Architectural Sciences Platform

Evaluation Process and Policies

All applications have undergone double blind peer review process. In addition, each paper was accepted and the process of publishing in the book was carried out through editorial oversight.

The published papers were presented and discussed at the meeting.

Full texts and abstracts published in accordance with the Congress Policy have been prepared in accordance with ethical rules and APA standards.

All authors are responsible for the content and format of their articles, both ethically and legally. The Editors and Publisher are not responsible in any way for articles published in the Congress Proceedings.

Presentation

Oral and Online Presentations

Aim of The Congress

This Symposium aims to bring together qualified scientists from Türkiye and abroad on a common international platform under the umbrella of Architectural Sciences and to enable different disciplines to share their valuable research.

Topics of The Congress

- Planning (Planning theories, planning paradigms, types of planning, regional planning, watershed planning, landscape planning, urban planning, rural planning, planning and protection, spatial and temporal changes, site selection methods, etc.)
- Design (Design theories, Space, Building, Urban, Landscape, Rural, Village, Tourism, Recreational, Environment, Interial Architecture, Plantation, Industrial Products, Ecological, Universal, Disabled, etc.)
- Sociology / Psychology / Art / Philosophy / History / Identity / Theory / Aesthetics
- Protected Areas / Natural and Cultural Heritage Protection / Documentation / Renovation / Repair / Restoration / Soil sealing
- Tourism / Recreation / Cultural Tourism / Nature Tourism / Ecotourism / Archeology
- Climate Change / Renewable Energy / Energy saving / Energy Transition / Water / Sustainability / Ecology/ Environment / Sustainable Development
- Smart and Ecological Cities / Urbanizm / Landscape / Open and Green Spaces / Green infrastructure / Transportation / Urban Agriculture / Urban Renewal / Transformation
- Building Materials / Green Buildings / Urban Accessories and Furniture / Landscape materials/ Landscape Plant Materials and Using/ Plant Cultivation and Use
- Technology / Artificial Intelligence / Digital Architecture and 3D Software and Printer, GIS, Remote sensing
- Health / Pandemic / Food / Occupational Health and Safety
- Higher Education in Architectural Sciences / R&D / Scientific Researches / Publications
- Future of Architectural Sciences / Utopia / Space Architecture / Water Architecture
- Economic / Policies / Legislation / Management / Governance / Practices / Sectoral Problems

Participants Countries

Algeria, Azerbaijan, Bangladesh, Ethiopia, Italy, Iran, India, Malaysia, Moldova, Morocco, Nigeria, Northern Cyprus, Pakistan, Poland, Romania, Türkiye, Ukraine

Total Accepted Articles: 265

Number of Rejected Papers: 25
The Number of Accepted Papers from Türkiye: 119
The Number of Accepted Full Papers from Other Countries: 146

October 29-30-31, 2025 / Demre, Antalya, Türkiye

Honorary Board

- **Emin BAĞLI**

Demre District Governor, Demre Türkiye

- **Fahri DURAN**

Mayor of Demre Municipality, Demre, Türkiye

Head of the Organising Committee

- **Prof. Dr. Atila GÜL**

Süleyman Demirel University, Faculty of Architecture, Department of Landscape Architecture, Isparta- Türkiye

Vice Heads of the Organising Committee

- **Prof. Dr. Öner DEMİREL**

Kırıkkale University, Faculty of Fine Arts, Department of Landscape Architecture, Kırıkkale- Türkiye

- **Prof. Dr. Şule ORMAN**

Akdeniz University Demre Dr. Hasan Unal Vocational School Director, Demre, Türkiye

- **Prof. Dr. Ümit ARPACIOĞLU**

Mimar Sinan Fine Arts University, Faculty of Architecture, Department of Architecture, Department of Building Physics and Materials, Istanbul - Türkiye

- **Prof. Dr. Nevzat ÇEVİK**

Akdeniz University Department of Archaeology Antalya, Türkiye

- **Salih GÜNAY**

Demre Deputy Mayor, Demre, Türkiye

- **Osman YATKIN**

Demre Deputy Mayor, Demre, Türkiye

- **Assoc. Prof. Dr. Ebru Fatma FINDIK**

Hatay Mustafa Kemal University, Faculty of Science and Letters, Department of Art History, Hatay- Türkiye

- **Çağrı YOLUK**

Demre Municipality Park and Gardens Manager, Demre, Türkiye

- **Assist. Prof. Dr. Ahmet FİDAN**

Chairman of Federation of Culture-Art, Research, Nature and Environment Associations (KADOÇED) Ordu-Türkiye

- **Assist. Prof. Dr. Mert ÇAKIR**

Süleyman Demirel University, Faculty of Architecture, Department of Landscape Architecture, Isparta- Türkiye

- **Assist. Prof. Dr. Gizem DİNÇ**

Süleyman Demirel University, Faculty of Architecture, Department of Landscape Architecture, Isparta- Türkiye

SYMPOSIUM COORDINATORS

Dr. Atabek MOVLYANOV (IKSAD Scientific Support Coordinator)

Dr. Alina AMANZHOLOVA (IKSAD Scientific Support Coordinator)

