

3.1 Case A: Baitul Aman (c. 1939)

- **Location:** Chashara, Narayanganj

- **Historical context:** Late colonial Bengal, Partition-Era memories, Early Post-Independence Transformation
- **Original owner:** Khan Saheb Osman Alee

Figure 1. Colonial House: Baitul Aman

Form / Plan: A typical traditional residence features a symmetrical façade with a central portico. The plan is organized around a central hall, with rooms arranged on both sides in enfilade alignment. A courtyard/intermediate space enhances ventilation and circulation. Residential zones are kept separate from service blocks like kitchens and servant quarters. Wealthy homes commonly include a porte-cochère for sheltered arrival.

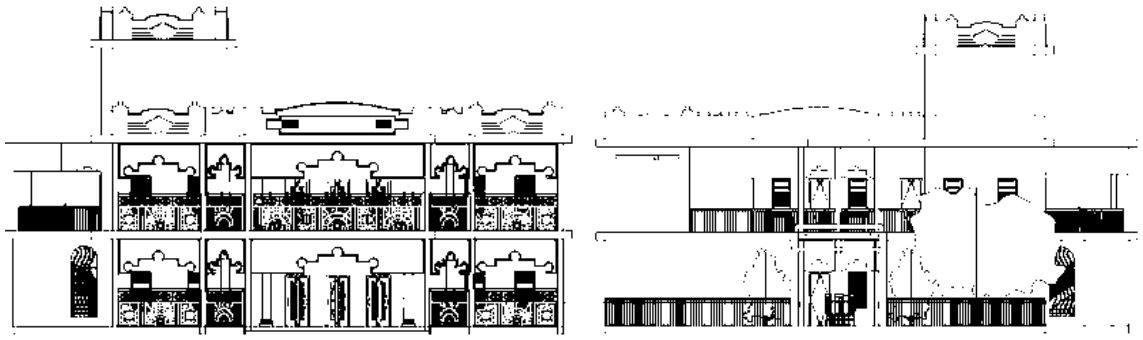

Figure 2. Front & back elevation of Colonial House: Baitul Aman (Fenestration)

Façade and Openings: The façade typically features classical columns (Doric, Ionic, or Corinthian) supporting a pediment and a cornice with dentils. Openings often include semicircular or segmental arches, with occasional cusped/Mughal forms in Indo-Saracenic designs. Houses commonly use tall French windows fitted with louvered shutters, as well as fanlights—either crescent-shaped or rectangular—above doors. Decorative elements include wrought-iron or cast-iron grills, railings, and balustrades along verandahs.

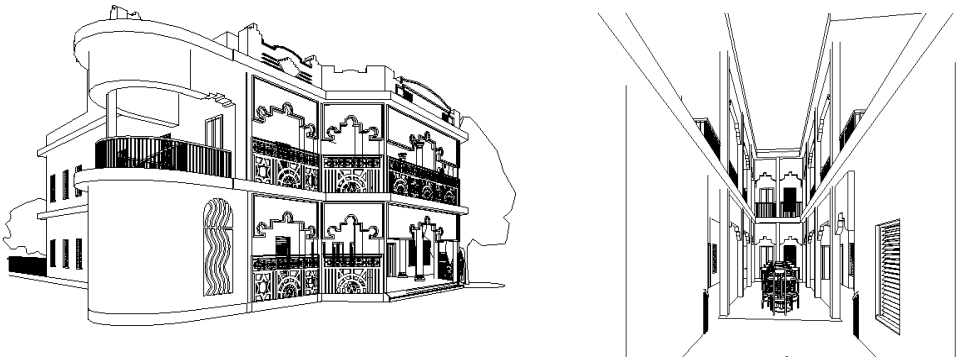

Figure 3. Axonometric view & central courtyard of Baitul Aman: Colonial House

Building Ornamentation: Ornamentation commonly includes stucco scrollwork, medallions, and cartouches, supported by angular pilasters and string courses that structure the façade. Arches are often highlighted with keystones, while dentils beneath the cornice add classical detailing. Rooflines frequently feature parapet balustrades. In later periods, Art Deco elements appear, such as sunburst motifs, horizontal banding, and distinctive circular porthole windows.

Climate Responses: Climate-responsive features include very high ceilings for heat dissipation and deep verandas/overhangs to protect from sun and rain. Buildings often use thick walls to maintain thermal comfort and rely on cross-ventilation created by opposite windows and doors. Additional airflow is ensured through ventilators, clerestory openings, and louvers.

Landscape & Gateway: Exterior settings typically include a small front garden or driveway leading to the house. The property is marked by an ornamental arch-gate with a boundary wall, often displaying a nameplate, crest or monogram, and sometimes a flagpole. Approaches are enhanced with formal entry landscaping, emphasizing symmetry and civic presence.

Figure 4. Left & right elevation of Baitul Aman: Colonial House

3.2 Case Study - B: Sardar House (Build: 1920 AD)

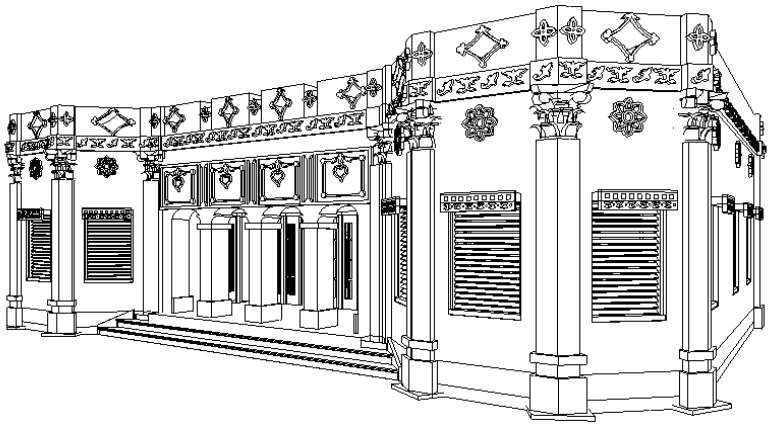

Figure 5. Perspectives view of colonial establishments – Sardar House

- **Location:** Nabiganj, Narayanganj
- **History:** History of Colonial Bengal
- **Owner:** Sardar Family
- **Origin:** 1920 AD

Figure Shows: Ground Floor Plan & Roof Floor Plan of Ancient Sardar House

Form and Plan: The form typically presents a symmetrical façade highlighted by a central front portico. The interior is organized around a central hall or drawing room, with adjoining rooms arranged in enfilade alignment. Many layouts include a courtyard or inner court for light and ventilation. The overall plan maintains functional separation between residential areas and service blocks, such as the kitchen, store, and servant quarters.

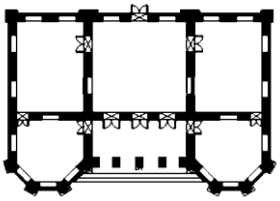

Figure 6. Ground floor plan & 1st floor plan of Sardar House

Façade and Openings: The façade often features classical columns (Ionic or Corinthian) supporting a pediment, with a cornice detailed with dentils. Openings typically include semicircular or segmental arches, with occasional cusped/Mughal arches in hybrid styles. Houses commonly use tall French windows with louvered shutters, along with crescent or rectangular fanlights above doors. Decorative metalwork appears in cast-iron and wrought-iron railings, grills, and verandah balustrades.

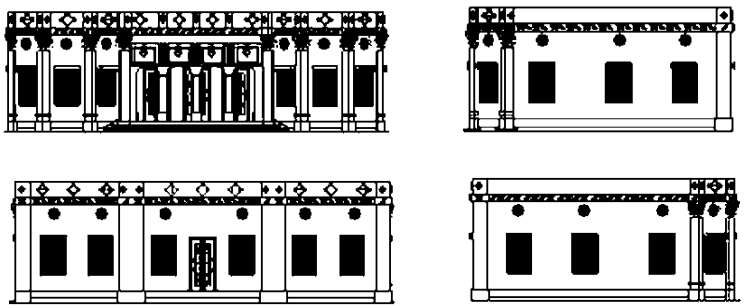

Figure 7. Front & back elevation of Sardar House

Building Ornamentations: Ornamentation commonly includes stucco scrollwork, cartouches, and medallions, supported by angular pilasters and string courses that articulate the façade. Arches are often emphasized with keystones, while toothed dentils and parapet balustrades provide classical detailing. Later adaptations incorporate Art Deco motifs, such as sunburst patterns, horizontal bands, and porthole-style circular windows.

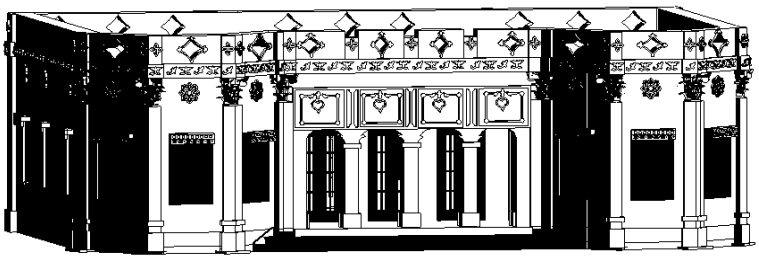

Figure 8. Building ornamentation of Sardar House

Climate Response: Climate adaptations include very high ceilings for heat dissipation and deep verandas with extended overhangs for sun and rain protection. Buildings typically use thick walls for thermal comfort and rely on cross-ventilation through opposite openings. Additional airflow and daylight are achieved through ventilators, clerestory windows, and louvers.

Landscape and Gateway: The exterior layout often includes a small front garden or driveway leading to the house. Entry is marked by an ornamental arch-gate with a boundary wall**,** frequently accompanied by a flagpole and nameplate**.** Many properties also display a crest or monogram**,** reinforcing identity and formality at the gateway.

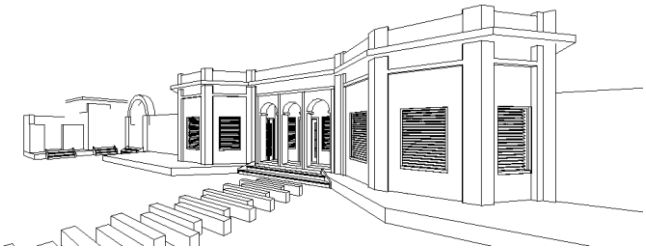

Figure 9. Building ornamentation of Sardar House

3.3 Case C: Jyotir Basu House (c. 1920s)

Location: Baradi, Narayanganj

History: History of Bengal Colonial, Partition of Bengal, 1952 & 1971

Origin: 1940s

Owner: Jyoti Basu

A river-facing house characterized by a wrap-around verandah and high ceilings, using the river-edge as a climatic and symbolic asset. The riverfront orientation heightens the building's presence and adds a unique dimension to the notion of loftiness.

Form/Plan: The plan is strictly symmetrical, arranged in a rectangular layout with a long central hall flanked by rooms on both sides in an enfilade configuration. The façade features a grand front portico and wide verandas, creating spacious shaded outdoor areas. Front and rear courtyards support cross-ventilation and serve as communal spaces. A separate service wing or annex, containing the kitchen, storage, and servant quarters, is positioned apart from the main residential block to maintain functional separation.

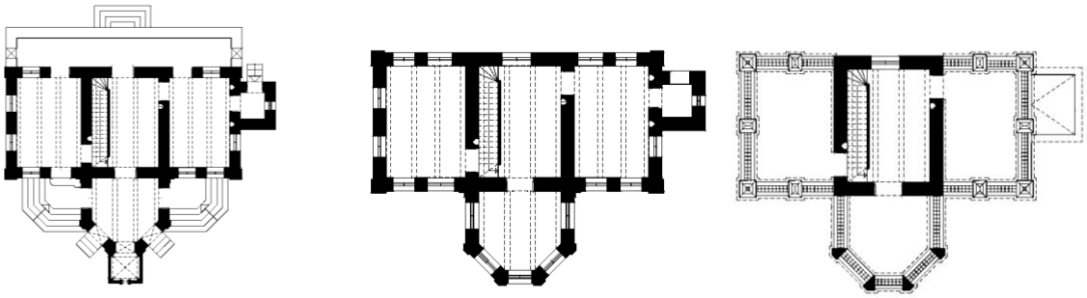

Figure 10. Ground,1st & 2nd floor plan of Jyotir Basu House

Facade and Openings: The façade is symmetrical, marked by a central portico supported by Doric columns, reflecting strong neoclassical influence. Openings are arranged in a balanced manner, with tall doors and windows fitted with louvered wooden shutters and wrought-iron grills for ventilation and security. Arched verandahs and entrances use semi-circular or trefoil (pointed) arch forms to enhance visual richness. Exterior detailing includes ornamental cast-iron railings on

balconies and verandahs. The main entry features intricately carved wooden doors with traditional Bengali motifs, integrating local craftsmanship into the colonial façade.

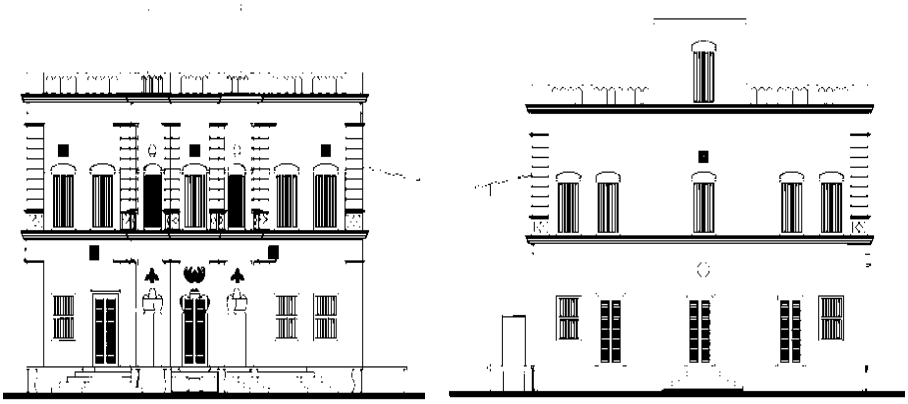

Figure 11. Front and back elevation of Jyotir Basu House

Building Ornamentation: Ornamentation combines brick and stucco work, with mud brick construction suited to the tropical climate and stucco used for smooth finishes and decorative motifs, showing both colonial and Sultanate influences. Wooden detailing, mainly in teak, appears in beams, floors, doors, windows, and railings, with carved balustrades and trusses reflecting mixed local and European craftsmanship. Wrought-iron elements are used in balconies, parapets, gates, and window grills, adding structural strength and decorative refinement to façades and verandahs.

Figure 12. Jyotir Basu House

4. Findings and Discussion

Loftiness in colonial Bengal cannot be understood simply as the height of a structure; rather, it reflects a multi-dimensional architectural experience. Height certainly plays a role—tall ceilings, elevated plinths, and expansive volumes created an immediate sense of openness—but loftiness was equally shaped by environmental and cultural necessities (Afzal, 2019). Generous ventilation,

often achieved through clerestories, transoms, and high openings, contributed to both climatic comfort and a psychological perception of grandeur, aligning with the longstanding climatic logic of Bengali vernacular architecture (Ahmed, 1984).

The sequence of thresholds, beginning from the street-facing entrance to the semi-public verandah and finally into the private inner rooms, established a rhythm of spatial expansion and contraction. This progression heightened the sense of arrival and reinforced social hierarchies embedded in domestic layouts during the colonial period (Sengupta, 2007). Symbolic components such as porticos, pediments, and classical orders did not merely decorate façades; they functioned as markers of status, modernity, and alignment with global architectural trends tied to imperial authority (The Daily Star, 2018).

At the same time, the verandah—typically broad, shaded, and climatically responsive—acted not only as a buffer zone but also as a lived space, blurring the boundary between exterior and interior. This fusion of European representational elements with the spatial logic of Bengali dwelling practices epitomizes the hybrid architectural ethos of colonial domesticity in Bengal (Bengal Institute for Architecture, Landscapes & Settlements, n.d.).

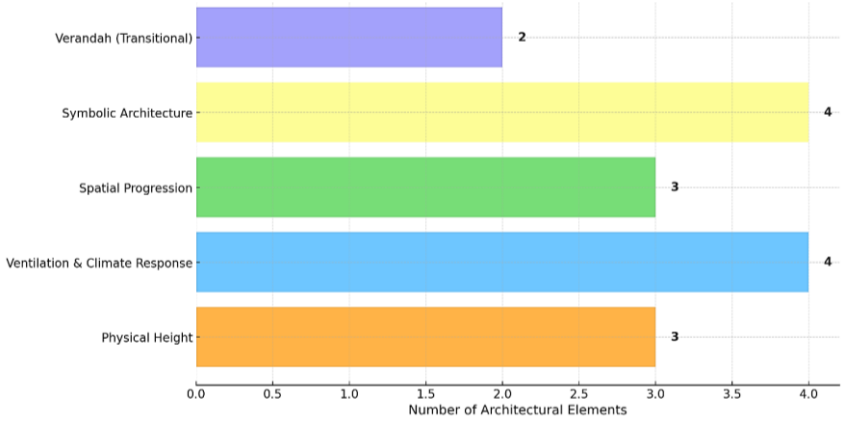

Figure 13. An infographic chart: Architectural elements shaping loftiness "Colonial Bengal Architecture".

The architectural character of colonial Bengal ultimately emerged from a hybridization of European classicism and Bengali domestic traditions. Classical elements Corinthian or Ionic columns, dentil cornices, cartouches, and symmetrical façades were selectively absorbed, reinterpreted, and often localized with brick-and-plaster craftsmanship. These motifs coexisted with deeply rooted Bengali features such as internal courtyards, which enabled light penetration and family-centric activities. The verandah became an adaptive space, functioning as a transitional room suited to the humid climate. Louvers, wooden screens, and jalis allowed filtered light and cross-ventilation, demonstrating a sensitivity to tropical environmental conditions.

This hybrid architecture was not merely aesthetic it reflected social aspiration, climatic intelligence, and cultural negotiation. By merging global stylistic symbols with indigenous spatial

logic, colonial Bengali homes produced a distinct architectural identity rooted in both tradition and modernity.

5. Conclusion and Recommendations

The study demonstrates that the sense of colonial loftiness in Narayanganj is not the result of ornamentation alone but a careful integration of architectural expression, climatic response, and social order. The examined houses consistently reveal three core characteristics. First, classical stylistic frontality provides a dignified and imposing façade that communicates authority. Second, climatic intelligence is embedded in the use of deep verandahs, elevated plinths, generous ceiling heights, and cross-ventilated interiors—elements that negotiate heat, humidity, and seasonal variation with remarkable efficiency. Third, spatial organization reflects social hierarchy, where circulation patterns, entry sequences, and room arrangements quietly articulate cultural values and domestic structures. Together, these components form a cohesive architectural identity that distinguishes colonial-era dwellings in the region.

Future preservation or adaptive reuse efforts must prioritize the intrinsic logics that shaped these buildings. Renovations should respect original volumetric proportions, maintain verandah depth and ceiling height, and safeguard the transitional thresholds that define movement and privacy. Climate-responsive strategies such as cross-ventilation and shading should be retained or sensitively enhanced rather than replaced with incompatible modern interventions. Documentation, community awareness, and regulatory guidance can further support conservation. By aligning contemporary needs with historical intelligence, Narayanganj's colonial houses can remain culturally meaningful and environmentally functional for generations to come.

Conserving colonial Bengali houses requires respecting their original spatial qualities and climatic logic. The height-to-void ratios and deep verandahs should be preserved to maintain natural ventilation, avoiding additions like false ceilings. Modern services must be inserted through reversible, non-destructive methods to protect historic materials. Plinths and damp-prone areas should be strengthened with breathable, lime-based finishes rather than synthetic coatings. During adaptive reuse, it is essential to retain the traditional circulation hierarchy, ensuring that new functions such as cafés, boutiques, or museums do not obstruct original movement patterns or visual axes. The façade and its classical elements, including columns, pediments, railings, and stucco details, must be carefully conserved through gentle cleaning and material-matched repairs. Overall, interventions should enhance usability while safeguarding the building's historical, climatic, and architectural character.

Thanks and Information Note

The authors thank local residents, caretakers, and Narayanganj heritage enthusiasts for their support and narratives. The researchers also acknowledge access to municipal archives and the guidance of conference organizers and reviewers.

Abstract

Creating Ideal Cities: Many architectural and urbanist works and ideas, such as those of Plato, Leone Battista Alberti, Filarete, and Vitruvius, have concerned themselves with creating and developing ideal living conditions for humanity. The concept of the ideal city, which gained widespread acceptance in Europe after Plato, can be said to have begun with Francesco Eiximenic's (1340-1409) introduction of the "planned city" (bastide) as the "ideal city" (la ville idéale). A review of numerous researchers throughout history reveals that they have worked on the importance of healthy and planned cities and have emphasized their importance. The concept of a healthy city was first introduced in 1987, and we see this concept in the literature at the same time. The Healthy Cities Project, which became a project, was implemented in a five-year phase in numerous countries around the world. Threats to public health—workplace conditions, deaths from infectious diseases, and sewage problems—have created a need for healthy cities. To this end, a healthy cities project network was envisioned, and parameters were established for this purpose. The WHO has parameters for this. For healthy cities, there are the slow city movement, the slow city concept, and the criteria for becoming a slow city. There are exemplary cities around the world that address these issues. Research is ongoing on this topic. The key here is to protect all living things, flora, and human health, and to create environmental conditions that support them.

Keywords: Environment, environmental protection, healthy cities

1. Introduction

Historical Development Process

Creating ideal cities: Many architectural and urbanist works and ideas, such as those of Plato, Leone Battista Alberti, Filarete, and Vitruvius, were concerned with creating and developing ideal living conditions for humanity. The concept of the ideal city, which gained widespread acceptance in Europe after Plato, can be said to have begun with Francesco Eiximenic's (1340-1409) introduction of the "planned city" (bastide) as the "ideal city" (la ville idéale). A review of numerous researchers throughout history reveals that they have explored the importance of healthy and planned cities and have striven to emphasize the importance of this concept. Creating an orderly, healthy, aesthetically pleasing, practical, easily accessible, and usable order throughout history has proven difficult. Efforts to achieve beauty and betterment have drawn not only from theoretical and applied sciences but also from art. The breadth of artists' imagination and beauty have inspired them. When we consider artists of the past, we see their interest in disciplines such

as mathematics, astronomy, biology, chemistry, medicine, and so on. And they proved to be exceptionally good in these areas. This provided them with a holistic perspective, helping and leading the world to a new level. For example, Albrecht Dürer was a pioneer of linear cities. Lonardo da Vinci and Piranes, who addressed the separation of social classes in his ideal city, continue to inspire and guide us even today by emphasizing the importance of creativity, imagination, and experimentation. Unfortunately, Lonardo da Vinci was unable to implement his ideal city plan in his lifetime. His theory remains a source of inspiration for academics. His geometric urban plan, particularly for infrastructure and sewage systems, is a prime example. Thomas More criticized city plans in 1517. These ideal city projects progressed slowly until the 19th century. The 19th century focused on the concept of the ideal city, and many researchers worked on it. However, these constructs remained limited to science fiction for metropolises. At the end of the Industrial Revolution, this concept resurfaced, and attempts were made to critically examine it. Researchers on this topic differed in their perspectives. For example, one group prioritized large natural areas and parks alongside tall skyscrapers, while another group also sought to design metropolises in the suburbs. Furthermore, in an effort to promote social justice in every aspect, parks and gardens were designed as rest areas, and common areas and living spaces, especially in nature, for everyone of all classes to use. These designs were also influenced by economics and politics. For example, Central Park in New York City, USA, was designed under the influence of this approach of the time (2,6,7,8).

2. Healthy City

Cities in developed, developing, and even at the very beginning of the world are constantly and rapidly transforming and changing. Living cities, like a puzzle, constantly evolve and respond to people's needs. Here, the two concepts of health and city are in constant relationship. This relationship is crucial for the health of animals and humans, nature, and plants (11).

If we examine the concept of health, it is a state of complete well-being in every aspect. If we look at the concept of city, we see the terms "city" and "city." Furthermore, for the population living here, it is a non-agricultural living space where industry, commerce, the service sector, and the people involved in its management are settled (22).

The health environment is the social context and daily activities within which organizational, environmental, and individual influences interact to influence health and well-being. It is here that people work, learn, play, create, and live healthily (11, 18, 19).

Considering the concept of urban health, we can say that it is a state of well-being in every aspect (11,21).

A healthy city is a concept that expands the resources of communities, creating and improving them, both positively and negatively (20, 22).

Sustainable healthy city is the concept that ensures the continuous development of people living in the city, their natural environments and systems, now and in the future (11,20).

The Healthy City Movement; Research on the concept of healthy cities emerged in 1987 with support from the WHO. The Healthy Cities Project, which became a project, was implemented in

a five-year phase in numerous countries around the world (5). Threats to public health in Western countries—workplace conditions, deaths from infectious diseases, and sewage problems—have led them to recognize the need for healthy cities in urban settings (14).

The Healthy Cities Network consists of five regions: the Western Pacific Network, the Eastern Mediterranean Network, the American Network, the European Network, and the Southeast Asian Network.

City Health Profile; A public health report. It is an analysis of the city's health and its determinants. It includes the city's health status, demographics, environmental conditions and differences, policies, and services (15,19).

Healthy City Ecosystem: The interaction between individuals and businesses within a city and their surroundings (11).

The Digital Healthy City Ecosystem is the transfer of the healthy city ecosystem to a digital service provider network. In other words, it is the technology platform that connects digital service provider systems and forms the digital backbone among ecosystem members (4, 22).

City Health Policies: The process of making cities healthy and evaluating them through public policies (3, 11).

The health of a city benefits both people and nature. It also supports the national economy. It contributes to the peaceful and prosperous life of people and institutions. There is no class distinction among the people. There is equality, balance, and justice. There is no administrative weakness. The rules are clear and applied equally and fairly to everyone. Most importantly, improving and developing health. The development of the city and its people is fundamental. This development encompasses human, social, economic, urban, and sustainable development. In the context of the healthy city vision, it represents people, prosperity, the earth, space, peace, and participation.

If we examine the fundamental characteristics of healthy cities, the most fundamental aspect is the health of people and the surrounding environment. This involves adopting and implementing healthy cities within the context of the social determinants of health. This will positively impact the interaction between people, nature, and the environment (31, 32, 33). In this sense, the fundamental characteristics of healthy cities are:

- Establishment of national and international networks, global governance, and collaboration.
- Monitoring and evaluation
- Transparency, the rule of law, and accountability.
- Intersectoral collaboration.
- Ensuring community participation in policy making and implementation.
- Improving and developing health requires good governance.
- Health equity and human development are at the core of government policies and actions.

• Strong political commitment to optimal health and human development.

3. Characteristics of Healthy Cities

Urban health is defined as a city that constantly interacts with, creates, and improves its physical and social environment, enabling its inhabitants to fulfill all their functions and develop their highest potential, while also supporting each other (1). In such a city, the lives of its inhabitants are facilitated by calm, peaceful, and healthy spaces where people can comfortably carry out their work. These are safe environments that provide people with easy access to community resources that regulate and improve the conditions in their environment (19). At the 1996 forum in Geneva, the consensus was that "individuals' physical health, psychological health, individual beliefs, and social relationships are directly affected by the health of the environment" (18, 29, 31, 33). There are several parameters for a healthy city. These are:

• ***Healthy City Planning:*** It's important to start with the neighborhood for this planning. Planning begins with neighborhoods, the smallest units in cities. It's crucial to secure policy, neighborhood capacity, and institutional support for this.

• ***Healthy Transportation:*** Transportation should be equitable and fair for everyone. Furthermore, everyone should be able to easily reach their workplace without using a vehicle.

• ***Security:*** All city streets, homes, and all areas of residence—women, children, the elderly, the disabled, and young people—in other words, all people and animals—are safe and secure within the vegetation. They are places where people can move freely.

• ***Housing and Transformation:*** They are environments that facilitate people's access to nature, parks, and gardens, and that provide a comfortable environment for their travels. They are healthy environments that protect and improve individuals' health, allowing them to travel easily.

• ***Creativity and Livability:*** It is important to develop policies that foster the creativity of people in cities, and to increase and diversify cultural activities.

• ***Exposure to Noise and Pollution:*** Protecting children, a special group in urban communities, against toxic substances and adverse health effects. For example, these include indoor and outdoor pollution, tobacco smoke in all areas, and various noises. It is important to protect these areas, improve action, and ensure their sustainability.

• ***Climate Change and Public Health Emergencies:*** The health impacts of climate change and its impact on urban health, the health of cities worldwide, and interventions to protect human health during human movement crises.

The characteristics of a healthy city are also mentioned in the sources (23,24,25, 26, 30). If we briefly review these:

High-quality, safe, clean housing and environments

• A sustainable and stable ecosystem

• A just and equitable society where communities support each other at all times, in all ways, and under all circumstances, where strong and trustworthy people support each other, and where there is no one exploiting or favoring the powerful

• A vibrant, diverse, progressive, and innovative urban ecosystem

• Easy access to a wide range of resources

• An environment where interaction and communication are easy

• Participation of urban residents in decision-making

• The well-being and well-being of participating residents are prioritized

• Meeting the basic needs of urban residents (food, water, shelter, income, security, workspaces, recreational areas, etc.)

• The city's ability to live with its past, as well as its cultural, biological, and physical heritage, while encouraging groups and people to do so

• A city that aligns with healthy city parameters and behaviors and possesses features that enhance and improve these

• Easy access to healthcare facilities

• A city where public health and patient care services are easily accessible and optimal service is provided

• A city where health status, especially positive health status, is enhanced and negative health conditions can be addressed immediately.

World Health Organization's Healthy City Criteria

The principles of Health for All, along with the Ottawa Charter for Health Promotion, form the basic framework of the WHO's Healthy City Project (27). If we examine the WHO's Healthy City Criteria in this context, we can list the following (16, 21, 27, 28).

• A safe, clean, high-quality physical environment

• A balanced and sustainable ecosystem

• A strong and collaborative, successful society

• Individual participation in and influence over decisions affecting their own lives, health, and well-being

• Meeting the basic needs of all city residents

• Access to all available experiences and resources through diverse communication, interaction, and connections

• A diverse, vital, and innovative city economy

• Citizens who embrace their cultural, historical, and biological past and heritage

• High-quality and high-quality healthcare

Today, some of our habits in our fast-paced, modern life lead to a number of health problems (such as joint diseases due to a sedentary lifestyle, obesity, depression, and asthma). The indoor spaces we live in are disconnected from the earth and have become oxygen-poor spaces. In addition to air pollution, potential risks related to environmental and noise pollution in living spaces should be identified and made conducive to healthy living. Of course, simply improving the physical environment and the space itself will be insufficient. The space and physical environment should be considered together with social parameters, and problems can be resolved through this perspective (12, 13, 17).

4. Healthy Cities in Environmental Protection

We all agree on the importance of protecting the environment we live in, but the question arises as to whether there are any healthy cities in the world that do. Yes, there are examples of cities around the world that meet the criteria for a healthy city. But first, as people walk down the street in their daily lives, they notice their surroundings, for example:

• It's so beautiful when you see the flowers along the side of the road.

• I wish I lived here.

• The city has fewer trees; I wish there were fruit trees here.

• There's a need for a bike path.

• This is exactly the city I want to live in.

• If the environment were clean, I'd love to walk around.

Similar thoughts about the city we live in and the cities we visit may float through our minds. While there are different ideas and opinions about how to achieve a healthy city in the cities we live in or visit, people are united by common desires. Living a happy, healthy, and meaningful life is everyone's common desire (9, 10, 11, 31).

It can be an example of healthy green spaces.

Figure 1. Izmir Culture Park

The children's street in the Esenler district of Istanbul has been specially designed. It is a good example of a children's playground.

Figure 2. Children's street

Adana Flavor Festival can be an example of street food.

Figure 3. Adana Flavor Festival

The regular collection point for household waste collected in Istanbul is a good example of storage in the sense of healthy cities.

Figure 4. Waste Storage Area

It is a good example of a bicycle path for a healthy city.

Figure 5. Bicycle path

We could multiply these examples. We could also point to Central Park as an example from around the world.

Figure 6. Central Park

There are several new urbanization trends around the world aimed at making urban life more sustainable (29, 33). These include:

- New Urbanism
- Smart City
- Eco-City
- Low-Carbon City
- Green City
- Smart Growth
- Ecological Settlements and Green Architecture
- Ideal City
- Compact City
- Symbio City
- Landscrapers (Built-in settlements)

- Arcological City (Architecture + Ecology)
- Livable City
- Intelligible City
- Digital City
- Slow City

Abstract

Environmental education is critical for nursing students and nurses to develop ecological awareness, become more aware of environmental issues, and adopt sustainable living practices. Today, as environmental problems have become a global crisis, educational institutions play a strategic role in raising environmental awareness. Teachers and faculty members must emerge as key players in the effective implementation of environmental education. It has been stated that environmental knowledge and positive attitudes can only be imparted to students through environmentally conscious and responsible educators and peer leadership, and that environmental education can be ineffective in the absence of teachers and faculty. Environmental awareness and environmental literacy must be fostered in students and young people to foster a curiosity for understanding and examining the environment. Environmental education should not be limited to the mere transfer of theoretical knowledge. Critical thinking, questioning, and the development of an ethical attitude toward nature should be encouraged. Nature-based environmental education should be supported, and it is recommended that approaches such as place-based education, the forest school approach, the biophilia hypothesis and nature-connected learning, and the ecophobia hypothesis be incorporated into university environmental courses. Especially when viewed from the perspective of nursing, the relationship between health and the environment is fundamental, and it is thought that developing course curricula in this context will contribute to environmental education.

Keywords: Environment, environmental education, student nurse, student

1. Introduction

The Concept of Environment

The use of the concept of environment appears to date back to the 1970s (41). Since then, this concept has been used in various meanings across various disciplines and has undergone continuous development (10). The environment is the living environment of any living being (7). From an ecological perspective, the environment refers to all living and non-living entities. The definition of environment is "the totality of physical, chemical, biological, and social factors that may have a direct or indirect impact on human activities and living beings, either immediately or over a period of time" (25). The environment has been defined as the environments in which living beings and humans live, whether in nature or elsewhere (33). These are areas where living beings are connected to, influence, and influence other living beings (26). The environment is the ecosystem of a region (21). It is the environment and conditions in which living and non-living

beings exist (12). If we review all definitions, it is a very comprehensive area consisting of living and non-living beings. We can call this the environment.

The Emergence of Environmental Problems

Nature and humans, in other words, the environment and humans, are in constant communication and interaction. They cannot be separated or separated. The damage humans inflict on the environment has been recognized since the 21st century. The first humans appeared 5 million years ago, and the first living creatures 3.5 billion years ago. The Earth is approximately 4.6 billion years old. How sad it is that the damage humans inflict on the environment is only just beginning to be recognized (2). This recent awareness is quite significant. Climate change is rapidly threatening the Earth and its living creatures. Unfortunately, human awareness of this issue is very low.

Global population growth, the misuse of resources, and the exploitation of less developed countries, in particular, have not slowed down. Developed countries' constant use of global decisions to their advantage is unfortunately making the planet we live on uninhabitable. It is truly saddening that the lack of awareness in underdeveloped countries, the fact that developing countries are caught in the middle and trying to adapt to a rapidly changing world, is harming nature while doing so. Furthermore, the crucial problem of waste, clean water resources, and the pollution of soil are deteriorating the world we live in. The disconnection of people from nature in the developing world, coupled with their self-serving relationships with the environment, is unfortunately no longer tolerated by the planet and is increasingly prevalent. Unfortunately, rapid population growth and industrialization-based economies have led to the depletion of natural resources. The constant increase in technology, the resulting production and consumption, and people's desire for increased comfort are causing irreversible damage to nature (20).

Humanity, which has caused this situation, must solve the problem. Human interaction with nature is harmonious in the first stage because they are hunter-gatherers. It is a process of harmony with nature. The weapons of the people in this period were quite primitive. They struggled to avoid harm from animals and to find food. Their discovery and control of fire caused considerable damage to nature. However, in general, the first period is the stage of adaptation to nature and meeting their needs (3, 5).

The second stage involved the making and use of tools, particularly the learning to use iron. This period marked the transition to a settled life, the domestication of animals, and a continuation of the first period. The Neolithic period witnessed the first and most serious environmental degradation. Unfortunately, flaws in agricultural practices and the development of hunting methods began to degrade the fauna and flora—that is, the environment. During this period, the growth of the human population, the developing economy, and technology began to inflict damage on nature, from micro to macro (3).

The third stage was the industrial revolution. During this period, the human-environment relationship developed negatively. People's desire for dominance over their environment evolved into a passion for exploitation (4,11). It was during this period that humanity exploited the Earth. This process was accelerated by the idea of Bacon, Descartes, and Newton that "nature is a blessing bestowed upon humanity for a prosperous life and that humans have the right to consume it without

limit." Unfortunately, this idea not only sowed the seeds of the environmental crisis but also spread it. It led to serious global environmental problems and crises (27, 28). For example, the radioactive elements, DDTs, detergents, and synthetic plastics produced in the atomic bomb project during World War II can be exacerbated. Armament and wars, along with temporary economic interests, also initiated the search for solutions. The understanding of their detrimental global polluting effects on the environment coincided with the late 1950s and early 1960s. Development movements following wars, rapidly increasing global populations, shrinking living spaces, nuclear testing, the arms race, and the rapid depletion of natural resources, coupled with the rise of environmental problems, have all heightened political, economic, and artistic interest, as has the search for solutions (42). From a philosophical perspective, solutions are being proposed based on two opposing perspectives (ecological and mechanistic). However, the problems are worsening and persist.

2. Environmental Awareness and Mobility in the World and Turkey

Environmental awareness can be fostered through societies' recognition and understanding of the problems in their environment (8,17). Examples include the law enacted by Henry IV of England in 1534 to protect their wild birds. The French regulations on water quality in 1679 and the German "forest protection laws" (1). The Industrial Revolution was the beacon of awareness of environmental problems worldwide. The devastation caused by industrialization on the natural environment led some countries to become environmentally conscious.

The first legal development in Turkey on this issue was the 1982 Constitution. Article 56 of this law stated, "Everyone has the right to live in a healthy and balanced environment. It is the duty of the state and citizens to improve the environment, protect environmental health, and prevent environmental pollution..." (35) (37). The establishment of the Ministry of Environment in 1991 and the development of environmental awareness and sensitivity in schools affiliated with the Ministry of National Education were revisited (6). In subsequent processes, ministries and universities focused on this issue. The Paris Agreement was signed in 2015. In 2021, the Ministry of Environment and Urbanization changed its name to the Ministry of Environment, Urbanization and Climate Change (36).