Organizing Board Members

- Prof. Dr. Asena SOYLUK - Gazi University, Faculty of Architecture, Department of Architecture, Ankara-Türkiye
- Prof. Dr. Ayfer Aybike KARADAĞ - Düzce University, Faculty of Forestry, Department of Landscape Architecture, Düzce- Türkiye
- Prof. Dr. Ertan DÜZGÜNEŞ - Karadeniz Technical University, Faculty of Forestry, Department of Landscape Architecture, Trabzon-Türkiye
- Prof. Dr. Hilal Tendü GÖKTUĞ - Adnan Menderes University, Faculty of Agriculture, Department of Landscape Architecture, Aydın-Türkiye
- Prof. Dr. Kağan GÜNÇE - Eastern Mediterranean University, Department of Architecture, Interior Architecture, Famagusta- North Cyprus
- Prof. Dr. Murat AKTEN - Süleyman Demirel University, Faculty of Architecture, Department of Landscape Architecture, Isparta- Türkiye
- Prof. Dr Murat ZENGİN - Pamukkale University, Faculty of Architecture ve Design, Department of Architecture, Denizli-Türkiye
- Prof. Dr. Niyazi Uğur KOÇKAL - Akdeniz University, Faculty of Engineer, Department of Civil Engineering, Antalya- Türkiye

IMPORTANT

- To be able to make a meeting online, log in via **https://zoom.us/join** site, enter ID instead of "Meeting ID or Personal link Name'' and solidify the session.
- **Each presentation is limited to a maximum of 15 minutes.**
- **Session times should never be exceeded. It must be completed on time before the next session starts.**
- **Presentations can be presented in "English or Turkish". However, visual presentations must be "English text".**
- The Zoom application is free and no need to create an account.
- The Zoom application can be used without registration.
- The application works on tablets, phones, and PCs.
- Speakers must be connected to the session **15 minutes before** the presentation time.
- All Symposium participants can connect live and listen to all sessions.
- During the session, your camera should be turned on at least %70 of the session period
- Moderator is responsible for the presentation and scientific discussion (question-answer) section of the session.

TECHNICAL INFORMATION

- Make sure your computer has a microphone and is working.
- You should be able to use the screen sharing feature in Zoom.
- Attendance certificates will be sent to you as a pdf at the end of the Symposium.

Before you, log in to Zoom indicate Session and Hall number and your surname
(SESSION 1-HALL-1, XXXX)

Important Notice:

• The Protocol Opening and Panel event on October 29, 2025, in the Congress Program will take place at the Demre Municipality Culture Center Conference Hall.

•The in-face to face sessions of the Congress (October 31, 2025) will be held at the accommodation venue, the Mediterranean Fisheries Research, Production, and Education Institute Directorate Demre Education Center (Demre, Antalya).

ÖNEMLİ

- Sempozyumda Yazım Kurallarına uygun gönderilmiş ve bilim kurulundan geçen bildiriler için online (video konferans sistemi üzerinden) sunum imkanı sağlanmıştır.
- Online sunum yapabilmek için **https://zoom.us/join** sitesi üzerinden giriş yaparak "Meeting ID or Personal Link Name" yerine ID numarasını girerek oturuma katılabilirsiniz.
- **Her bir sunum en fazla 15 dakika ile sınırlandırılmıştır.**
- **Oturum süreleri kesinlikle aşılmamalıdır. Bir sonraki oturum başlamadan önce zamanında tamamlanmalıdır.**
- **Sunumlar "İngilizce veya Türkçe" sunulabilir. Ancak görsel sunumlar mutlaka "İngilizce metin" olmalıdır.**
- Zoom uygulaması ücretsizdir ve hesap oluşturmaya gerek yoktur.
- Zoom uygulaması kaydolmadan kullanılabilir.
- Uygulama tablet, telefon ve PC'lerde çalışmaktadır.
- Sunum yapacakların sunum saatinden **15 dk önce** oturuma bağlanmış olmaları gerekmektedir.
- Tüm katılımcılar oturumlara online katılıp dinleyebilir.
- Oturumdaki sunumlardan ve bilimsel tartışmalardan (soru-cevap) oturum başkanları sorumludur.

TEKNİK BİLGİLER

- Bilgisayarınızda çalışır durumda mikrofon bulunmalıdır.
- Zoom'da ekran paylaşma özelliği kullanılabilmelidir.
- Katılım belgeleri Sempozyum sonunda tarafınıza pdf olarak gönderilecektir.
- Sempozyum programında yer ve saat değişikliği gibi talepler dikkate alınmayacaktır.

Zoom'a girişte sırayla Oturum ve Salon numarasını ve Soyadınızı yazınız
(OTURUM 1-SALON-1, XXXXX)

Önemli Açıklama:

- **Kongre Programındaki 29 Ekim 2025 tarihindeki Protokol Açılışı ve Panel etkinliği Demre Belediyesi Kültür Merkezi Konferans Salonunda gerçekleşecektir.**
- **Kongrenin Yüzyüze Oturumları ise Konaklama yeri olan Akdeniz Su Ürünleri Araştırma, Üretme ve Eğitim Enstitüsü Müdürlüğü Demre Eğitim Merkezinde (Demre, Antalya) gerçekleştirilecektir.**

FACE TO FACE SESSIONS

October 30, 2025 (Thursday)

Congress Venue: Mediterranean Fisheries Research, Production and Training Institute Directorate Demre Training Centre- Demre, Antalya
(Akdeniz Su Ürünleri Araştırma, Üretme ve Eğitim Enstitüsü Müdürlüğü Demre Eğitim Merkezi- Demre, Antalya)