3. Environmental Education

It emerged when people who harmed nature realized that these problems could be solved by themselves. Environmental education will enable people to solve these problems through cognitive, affective, and behavioral education and training methods (32). The cognitive dimension encompasses the ability to understand the functioning and structure of nature, human-nature interactions, and the consequences of human damage to nature. The affective dimension encompasses caring, empathizing with living and non-living things, demonstrating protective attitudes, and valuing others (31). The behavioral dimension is the process of acquiring the competence to transfer cognitive and affective gains to real life. Raising individuals with environmental awareness is the primary goal of environmental education (13,14,15). Demonstrating beneficial environmental behaviors and transforming these behaviors into attitudes is called environmental awareness (14). Solving these problems can be achieved through

environmental awareness and consciousness. The goal of environmental education is to raise environmental awareness and equip individuals, communities, and communities with knowledge and skills. In addition, it aims to support and encourage individuals to develop positive behaviors regarding the environment and its problems over time. Furthermore, it also aims to actively participate in environmental protection and conservation activities (19). The goal of environmental education is to acquire the knowledge and experience to work on the environment, to be concerned about problems occurring in the environment, and to engage in solution-oriented behaviors (16). To achieve these goals, the "International Environmental Conference" was held in Tbilisi in 1977. This was the first conference. This conference is very important for environmental education. The conference determined the principles, objectives, and methods of implementation. Five concepts were emphasized: awareness, knowledge, attitude, skills, and participation. All of these concepts are crucial and interconnected. The lack or deficiency of any one of these concepts affects the understanding of the other concepts.

The characteristics of environmental education are outlined in the Tbilisi Declaration. These are:

1. It is an educational approach.

2. It lasts a lifetime.

3. It involves active responsibility.

4. It is interdisciplinary.

5. It is holistic.

6. Nature and humans are intertwined and in constant interaction.

7. It has a spiritual, aesthetic, moral, technological, economic, political, and social integrity.

8. It actively encourages learning.

9. It is related to the establishment of environmental ethics.

10. It examines and uses teaching and learning techniques in a broad theoretical and practical context.

11. It supports the development of positive knowledge, attitudes, and behaviors toward the environment (22).

While the Tbilisi Declaration mentioned above provides the foundation, it is crucial to define an applicable environmental education approach with the right approach. In today's world, environmental problems are very complex, and the number of areas they affect has increased, leading to the questioning of the adequacy of environmental education currently in use (19,20). Therefore, especially in recent years, it is crucial to find solutions to environmental problems, increase the diversity of solutions, and choose an environmental education approach that meets the needs of society. Approaches to this issue seek solutions to different aspects of environmental degradation from different perspectives (32). Various approaches exist on this topic. These include nature pedagogy, ecological learning, ecopedagogy, sustainability, education for the environment, and education about the environment.

Nature pedagogy is the process by which people live isolated and alienated from nature due to environmental destruction. Education intertwined with nature is envisioned (19). It is crucial for students to learn and experience nature. Students observe nature here. They experience what they know through affective awareness (20,34).

Ecological learning focuses on individuals re-perceiving themselves and their environment in nature and their social environments, and reorganizing themselves and society (9,23). The proliferation of environmental movements brings this approach to the forefront. Environmental movements are a process of environmental education. It is an approach that allows individuals to see the bottom of the iceberg of environmental problems (20).

Ecopedagogy addresses the relationships and interactions of individuals with each other and society at the core of environmental education. This interaction and communication prioritizes human knowledge and behavior in both environmental degradation and environmental improvement (20). It aims to foster respect and understanding for people, their cultures, nature, and its diversity through a critical perspective (18,29,30). This approach aims to foster lasting attitude and behavioral transformation (5,29,30). Environmental education prioritizes individuals' understanding and awareness of nature through social interaction (32).

Sustainability refers to the capacity of nature to meet human needs without depleting its resources. Sustainability requires adopting a development model that is balanced both environmentally and economically (39). This concept was discussed extensively, particularly in the 1987 Brundtland Report, which emphasized the need to increase environmental responsibility so that future generations can benefit from natural resources (44).

Education for the environment, is the awareness of the biophysical conditions surrounding individuals and the consideration of their social and cultural environment. The aim is to bring individuals into harmony with nature (9, 32).

Education about the environment, stems from ignorance and a lack of knowledge. It involves acquiring knowledge in familiar, traditional learning environments. Environmental education is about acquiring knowledge about the structure, working principles, and functioning of nature. Implementing this approach in schools does not allow for a more detailed examination of the causes of environmental degradation. Therefore, it is limited (32).

4. The Place and Importance of Environmental Education in Nursing

Environmental education is crucial for raising nurses' and nursing students' awareness of their environmental sensitivity. In light of all the information mentioned above, it is critical for schools that train nursing professionals to raise their awareness of environmental issues and to adopt sustainable living practices. Unfortunately, today, when environmental problems have become a global crisis, educational institutions play a strategic role in raising environmental awareness, and teachers and faculty members stand out as key players in the effective implementation of environmental education (24,38). It is clear how essential it is for nurses to graduate as members of a profession who are sensitive to the environment and their surroundings, and how crucial it is for education that can influence and support them in adopting awareness, sensitivity, attitudes, and

ethical understanding towards their environment (40,43). An examination of nursing school curricula, both domestically and internationally, reveals that environmental issues are primarily addressed through the "Public Health Nursing" course. Elective courses such as Environmental Health, Fundamentals of Environmental Health, and Environmental Literacy are also available. While encouraging, this is not sufficient. It is important to increase activities in nursing education programs that will further develop students' environmentally oriented knowledge, skills, and attitudes toward the environment, enable them to transfer these attitudes to their personal and professional lives, and encourage them to take an active role in and support environmental organizations and their activities. Additionally, large-scale research should be conducted to examine the environmental knowledge, skills, attitudes, and behaviors of nursing academics, nurse clinicians, and nursing students.

Abstract

Replacement theory is used in the decision-making process of replacing a used equipment with a substitute; mostly a new equipment of better usage. The problem of replacement arises when any one of the components of productive resources, such as; machinery, building and men deteriorates due to time or usage; therefore, the replacement might be necessary due to the deteriorating property or failure or breakdown of particular equipment. A program was then written in C++ to compute the replacement metrics. The number of unit replacement was accepted as 10000, the probabilities for p1 to p10 were considered. The value for the costs of replacement was accepted as ₦300. The mean life failure at long run was computed as 3.3 weeks and the average rate of failure in the long run was computed as 3030 per week. Individual replacement time was computed as 151.5 per week and the group replacement policy was then computed for week 1, 2, 3, and 4 as 300, 150, 133.33, and 150 respectively. The comparisons were done on the group replacement time for week 1 to 4, and the minimum cost replacement time is ₦133.33 per week. Therefore, the cost of replacement time is due at every three weeks.

Keywords: Replacement, policy, group replacement, individual replacement, paise, items, suddenly

1. Introduction

The problem of replacement arises when any one of the components of productive resources, such as; machinery, building and men deteriorates due to time or usage. For instance, a machine, which is purchased and installed in a production system, due to usage some of its components wear out and its efficiency is reduced, a building in which production activities are carried out, may leave cracks in walls, roof etc, and needs repair; a worker, when he is young, will work efficiently, as the time passes becomes old and his work efficiency falls down and after some time he will become unable to work. Thus the problem of replacement is experienced in systems where machines, individuals or capital assets are the main production or job performing units. The characteristics of these units is that their level of performance or efficiency decreases with time or usage and one has to formulate some suitable replacement policy regarding these units to keep the system up to some desired level of performance (Stephen, 2019).

Industries may have to take different type of decision such as: wait for complete failure of the item (which may result in some losses due to deterioration or to replace earlier at the expense of higher cost of the item; The expensive item may be considered individually to decide whether they should replace now or, if not, when it should be reconsidered for replacement; Whether the item is to be replaced by similar type of item or by different type for example item with latest technology. A separate but similar problem involves the replacement of items such as electric bulbs, radio tubes,

television parts, etc. of equipment which does not deteriorate with time but suddenly fails (Nwosu, 2020). The problem, in this case, is of finding which items to replace and whether or not to replace them in a group and, if so, when?

Different type of decision may be taken such as: Decision whether to wait for complete failure of the item (which may result in some losses due to deterioration or to replace earlier at the expense of higher cost of the item; The expensive item may be considered individually to decide whether we should replace now or, if not, when it should be reconsidered for replacement; Whether the item is to be replaced by similar type of item or by different type for example item with latest technology (Enogwe, 2021).

Almost all systems deteriorate with age or usage unless some of the corrective action is taken to maintain them. Repair and replacement policies are often implemented to reduce system deterioration and failure risk. Increasingly, complex systems have generated interest in the research of replacement theory. The ever increasing repair and maintenance cost necessitates the replacement of the equipment. However, there is sharp, clearly defined time which indicates the need for this replacement, the replacement policy, in this case, consist of calculating the increase operating cost, maintenance cost, forced idle time cost together with cost of replacing the new equipment (Gupta, 2016).

Failure Mechanism of Items

The word failure has got a wider meaning in industrial maintenance than what it has in our daily life. It is categorized in two classes. They are:

1. Gradual failure and

2. Sudden failure. (Progressive failure, Retrogressive failure and Random failure.

Gradual Failure: In this class as the life of the machine increases or due continuous usage, due to wear and tear of components of the facility, its efficiency deteriorates due to which the management can experience:

- Progressive increase in maintenance expenditure or operating costs,
- Decreased productivity of the equipment and
- Decrease in the value of the equipment i.e. resale value of the equipment/facility decreases. Examples of this category are: Automobiles, Machine tools, etc.

Sudden Failure: In this case, the items ultimately fail after a period of time. The life of the equipment cannot be predicted and is some sort of random variable. The period between installation and failure is not constant for any particular type of equipment but will follow some frequency distribution, which may be:

- Progressive failure: In this case probability of failure increases with the increase in life of an item. The best example is electrical bulbs and computer components.

- Retrogressive failure: Some items will have higher probability of failure in the beginning of their life, and as the time passes chances of failure becomes less. That is the ability of the item to survive in the initial period of life increases its expected life. The examples are newly installed machines in production systems, new vehicles, and infant baby (The probability of survival is very less in infant age, but once the baby get accustomed to nature, the probability of failure decreases).

- Random failure: In this class, constant probability of failure is associated with items that fails from random causes such as physical shocks, not related to age. In such cases all items fail before aging has any effect.

Replacement of Items that Fail Completely and Suddenly

There are certain items or systems or products, whose probability of failure increases with time. They may work with designed efficiency throughout their life and if they fail to act they fail suddenly. The nature of these items is they are costly to replace at the same time and their failure affect the functioning of entire system. For example, resistors, components of air conditioning unit and certain electrical components, if they are not replaced immediately, then loss of production, idle labour; idle raw materials, etc. are the results. It is evident failure of such items cause's heavy losses to the organization. Such situations demand the formulation of a policy, which will help the organization to avoid losses (Murthy, 2019).Sometimes it is better to replace the item before it fails so that the expected losses due to failure can be avoided. The following courses of action can be followed:

a) Individual replacement policy: This policy states that replace the item soon after its failure. Here the cost of replacement will be somewhat greater as the item is to be purchased individually from the seller as and when it fails. From the time of failure to the replacement, the system remains idle. More than that, as the item is purchased individually, the cost of the item may be more. In case, the component or the item is not available in the local market, one have to get it from other places, where the procurement cost may be higher for individual purchase. If the management wants to adopt this policy, it may have to waste its time and money also the losses due to failure. It is denoted with the equation below:

$$A_{(n)} = A_0 * C_i = \frac{N}{E(X)} C_i$$

b) Group replacement policy: If the organization has got the statistics of failure of the items, it can calculate the average life of the item and replace the item before it fails, so that the system can work without break. In this case, all the items, even they are in good working condition, are replaced at a stipulated period as calculated by the organization by using the group replacement policy. One thing is to remember is that, in case any item fails, before the calculated group replacement period, it is replaced individually immediately after failure. Hence this policy utilizes the strategy of both individual replacement and group replacement. The probability distribution of the failure of the item in a system can be determined by mortality tables for life testing techniques. It is denoted with the equation below:

$$A_{(n)} = \frac{C_n}{n} = NC_g + \frac{C_i \sum_{X=1}^{n-1} N(X)}{n}$$

2. Research Methods

The replacement of the items that fail suddenly was evaluated. Average rate of failure was computed. Individual and group replacements were obtained. The total number of items initially in the system (N), the probability of failure of items (P), and the expected life of the item (E(X)) were used as the input variables. A computer program was then written in C++. The outputs were presented as numerals, and tables.

Conceptual Framework

A conceptual framework illustrates the expected relationship between the research variables. It defines the relevant objectives for the research process and maps out how they come together to draw coherent conclusions.

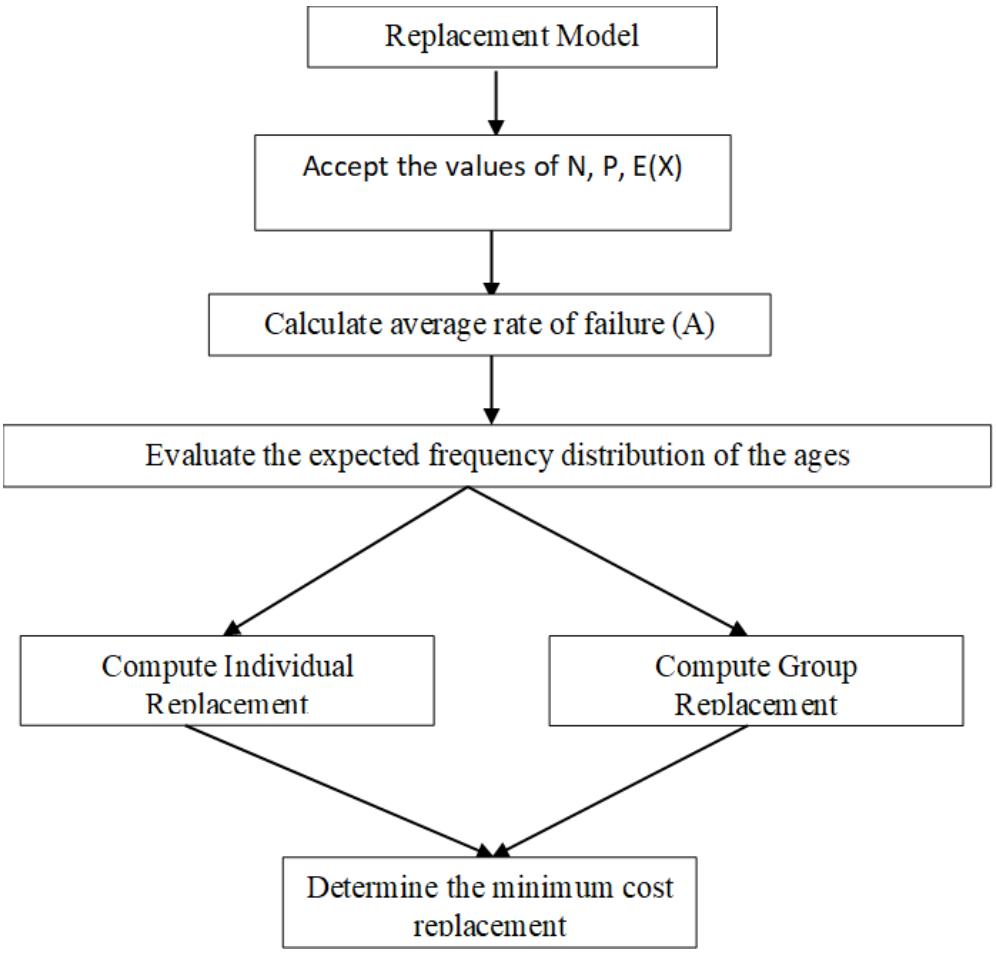

Figure 1. Conceptual Framework of the Model

Input Variables and Results Analysis

Replacement analyses for individual and group replacement policy were implemented in C++ programming language. When a user lunches the Dev C++ application, the user accepts the number of replacement unit, probabilities and the cost of replacement. The expected number of units to be replaced in each week 1 to 7, rate of failures expected in the long run, the expected frequency distribution in the long run, individual and group replacement on failure costs of 5 paise each would be display as output.

Table 1. Input variables for number of unit replaced, probabilities and cost of replacement

NUMBER OF UNIT REPLACED (N_0)	PROBABILITIES		COSTS OF REPLACEMENT (₦)
10000	P1	0.1	500
	P2	0.5	
	P3	0.2	
	P4	0.4	
	P5	0.9	
	P6	0.3	
	P7	0.0	
	P8	0.8	
	P9	0.7	
	P10	0.6	

Table 2: The output result of the mean life failure, average rate of failure, expected frequency distribution of ages, individual replacement policy and group replacement policy.

The Mean Life Failure At Long Run (Weeks)	Average Rate of Failure In The Long Run (Per Week)	Expected Frequency Distribution of Ages At The Beginning of 8th Week	Individual Replace-Ment Policy	Weeks	Group Replacement Policy
28.3	353	39507.4	17.65	1	500
				2	250
				3	251. 667
				4	226.375

3. Discussion and Findings

From table 1 above, the number of unit replacement was accepted as 10000, the probabilities accepted for p1, p2, p3, p4, p5, p6, p7, p8, p9 and p10 are 0.0, 0.2, 0.4, 0.3, 0.1, 0.0, 0.0, 0.0, 0.0 and 0.0 respectively. The value for the costs of replacement was accepted as ₦300. The mean life failure at long run was computed as 3.3 weeks and the average rate of failure in the long run was computed as 3030 per week.

From table 2 above, the average rate of failure was then multiply by the percentage of costs of 5 paise and the individual replacement time was computed as 151.5 per week. The group replacement policy was then computed for week 1, 2, 3, and 4 as 300, 150, 133.33, and 150 respectively. Therefore, the minimum cost replacement policy in group replacement is at every three weeks for a cost of ₦133.33 per week.

4. Conclusion

Analysis of replacement models for items that fails suddenly was computed using C++ program. The number of unit replacement, probabilities and the value for the costs of replacement were accepted in the program. The mean life failure at long run, average rate of failure, individual replacement time**,** and the group replacement time were computed.

The number of unit replacement was accepted as 10000, the probabilities for p1 to p10 were considered. The value for the costs of replacement was accepted as ₦300. The mean life failure at long run was computed as 3.3 weeks and the average rate of failure in the long run was computed as 3030 per week. Individual replacement time was computed as 151.5 per week and the group replacement policy was then computed for week 1, 2, 3, and 4 as 300, 150, 133.33, and 150 respectively. The comparisons were done on the group replacement time for week 1 to 4, and the minimum cost replacement time is ₦133.33 per week. Therefore, the cost of replacement time is due at every three weeks.

Recommendations

Based on the results from the analysis, it is recommended that:

1. Since the cost of replacement time is due at every three weeks, the group replacement should be done every three weeks.
2. There should be need to consider other values for the number of unit replacement to compare the above metrics.
3. More research should be conducted on the replacement analysis because of it significance to the society.

Abstract

Rapid urbanization has increasingly distanced individuals from natural environments, raising questions about the human experience within built spaces. Biophilic design, which integrates elements such as natural light, vegetation, water features, natural materials, and spatial configurations, offers a restorative approach to workplace environments. This study evaluated users' preferred biophilic design elements in commercial office buildings in Abuja, with the aim of understanding how natural features and spatial qualities influence comfort, well-being, and workplace satisfaction. A quantitative methodology was adopted using structured surveys to collect responses from office users across diverse professional and demographic backgrounds. Participants assessed biophilic elements categorized as direct experience of nature (light, vegetation, water), indirect experience of nature (natural materials, colours, patterns), and experience of space and place (variability, refuge, prospect). The findings revealed a strong preference for natural light and indoor vegetation, which were consistently ranked as the most impactful on comfort and productivity. In contrast, water features and highly variable spatial forms were less prioritized. Analysis underscored the importance of user engagement in workplace design, demonstrating that aligning design strategies with user preferences enhances well-being, satisfaction, and sustainable office practices. The study concludes that architects, designers, and facility managers should integrate user-preferred natural elements into both new and existing workplaces. Doing so fosters restorative, human-centred, and culturally meaningful environments that support long-term user satisfaction while contributing to sustainable building practices.

Keywords: Biophilic design, user preferences, office buildings, workplace well-being, indoor environmental quality, Abuja

1. Introduction

The concept of *biophilia*, derived from the Greek terms *bios* (life) and *philia* (love), encapsulates the innate human tendency to affiliate with life and natural systems. This notion forms the theoretical foundation of biophilic design, which promotes the deliberate integration of natural elements into architecture, urban planning, and governance (Cortina, 2024). Zhong et al. (2022) assert that biophilic design extends beyond the mere inclusion of greenery; it encompasses a wide range of experiences which are physical, sensory, morphological, material, and even spiritual that reconnect humans with their natural environment.

Empirical studies such as Aerts et al. (2018) and Hao et al. (2024) affirm that incorporating natural features such as daylight, vegetation, and ventilation yields significant benefits, including improved health, enhanced well-being, and greater productivity within the built environment. Conversely, technological progress and the increasing dominance of sealed, artificial environments have weakened human contact with nature, with adverse effects on physical, mental, and emotional well-being (Harper & Snowden, 2017; Bianchi et al., 2024). In Nigeria, for instance,

many office buildings in Abuja are characterized by heavily glazed façades and fully air-conditioned interiors, which often limit direct access to daylight, natural ventilation, and greenery, thereby exacerbating the disconnect between workers and their natural surroundings.

Research demonstrates that access to natural light, open spatial configurations, and visual or physical contact with greenery promotes restorative experiences, elevating mood, cognitive performance, and workplace satisfaction (Bolouki et al., 2025; Ergan et al., 2019). For example, Ergan et al. (2019) found that employees in offices with unobstructed views of green landscapes reported reduced stress levels and higher levels of job satisfaction compared to those in enclosed, windowless spaces.

Since the late 1980s, sustainability discourses have reintroduced nature as a vital inspiration in architectural practice, positioning biophilic design as a critical frontier in sustainable architecture (Zhong et al., 2022). The growing prominence of environmental responsibility, especially in the post-COVID-19 era, has amplified the demand for frameworks that integrate biophilia, ecology, and inclusive design principles. These frameworks not only promote physical and psychological health but also support social well-being in the built environment (Reinmueller, 2023).

Within contemporary workplaces, the paradigm has shifted from mere productivity to a broader emphasis on user experience, holistic development and well-being. The studies of Niza et al. (2024) and Felgueiras et al. (2023) highlighted that elevated stress levels in office settings are often linked to poor environmental quality, which diminishes productivity. Conversely, natural environments exhibit restorative potential, alleviating stress and fostering resilience (Gunawardena & Steemers, 2023). As a result, integrating biophilic strategies into workplace design is increasingly recognized as a pathway to healthier, more meaningful, and human-centred workspaces (Rao et al., 2025; Issac, 2024).

However, while research on biophilic design has expanded in Western and Asian contexts, limited studies have explored user preferences in African office environments. This gap is particularly significant given the rapid urban growth and evolving workplace cultures in cities such as Abuja. Consequently, this study evaluates users' preferred biophilic design elements in commercial office buildings in Abuja, Nigeria. Abuja is selected as the case study location due to its position as the nation's administrative capital, its concentration of high-rise office developments, and its representative role in shaping modern workplace design across the country. The aim is to identify features that most significantly influence workplace satisfaction, well-being, and performance.

2. Biophilic Design and Its Principles

According to Andreucci et al. (2021) and Panagopoulos et al. (2021), biophilic design is a holistic approach that prioritizes human well-being, minimizes environmental damage, and enhances the resilience of the built environment. Biophilic design is not a temporary trend but grounded in biophilia theory, which emphasizes humanity's innate affinity for nature and the need to reconnect people with natural systems. Consequently, as Barbiero and Berto (2021) explain, it responds to the growing demand for nature-integrated spaces in architecture, city planning, and sustainability practices.

The application of biophilic concepts spans a wide range of building typologies. Abdelaal (2019) highlights their use in residential, commercial, educational, and healthcare facilities, where eco-friendly technologies and green infrastructure enhance resilience. Similarly, Paul et al. (2024) emphasize that these strategies support long-term sustainability goals. Beyond functionality, Richardson and Butler (2022) note that biophilic principles foster continuous interaction with nature, strengthening emotional connections to the built environment. At multiple scales ranging from urban planning to architectural detailing, biophilic design employs human-centred strategies that appeal to the senses (Dalay & Aytaç, 2022).

Empirical evidence also demonstrates its psychological and physiological benefits. Soderlund and Newman (2015), for example, found that exposure to natural features reduces stress, enhances mental health, and improves productivity. More recent studies confirm these effects in workplace settings, showing that natural cues positively shape psychological responses and perceptions of quality (Song et al., 2022). Likewise, Ariyawansa et al. (2022) identify key biophilic triggers that enrich user experiences, while Ifebi et al. (2024) demonstrate how natural components foster tranquillity and well-being across offices, healthcare, and educational spaces.

Despite these benefits, Richardson and Butler (2022) caution that more comprehensive frameworks are required to maximize the potential of nature connectivity. This gap is particularly relevant to the present study, as it motivates the evaluation of user preferences for biophilic design in Abuja's commercial office buildings. In this context, even small-scale interventions, such as the integration of natural light, indoor plants, or water features can transform workplace environments (Khanzadeh, 2024). As Dalay and Aytaç (2022) argue, in an era of rapid urbanization where people are increasingly detached from nature, biophilic design is not only an ecological strategy but also a determinant of workplace quality. Its integration into commercial office buildings is therefore significant, offering the potential to improve user satisfaction, job performance, and overall well-being.

3. Biophilia and Office Design

Office design is widely recognised as a multidimensional construct encompassing building components, spatial layout, indoor environmental quality (IEQ), and organisational culture, all of which jointly influence users' wellbeing and productivity. Scholars argue that the workplace functions as a psychophysical system where physical conditions and users' perceptions interact to shape satisfaction and performance outcomes (Roskams & Haynes, 2021; Zhang, 2025).

Within this system, layout and IEQ have emerged as vital design factors. They facilitate efficient task performance, reduce stress, and support communication and supervision (Appel-Meulenbroek et al., 2018). Among IEQ parameters, daylighting, thermal comfort, air quality, acoustics, and visual access to nature are the most influential. According to Manfredini et al. (2023) and Negarestan (2025), natural light and views of greenery not only regulate circadian rhythms but also reduce stress and enhance job satisfaction and recovery rates. Similarly, indoor planting and biophilic cues have been shown to improve attention and lower absenteeism (Fadda et al., 2023; Altaf & Billington, 2025). Lighting quality more broadly has direct effects on mood and

performance, while poor acoustics and noise distractions consistently emerge as major contributors to reduced concentration and dissatisfaction (Kang et al., 2017; Kim & De Dear, 2013).

Thermal comfort is also strongly linked to productivity, with studies often identifying an optimal temperature range of 21–22°C (Seppänen et al., 2006; Wargocki et al., 2012). However, this benchmark largely derives from temperate-climate studies and requires contextual adjustment for tropical regions such as Abuja, where adaptive thermal comfort models suggest slightly higher ranges may be more suitable (Nimlyat et al., 2023). Similarly, adequate ventilation and low-emission materials significantly improve wellbeing and reduce sick-building symptoms.

These studies show workplace wellbeing depends not on single elements but on the integration of biophilic and IEQ features. Effective design strategies combine daylight and views, ventilation and thermal control, greenery and micro-restorative spaces, alongside acoustic and material considerations. Furthermore, providing occupants with adaptive control over these conditions is very important. Localised control allows employees to adjust to comfort variations in real time, while simultaneously supporting energy-efficient building management—an important consideration in climates like Abuja where cooling demands are high (Loengbudnark et al., 2023; De Dear et al., 2013). These empirical findings affirm the centrality of preferred biophilic elements, particularly daylight, vegetation, natural views, ventilation, and thermal comfort, in shaping job satisfaction and workplace performance within commercial office environments.

4. Biophilic Design Elements in Commercial Office Buildings

Biophilic design advances the principle that human health and productivity are significantly enhanced when built environments reconnect occupants with nature. Kellert and Calabrese (2015) argue that this reconnection must be systematic and holistic, since fragmented or decorative applications diminish its effectiveness. In commercial office buildings, where employees spend extended periods in controlled environments, biophilic interventions are particularly valuable. They can reduce stress, foster cognitive restoration, and strengthen job satisfaction.

Kellert (2012) categorizes biophilic attributes into direct experience of nature, indirect experience of nature, and experience of space and place. Each provides distinct but complementary contributions to workplace well-being. Direct experiences, such as access to natural light, fresh air, vegetation, water, and outdoor views, are strongly correlated with improved concentration and reduced stress. Green walls, indoor planting, and rooftop gardens not only moderate indoor climates but also provide restorative micro-environments that mitigate the sterility of enclosed offices (Abdulkadir & Olagunju, 2023).

Indirect experiences operate through natural analogues such as textures, colours, and natural materials that elicit affective responses linked to ecological memory (Kellert, 2006). In commercial offices, finishes in timber, natural fibres, or biomorphic forms can create a calming ambience and enhance satisfaction, even in settings with limited direct access to nature.

The experience of space and place, by contrast, encompasses more abstract spatial strategies, including refuge and prospect, as well as complexity, order, and mystery (Duarte, 2017; Dosen & Ostwald, 2013). In office settings, this translates into layouts that balance open-plan expansiveness

with private nooks, alongside circulation paths that encourage curiosity and engagement. These spatial qualities resonate with evolutionary preferences for safety, exploration, and sensory stimulation. Moreover, multisensory cues such as the sound of water, the flow of air, and the tactile qualities of surfaces extend beyond visual perception to improve comfort, creativity, and overall cognitive well-being in office environments (Kellert & Calabrese, 2015).

Building on these conceptual foundations, Ryan et al. (2014) and Browning et al. (2015) identified 15 patterns of biophilic design organized across the three categories above, offering practical guidelines for application in contemporary workplaces. These patterns highlight the tangible links between nature-health interactions and workplace performance. In the present study, they provided the conceptual framework that informed both the analysis and interpretation of findings, ensuring that design recommendations are anchored in established biophilic theory.

5. Methodology

This study adopted a descriptive research design. The design enabled the examination of nine key biophilic attributes which include, natural lighting, ventilation, vegetation, water features, natural materials, and spatial variability, considered as independent variables influencing workplace well-being, stress reduction, and job satisfaction. A quantitative approach was employed, involving the administration of structured questionnaires to two groups: office users (N = 214) and building professionals (N = 103). The research focused on high-rise commercial office buildings in Abuja, Nigeria, selected through purposive sampling to capture buildings with significant occupancy rates, modern design features, and compliance with minimum building standards. Within these buildings, simple random sampling was used to administer questionnaires to occupants who spend at least 80% of their work hours in the offices, while auxiliary staff were excluded.

The survey instruments comprised predominantly closed-ended items rated on 5-point Likert scales, supplemented by targeted open-ended responses. Reliability testing using Cronbach's alpha yielded a coefficient of 0.97, indicating excellent internal consistency of the measures. Data analysis employed both descriptive and inferential statistical techniques. Descriptive statistics, including frequencies, percentages, and graphical representations, were used to summarise demographic characteristics and highlight patterns in user and professional preferences for biophilic design elements. To examine associations between variables, inferential analyses were conducted. A chi-square test assessed the relationship between the perceived biophilic quality of office spaces and job satisfaction, while Spearman's rank-order correlation measured the strength and direction of relationships between specific biophilic features (such as natural light, ventilation, greenery, and water features) and workplace outcomes such as comfort, productivity, stress reduction, and satisfaction. These non-parametric tests were selected given the ordinal nature of Likert-scale data and the non-normal distribution of responses. All analyses were conducted using SPSS (Version 26.0).

6. Results And Discussion

To explore which biophilic design elements most resonate with office users in Abuja, the study examined respondents' understanding of what constitutes a biophilic workplace through selection of defining characteristics, including natural light, plant integration and views of nature. Building

on this foundational understanding, building practitioners and professionals indicated biophilic design elements considered most effective for enhancing job satisfaction and well-being in office settings. The demographic profile of respondents indicates a predominantly young workforce, with the largest age group being 26–35 years (46.7%), followed by under-25 (20.6%), while only 1.4% were over 65, suggesting that receptiveness to innovative workplace interventions such as biophilic design may be shaped by youth dominance. Gender distribution shows a male majority (62.2%), with females comprising 36.0% and 1.9% preferring not to disclose, a factor to be considered in interpreting gender-based differences in preferences.

General perception of biophilic design element

Table 1 summarises respondents' selections of biophilic features considered most effective for enhancing job satisfaction and well-being. Natural light emerged as the most endorsed element, with 85.98% of participants identifying it as significant. Natural ventilation and fresh air followed closely at 84.11%, while thermal comfort with high air quality was selected by 72.90%. Views of nature from windows (72.43%) and a strong visual connection with nature (65.89%) also ranked highly. Indoor plants and greenery (60.75%) and the use of natural materials such as wood or stone (60.28%) were each chosen by over 60% of respondents. Natural patterns and colours were cited by 51.40%, while nature-themed artwork (42.06%) and water features (31.71%) were less frequently selected.

When compared with international studies, these results show both convergences and divergences. For instance, the prioritisation of daylight aligns with findings from Kellert and Calabrese (2015) and Browning et al. (2014), who emphasise natural light as one of the most universally recognised drivers of well-being in workplace environments globally. Similarly, the high value placed on views of nature echoes evidence from Ohly et al. (2016), who demonstrated that visual access to greenery reduces stress and supports attentional restoration. However, Abuja respondents' comparatively lower emphasis on water features (31.71%) contrasts with findings from North American and European studies, where aquatic elements are often highlighted as restorative (Geist & Hawkins, 2016). This suggests that contextual and cultural factors may mediate the relative salience of certain biophilic elements in Nigerian workplaces.

Table 1. Selected biophilic features considered most effective for improving job satisfaction and well-being

Biophilic Feature	Count	Percentage (%)
Indoor plants and greenery	130	60.75
Natural Light	184	85.98
Views of nature from windows	155	72.43
Natural ventilation and fresh air	180	84.11
Natural materials	129	60.28

Water features	70	31.71
Nature-themed artwork	90	42.06
Visual connection with nature	141	65.89
Natural patterns & colours	110	51.40
Thermal comfort and air quality	156	72.90

Professional Perception of Biophilic Design Element

Table 2 presents the preferences of building professionals (N = 103), including architects, engineers, and facility managers, regarding the most important biophilic design elements for enhancing office user satisfaction and well-being. Providing access to outdoor nature (for example, courtyards or terraces) was ranked highest, with 76.7% identifying it as the top priority. Natural lighting and views followed closely at 72.8%, while indoor plants and greenery were selected by 70.9%. Just over half (50.5%) prioritised the use of natural materials such as wood or stone, while 40.8% highlighted water features such as fountains or aquaria. These preferences are broadly consistent with literature highlighting direct contact with nature as the most valued biophilic design strategy (Richardson & Butler, 2022). Yet, the prominence of outdoor courtyards and terraces in the Abuja context may reflect climatic and cultural conditions, differing from colder-climate studies where interior vegetation often dominates biophilic interventions.

Table 2. Most important biophilic design element in offices as identified by building professionals (N=103)

Biophilic Element	**Count**	**Percentage (%)**
Incorporates water features (such as fountains, aquariums)	42	40.78
Uses natural materials (wood, stone, bamboo)	52	50.49
Uses plants and greenery indoors	73	70.87
Makes use of natural lighting and views	73	72.82
Provides access to outdoor nature (courtyards, roof gardens)	79	76.70

Association between biophilic feel and job satisfaction

To examine how the exposure to and incorporation of biophilic elements influenced key workplace outcomes, including perceived comfort, productivity, stress reduction, and overall job satisfaction, respondents rated their agreement with related statements on a five-point Likert scale. Spearman's rank-order correlations were computed to assess associations between the overall implementation of biophilic elements in the office and each outcome index. Open-text responses were thematically analysed to identify whether design impacts were perceived as positive, negative, or neutral.

Table 3 cross-tabulates respondents' overall rating of the "biophilic feel" of their office (on a 1–5 scale) against their reported impact on job satisfaction (Negative, Neutral, Positive). A clear pattern emerges: as the biophilic feel score increases, the proportion of respondents reporting a positive impact rises sharply, from 37.5% at score 1 to 75.9% at score 3, while negative evaluations decline to zero at the highest biophilic rating.

Table 3. Contingency table

Biophilic feel of office / impact on job satisfaction	Negative	Neutral	Positive
1	4	6	6
2	8	16	41
3	5	16	66
4	2	13	22
5	0	2	7

As seen in Table 4, a chi-square test of independence confirmed that this distribution differs significantly from chance ($\chi^2(8) = 15.65$, $p = 0.048$, Cramer's $V = 0.21$), indicating a small-to-moderate effect size. In other words, employees who experience stronger biophilic elements are significantly more likely to report positive effects on their job satisfaction.

Table 4. Chi square test results

Chi Square Statistics	df	p-value
15.65	8	0.048

Correlation analysis of specific biophilic elements and perceived outcome

As revealed in Figure 1, to further explore the interrelationships between biophilic design features, a Spearman correlation heatmap was generated. The heatmap illustrates the strength and direction of associations across the ten survey items (Q1–Q10). Darker red shades denote stronger positive correlations, while lighter tones represent weaker associations; blue tones indicate negative correlations. Strong to very strong correlations ($\rho \geq 0.70$) are evident between Q2 (productivity with views of nature) and Q6 (indoor plants, $\rho = 0.71$), Q3 (water features) and Q7 (nature-themed artwork, $\rho = 0.74$), and Q6 (indoor plants) with Q10 (breakout spaces/indoor gardens, $\rho = 0.75$).

These results indicate that vegetation, natural views, and flexible restorative spaces tend to reinforce one another as integrated aspects of a biophilic workplace. Moderate to strong correlations ($\rho = 0.50–0.69$) were also observed, particularly between Q4 (natural materials) and Q5 (daylight, $\rho = 0.63$), and between Q5 (daylight) and Q8 (natural ventilation and air quality, $\rho = 0.69$), suggesting that materiality, daylight, and ventilation are perceived as mutually reinforcing

environmental qualities. These patterns resonate with Kellert and Calabrese (2015), who emphasise multisensory layering as a cornerstone of biophilic effectiveness.

By contrast, Q1 (overall biophilic feel of the office) exhibited weak and slightly negative correlations with individual features (ρ ranging from –0.17 to –0.05). The negative values indicate not merely weak but, in some cases, inverse associations, suggesting that employees' holistic sense of a "biophilic workplace" may not align directly with the presence of specific features. This supports the interpretation that biophilic feel is an emergent construct shaped by the cumulative integration of multiple features rather than any single dominant element (Andreucci et al., 2021). Consequently, workplace design strategies should avoid overemphasising one feature, such as greenery or daylight at the expense of holistic integration. This conclusion is reinforced by the chi-square results in Table 3.