THURSDAY – October 30, 2025 Antalya (Demre)-Türkiye Time: 9:00-10:45 (Face to Face)		
SESSION-1, LİKYA HALL / OTURUM-1, LİKYA SALONU • MODERATOR: Prof. Dr. Öner DEMİREL		
TITLE	**AUTHORS**	**AFFILIATION**
Development of Hospital Garden Design	• Melike Sağlam • Sima Pouya	Inonu University, Türkiye
Expert Opinions and Evaluation Within the Scope of Urban Forest Management	• Öner Demirel • Bilgenur Ak • Meryem Bihter Bingül Bulut	Kırıkkale University, Kırıkkale-Türkiye
Current Status and Analysis of Demre (Antalya) Urban Green Areas	• Atila Gül • Sibel Akten • Hüseyin Batuhan Dündar • Çağrı Yoluk	Süleyman Demirel University, Türkiye Isparta University of Applied Sciences, Türkiye Director of Parks and Gardens at Demre Municipality Demre, Antalya, Türkiye
Acoustic Identity in Cultural Landscapes: Local Sounds, Memories, and Spatial Attachment	• Sıla Günaçan Odabaşı • Ebru Erbaş Gürler	Istanbul Medipol University, Türkiye
	•	
	•	

THURSDAY – October 30, 2025 Antalya (Demre)-Türkiye Time 9:00-10:45 (Face to Face)		
SESSION-2, MYRA HALL / OTURUM-2, MYRA SALONU MODERATOR: Assoc. Prof. Dr. Şirin Gülcen Eren		
TITLE	**AUTHORS**	**AFFILIATION**
Reimagining the City: Utopian and Dystopian Perspectives in Contemporary Urban Planning	• Mehmet Can Akdağ • Şirin Gülcen Eren	Süleyman Demirel University, Türkiye
An Evaluation of The Conservation Hıstory, Archaeological Findings, and The "Heritage For The Future" Project of The Church of St. Nicholas	• Ebru Fatma Findik	Hatay Mustafa Kemal University, Türkiye
Analysis of the Relationship Between Perception, Experience, Image, and Memory in the Context of Fictional Spaces in the Film "Room"	• Esra Tokuç • Serhat Anıktar	İstanbul Sabahattin Zaim University, Türkiye
Mobility As Cultural Heritage: Rethinking Yörük Settlements Through Spatial Practices	• Uğur Efe Uçar • Ethem Gürer	Istanbul Technical University, Türkiye
Forms of Influence of Financial Infrastructure on Entrepreneurship in The Republic of Azerbaijan	• Vuqar Nazarov	Azerbaijan University of Tourism and Management
	•	

THURSDAY – October 30, 2025 Antalya (Demre)-Türkiye Time 9:00-10:45 (Face to Face) SESSION-2,KEKOVA HALL / OTURUM-3, KEKOVA SALONU MODERATOR: Prof. Dr. Murat Akten		
TITLE	**AUTHORS**	**AFFILIATION**
Integration of Eye Tracking Technology Into the Urban Green Space Planning	• Murat Yeşil • Mesut Güzel • Rabia Nurefşan Açıkgözü • Eda ŞentürK	Ordu University, Türkiye
Voicenote: Mobile App for Taking Voice and Written Notes	• Ceydanur Duman, • Büşra Takgil	Düzce University, Türkiye
Iot and Mobile Application Based Smart Environment Monitoring and Drug Deterioration Prediction System Design	• Bedirhan Korkmaz, • Büşra Takgil	Düzce University, Türkiye
Enhancing Urban Microclimate Through a Digital Twin–Based Approach: The Case Study of Kaymakkapı Square, Isparta	• Aslı İlayda Koçak • Murat Akten	Süleyman Demirel University, Türkiye
Thematic Review of Machine Learning Methods in Landscape Planning Processes	• Aslı İlayda Koçak • Murat Akten	Süleyman Demirel University, Türkiye
HVAC Condensate Landscape Applications and Water–Energy–Carbon Impacts	• Buğrahan Çetinkaya • Murat Akten	Süleyman Demirel University, Türkiye

THURSDAY – October 30, 2025 Antalya (Demre)-Türkiye Time 11:00-12:45 (Face to Face)		
SESSION-4, LİKYA Hall / OTURUM-4, LİKYA SALON MODERATOR: Assoc. Prof. Dr. Berrin Şahin Diri		
TITLE	**AUTHORS**	**AFFILIATION**
The Lifecycle Assessment Analysis: Recycled Concrete Aggregate Incorporating Boron	• Seda Nur Alkan • Gamze Doğdu Yücetürk • Özkan Şengül	İstanbul Medipol University, Türkiye Bolu Abant İzzet Baysal University, Türkiye İstanbul Technical University, Türkiye
Comparison of Survey Results on the Use of External Wall Filling Materials and the Usage Trends of These Materials in the Construction Sector in Türkiye	• Berrin Şahin Diri • Ahmet Cüneyd Diri	Mimar Sinan Fine Arts University, Türkiye
Innovations Brought by 3D Printing Technology to Concrete Element Production	• Berrin Şahin Diri	Mimar Sinan Fine Arts University, Türkiye
From Cognitive Tool to Pedagogical Assistant: Rethinking AI in Interior Design Education Through Student Insights	• Gözde Gökdemir • Hande Zeynep Kayan	Istanbul Technical University, Türkiye
An Investigation into the Potential of Artificial Intelligence Applications in Low Earth Orbit Satellite Systems for Urban Planning Applications	• Elif Eda Takgil • Ali Çalhan • Murtaza Cicioğlu	Düzce University, Türkiye
Rainwater Design and Management in Housing Estate Gardens	• Melisa Eken • Irem Kaya • Ece Yıldız • Hatice Ada	Süleyman Demirel University, Türkiye