Taken together, the correlation and chi-square findings highlight a critical distinction. On the one hand, individual features such as daylight, indoor plants, or breakout spaces are strongly interlinked and valued by employees; on the other hand, the global perception of biophilic quality and its predictive relationship with job satisfaction depends on the holistic integration of multiple features. This dual insight aligns with global evidence that piecemeal application of biophilic strategies is less effective than layered, multisensory design approaches (Yin et al., 2024). In the Abuja context, this suggests that organisations seeking to improve workplace well-being should prioritise integrated strategies that combine daylight, vegetation, ventilation, natural materials, and restorative spaces, rather than privileging a single element in isolation.

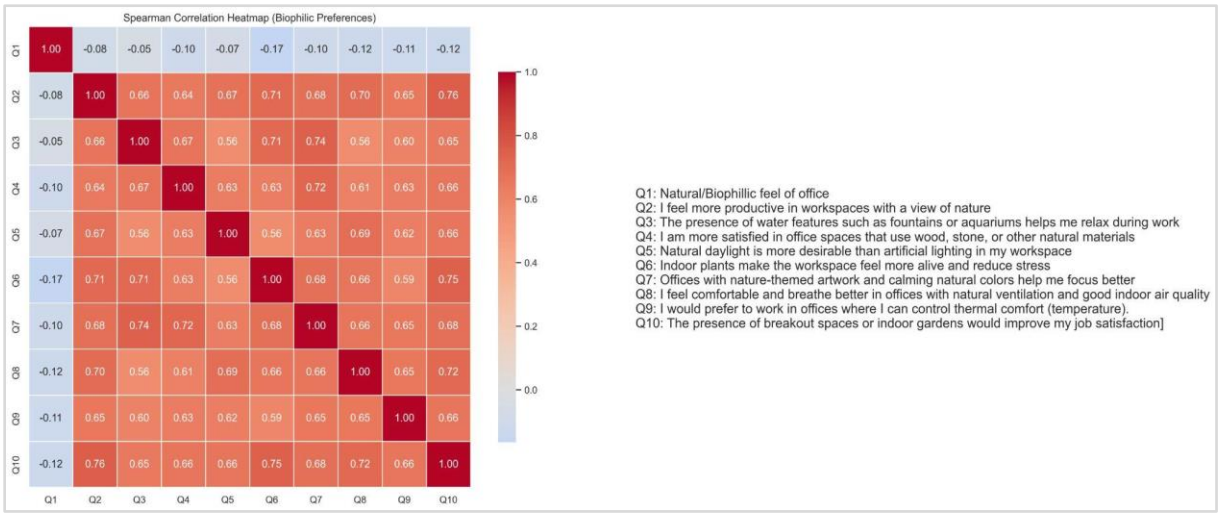

Figure 1. Heatmap of relationship between biophilic feel of offices and rating of job satisfaction

7. Conclusion

This study validates that biophilic design elements are highly valued by office users and building professionals in Abuja, with consistent evidence that natural light, ventilation, views of nature, and

indoor greenery are central to enhancing workplace comfort, productivity, and well-being. As such, these elements should be should be reflected in design strategies that maximize daylight, views, and ventilation while supporting acoustic comfort. The statistically significant association between the perceived biophilic quality of office environments and job satisfaction ($\chi^2(8) = 15.65$, $p = 0.048$, Cramer's $V = 0.21$) provides empirical support for the theoretical premise that human affinity for nature supports healthier and more fulfilling workplace experiences. Moreover, beyond significance, specific correlation patterns highlight how integrated strategies yield complementary benefits. For instance, the strong association between breakout spaces and productivity ($\rho = 0.76$) suggests that informal, socially supportive areas may reinforce the positive effects of nature views by providing restorative opportunities within the office. Similarly, the close links between ventilation, thermal comfort, and well-being ($\rho \geq 0.72$) highlighted that comfort-oriented design interventions do not function in isolation but collectively shape holistic user satisfaction.

While decorative features such as water elements and nature-themed artwork were not among the highest priorities, their positive associations with vegetation ($\rho = 0.74$) suggest they can enhance the sensory diversity of office environments when integrated thoughtfully. This echoes findings from biophilic design research emphasizing the cumulative impact of multisensory experiences in fostering vibrant and engaging environments (Ryan et al., 2014). Importantly, both office users and professionals highlighted outdoor access and natural light as critical to achieving optimal workplace outcomes, confirming their primacy across contexts. In conclusion, the findings reinforce the necessity of embedding a broad palette of biophilic elements into commercial office design in Abuja, advancing workplace satisfaction and productivity while simultaneously aligning with sustainable building practices and contributing to healthier, more resilient urban futures.

Abstract

Despite the increase in recognition given to sustainable property innovations such as green walls for environmental, social and economic benefits, there has been a dearth in the study of the extent of impact of this innovation on residential properties' values particularly in Nigeria. As a result, this study assessed the impact of green walls in residential property development on the rental values of the properties in Ibadan, Oyo State, Nigeria. The study adopted survey design approach to illicit information from 230 respondents which comprises of registered estate surveyor and valuer's firms and residents of the residential properties in Ibadan. out of which, two hundred (200) responses were retrieved and analyzed using descriptive and inferential statistical tools such as Percentage Frequency table, Independent T-Tests and Stepwise Multiple Regression. The Findings revealed a high level of user satisfaction with aesthetics, thermal comfort and environmental benefits of green walls, while the stepwise regression confirms that green walls significantly influenced residential property values, explaining up to 20.5% of the variance in rental performance. The study recommends the incorporation of natural plants on residential properties by developers in the course of planning and execution of the project since it enhances users' satisfaction and property values.

Keywords: Green wall, residential property, sustainable, value

1. Introduction

Climate change has made the need for sustainable urban planning and green infrastructure highly necessary and increasingly urgent (Akpabio et al., 2019) and as a response, the integration of green infrastructure such as green walls has become a popular strategy in urban development most especially in developed nations of the world. Green walls, also called living walls (internal) or vertical gardens is regarded as vegetative systems that have been designed to enhance building facades through plant incorporation in vertical structures. These walls are usually created when interior or exterior surfaces of a building is covered with vegetation thereby promoting sustainability and at the same time serving as a shield against environmental hazards, and are therefore considered as important component of sustainable urban development (Perini et al. 2011, Susorova et al.2013; Perini & Rosasco. 2013).

The impact of green walls on rental values and property prices in Ibadan has not been systematically studied. The absence of clear data on whether properties with green walls command higher rental rates or sale prices compared to those without poses a challenge for stakeholders. The level of satisfaction among users of green walls in residential properties remains unknown. User

experiences with green wall whether positive or negative can influence future adoption rates and perceptions of value. Without understanding how satisfied residents are with these features, it is challenging to determine their long-term viability and appeal. The difference in rental values between properties with and without green walls has not been explored in the study area. While green features are often associated with higher property values in other regions, it is unclear whether this trend holds true in Ibadan's real estate market. Beyond rental income, the overall effect of green walls on residential property values in Ibadan is not well understood. While studies in developed countries have demonstrated that green infrastructure can increase property values (Deng & Wu, 2014), these findings may not be directly applicable to the Nigerian context. This lack of information makes it difficult for property developers and investors to assess whether green walls provide a financial return on investment. Thus, this study aims to examine level of satisfaction of users with green walls in residential properties, measure the difference in rental values of residential properties with and without green walls between 2015-2025 and assess the impact of the green walls on residential property values in Ibadan.

Understanding how green walls impact property values in Ibadan will not only shed light on consumer behavior in a developing city but also provide data-driven recommendations for developers and policymakers. This study seeks to assess the impacts of green walls on property values in Ibadan, Oyo State. It examines how green walls influence buyer and tenant preferences market demand, and overall property valuation in the context of a developing city. By addressing these questions, the research aims to provide valuable insights for property developers, urban planners, and policymakers on the role of green infrastructure in promoting sustainable development and enhancing real estate value. The findings from this study will also contribute to the broader discourse on sustainable urban design in emerging economies.

This study focuses on residential property values within selected areas in Ibadan, Oyo state, Nigeria. Ibadan was chosen as the study location due to its unique blend of historical, environmental, and urban development characteristics that make it an ideal context for analyzing the value implications of sustainable building features such as green walls. The study is limited to selected residential neighborhoods within Ibadan where green walls have been observed or implemented. These areas include neighbourhood such as Bodija, Agodi GRA, Oluyole Estate, and Jericho, all of which are characterized by a mix of medium to high-income residential developments and a growing prevalence of eco-conscious architectural features.

2. Literature Review

2.1. User Satisfaction with Green Walls in Residential Properties

Francis and Lorimer (2011) argued that living walls create biophilic connections that can enhance occupant's psychological wellbeing, reporting that more than 80% of surveyed respondents in Melbourne housing estates experienced increased life satisfaction and perceived tranquility after the installation of vertical greenery. Quantitative reviews further reinforced these findings. Molla (2015) synthesized over forty empirical assessments of urban green infrastructure and reported that green walls consistently scored above 4 on a 5-point satisfaction scale for parameters such as noise reduction, privacy enhancement and sense of community, although scores varied by climate

zone and maintenance regime. Despite positive satisfaction indicators, other researchers caution that poor system performance can erode support. Ottelé, Perini, Fraaij, Haas, and Raiteri (2011) document cases in temperate Europe where malfunctioning irrigation and plant mortality led to satisfaction scores below 3, prompting early decommissioning in two of five pilot sites.

2.2. Difference in Rental Value of Residential Properties with and without Green Walls

Investigating how green wall installations influence rental values is essential for understanding their economic viability in residential markets. While substantial literature documents the sale-price premiums associated with landscape features, the specific effect of vertical greenery on rent remains underexplored. For instance, Rosen's (1974) hedonic pricing theory provides the foundational framework, positing that property attributes both structural and environmental are capitalized into the market prices. However, Rosier (1999) was unable to disaggregate sale from rental markets. Meanwhile, Aigbavboa, Thwala, Ademiloye, and Oshodi (2024) applied random forest algorithm to predict monthly rentals from data elicited from 2,500 online listings of green features such as facades and living walls in Cape Town. The results revealed that vertical greenery appeared in fewer than 5% of listings and on an average, contributed less than 1% premium to predicated rent values attributing this muted effect to both the novelty of the technology and weak market recognition of green walls as a value-adding amenity. On the other hand, insights from Nigeria and comparable West African contexts further underscore the need for localized rental analyses. Ayodele and Olawande (2018), using a similar hedonic approach combined with homeowner questionnaires in Abeokuta, observed that respondents perceived green walls as experimental and beyond typical maintenance capacities. Consequently, rental listings in these markets rarely highlight green wall benefits, leaving landlords with little incentive to invest.

2.3. Effect of Green Walls on the Values of Residential Properties

Early hedonic-pricing studies demonstrated that landscape features in general such as mature trees, manicured lawns, and decorative shrubbery tend to be capitalized into higher sale prices (Rosiers, 1999; Morley, 2008). Building on this foundation, researchers have been able to isolate the contribution of vertical greenery systems. Jim and Chen (2010) conducted a post-occupancy survey in Hong Kong on high-rise condominiums. Results revealed that the units adjacent green façades have achieved price/m^2 increases of 3.5% relative to matched comparators, attributing this gain to enhanced visual amenity and reduced façade-surface temperatures during summer months. Their spatially explicit hedonic model incorporated distance-decay functions to account for the diminishing effect of greenery visibility with increasing floor height.Perini and Rosasco (2013) conducted a cost-benefit analysis comparing living wall systems to conventional façades in Italy and Spain using market sales data from over 200 properties. Hedonic regression techniques were applied and findings revealed that homes with professionally installed green walls commanded sale price premiums of 4-6%, after controlling for floor area, age, location and horizontal landscaping. Their results held under sensitivity tests for maintenance cost variations, suggesting that buyers valued the environmental and aesthetic benefits sufficiently to pay a notable premium. Meanwhile, Manso and Castro-Gomes (2015) extended the work though the meta-analysis of 17 hedonic pricing publications on green façades and living walls. The survey reported an average sales price uplift of 5.2% (95 % CI: 3.8 – 6.6 %), with higher premiums in temperate climates

where green walls deliver pronounced thermal comfort improvements. Their review also highlighted methodological consistency in controlling for structural attributes and neighbourhood characteristics, reinforcing the robustness of the observed premium.

3. Methodology

The study adopts the survey research design approach to elicit data from a large number of respondents within a relatively short period. This survey research design would facilitate the use of structured instruments such as questionnaires to elicit responses from participants which comprises of principal stakeholders in Ibadan residential property market and classified into two categories; registered estate surveying and valuation firms and residential property owners/tenants in Ibadan. For the purpose of this study, 70 practicing professionals gotten from the Nigerian Institution of Estate Surveyors and Valuers (NIESV) Oyo state directory and 160 residential property owners who have installed or currently installing green walls in their buildings complied from Oyo State Ministry of Lands and Housing is adopted as the sample size while data obtained would analyzed using Weighted Mean Score (WMS), Independent T-test and Stepwise Regression.

The Study Area

Ibadan city, with an estimated population of about 3 million people, is one of the largest urban centers in Africa renowned for its rich cultural heritage and rapid urbanization (Raheem & Adebayo, 2016). This population growth, coupled with the sprawling nature of urban development has led to increased pressure on residential infrastructures and environmental resources. The dynamic mix of traditional and modern housing in Ibadan provides a unique context to assess the factors influencing the rate of adoption of green walls in residential property development in Ibadan.

4. Results and Discussion

Table 1. User satisfaction with green wall in residential property developments in Ibadan

	Agodi GRA		**Bodija Area**		**Jericho Area**		**Oluyole Area**	
User Satisfaction	**Mean**	**Rank**	**Mean**	**Rank**	**Mean**	**Rank**	**Mean**	**Rank**
The green wall contributes to a quieter, more peaceful space	3.58	1st	3.22	2nd	3.00	8th	2.57	12th
The green wall is easy to maintain	3.42	2nd	3.03	5th	2.93	12th	3.10	4th
I am satisfied with the overall appearance of the green wall	3.28	3rd	2.92	7th	2.97	10th	3.40	1st
The green wall promotes a healthier indoor environment	3.22	4th	3.00	6th	3.25	1st	3.26	2nd
I would recommend green walls to others	3.17	5th	3.08	4th	3.25	1st	2.81	9th

The installation process of green wall was satisfactory	3.17	6th	3.56	1st	3.03	5th	2.90	7th
The green wall has enhanced the aesthetic appeal of my home	2.97	7th	2.56	12th	3.25	1st	2.74	10th
The green wall reduces indoor heat in my home	2.92	8th	2.89	8th	2.98	9th	2.71	11th
The green wall has improved indoor air quality	2.86	9th	2.75	11th	3.02	7th	2.93	6th
The green wall gives me a sense of pride in my residence	2.78	10th	2.83	9th	2.95	11th	3.14	3rd
The green wall has increased the value of my property	2.72	11th	2.83	9th	3.03	5th	3.10	4th
The green wall makes me feel more connected to nature.	2.72	12th	3.17	3rd	3.25	1st	2.88	8th

Source: Field Survey, 2025

The findings presented in Table 1 provide insights into user satisfaction with green walls in selected residential neighbourhoods of Ibadan; Agodi Bodija, Jericho and Oluyole Area. The Table revealed that in Agodi GRA, overall satisfaction levels were moderate to high, with mean values ranging from 3.58 to 2.72 across the 12 satisfaction indicators, all statistically significant at $p < 0.001$. This indicates that residents consistently recognize multiple benefits of green walls, though the degree of satisfaction varies depending on the specific dimension assessed with the most highly rated satisfaction factor as the green wall contributes to a quieter, more peaceful space (Mean = 3.58, Ranked 1st). This finding highlights the role of green walls in providing sound insulation and enhancing tranquility in residential environments. It is consistent with studies that emphasize the noise-buffering potential of green facades, particularly in urban areas where external noise pollution is a key concern (Azkorra et al., 2015). The second- ranked factor, ease of maintenance (Mean = 3.42), further demonstrates that residents value practicality, and when maintenance demands are manageable, satisfaction is significantly enhanced while deeper affective or long-term benefits such as sense of pride (Mean = 2.78), increased property value (Mean = 2.72), and connectedness to nature (Mean = 2.72) were rated lowest as 10th, 11th and 12th respectively. This indicates that residents are less convinced of the symbolic, financial, or emotional value of green walls compared to their functional contributions.

Overall, the analysis reveals a layered pattern of satisfaction: functional benefits (peace and maintenance) dominate, aesthetic and ecological benefits occupy the middle tier, while symbolic and long-term values are perceived as least impactful. The differences in mean values (from 3.58 to 2.72) illustrate that while residents are broadly satisfied, satisfaction is uneven across dimensions. In relation to the study objective, the findings demonstrate that users of green walls in Agodi GRA are moderately satisfied, with the strongest appreciation for functional performance

and ease of upkeep, but with lower satisfaction in areas tied to environmental performance, symbolic value, and economic return.

Also, Table 1 presents the level of user satisfaction of green walls in Bodija. The results show a moderate level of satisfaction with mean values ranging from 3.56 to 2.56 and all statistically significant at $p<0.001$, thus, indicating that while residents recognize the benefits of green walls, satisfaction is uneven across the different dimensions assessed. It was discovered that the most highly rated indicator is the satisfaction with the installation process (Mean = 3.56, Rank 1st), suggesting that respondents were positively impressed with how green walls were introduced into their properties. This score is notably higher than the lowest-ranked factor, aesthetic appeal of homes (Mean = 2.56, Rank 12th), showing a mean gap of 1.0 point. This suggests that while users in Bodija value the process of implementation, they are less convinced of the visual or aesthetic transformation green walls provide. Overall, the analysis of Bodija demonstrates that satisfaction is strongest with the installation process and functional benefits (peace and connectedness to nature), while aesthetic and long-term economic impacts are less convincing to users. The difference in mean scores (from 3.56 to 2.56) reflects a full one-point variation, underscoring a moderate but uneven pattern of satisfaction. In relation to the study objective, the findings suggest that users in Bodija are moderately satisfied, particularly with the installation and experiential benefits, but display lower satisfaction with symbolic, visual, and property value contributions of green walls.

Furthermore, Table 1 shows that in Jericho Area, the top ranked indicators were clustered at the same mean score of 3.25, including recommendations to others, enhanced aesthetic appeal, healthier indoor environment and connectedness to nature and all ranked 1st. This clustering shows that users strongly associate green walls with visible, experiential, and ecological benefits while the willingness to recommend to others further suggests a positive general disposition toward green wall systems among residents. This finding aligns with previous research that highlights social endorsement and peer influence as important drivers of technology diffusion in sustainable housing (Darko & Chan, 2018). The results also show that the mean values were ranged from 3.25 to 2.93, all statistically significant at $p < 0.001$, indicating a relatively narrow satisfaction range compared to Agodi and Bodija. This suggests that residents in Jericho reported more uniform levels of satisfaction, with no single factor standing out as overwhelmingly high or low. Overall, the analysis of Jericho demonstrates that satisfaction is strongest in aesthetic, ecological, and experiential dimensions, with a consistently moderate appraisal across functional, economic, and symbolic benefits. The narrow range of mean scores (3.25–2.93) implies a balanced satisfaction profile, where no aspect of user experience is considered extremely weak but also none are rated exceptionally high. In relation to the study objective, the findings suggest that users in Jericho are moderately and consistently satisfied, particularly valuing the aesthetic appeal, environmental benefits, and connectedness to nature provided by green walls, with less emphasis placed on property value, maintenance, and symbolic pride.