THURSDAY – October 30, 2025 Antalya (Demre)-Türkiye Time 11:00-12:45 (Face to Face)		
SESSION-5, MYRA HALL / OTURUM-5, MYRA SALONU MODERATOR: Prof. Dr. Ufuk Coşgun		
TITLE	**AUTHORS**	**AFFILIATION**
Principles and Guidelines for Planning Restoration in Forest Fire-Affected Areas	• Ufuk Coşgun • Sohaib K M Abujayyab	Karabük University, Türkiye
Child-Friendly Street Designs in Urban Areas	• Habibe Atak • Gülbin Çetinkale Demirkan	Niğde Ömer Halisdemir Üniversitesi, Türkiye
Therapeutic Garden Designs as Support in Oncology Hospitals	• İpek İpekli • Gülbin Çetinkale Demirkan	Niğde Ömer Halisdemir Üniversitesi, Türkiye
A Sustainable Development Allegory: Entelköy Efeköy'e Karşı and SDGS	• Pınar Zeğerek Altunbey	Nigde Omer Halisdemir University, Türkiye
Effects of Climate Change on the Physiology of Ornamental Plants	• Bahar Sancar	Düzce University, Türkiye
Stress Tolerance in Ornamental Plants	• Bahar Sancar	Düzce University, Türkiye

THURSDAY – October 30, 2025 Antalya (Demre)-Türkiye Time 11:00-13:00 (Face to Face)		
SESSION-6, KEKOVA HALL / OTURUM-6, KEKOVA SALON • MODERATOR: Assist Prof. Dr. Ahmet Fidan		
TITLE	**AUTHORS**	**AFFILIATION**
Classification of Kinetic Building Components in Contemporary Architecture	• Hatice Eda Gül • Nazire Tuğçe Yenice • Yenal Akgün	Dokuz Eylül University, Türkiye
The Assessment of Key Factors Sustainable Smart Cities	• Ahmet Fidan • Esra Bayır • Pelin Karaçar • Aysun Ferrah Güner	Ordu University, Türkiye İstanbul Medipol University, Türkiye
Spatial Distributions of Land Use/Land Cover (LULC) in the Demre Stream Corridor: Assessment of Current Issue	• Hüseyin Batuhan Dündar • Atila Gül • Sibel Akten	Süleyman Demirel University, Türkiye Isparta University of Applied Sciences, Türkiye
Determining Route Selection Criteria for the Creation of a Bicycle Route in the Context of Diversifying Cultural Tourism	• Sibel Akten • Atila Gül • Hüseyin Batuhan Dündar	Isparta University of Applied Sciences, Türkiye Süleyman Demirel University, Türkiye
Examining Secondary School Landscape Spaces from a Design Perspective in the Climate Change Adaptation Process	• Sibel Akten • Atila Gül	Isparta University of Applied Sciences, Türkiye Süleyman Demirel University, Türkiye
Reflections of the Bauhaus Approach to Materials in Modern and Contemporary Architecture	• İskender Emre Gül • Şebnem Ertaş Beşir	Akdeniz University, Türkiye
An Evaluation of The Restoratıon of Seyh Mehmet Emin Efendi Lodge to Create An Effective Protection-Use Balance by Re-Functioning	• Eyüp Salih Elmas	Ministry of Environment, Urbanization and Climate Change, Istanbul Provincial Directorate, Istanbul-Türkiye

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 09:00-10:45 (Online)		
SESSION-8, HALL-2 / OTURUM 8, SALON-2 • MODERATOR: Prof. Dr. Ümit Turgay Arpacıoğlu		
TITLE	**AUTHORS**	**AFFILIATION**
Development of Lignin-Modified Phenol-Formaldehyde Resins: Sustainability Effect in The Furniture Industry	• Fatma Pınar Senkon, • Busra Şimşek, • Franz Zeppetzauer, • Birgit Kamm, • Arif Akıllılar	Tosunogullari Furniture Industry and Trade Inc., Department of R&D, Konya-Türkiye Necmettin Erbakan University, Türkiye Kompetenzzentrum Holz GmbH- Wood K plus, Linz, Austria
A Study on The Use of Parametric Design Tools in Architectural Education	• Berfin Yılmaz • Ümit Arpacıoğlu	Istanbul Aydın University, Türkiye Mimar Sinan Fine Arts University, Türkiye
An Examination of Lighting Use in Exhibition Spaces Within the Context of Refunctioned Museum Buildings Through Sample Studies	• Kübra Civelek Kalınca • Menşure Kübra Müezzinoğlu	Firat University, Türkiye
The Impact of the White Cube Paradigm on Interior Design in Contemporary Art Museums: A Comparative Analysis of İstanbul Modern and New York Moma	• Sena Yılmaz • Menşure Kübra Müezzinoğlu	Firat University, Türkiye
Investigating The Effects of Transport Factor on Structural Systems' Life Cycle Environmental Performance	• Neriman Gül Çelebi • Ümit Arpacıoğlu	Mimar Sinan Fine Arts University, Türkiye
The Effects of Material on Spatial Atmosphere in Architectural Design Approaches Adopting a Minimalist Attitude	• İremnur Muslu • Ümit Turgay Arpacıoğlu	Mimar Sinan Fine Arts University, Türkiye

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 09:00-10:45 (Online)		
SESSION-9, HALL-3 / OTURUM 9, SALON-3 •MODERATOR: Assist Prof. Dr. Gizem Dinç		
TITLE	**AUTHORS**	**AFFILIATION**
Architectural Creativity Through Generative Ai: Evaluating Dall·E, Midjourney, And Stable Diffusion	•Minel Kurtuluş	Istanbul Gelisim University, Türkiye
The Impact of Flexible Classrooms on Learning in Scandinavian Schools from an Ant Perspective	•Nihansu Kücü •Sıdıka Benan Çelikel • Şebnem Ertaş Beşir	Akdeniz University, Türkiye
The Impact of Female Patrons on Urban Form in the Principalities and Ottoman Periods: The Manisa Example	•Yağmur Burcu Güneş •Şebnem Çakaloğulları	Izmir Democracy University, Türkiye Manisa Celal Bayar University, Türkiye
An Examination of Post-Disaster Housing Design in The Context of Regional and Climatic Adaptation	•Emine Şeyma Erkan •Nilay Coşgun •Elif Özer Yüksel	Istanbul Rumeli University, Türkiye Gebze Technical University, Türkiye
Adaptive Reuse of Dead Malls Into Healthcare Facilities	•Dilara Berk Coşkun •Kunter Manisa	Yildiz Technical University, Türkiye
Cappadocia of Traces: Temporary and Permanent Layers	•Emine Akcan Şirin	İstanbul Ticaret University, Türkiye

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 09:00-10:45 (Online)		
SESSION-10, HALL-4 / OTURUM 10, SALON-4 **MODERATOR: Aissam Gaagai**		
TITLE	**AUTHORS**	**AFFILIATION**
From Farm to Cup: The Interplay of Sustainability and Governance in Ethiopia's Coffee Value Chain for Sustainable Development	• Sintayehu Assefa Yirga	Hawassa University, Ethiopia
Utilizing Recycled Aggregate Concrete	• ChayarajuBalaSai • Nadagouda Kalyani • K.Tharani	G. Pulla Reddy Engineering
Perceived Effects of Fuelwood Energy Exploitation on Livelihood of Farming Households in Bauchi and Gombe States, Nigeria	• Sani Madi Yakubutate • Hannatu Ohunene Yusuf • Fadlullah Olayiwola Issa • Omadachi Ogbodo Ugbabe	Federal College of Horticulture Dadin Kowa, Gombe State Ahmadu Bello University Zaria, Kaduna State
Integration of Green Jobs in Architectural Carpentry and Joinery Practices for a Sustainable Environment in Gombe State	• Dr. Sale, • Nimrod Kamo • Yakubu Molta Nitte, • Bala Japhet Amatiga	Federal College Of Education, Gidan-Madi, Sokoto State
Threads of Escape: Adaptive Reuse of Trains	• Hira Zaina • Rimsha Imran • Maha Tariq	Hira Zainab Interior Designer Lahore College for Women University, Lahore, Pakistan
Problem of the Quality of Groundwater from Doucen Plain Intended for Irrigation and Its Assessment	• Aissam Gaagai, • Mallem Salah Eddine, • Ali Athamna, • Kebaili Feriel Kheira, • Ridha Lahkel, • Aouissi Hani Amir	Scientific and Technical Research Center on Arid Regions (CRSTRA), Algeria University of Batna 2, 05078 Fesdis, Algeria. Badji Mokhtar Annaba University, Algeria
Computer Solution to Replacement Models for Items that Fails Suddenly	• Alfa Mohammed, Abdulrahman Mohammed Saba	Federal Polytechnic Bida, Nigeria

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 09:00-10:45 (Online)		
SESSION-11, HALL-5/ OTURUM 11 SALON-5 MODERATOR: Moses Adeolu Agoi		
TITLE	**AUTHORS**	**AFFILIATION**
Dam Failure Mechanisms and Risk Assessment	• Aissam Gaagai, • Mallem Salah Eddine, • Ali Athamna, • Kebaili Feriel Kheira, • Ridha Lakhel, • Aouissi Hani Amir	Scientific and Technical Research Center on Arid Regions (CRSTRA), Algeria University of Batna 2, 05078 Fesdis, Algeria. Badji Mokhtar Annaba University, Algeria
Smart Fabrıcatıon and Automated Buıldıng Technologies	• Kishore R, • Vaishnavi. K, • Keerthana. V, • Meenatchi. S, • Dr. Saravanan	Bharath Institute of Higher Education and Research, India
Quantitative Effects of Soft Skills on Project Success: Evidence from Construction Practitioners in Nigeria	• Greg Odee Ikwe	Bingham University, Nigeria
Emerging AI Regimes and Contemporary Filmmaking in Nigeria: Governance, Practice, and Creative Futures	• Rotimi-Williams Bello	University of Africa, Nigeria
Cybersecurity Rısks In Smart Building Infrastructure	• Moses Adeolu Agoı • Samuel Olayiwola Ajaga • David Oladimeji Ajıbode • Oluwanifemi Opeyemi Agoı	Lagos State University of Education, Lagos Nigeria.
Integration of Informal Interactive Space in a Design of Faculty of Architecture	• Muhammed Abdullahi Adoku	Federal University of Technology Minna, Nigeria
Assessment of Aquifer Protective Capacity and Corrosivity Around Solid Waste Dumpsites in Parts of Minna Metropolis, North-Central, Nigeria	• Balarabe J.J., • Rafiu A.A., • Adetona A., • Shehu J., • Salihu, Y.L.	Federal University of Technology Minna, Niger State, Nigeria