Finally, the Table reveals the dimensions of the level of user satisfaction of green walls in residential properties in Oluyole. The findings revealed that mean scores of the indicators ranged from 3.40 to 2.57, with all being statistically significant at $p < 0.001$. Thus, suggesting that users

generally express moderate satisfaction but with notable variation across different aspects of green wall experience. The Table further reveals that the highest rated factor was overall appearance of the green wall (Mean = 3.40, Rank 1st), highlighting that residents in Oluyole place strong emphasis on the visual and aesthetic contribution of green walls to their homes. This was followed by promotion of a healthier indoor environment (Mean = 3.26, Rank 2nd) and sense of pride in residence (Mean = 3.14, Rank 3rd). These results suggest that users in this area are particularly appreciative of the symbolic and ecological benefits of green walls, which enhance both personal satisfaction and perceived well- being. In the long run, the overall analysis of Oluyole indicates that satisfaction is strongest in aesthetic and ecological dimensions (appearance, healthier indoor environment, pride in residence), while thermal, acoustic, and advocacy-related benefits are perceived less positively. The difference of 0.83 points between the top-ranked and lowest-ranked indicators (3.40 vs. 2.57) highlights a broader variation in satisfaction compared to Jericho, where responses clustered more narrowly. In relation to the study objective, the findings suggest that users in Oluyole are moderately satisfied overall, with clear appreciation for visual and symbolic value, but with weaker satisfaction in relation to environmental performance and broader social endorsement of green walls.

Table 2. Independent Sample T-test Results on Rent of Residential Properties with or without Green Wall in Ibadan from 2015-2025

	Agodi GRA			Bodija			Jericho Area			Oluyole Area		
Property Type	GWMR	NGWMR	p-value	GWMR	NGWMR	p-value	GWMR	NGWMR	p-value	GWMR	NGWMR	p-value
2-bed	472,727	287,273	0.03	477,273	409,091	0.54	804,545	510,901	0.17	368,182	260,000	0.25
3-bed	631,818	495,455	0.18	913,636	600,000	0.13	945,455	727,273	0.43	509,091	477,273	0.85

Source: Field Survey, 2025
Key: GWM- Green Walled Mean Rent, NGWM – Non-Green Walled Mean Rent, Sig. – Significance Level, S – Significant, N.S – Not Significant

Table 2 presents the statistical independent t-test results to compare the mean rental values of residential properties (2-bedroom, 3-bedroom and 4-bedroom flats and duplex) with and without green walls in selected residential neighbourhoods in Ibadan from 2015-2025 and to also determine the significant differences existing between the two groups. The Table reveals that in Agodi GRA, only 2-bedroom flats showed a statistically significant difference in rental values between properties with and without green walls ($p=0.03 <0.05$), thereby suggesting that in the lower-to-middle rental segment, tenants were more sensitive to the added benefits of green walls, which may include improved comfort, aesthetics, and perceived modernity. However, for 3-Bedroom, 4-Bedroom, and Duplex categories, the observed rental premiums, though visible in raw figures, were not statistically significant ($p > 0.05$). This implies that higher-income tenants may

prioritize size, luxury finishes, and location over sustainable features when negotiating rents.

The Table also presented the results from Bodija and it shows that there is no statistically significant rental difference across all property types ($p<0.05$) surveyed. Although mean rental differences were positive ₦68,182 for 2-Bedroom, ₦313,636 for 3-Bedroom, ₦150,000 for 4-Bedroom, and ₦181,818 for Duplexes, the p-values show that these differences are not strong enough to conclude a consistent rental premium attributable to green walls in Bodija. This suggests that while green walls added aesthetic and functional appeal, other rental determinants such as location within Bodija, structural features, and market demand dynamics had greater influence on rent levels. The lack of statistical significance highlights that Bodija's rental market, although responsive to sustainability features, does not yet consistently capitalize green walls as a decisive factor in determining rental values. In comparison with findings from Agodi, where smaller units showed significant rental differences, the Bodija results indicate a slower pace of acceptance. This may be explained by the socio-economic profile of Bodija tenants, who prioritize larger housing and prestige features over eco-friendly designs.

Meanwhile, in Jericho Area, a similar result was presented as there is no statistically significant rental difference across all property types as all p-values were found to be > 0.05. This outcome suggests that although tenants in Jericho recognized and appreciated the aesthetic and environmental benefits of green walls, these features did not yet carry sufficient weight to significantly alter rental pricing dynamics. In comparison to Agodi, where smaller units showed significant differences, Jericho reflects a market segment where tenants may prioritize broader prestige features and location advantages over sustainable design elements.

The results on Oluyole presented in Table 2 reveals that the observed differences were not statistically significant across all property types (all p-values > 0.05). This suggests that although green walls were associated with higher rents in some cases, the effect was inconsistent and not strong enough to be generalized statistically within Oluyole. These findings highlight an important hint, while tenants in Oluyole may appreciate the environmental and aesthetic benefits of green walls, other factors such as property location within the estate, design features, and economic conditions appear to play a stronger role in determining rents. Comparatively, Oluyole's results align more closely with Bodija and Jericho than with Agodi. Whereas Agodi's 2-Bedroom market demonstrated significant rental differences, Oluyole's results confirm that tenants in this location have not yet attached strong financial value to sustainable features like green walls. For developers, this suggests that while green walls can serve as a marketing tool, their impact on rental returns remains limited in Oluyole.

These findings are consistent with hedonic pricing theory (Rosen, 1974), which posits that property rents reflect the bundle of attributes each unit offers. Green walls serve as functional and aesthetic amenities, but their relative weight in rental determination differs by market segment. The results also mirror Rogers' (2003) diffusion-of-innovation framework: adoption and appreciation begin with early segments (smaller units), while higher-end markets take longer to integrate such innovations as defining value drivers. In comparison with international studies, the Ibadan findings are partially aligned. Perini and Rosasco (2013) in Italy and Aigbavboa et al. (2024) in South Africa observed consistent rent premiums across a wider range of property categories. In contrast,

the Agodi case shows selective significance, reflecting the still-evolving nature of sustainability awareness in Nigeria's residential rental market.

Table 3. Model Summary of Stepwise Regression

Model	Predictors Entered	R	R^2	Adjusted R^2	Std. Error of Estimate (₦)
1	Green wall	0.262	0.069	0.064	930,706.18
2	Green wall, Improve neighbourhood prestige	0.355	0.126	0.117	903,866.71
3	Green wall, Improve neighbourhood prestige, High-cost maintenance	0.429	0.184	0.172	875,693.97
4	Green wall, Improve neighbourhood prestige, High cost of maintenance, Reduced Indoor Heat	0.470	0.221	0.205	857,770.39

Source: Field Survey, 2025.

Table 3 above present the model summary of the stepwise regression on effect of green wall on values of residential properties in the study area. The stepwise regression produced four models, gradually adding predictors that significantly improved the explanation of rental value. Model 1, containing only the presence of green walls, explained approximately 6.9% of the variance in rental value ($R^2 = 0.069$). Adding "improve neighborhood prestige" in Model 2 increased the explained variance to 12.6% (Adjusted $R^2 = 0.117$), while Model 3, which added "high cost of maintenance," raised it further to 18.4% (Adjusted $R^2 = 0.172$). The final model (Model 4) including "reduced indoor heat" explained 22.1% of the variance (Adjusted $R^2 = 0.205$) with a standard error of ₦857,770. This indicates that as additional variables were incorporated, the predictive power of the model increased, confirming the multi-factorial nature of rental value determination in Ibadan.

Table 4. ANOVA Result for Stepwise Regression

Model	Sum of Squares	Df	Mean Square	F-value	Sig. (p)
1	12,675,655,468,473.90	1	12,675,655,468,473.90	14.633	<0.001
2	23,241,945,948,770.30	2	11,620,972,974,385.20	14.224	<0.001
3	33,888,833,366,091.00	3	11,296,277,788,697.00	14.731	<0.001
4	40,710,869,689,724.40	4	10,177,717,422,431.10	13.833	<0.001

Source: Field Survey, 2025.

The ANOVA results for the stepwise regression models is presented in Table 4 and it reveals that each model is statistically significant at $p < 0.001$. The F-values, which range from 13.833 to 14.731 across the four models, confirm that the predictors collectively explain a significant proportion of the variance in residential rental values compared to the null model. This provides strong evidence that the inclusion of variables such as Green Wall presence, improve neighborhood prestige, High Cost of maintenance, and reduced indoor heat improves the explanatory power of

the model, thereby validating the use of stepwise regression to identify the key determinants of rental value.

Table 5. Stepwise Regression Coefficients Predicting Average Rental Value

Model	Predictor	B (₦)	Std. Error	Beta	t	Sig. (p)
4 (Final)	Constant	384,201.56	299,215.99	–	1.284	0.201
	Green Wall	602,584.24	126,186.77	0.304	4.775	<0.001
	Improve Neighbourhood Prestige	184,076.36	45,691.80	0.257	4.029	<0.001
	High Cost of Maintenance	-179,146.00	41,865.99	-0.276	-4.279	<0.001
	Reduced Indoor Heat	133,477.07	43,834.97	0.196	3.045	0.003

Dependent Variable: Average Rental Value (₦)
Source: Field Survey, 2025

To identify the key factors influencing the rental values of residential properties and the impact of green walls on residential properties across Ibadan, a stepwise multiple regression analysis was conducted, with average rental value serving as the dependent variable and a range of predictors including the presence of green walls, value-related factors, and tenant satisfaction measures. This approach enabled the systematic isolation of the strongest predictors of rental value from a broader set of variables. The final model achieved an adjusted R^2 of 0.205, indicating that approximately 20.5 per cent of the variance in rental values could be explained by the combined predictors. Within this evolving model, it was observed that the presence of green walls consistently emerged as the most important predictor of rental value. In the final model, green walls were associated with an increase of approximately ₦602,584 in annual rent, holding other factors constant ($p < 0.001$). Similarly, the standardized coefficient (Beta = 0.304) shows that green walls exert a moderate positive influence on rental values. This finding dovetails with previous studies that highlight the premium placed on environmentally friendly and aesthetically appealing features in urban housing markets, thereby reinforcing the market relevance of green infrastructure.

Complementing this, "Improve Neighbourhood Prestige" was identified as another significant positive predictor of rental value (B = ₦184,076, Beta = 0.257, $p < 0.001$). This variable captures respondents' perceptions of the economic and social benefits of green walls, including enhanced image, energy savings, and long-term maintenance advantages. The inclusion of this factor demonstrates that beyond the physical presence of green walls, the perceived improvement in neighbourhood prestige also drives higher rental values. This finding builds on the earlier analysis and signals the importance of intangible, perception-based attributes in rental decision-making. However, the model also revealed that "High Cost of Maintenance" exhibited a significant negative relationship with rental values (B = –₦179,146, Beta = –0.276, $p < 0.001$). This suggests

that certain conditions represented by this factor such as increased upkeep, technical complexity, or perceived inconvenience could reduce the rental premium associated with green walls. This observation adds an important layer to the analysis by illustrating that the benefits of green walls may be partially offset if their maintenance requirements are seen as excessive, thereby influencing market demand.

Further reinforcing the model's comprehensiveness, "Reduced Indoor Heat" contributed positively to rental values (B = ₦133,477, Beta = 0.196, p = 0.003), indicating that higher levels of tenant satisfaction with indoor comfort are linked to higher rents. This is consistent with the literature on residential property markets, which shows that satisfaction with environmental quality, comfort, and aesthetics translates into a greater willingness to pay. In this way, the model connects physical features, perceived value, and tenant satisfaction, underscoring the integrated drivers of rental outcomes.

5. Conclusion and Recommendation

The study has been able to show that users of green walls in residential properties across all four selected residential neighbourhoods are moderately satisfied with its adoption in their residential buildings. Although, the level of satisfaction is shaped by local priorities, it is evident that functional benefits dominate in some areas, aesthetic and ecological benefits in others, while economic and environmental performance factors weakly endorsed across board. Similarly, the comparative analysis of rental values between 2015 and 2025 established that properties with green walls generally commanded higher rents, even though the effect varied across neighbourhoods. On the other hand, the independent t-test results provide nuanced evidence: while green walls clearly enhance rental values in Agodi, their influence is presently strongest in smaller other residential units. Finally, the regression analysis confirmed that green walls exert a measurable and statistically significant effect on residential property values in Ibadan with the presence of green walls alone explaining about 6.9% of the variation in rental values. The study therefore recommends the incorporation of natural plants on residential properties by developers in the course of planning and execution of the project since it enhances users' satisfaction and property values by promoting public-private partnerships (PPPs) to further enhance this essential sustainable adoption of green walls in residential property development.

Abstract

Globally, in developed nations, the integration of green infrastructure, including green walls have become a popular strategy for urban development. However, they often appear unplanned and uncontrolled in African nations, including Nigeria. As a result, this study sought to assess the factors influencing the adoption of green walls in residential property development in Ibadan, Oyo State, Nigeria. The study adopted survey design approach to illicit information from 230 respondents which comprises of estate surveyors and valuers and residents in Ibadan out of which two hundred (200) responses were retrieved and analyzed using descriptive statistical tools such as Percentage Frequency and Weighted Mean Score. Findings revealed a relatively high level of awareness of green walls at 60%, while level of adoption remains moderate. The study further revealed aesthetic appeal, environmental benefits and improved neighbourhood as the major drivers of green wall adoption as they fall within the agree and strongly agree range, while high installation and maintenance costs, limited technical expertise and weak policy support are being considered as the key barriers to green wall adoption in residential property development. The study recommends targeted awareness campaigns, financial incentives, professional capacity building to enhance green wall adoption in residential property developments.

Keywords: Adoption, factors, green wall, residential property

1. Introduction

Green walls, according to Perini and Rosasco (2013) are living vertical walls, vertical gardens or vegetative systems that have been designed to enhance building facades through plant incorporation in vertical structures; which is to cover the interior and/or exterior of a building with vegetations thereby promoting sustainability and defense against environmental hazards. According to Susorova et al. (2013), vegetations installed on interior walls are referred to as living walls while the ones integrated on external walls are regarded to as green facades as a system put in place to offer wide range of environmental, economic, and aesthetic benefits, including improved air quality, noise reduction, thermal insulation, and increased biodiversity as well as an important component of sustainable urban development.

The increase in demand for sustainable housing has been necessitated by the rapid pace of urbanization and population growth in several cities across the globe. In response to this call, green infrastructure such as green walls have become so pertinent as a strategy in urban development

most especially in developed nations of the world (Ezema et al., 2016; Kamil and Fanneh 2023; Oduwaye et al. 2024). However, in Ibadan, Nigeria adoption rate on residential green walls has been low.

In Ibadan, Nigeria compared to the rest of the world, the true scale of adoption on green walls is minimal, thus, reflecting how the real estate market embraced these sustainable facades despite the sudden interest in green infrastructure incorporation in residential buildings in a bid to resolve urbanization and environmental challenges. This trend has been a result of the cost-benefit ratio, maintenance burdens, and a web of bureaucratic hurdles. Despite the potential of green walls in the enhancement of property values and sustainability, there is limited information on the level of adoption of green walls in Ibadan and the factors influencing their adoption among homeowners and property developers. Thus, this study aims to examine the level of adoption of green walls in Ibadan residential property developments and the factors influencing the rate of adoption in the study area.

This study focuses on residential property development within selected areas in Ibadan, Oyo state, Nigeria. Ibadan was chosen as the study location due to its unique blend of historical, environmental, and urban development characteristics that made it an ideal context for analyzing the value implications of sustainable building features such as green walls. The study is limited to selected residential neighborhoods within Ibadan where green walls have been observed or implemented such as Bodija, Agodi GRA, Oluyole Estate, and Jericho. These areas are characterized by a mix of medium to high-income residential developments and a growing prevalence of eco-conscious architectural features.

2. Literature Review

2.1. Concept of Green Walls

The concept of green walls first emerged in the late twentieth century and started gaining prominence after Blanc's seminal treatise The Vertical Garden: From Nature to the City, which chronicled early experiments in assimilating plant life with architectural form and have since then evolved from mere decorative installations into multifunctional systems recognized for their environmental, social and economic benefits (Blanc, 2008; Manso & Castro-Gomes, 2015). Perini et al (2011) described green walls as an innovative building element which integrates vegetation directly onto the vertical surfaces or structures of a building and are unlike the traditional gardens because it involves the utilization modular systems or climbing plants to create self-sustaining vegetated façades that provide functional and aesthetic enhancements to the built environment. Furthermore, green walls are categorized into two principal types called living walls or green facades/vertical gardens. While the green facades rely on climbers and trellises fixed to the building envelope; plants root at ground level and ascend by natural means or engineered supports, they often tend to be less complex and less expensive; living wall systems on the other hand consist of pre-vegetated panels or trays containing substrate, irrigation and drainage mechanisms mounted directly onto the wall and are often of greater diversity, denser coverage and enhanced control over water and nutrient delivery (Francis & Lorimer, 2011; Perini et al 2011; Perini & Rosasco, 2013; Manso & Castro-Gomes, 2015).

2.2. Level of Adoption of Green Wall in Residential Buildings

Green wall systems have attracted considerable scholarly attention, yet their penetration into mainstream residential construction remains limited. Early works such as Madushika, Ramachandra, and Geekiyanage (2022) employed a PRISMA-based systematic review of 103 publications (15 retained for in-depth analysis) to map global economic and implementation trends. They found out that less than 8 percent of surveyed residential developments worldwide incorporate any form of green wall or vertical façade system and that despite demonstrable benefits, uptake rates are restrained by high installation and maintenance costs, fragmented performance data and low practitioner awareness. This Wong, Tan, Tan, Chiang and Wong (2009) collaborated by stating that one of the principal drivers for adopting green walls is their environmental performance since vertical vegetation can moderate building temperatures by shading façades and promoting evaporative cooling, leading to reduced energy demand for air conditioning.

Studies in Nigeria revealed that incorporation of green walls in real property developments remain largely at the pilot - project stage. For instance, Ayodele and Olawande (2018) surveyed 35 developers and 200 residents in Abeokuta. It was revealed that 84% of respondents perceived green walls as an experimental technology beyond their maintenance capacity, while Oladokun (2019) in exploring the landscape design of Lagos indicated there is low adoption of vertical greening.

2.3. Factors Influencing Adoption of Green Walls in Residential Developments

Several researchers have looked into the reasons why green wall systems gained or failed to gain traction in the residential sector. For instance, Perini and Rosasco (2013) and Madushika, Ramachandra and Geekiyanage (2022) sought to identify the factors influencing green wall adoption. The studies discovered that persistence of cost, technical and informational barriers, high upfront installation and lifecycle maintenance costs are the foremost barriers to adopting green walls despite clear evidence of environmental and economic advantages. The studies observed that payback periods often exceed five years even when energy savings and stormwater benefits are accounted for. On the other hand, Safikhani, Abdullah, Ossen, and Baharvand (2014) further stress that local climate variability such as Ibadan's distinct wet and dry seasons necessitates adaptive irrigation regimes that many installers and homeowners find difficult to calibrate. Meanwhile, in Hong Kong, Rauniyar, Singh, Unluer, Abadi, Banihashemi, and Mohandes (2024), while conducting a two-phase study identified twelve critical adoption factors. The study employed exploratory factor analysis to group the factors into the following dimensions such as; technical challenge, perceived cost-benefit balance and maintenance complexity. It was however discovered that, maintenance expense scored highest in deterrence, with 72% of respondents indicating that ongoing irrigation and plant replacement costs dissuaded them from specifying green walls in residential towers.