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 09:00-10:45 (Online)		
SESSION-12, HALL-6/ OTURUM 12 SALON-6 MODERATOR: Dr. Bhawana Pal		
TITLE	**AUTHORS**	**AFFILIATION**
On The Influence of the Number and Location of Elliptical İnclusions on the Deformation Process of a Cylindrical Shell With a Circular Hole	• Eteri Hart • Oleksandr Shebanov	Oles Honchar Dnipro National University, Dnipro, Ukraine
A Holistic Conceptual Framework for Biophilic Design in Healthcare Environments: Enhancing Elderly Well-Being Through Environmental Integration	• Aylar Ranjbarian, • Mehrdad Karimimoshaver	Bu-Ali Sina University, Hamedan, Iran
Integrating Spatial and Environmental Needs in Architectural Education Design	• A.J. Simon, • D. O Alonge, • E. Udoko	Federal University of Technology, Minna, Nigeria
Sick Building Syndrome and Toxıcological Assessment of Constructıon Materials Among Workers and Residents in Dutse Metropolıs, Jıgawa State, Nigeria	• Bate Garba Barde	Federal University Dutse, Jigawa State, Nigeria
Contribution of Rural Infrastructure Development Fund (RIDF) in rural prosperity in India	• Bhawana Pal	Bankers Institute of Rural Development, Kolkatai India
Effect of Green Wall on Residential Property Values in Ibadan, Nigeria	• Nnaemeka Bethel Ezeokoli, • Ayooluwa Adeboye Adelakun • Dorcas Popoola	Federal University of Technology Akure, Nigeria
The Role of Artificial Intelligence in Creating Public Value in Local Government: Evidence from Hyderabad City, Pakistan	• Dr. Liaquat Ali Rahoo • Dr. Muhammad Nawaz Tunio	Mehran University of Engineering and Technology, Jamshoro University of Sufism and Modern Sciences, Bhitshah

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 11:00-12:45 (Online)		
SESSION-13, HALL-1 / OTURUM 13, SALON-1 MODERATOR: Assoc. Prof. Dr. Feran Aşur		
TITLE	**AUTHORS**	**AFFILIATION**
In Search of Thermal Comfort: Forgotten Design and Planning Principles for Cities	• Nursevil Yuca • Feran Aşur	Van Yüzüncü Yil University, Türkiye
Climate-Concerned Urban Furniture in the Urban Landscape	• Feran Aşur • Nursevil Yuca	Van Yuzuncu Yil University, Türkiye
Comparative Performance of Adaptive Façade Systems in Different Climate Types: An Evaluation of Three Buildings	• Esra Nur Arvas • Ümit Turgay Arpacıoğlu	Mimar Sinan Fine Arts University, Turkey
Reclaiming Urban Squares: A Citizen-Centered Assessment of Aliağa Democracy Square in İzmir	• Pelin Özden	İzmir Kavram Vocational School, Türkiye
The Role of Light Shelf Systems in Architectural Design: An Examination in The Context of Visual Comfort and Energy Efficiency	• Sümeyra Akgün • Ümit Arpacıoğlu	Altınbas University, Türkiye Mimar Sinan Fine Arts University, Türkiye
Sinan & Zaha: Shaping the Urban Skyline Through the “Art of Structure & Geometry”	• Ürün Biçer • Serkan Yaşar Erdinç	İstanbul Beykent University, Türkiye

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 11:00-12:45 (Online)		
SESSION-14, HALL-2 / OTURUM 14, SALON-2 • MODERATOR: Assoc. Prof. Dr. Hayriye Hale Kozlu		
TITLE	**AUTHORS**	**AFFILIATION**
Technical Contributions of Civil Engineering in the Intervention Processes for the Conservation of Historical and Cultural Heritage and the Comparative Analysis of the Role of Related Courses in Architectural Graduate Programs	• Pınar Arık • Hayriye Hale Kozlu	Erciyes University, Türkiye
Daylight Usage in Architectural Structure	• Zübeyde Çiçek • Halil Sevim	KTO Karatay University, Türkiye
Assessing Soundscape Quality in Urban Open and Green Spaces	• Gizem Delikan • Sima PouyA	Inönü University, Türkiye
Human-Centered Approaches to Educational Furniture Design: Ergonomic Analysis of Classroom Desks	• Emre Ecevit • Merve Bilgen Işik	Kayseri University, Türkiye
The Role of Streets and Avenues in The Formation of City Identity; Gaziantep Karagöz Street	• Ebru Begün Saçıkara • Meltem Barış Ararat	Hasan Kalyoncu University, Türkiye
Timber Decay in Gaziköy Houses and The Sustainability of the Rural Fabric	• Özlem Bozkurt	Tekirdağ Namık Kemal University, Türkiye

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 11:00-12:45 (Online)		
SESSION-15, HALL-3 / OTURUM 15, SALON-3 • MODERATOR: Prof. Dr. Asena Soyluk		
TITLE	**AUTHORS**	**AFFILIATION**
An Experience-Based Mapping of The Samsun City-Center	• Hande Asar	Ondokuz Mayıs University, Türkiye
A Discussion on the Spatial Atmosphere: The Example of Samsun Süleyman Pasha Madrasah	• Hande Asar	Ondokuz Mayıs University, Türkiye
Comparative Assessment of Simulation Tools in The Scope of Indoor Air Quality	• Rana Kibaroğlu Kantarcı • Elif Özer Yüksel	Gebze Technical University, Kocaeli-Türkiye
An Examination at the Intersection of Cinema and Architecture: The Rings of Power - The Land of Numenor	• Tolgay İnanç • Halil Sevim	KTO Karatay University, Konya- Türkiye
Digitalization of Sustainability in Steel Structure Design Projects	• Esin Şahin • Kerim Koç	Yildiz Technical University, Turkey
Evaluation of Room Acoustics in Auditoriums in the Context of Speech Intelligibility: An Examination of a University Auditorium	• Okan Şimşek	Adana Alparslan Türkeş Science and Technology University, Türkiye

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 11:00-12:45 (Online)		
SESSION-16, HALL-4/ OTURUM 16, SALON-4 **MODERATOR: Hachimi Dahhaoui**		
TITLE	**AUTHORS**	**AFFILIATION**
Photoresponsive Behavior of N-Acylhydrazones: A Study of Solvent-Dependent E/Z Isomerization	• Yahya Boubekri, • Siham Slassi, • Mohammed Aarjane, • Amina Amine	Université Moulay Ismail, Faculté des Sciences –Meknès, Maroc. University Hassan II of Casablanca, Casablanca, Morocco Hassan II University, Casablanca, Morocco
Integrating Sustainable Construction Practices Into Building Design Without Compromising Cost and Quality	• Amusan Timothy Oladele	Joseph Ayo Babalola University, Ikeji-Arakeji, Osun State, Nigeria
Cost And Risk Management in Ukrainian Construction Projects Through International Project Management Standards	• Volodymyr Meshcheriakov • Anastasiia Chornonoh	State Biotechnological University, Ukraine
Public Squares Along Didouche Mourad Street In Skikda: Urban Continuities and Transformations	• Boukerma Rima • Mansouri Lamia • Bouaroudj Radia • Mekki Sana • Azzam Roufaida	University of Algiers 1 Benyoucef Benkhedda
Choosing A Slope-Stability Method Under Groundwater Conditions: A Decision-Oriented Reframing of an Inter-Software Comparison	• Hachimi Dahhaoui, • Abdeldjalil Zadjaoui, • Mohammed Bekhti, • Naima Belkadi	University of Tlemcen, Algeria
Rapid Estimation of Secondary Creep in Soft Clays Using Machine Learning	• Hachimi Dahhaoui	University of Tlemcen, Algeria

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 11:00-12:45 (Online)		
SESSION-17, HALL-5 / OTURUM 17, SALON-5 • **MODERATOR: Assoc Prof. Marcelina Krupa-Małkiewicz**		
TITLE	**AUTHORS**	**AFFILIATION**
Enhanced Adsorptive Performance of Modified Clay for Efficient Dye Removal from Wastewater	• Soumaya Matchi • Adil El Yadini • Hanae Ouaddari • Abdelkbir Bellaouchou	Mohammed V University, Faculty of Sciences, Department of Chemistry, Rabat, Morocco
Development of Smart Biosensors for Real-Time Glucose Monitoring	• David.G. • Deepak.S. • Palanisamy.A. • Ravi.C. • N Jayaramakani. • R. Srinivasan	Bharath Institute of Higher Education and Research, Chennai 600073, India
Comparison of the Effectiveness of Silicon and Nanosilicon in Stimulating the Growth of Lycium Chinense Mill. Shoot Cultures in Vitro	• Marcelina Krupa-Małkiewicz • Ireneusz Ochmian	West Pomeranian University of Technology Szczecin, Poland
Conceptual Considerations on the Application of The Precautionary Principle in The Environmental Law Relationship	• Mihaela (Bejenari) Cojocaru	"Stefan cel Mare" Academy of the Ministry of Internal Affairs
Toxic Tanning: Assessing Environmental Pollution and Occupational Health Risks in the Leather Industry	• Seifeslasie Asmamaw • Esayas Shegaw	Bahir Dar University, Ethiopia Debre Tabor University, Ethiopia
Economic Implications of Climate Change on Rice *(Oryza sativa)* Production in Bangladesh	• Most. Mokarroma • Arifa Yeasmin • Md. Salauddin Sohan • Md. Sakhawat Hosen Sourav • Md.Alshahria • Md. Sazzadul Isla • Md. Mizanur Rahman	University of Rajshahi, Rajshahi, Bangladesh