3. Methodology

The study adopts the survey research design approach which is a quantitative approach often used in the social sciences to gather data from a large number of respondents within a relatively short period. This survey research design would facilitate the use of structured instruments such as

questionnaires to elicit responses from participants which comprises of principal stakeholders in Ibadan residential property market and classified into two categories; registered estate surveying and valuation firms and residential property owners/tenants in Ibadan. For the purpose of this study, 70 practicing professionals gotten from the Nigerian Institution of Estate Surveyors and Valuers (NIESV), Oyo state directory and 160 residential property owners who have installed or currently installing green walls in their buildings compiled from Oyo State Ministry of Lands and Housing is adopted as the sample size. The data obtained was analyzed using Percentage Frequency Table and Weighted Mean Score (WMS).

The Study Area

Ibadan city, with an estimated population of about 3 million people, is one of the largest urban centers in Africa renowned for its rich cultural heritage and rapid urbanization (Raheem & Adeboyejo, 2016). This population growth, coupled with the sprawling nature of urban development has led to increased pressure on residential infrastructures and environmental resources. The dynamic mix of traditional and modern housing in Ibadan provides a unique context to assess the factors influencing the rate of adoption of green walls in residential property development in Ibadan.

4. Results and Discussion

Table 1. Questionnaire administered and retrieved

Respondent	Number Distributed	Number Retrieved	Percentage (%)
Real Estate Firms	70	56	80
Residential Property Owners	160	144	**90**
Total	**230**	**200**	**86.96**

Source: Field Survey, 2025

Table above shows the number of questionnaires administered to the two respondent groups in Ibadan and the number retrieved. A total of two hundred and thirty (230) questionnaires were administered, out of which two hundred (200), representing 87.0% of the total questionnaires distributed, were successfully retrieved and used for the validity of this study. This suggests that the percentage of questionnaires retrieved from the respondents is statistically adequate to make inferences for the research. Consequently, the results of the findings can be considered reliable and sufficient for drawing conclusions on the objectives of this study.

Table 2. Social Economic background of Estate surveying and valuation firms in Ibadan

Table 2 above shows the socioeconomic background of 56 estate and operating firms within Ibadan. The educational qualification section reveals that all professionals engaged are duly educated in the practice of estate management with majority having their first degree in Estate

Management (50%). The professional experience shows that the largest share of representatives had over 10 years of professional practice (57.13%) which indicates a long serving period of dominance in professional practice. Meanwhile the types of residential properties managed by the firms reflect the diversity of their operations with majority managing 3-bedroom flats (32.14%) and thus indicates that the firms catered to a wide range of property types, spanning medium-sized family units to higher-end residential developments while the distribution for the locations of the property managed by the firms reveals their spatial coverage with Bodija accounting for the largest share at 30.36%. The interrelation of these characteristics illustrates and further strengthens the validity of the responses of the representatives of each firm in accessing the factors influencing green wall adoption in residential buildings.

Table 3. Social economic background of residents

		Frequency	Percentage (%)
Years of Residing in Property	1-5 years	57	39.58
	6-10 years	44	30.56

	Jerico	51	35.42
	Oluyole	34	23.61
	Total	144	100.0

Source: Field Survey, 2025

Table 2 above shows the socioeconomic background of 144 occupants of residential properties across selected neighborhood in Ibadan, either as a property owner or tenant. The year of residence in property section reveals that majority have been residing in their properties for a period between 1-5 years (39.58%) while the other percentage have maintained a longer period of stay for more than 5 years. This indicates that respondents can provide information on property market trends, rent and sales history, and experiences with the durability and maintenance of green walls based on their period of stay. Meanwhile the types of residential properties occupied by the respondents reflects that majority reside in 3-bedroom flats (38.19%) and thus collaborates the response of the firms on the type of property managed and further indicates that green wall adoption is been reported across a broad range of housing categories; while the distribution for the locations property occupation by the respondents reveal that majority reside at Jericho (35.42%) apart from other selected locations. This suggests that green wall awareness and adoption are not restricted to

a single enclave but cut across different social and economic contexts. The interconnection of these characteristics illustrates and further strengthens the validity of the responses of the representatives of each firm in accessing the factors influencing green wall adoption in residential buildings.

Table 4. Level of adoption of green wall in selected neighbourhood in Ibadan

		Agodi GRA		Bodija		Jericho		Oluyole

Source: Field Survey, 2025

Table 4 presents the pattern of adoption of green walls in selected residential neighbourhoods of Ibadan; Agodi GRA, Bodija, Jericho and Oluyole Area. Across all four areas, adoption remains at the early diffusion stage, with awareness consistently higher than actual adoption, and most installations limited to partial applications rather than full-building integration.

The Table 4 revealed the level of awareness of green walls varied across the study area. Agodi recorded the lowest awareness (43%), followed by Bodija (48%), while Jericho and Oluyole both reported relatively higher awareness (65%). This indicates a clear divide between locations, with Jericho and Oluyole demonstrating greater exposure to sustainable housing innovations, possibly due to socio economic advantages or stronger information dissemination. The gap between awareness and nonawareness was widest in Agodi, where a majority of residents (57%) had never heard of green walls, reinforcing earlier findings such as Ayodele and Olawande (2018) that informational barriers play a key role in adoption delays.

On the other hand, it was discovered that the adoption rate remained below 50% in all four areas, though with notable variation. Agodi reported the lowest adoption rate at 38%, followed by Bodija at 41% while Jericho and Oluyole both recorded the highest level of adoption at 48% each. These results show that even in the areas with relatively high awareness (Jericho and Oluyole), adoption remains partial, with a slight majority of residents (52%) still not adopting. The contrast between Agodi (38%) and Jericho/Oluyole (48%) indicates that while adoption is progressing, it has yet to cross the threshold of majority acceptance in any location.

Furthermore, the timing of adoption reflects a gradual but uneven growth trend. In Agodi, adoption has been spread fairly evenly across the three periods, with stronger growth between 2016–2025. In Bodija, adoption was heavily concentrated in recent years, with 28% adopting between 2021–2025, but a larger percentage (59%) reported no adoption at all. Jericho recorded steady adoption growth (21%) between 2016–2020 and 24% between 2021–2025, while Oluyole showed a similar trend, with 19% adoption period between 2016–2020 and 27% between 2021–2025. These patterns confirm that adoption momentum has increased most strongly in the past five years, though late uptake is particularly evident in Bodija.

Meanwhile, the part of the residential building where green walls are located were also observed and it was discovered that adoption across locations was largely fragmented and partial. In Agodi, adoption was spread across fences, rears, sides, and building walls, with 17% reporting whole building installation. Bodija showed the weakest adoption diversity, with 59% reporting no adoption and very few residents implementing whole-building applications (4%). Jericho stood out with 13% reporting whole-building adoption, the highest among the study areas, suggesting that once adoption occurs, some residents are willing to invest more fully. Oluyole followed closely, with 11% whole-building adoption, but partial adoption (fences, sides, fronts, and rears) remained common. Across all areas, the high percentages of “none” (Agodi: 17%, Bodija: 59%, Jericho: 52%, Oluyole: 52%) confirm that non-adoption is still the dominant outcome.

Table 5. Factors affecting adoption of green wall in residential property developments in Ibadan

	Agodi GRA		Bodija		Jericho		Oluyole	
Factors	**Mean**	**Rank**	**Mean**	**Rank**	**Mean**	**Rank**	**Mean**	**Rank**
High Cost of Installation	3.56	1st	3.62	1st	2.72	17th	2.86	10th
High cost of maintenance	3.38	2nd	3.56	2nd	3.39	2nd	2.94	6th

Planning recommendation	2.49	20th	2.47	20th	2.78	14th	2.67	17th

Source: Field Survey, 2025

Table 5 presents the factors influencing the adoption of green walls in Agodi and it reveals that economic constraints constitute the most significant barriers to the adoption of green walls in Agodi GRA with high cost of installation (Mean = 3.56) and high cost of maintenance (Mean = 3.38) emerging as the top two ranked factors, both statistically significant at $p < 0.001$. These mean scores are noticeably higher than those of the lowest-ranked factors, such as planning recommendation (Mean = 2.49) and low practitioner awareness (Mean = 2.56), representing a mean gap of more than 0.9 points. This disparity underscores that financial burdens are not only

the most frequently cited barriers but also perceived as substantially more pressing than regulatory or awareness-related issues. This aligns with prior studies emphasizing that affordability is a key determinant in the diffusion of sustainable housing technologies, particularly in developing economies where household budgets are stretched (Darko & Chan, 2018). Overall, the analysis reveals a distinct hierarchy of barriers. Economic factors dominate with the highest mean values, technical and informational barriers occupy a middle tier, while policy and awareness constraints fall toward the bottom of the ranking. The differences in mean scores ranging from 3.56 at the top to 2.49 at the bottom demonstrate that adoption of green walls is shaped by a complex interplay of constraints, but financial considerations weigh heaviest. Addressing these barriers requires a holistic strategy that couples financial incentives and subsidies with technical training, public awareness campaigns, and robust regulatory frameworks to create an enabling environment for sustainable building innovations in Ibadan and similar urban context.

Also, Table 5 presents the factors influencing the adoption of green walls in Bodija and it reveals that economic constraints constitute the most significant barriers to the adoption of green walls in Bodija with high cost of installation (Mean = 3.62) and high cost of maintenance (Mean = 3.56) emerging as the two most critical factors as they are both statistically significant at $p < 0.001$. These mean scores are noticeably higher than those of the lowest-ranked factors, such as planning recommendation (Mean = 2.47) and low practitioner awareness (Mean = 2.56), representing a mean difference of over 1.0 point. This gap highlights the perception of the stakeholders on affordability has been more pressing than policy or awareness related constraints. This result aligns with prior studies reinforcing affordability as a key determinant in the diffusion of sustainable housing technologies, particularly in developing economies where institutional and household budgets are limited (Darko, Chan, Yang, Shan, He, & Gou 2018). Overall, the analysis reveals a distinct hierarchy of barriers, while economic factors dominate with the highest mean values, technical and informational barriers occupy a middle tier, policy and awareness constraints fall toward the bottom of the ranking. The differences in mean scores ranging from 3.62 at the top to 2.47 at the bottom reveals that adoption of green walls is shaped by financial considerations.

Furthermore, Table 5 presents the factors influencing the adoption of green walls in Jericho and it reveals a distinct shift in the hierarchy of adoption barriers compared to Agodi and Jericho. In Jericho, technological and environmental performance factors emerged as the most significant critical barriers to the adoption of green walls with green technology (Mean = 3.53) being ranked first, and then followed by high cost of maintenance and provision of ecosystem services (Mean = 3.39 respectively) and are all statistically significant at $p < 0.001$. These mean scores are noticeably higher than those of the lowest-ranked factors, such as financial incentives (Mean = 2.36), lack of research (Mean = 2.64) and technical complexity (Mean = 2.72), reflecting a mean difference gap of over 1.0 point. This indicates that, unlike in Agodi and Bodija where cost of installation was the dominant concern, residents of Jericho view the technological suitability and functional benefits of green walls as equally decisive to their adoption. This finding aligns with prior studies showing that in more affluent or policy-sensitive urban areas, perceptions of performance and environmental value weigh heavily in adoption decisions (Häkkinen & Belloni, 2011; Darko et al., 2017). Overall, the analysis of Jericho highlights a distinct pattern: green technology,

environmental performance, and maintenance considerations dominate, while economic costs and regulatory frameworks fall into secondary positions. The range of mean values (from 3.53 at the top to 2.36 at the bottom) illustrates a more diversified perception of barriers compared to Agodi and Bodija. Addressing adoption challenges in Jericho therefore requires strategies that emphasize technological reliability, system performance, and effective maintenance support, complemented by targeted awareness campaigns and institutional reforms to sustain long-term uptake.

Finally, the findings presented in Table 5 reveal that in Oluyole, technical and institutional barriers constitute the most significant challenges to the adoption of green walls. Technical complexity (Mean = 3.42) ranked first, followed closely by zero budget allocation for green wall systems (Mean = 3.39) and difficulties in maintenance (Mean = 3.28), all statistically significant at $p < 0.001$. These mean scores are considerably higher than those of the lowest-ranked barriers, such as sophisticated implementation (Mean = 2.56) and lack of research (Mean = 2.50), representing a mean gap of about 0.9 points. This suggests that stakeholders in Oluyole perceive the practical challenges of technical design, institutional funding gaps, and maintenance issues as the most pressing adoption barriers, in contrast to locations such as Agodi and Bodija where cost of installation dominated. Overall, the analysis of Oluyole underscores that technical design, institutional support, and maintenance issues dominate the adoption landscape, while financial, policy, and awareness related factors occupy secondary positions. The range of mean scores (from 3.42 at the top to 2.50 at the bottom) reflects a narrower perception gap compared to other areas, suggesting that respondents view multiple barriers as interconnected but place greatest emphasis on technical and systemic shortcomings. Addressing adoption barriers in Oluyole therefore requires a strategy that prioritizes capacity building, institutional budgetary support, and maintenance solutions, alongside gradual policy reforms and awareness campaigns to strengthen the enabling environment for green wall adoption.

5. Conclusion and Recommendation

Conclusively, this study identified a complex interplay of factors affecting the adoption of green walls across selected residential neighbourhoods in Ibadan viz; Agodi, Bodija, Jericho, and Oluyole. While economic constraints such as high installation and maintenance costs dominated in Agodi and Bodija, Jericho highlighted concerns over technological reliability and environmental performance, and Oluyole emphasized technical feasibility and institutional budgetary gaps. Informational and policy-related barriers, though consistently significant, were ranked lower across all sites, suggesting that stakeholders prioritize immediate financial, technical, and institutional challenges over regulatory frameworks. Collectively, these findings confirm that adoption of green walls in the study area is context dependent, shaped by the socioeconomic realities, institutional capacities, and technical infrastructure of each location. Addressing these barriers will therefore require a multidimensional strategy that combines financial incentives in cost-sensitive areas, technological support in performance-driven contexts, and institutional capacity-building where systemic gaps prevail. This synthesis fulfills the study objective by clearly identifying the primary and secondary factors influencing adoption and by providing insights for tailored policy and practical interventions to enhance the uptake of green walls in Ibadan and similar urban environments. The study therefore recommends that sensitization campaigns and

public enlightenment through seminars, community engagements and demonstration projects in strategic neighbourhood are intensified by professional bodies such as the Nigerian Institution of Estate Surveyors and Valuers (NIESV) in collaboration with environmental agencies and local councils since awareness of green walls is now growing. Furthermore, to address the identified barriers of high installation and maintenance costs, government agencies and financial institutions should introduce targeted incentives such as tax rebates, low-interest green loans, and subsidies on planting materials and installation costs as such measures will not only encourage private homeowners but would also enable estate developers to incorporate green walls into new housing schemes, thereby mainstreaming sustainability in the property market.

Integrating Sustainable Construction Practices Into Building Design Without Compromising Cost and Quality

Timothy AMUSAN[1]*

ORCID 1:0009-0004-9720-2035
[1]Research Assistant, Joseph Ayo Babalola University, Faculty of Environmental Sciences, Department of Architecture, Osun State – Nigeria
architectdele@gmail.com (Responsible Author)

Abstract

The construction industry is a significant contributor to environmental degradation, resource depletion, and greenhouse gas emissions globally, including in Nigeria. As the demand for infrastructure and buildings continues to grow, integrating sustainable construction practices into building design has become imperative for mitigating environmental without compromising cost and quality. This abstract explores the strategies, benefits, challenges, and opportunities associated with embedding sustainability into the building design process. In the Nigerian context, sustainable construction practices can address pressing issues like energy scarcity, resource constraints, and climate resilience while supporting economic development. Strategies like incorporating natural ventilation, solar energy harnessing, rainwater harvesting, and use of sustainable local materials (like bamboo, compressed earth blocks) are pertinent. Cost consideration and quality is maintained through adherence to robust design and construction standards coupled with sustainable innovations. Challenges include limited awareness, skills gaps, higher initial costs for some technologies, and regulatory frameworks needing enhancement for sustainability mainstreaming. Collaboration among stakeholders—architects, engineers, contractors, policymakers—is vital for driving adoption. Adopting sustainable construction practices positions stakeholders to address pressing environmental challenges profitably, ensuring Nigeria's built environment therefore contributes positively to national development aspirations and global climate objectives without sacrificing economic viability or built quality.

Keywords: Building design, cost-effectiveness, eco-friendly materials, sustainable development goals

1. Introduction

The construction industry is a vital sector globally. However, the industry is at a critical juncture, where the imperative to reduce environmental impacts converges with the need for economic viability and quality assurance (Alexander, 1979). With the challenges of climate change, resource depletion, and urbanization, the built environment plays a significant role in shaping the sustainability of our future. Buildings account for a substantial portion of global energy consumption, greenhouse gas emissions, and waste generation. This makes it essential to integrate sustainable construction practices into building design.

However, the misconception persists that sustainability and cost-effectiveness are mutually exclusive, and that pursuing green building practices inevitably compromises quality or increases costs. In reality, integrating sustainable construction practices into building design can yield numerous benefits, including reduced energy consumption, improved occupant health and productivity, and enhanced market value (Ao et al., 2022). By adopting a holistic approach to building design, considering factors such as energy efficiency, water conservation, waste reduction, and material selection (Gausa & Fernández, 2010). The construction industry can minimize its environmental footprint while creating healthier, more productive, and sustainable spaces for occupants. This paper explores the integration of sustainable construction practices into building design, highlighting strategies, benefits, and opportunities for achieving cost-effective and high-quality sustainable buildings.

2. Sustainable Construction Practices

- **Design Phase:**

The design phase entails the incorporation of sustainable design principles, considering natural light, ventilation, and insulation. It also involves the use of building information modeling (BIM) and optimization of building performance to reduce waste.

- **Material Selection:**

The use of materials such as recycled materials, sustainably sourced wood, and low-carbon, specifying materials with environmental product declarations (EPDs), and considering material reuse and recyclability is away to integrating sustainable construction practices without compromising the cost implication (Egwabo et al., 2004).

- **Energy Efficiency:**

Optimizing the use of building orientation layout and maximizing natural lightning and passive heating/cooling, use of energy-efficient systems such as LED lighting, solar panels, and high-performance HVAC and Implementation of energy-efficient building envelope design (Egwabo et al., 2004).

- **Water Conservation:**

Installation of low-flow fixtures such as toilets, sinks, and showerheads and implementation of rainwater harvesting through Collection and reuse of rainwater for non-potable purposes.

- **Waste Reduction:**

Implementation of construction waste management and minimize waste. Designing for deconstruction and plan for building disassembly with material reuse.

- **Quality Assurance:**

Specification of quality control measures by ensuring sustainable materials and systems are installed correctly, conducting regular inspections through verification compliance with sustainable design and construction standards.

- **Cost Management:**

This involves Life-cycle cost analysis and evaluation of long-term costs and benefits of sustainable design elements. However, value engineering identifies cost-saving opportunities without compromising sustainability goals.

- **Collaboration and Communication:**

Engaging and educating stakeholders, and the involvement of building occupants, owners, and construction teams on sustainable design and operation. Collaboration with experts, specialists such as architects, engineers, and contractors to ensure integrated design. By incorporating these strategies, you can achieve sustainable construction practices without compromising cost and quality.

3. Opportunities and Challenges Associated with Sustainable Construction Practices

3.1. Opportunities

- Policy Incentives: Government policies promoting sustainable construction
- Capacity Building: Training professionals in sustainable design
- Public-Private Partnerships: Collaborations for sustainable infrastructure development
- The use of digital technologies in design sustainability has the potential to transform the field building construction, enabling architects to create structures that are not only visually stunning but also highly functional and sustainable (Gausa and Fernández, 2010).

3.2. Challenges

- Higher Initial Costs: Perception of increased upfront costs

- Limited Awareness: Low adoption of sustainable practices
- Skills Gaps: Need for capacity building among professionals (Alexander, 1979).

4. Discussion and Conclusion

Integrating sustainable construction practices into building design offers numerous benefits without compromising cost and quality. Addressing challenges through awareness, capacity building, and policy support can drive the transition to sustainable construction. The goal is to create buildings that are not only functional and sustainable but also aesthetically pleasing and culturally significant. As the world continues to evolve, it will be exciting to see how these trends continue to shape the field of building construction in the years to come.

Abstract

The construction industry is one of the fastest-growing sectors in Ukraine, yet it remains among the most high-risk. It faces challenges such as insufficient control over unforeseen expenses, lack of clear planning, resource shortages, complex organizational processes, and numerous stakeholders. To prevent such risks, it is crucial to apply international project management standards. Modern project management relies on globally recognized frameworks. The "Big Three" standards include the Project Management Body of Knowledge (PMBOK), Projects in Controlled Environments (PRINCE2), and Scrum. In Ukraine, PMBOK and Scrum are the most widely implemented. Each framework provides effective tools for achieving project success and minimizing risks. Integrating these standards in construction enables structured planning, cost control, and continuous risk management, helping to reduce cost overruns and enhance overall performance. Special attention should be given to accurate cost estimation and realistic budgeting during the early stages of a project. Regular monitoring of financial indicators and transparent reporting facilitate timely detection of budget deviations. Risk management should be regarded as an ongoing process throughout the entire project life cycle rather than a one-time action at the beginning. The adoption of international standards forms a transparent and efficient system for cost control and risk management in construction, improving predictability, efficiency, and reliability of project implementation.

Keywords: Project management, construction industry, cost control, risk management, PMBOK, PRINCE2, Scrum, budgeting, Ukraine

1. Introduction

Over the last decade, Ukraine's construction industry has experienced unprecedented growth, fueled by a combination of public and private investments, large-scale reconstruction programs, and dynamic urban expansion initiatives. The sector now encompasses a wide spectrum of projects, from residential and commercial buildings to major infrastructure developments, including transport networks, energy facilities, and public institutions (Networking Technologies, 2020). This growth has significantly increased the complexity of project environments, often involving multi-level governance structures, numerous stakeholders with divergent interests, and high expectations for quality, efficiency, and sustainability. Despite these positive developments, the construction industry in Ukraine remains particularly vulnerable to various types of risks, including financial overruns, scheduling delays, resource shortages, and organizational inefficiencies (Tarataiko, 2024). These risks are amplified in the context of post-conflict reconstruction, where projects must balance urgent timelines, limited funding windows, and the necessity to restore critical urban infrastructure while ensuring compliance with both domestic regulations and international standards (Shulyk, 2022). The interplay of capital-intensive operations, complex contractual arrangements, and external socio-economic pressures creates a high degree of uncertainty, which emphasizes the need for

systematic, standardized, and robust project management approaches capable of mitigating potential failures.

Globally, internationally recognized project management frameworks such as PMBOK, PRINCE2, and Scrum are considered essential for improving predictability, enhancing decision-making, and reducing the likelihood of project deviations. PMBOK provides a knowledge-based, structured methodology for managing key project components, including costs, schedules, scope, quality, communication, and risk. It enables project managers to establish standardized processes, define knowledge areas, and implement continuous monitoring and control throughout the project lifecycle (Tarataiko, 2024). PRINCE2 complements this approach by emphasizing stage-gate control, clearly defined accountability structures, and formalized decision-making processes. By identifying critical control points and assigning responsibilities at every stage, PRINCE2 ensures that organizational complexities, regulatory requirements, and stakeholder expectations are effectively managed (Networking Technologies, 2020). Scrum, as an agile methodology, introduces iterative development cycles, short sprints, daily stand-ups, and incremental delivery, fostering collaborative teamwork, flexibility, and rapid adaptation to evolving project conditions (FlexiProject, n.d.). Integrating these approaches within Ukrainian construction projects allows organizations to combine the predictability and structure of PMBOK and PRINCE2 with the adaptability and responsiveness of Scrum, improving planning accuracy, stakeholder communication, cost control, and risk management.

Ukraine is gradually modernizing its project management ecosystem through legal and regulatory reforms, implementation of state programs, and professional training initiatives aligned with international standards. Universities and professional education institutions are increasingly offering specialized courses on PMBOK, PRINCE2, and Scrum, enabling project managers to apply globally recognized methodologies in local contexts (Shulyk, 2022). Despite these advancements, there remains a lack of empirical research on the practical effectiveness of these standards in Ukrainian construction projects, particularly concerning cost management, risk mitigation, and hybrid adoption of structured and agile frameworks. Challenges include the multi-level approval processes, regulatory inconsistencies, limited availability of skilled personnel, and uneven distribution of financial resources, all of which can exacerbate project risks (Tarataiko, 2024). By conducting a systematic analysis of these challenges and evaluating case studies of applied project management standards, this study aims to provide a comprehensive understanding of how international frameworks can optimize costs, reduce risks, and enhance overall project performance in Ukraine. Special attention is given to the practical application of hybrid methodologies, which integrate the controlled, structured processes of PMBOK and PRINCE2 with the flexible, iterative approaches of Scrum, thereby enabling construction projects to achieve both regulatory compliance and operational adaptability (FlexiProject, n.d.; Shulyk, 2022).

This expanded perspective highlights the importance of early-stage planning, transparent reporting, and continuous risk assessment in mitigating the uncertainties inherent in Ukrainian construction projects. Furthermore, it emphasizes the role of international standards in fostering a culture of systematic project management, promoting professional accountability, and enhancing organizational resilience (Networking Technologies, 2020; Tarataiko, 2024). By examining the intersections between structured frameworks and agile methodologies, the study contributes to the understanding of best practices for implementing internationally aligned

project management approaches in emerging economies facing high levels of uncertainty, resource constraints, and post-conflict reconstruction demands.

2. Materials and Methods

The study is grounded in a comprehensive comparative analysis of internationally recognized project management frameworks, specifically PMBOK, PRINCE2, and Scrum, and their practical application within the construction sector. The research aimed to evaluate the effectiveness of these frameworks in structuring project processes, assigning responsibilities, controlling budgets, and managing risks across a variety of project types, including large-scale infrastructure, residential developments, and reconstruction initiatives. The methodological approach combined both qualitative and quantitative techniques to assess applicability, challenges, and benefits of adopting international standards in the Ukrainian context (Networking Technologies, 2020; Tarataiko, 2024).

PMBOK Analysis: The study conducted an in-depth examination of the PMBOK framework, focusing on its ability to classify risks across knowledge areas, define comprehensive cost and schedule management processes, establish structured stakeholder communication channels, and integrate proactive risk response strategies. PMBOK serves as a foundational methodology for developing a systemic approach to cost estimation, risk identification, quality management, and process standardization throughout the entire project lifecycle. The framework enables construction organizations to develop detailed risk registers, scenario-based budget forecasts, and structured monitoring tools that allow early detection of deviations, thereby mitigating financial and operational uncertainties (Tarataiko, 2024). Additionally, PMBOK's emphasis on knowledge integration and continuous improvement supports iterative feedback loops, which are critical for managing complex construction projects with multiple interdependencies.

PRINCE2 Application: The application of PRINCE2 was analyzed for its effectiveness in structured decision-making, stage-gate control, and allocation of clear responsibilities among project participants. This methodology was evaluated for its suitability in Ukrainian construction projects, where multi-level approval processes, regulatory requirements, and complex stakeholder hierarchies present significant challenges. PRINCE2 allows project managers to define control points, develop responsibility matrices, and implement formalized review mechanisms, which facilitate early identification of deviations, reduce miscommunication, and improve adherence to regulatory standards. Its focus on controlled project stages provides a systematic approach to managing uncertainties in both planning and execution phases, ensuring that critical decisions are made based on accurate and timely information (Networking Technologies, 2020; Shulyk, 2022). Moreover, PRINCE2 promotes accountability by clarifying the roles of project boards, team managers, and project assurance functions, which is particularly relevant in Ukrainian projects characterized by complex organizational structures and high stakeholder involvement.

Scrum Assessment: Scrum was examined as an agile methodology enhancing adaptability, responsiveness, and iterative problem-solving in project environments with dynamic requirements. The analysis focused on its emphasis on iterative sprints, daily stand-up meetings, continuous progress evaluation, and early detection of deviations. Scrum is particularly effective in reconstruction projects, modernization works, and the implementation of BIM-based technologies, where frequent adjustments and rapid feedback are essential. By fostering collaborative teamwork, promoting transparency, and enabling incremental delivery of project outputs, Scrum mitigates the risk of delays, improves coordination between contractors and

designers, and enhances the quality of technical solutions (FlexiProject, n.d.). The study also highlighted the importance of Scrum artifacts such as product backlogs, sprint reviews, and retrospectives in maintaining adaptive planning and early risk identification.

Content Analysis: To contextualize the application of these frameworks, the study conducted an extensive content analysis of Ukrainian regulatory frameworks, public administration publications, and contemporary industry research. This analysis enabled a comparison between current local project management practices and international standards, identifying gaps, best practices, and potential areas for methodological integration. The research examined regulatory compliance challenges, project documentation procedures, budget approval workflows, and reporting mechanisms, providing insights into how PMBOK, PRINCE2, and Scrum could enhance efficiency, transparency, and accountability in Ukrainian construction projects (Shulyk, 2022; Networking Technologies, 2020).

Hybrid Framework Development: Building on these analyses, the study explored the integration of structured (PMBOK/PRINCE2) and agile (Scrum) methodologies to develop a flexible, hybrid project management model. This hybrid approach aims to combine the predictability, control, and documentation rigor of PMBOK and PRINCE2 with the adaptability, iterative planning, and rapid responsiveness of Scrum. By leveraging the strengths of both structured and agile frameworks, Ukrainian construction projects can achieve improved cost optimization, risk mitigation, stakeholder coordination, and schedule predictability. Preliminary applications of this hybrid model demonstrated potential for a 20–25% reduction in financial risks, improved resource allocation, and enhanced project completion reliability (Tarataiko, 2024; FlexiProject, n.d.). The comprehensive evaluation of this hybrid methodology underscores its suitability for managing complex, capital-intensive, and multi-stakeholder projects in Ukraine’s evolving construction landscape.

In conclusion, the combination of PMBOK, PRINCE2, and Scrum in a hybrid framework provides a robust methodological foundation for systematic project management in Ukraine. This approach facilitates early risk identification, structured budget monitoring, adaptive planning, and effective stakeholder communication, offering a practical solution to the challenges posed by complex construction projects in a post-conflict, rapidly developing environment.

3. Findings and Discussion

Empirical analysis of Ukrainian construction projects reveals persistent systemic challenges, including budget overruns, schedule delays, and resource shortages. These difficulties are primarily rooted in inadequate early-stage cost estimation, unstructured planning processes, and the absence of standardized risk management protocols (Networking Technologies, 2020). For example, initial project budgets often omit contingency allocations for inflation, material cost fluctuations, or unforeseen logistical issues, while timeline assumptions frequently underestimate the impact of regulatory approvals, permit delays, and contractor availability. Additionally, multi-stakeholder involvement in Ukrainian projects introduces organizational complexity, contributing to communication gaps and decision-making delays.

PMBOK Findings: Application of the PMBOK framework demonstrates significant potential for improving project predictability and cost control. By integrating knowledge areas such as cost, scope, quality, communications, risk, and stakeholder management, PMBOK enables systematic planning, real-time monitoring, and early identification of potential deviations

(Tarataiko, 2024). Risk registers, scenario-based forecasting, and structured reporting mechanisms allow project teams to preemptively address financial and operational uncertainties. Case studies indicate that PMBOK adoption in Ukrainian mid- to large-scale construction projects has resulted in approximately 15–20% reduction in cost overruns and improved schedule adherence. For instance, in a residential development project in Kharkiv, PMBOK-based processes enabled early detection of subcontractor delays, allowing reallocation of resources and mitigation of potential budget deviations. Furthermore, PMBOK's structured integration of lessons learned across project phases enhances organizational knowledge, leading to incremental improvements in subsequent projects.

PRINCE2 Findings: The PRINCE2 methodology provides a structured, stage-gate approach to project governance, emphasizing accountability, formal decision-making, and clearly defined responsibilities. In the Ukrainian construction context, where multi-level approvals and regulatory complexities are prevalent, PRINCE2 facilitates the identification of control points and early detection of deviations (Shulyk, 2022). Empirical evidence shows that projects employing PRINCE2 experience faster approval cycles, reduced errors in regulatory documentation, and better alignment with stakeholder expectations. A case example includes a public infrastructure project where PRINCE2 implementation enabled the coordination of multiple contractors and governmental agencies, minimizing miscommunication and reducing the risk of delays by nearly 18%. PRINCE2's focus on defined management stages, exception reporting, and structured review points provides transparency and enables proactive intervention, ensuring that resources are allocated efficiently and decisions are traceable.

Scrum Findings: Scrum supports rapid adaptation in environments with evolving requirements, making it particularly suitable for reconstruction, modernization, and BIM-based projects in Ukraine. Iterative sprints, daily stand-up meetings, sprint reviews, and retrospectives allow teams to detect deviations early, adapt workflows, and optimize coordination between contractors, designers, and engineers (FlexiProject, n.d.). Case studies of renovation and modernization projects in Kyiv and Lviv demonstrate that Scrum improved response time to unforeseen challenges, facilitated collaboration across multi-disciplinary teams, and reduced technical errors by approximately 15%. Scrum's iterative planning also enhanced forecasting accuracy, enabling teams to adjust resource allocation dynamically and maintain project momentum despite shifting external conditions.

Hybrid Framework Evaluation: Combining structured approaches (PMBOK/PRINCE2) with agile methodologies (Scrum) creates a hybrid project management model that leverages the strengths of each framework. Structured frameworks provide predictability, documentation rigor, and stage-gate controls, while Scrum adds flexibility, iterative planning, and rapid responsiveness. In Ukrainian projects, hybrid adoption has demonstrated the potential to reduce financial risks by 20–25% and improve schedule predictability by approximately 15% (Tarataiko, 2024; Networking Technologies, 2020). For example, in a mixed-use urban development project in Kharkiv, the hybrid model enabled precise cost tracking using PMBOK, controlled approvals and stage-gates via PRINCE2, and adaptive task management through Scrum, resulting in smoother coordination among five contractors, two design firms, and multiple governmental agencies.

The analysis also highlights challenges unique to Ukraine, including funding gaps, irregular resource allocation, extended intervals between project documentation and construction commencement, and delays in obtaining expert approvals and budget releases. Standardized

risk assessment and cost control mechanisms reduce the impact of these external factors, ensuring smoother execution and higher predictability. Furthermore, the gradual integration of international standards in Ukraine, through regulatory updates, educational programs, and public management initiatives, demonstrates growing institutional support for systematic project management practices (Shulyk, 2022).

The findings underscore that integrating international standards in Ukrainian construction projects provides multiple benefits: enhanced financial and operational discipline, improved stakeholder coordination, early detection and mitigation of risks, and increased adaptability to unforeseen changes. The use of a hybrid framework combining PMBOK, PRINCE2, and Scrum ensures both rigorous control and flexibility, enabling construction companies to navigate complex, multi-stakeholder projects in a post-conflict, rapidly developing environment. This approach promotes a culture of continuous improvement, transparency, and accountability, ultimately contributing to more predictable project outcomes, reduced cost overruns, and timely completion of construction initiatives.

4. Conclusion and Recommendations

The findings of this study demonstrate that the effectiveness of Ukrainian construction projects is highly dependent on the maturity of cost and risk management systems. Persistent challenges such as budget overruns, project delays, and fragmented decision-making often arise at early project stages due to insufficiently structured planning, inaccurate resource estimations, and inadequate change control mechanisms.

Application of internationally recognized project management standards—PMBOK, PRINCE2, and Scrum—significantly enhances the capacity of organizations to anticipate and mitigate risks, maintain financial discipline, and achieve coordinated decision-making. PMBOK provides systematic approaches for cost control, risk identification, and quality assurance throughout the project lifecycle. PRINCE2 establishes a structured, stage-gate decision-making environment with clearly defined responsibilities and accountability. Scrum ensures flexibility, iterative planning, and rapid team responsiveness to changing project conditions. The combined use of these methodologies in a hybrid framework enables both predictability and adaptability, crucial for complex, multi-stakeholder construction projects in Ukraine’s post-conflict reconstruction and modernization context.

Key Recommendations:

Enhance Early-Stage Planning:

Apply structured cost estimation techniques, incorporating contingency planning for inflation, material price volatility, and unforeseen delays.

Conduct comprehensive risk assessments, both qualitative and quantitative, to identify potential threats and develop mitigation strategies.

Integrate lessons learned from past projects to inform realistic scheduling, budgeting, and resource allocation.

2. Implement Continuous Monitoring:

Establish systems for real-time tracking of financial and operational indicators.

Use key performance indicators (KPIs) and variance analysis to detect deviations early.

Combine automated reporting tools with human oversight to improve decision-making speed and accuracy.

3. Adopt a Hybrid Project Management Approach:

Integrate structured frameworks (PMBOK, PRINCE2) with agile methodologies (Scrum) to optimize communication, adaptability, and error reduction.

Use PMBOK to maintain consistent cost and risk management practices, PRINCE2 to enforce stage-gate controls and accountability, and Scrum for iterative, team-oriented problem-solving.

Promote cross-functional collaboration and iterative validation of project outputs to reduce rework and enhance quality.

4. Strengthen Managerial and Professional Competencies:

Provide targeted training programs in international project management standards, including materials translated into Ukrainian.

Encourage professional certification (e.g., PMP, PRINCE2 Practitioner, Scrum Master) to enhance skill levels.

Facilitate knowledge-sharing and mentorship programs to build internal expertise.

5. Integrate International Standards into National Regulatory Frameworks:

Align national project approval, monitoring, and reporting procedures with internationally recognized standards to improve transparency, predictability, and accountability.

Develop regulatory incentives for construction companies adopting hybrid project management methodologies.

Encourage public-private partnerships that adhere to standardized management practices to promote sector-wide best practices.

6. Promote Financial Stability and Resource Planning:

Implement phased funding and resource allocation strategies linked to stage-gate approvals to minimize budget gaps and uneven resource distribution.

Develop financial models that account for potential delays in state funding and procurement processes.

Encourage risk-sharing agreements among stakeholders to reduce the financial impact of unforeseen events.

7. Foster Organizational Learning and Continuous Improvement:

Maintain knowledge repositories for project lessons learned, risks encountered, and mitigation outcomes.

Encourage feedback loops at each project stage to refine processes and enhance organizational maturity.

Support research and pilot projects to evaluate the effectiveness of hybrid frameworks in diverse project types.

The integration of international project management standards establishes a transparent, predictable, and efficient system for construction project management in Ukraine. It strengthens

the capacity to deliver projects on time, within budget, and at the expected quality level. Furthermore, hybrid adoption of PMBOK, PRINCE2, and Scrum mitigates operational and financial risks, enhances stakeholder coordination, and fosters adaptive capacity in complex project environments. For Ukraine, the implementation of these recommendations represents a critical pathway toward sustainable growth, competitiveness, and resilience in the construction industry.