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 11:00-12:45 (Online)		
SESSION-18, HALL-6/ OTURUM 18, SALON-6 MODERATOR: N.G. Kalyani Reddy		
TITLE	**AUTHORS**	**AFFILIATION**
Smart Design Solutions for University Housing: A Waste-Optimized Architectural Solution for Postgraduate Accommodation at Futminna	• Okonnah Samuel David	Federal University of Technology, Minna
Influence of Lighting Quality on Emotional And Cognitive Responses to Artworks: A Comparative Study of Prominent Art Galleries in Lagos State, Nigeria	• SA'AD Muhammad Abolakale, • Olakanbi Bolaji Abdulraheem	University of Ilorin, Kwara Nigeria University of Abuja, FCT, Abuja, Nigeria
Ai Tools in Architectural Design: Transforming Creativity, Efficiency, and Sustainability	• Abhigyan Ganguly, • Sandipan Biswas, • Nitai Paitya, • Shivnath Ghosh	Brainware University, Kolkata, India Amity Univeristy, Kolkata, India
Cybersecurity Risks in Smart Building Infrastructure	• Moses Adeolu Agoı • Samuel Olayiwola Ajaga • David Oladimeji Ajıbod • Oluwanifemi Opeyemi Agoı	Lagos State University of Education, Lagos Nigeria.
Artificial Intelligence And 3d Printing Technology in Construction: A Review	• N.G. Kalyani Reddy, • Chayaraju BalaSai, • K. Tharani	G Pulla Reddy Engineering College
From Beneficial Modulation to Adverse Toxicity: Dose-Dependent Insights into TBHQ Safety Thresholds	• Saha Anik, • Hossain Md. Tamim, • Datta Narayam, • Chowdhury Bappy, • Ranjan Acharjee Mahima, • Prank Md. Rasel, • Ahmad Monsur	Chattogram Veterinary and Animal Sciences University, Chattogram 4225, Bangladesh.

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 13:00-14:45 (Online)		
SESSION-19, HALL-1 / OTURUM 19, SALON-1 MODERATOR: Prof. Dr. Banu Çiçek Kurdoğlu		
TITLE	**AUTHORS**	**AFFILIATION**
GIS Tools in Spatial and Temporal Analysis of Land Use and Land Cover Changes: Molusce	• Çağla Aydemir • Ömer Kamil Örücü • Seda Örücü	Süleyman Demirel University, Türkiye
Integration of Virtual Reality (Vr)-Augmented Reality (Ar) and Mobile Applications in Urban Recreation Areas	• Seyhan Seyhan • Banu Çiçek Kurdoğlu	Karadeniz Technical University, Türkiye
How Do Urban Recreation Areas Contribute to Social Solidarity and Integration?	• Seyhan Seyhan • Banu Çiçek Kurdoğlu	Karadeniz Technical University, Türkiye
The Transformation of the Rami Barracks Into a Library: An Evaluation Within the Context of Adaptive Reuse	• Miskine Akar • Derya Su	Recep Tayyip Erdoğan University, Türkiye Fatih Sultan Mehmet University, Türkiye
Public Rest Areas in Shopping Centers: Samsun Piazza Mall	• Hande Yıldırım • Serap Faiz Büyükçam	Samsun University, Türkiye Ondokuz Mayıs University, Türkiye
Current Research Trends in Interior Architecture: A Conceptual Mapping	• Serap Faiz Büyükçam • Hande Yıldırım	Ondokuz Mayıs University, Türkiye Samsun University, Türkiye

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 13:00-14:45 (Online)		
SESSION-20, HALL-2 / OTURUM 20, SALON-2 MODERATOR: Assoc. Prof. Dr. Elif Sağlık		
TITLE	**AUTHORS**	**AFFILIATION**
The effects and Limitations of Safety Standards on Creative Designs in Children's Play Areas	• Elif Sağlık • Efe Arda Hasanoğlu	Çanakkale Onsekiz Mart University, Türkiye
Visualizing the impact of Modularity and Mobility on Contemporary Urban Design Using AI, Inspired by Archigram.	• Elif Sağlık • Fatma Erdoğan	Çanakkale Onsekiz Mart University, Türkiye
Conceptual Transitions and Reflections from Landscape Performance Assessment to Design Practice	• Mahmut Can Ast • Elif Sağlık	Çanakkale Onsekiz Mart University, Türkiye
Nature-Based Open Space Approaches for Sustainable Campus Life	• Emirhan Aks • Alper Sağlık	Çanakkale Onsekiz Mart University, Türkiye
Contributions of the “Placemaking” Approach to the Urban Environment	• Pınar Özge Parlak • Elif Bayramoğlu	Karadeniz Technical University, Türkiye
Nature-Based and Digital Solutions for Flood-Resilient Urban Systems	• Pınar Özge Parlak • Elif Bayramoğlu	Karadeniz Technical University, Türkiye

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 13:00-14:45 (Online)		
SESSION-21, HALL-3 / OTURUM 21, SALON-3 • **MODERATOR: Assoc. Prof. Dr. M. Bihter Bingül Bulut**		
TITLE	**AUTHORS**	**AFFILIATION**
The Social Implications of the Climate Crisis	• Hatice Gözde Özkarakay • Murat Akten	Süleyman Demirel University, Türkiye
Ecological Compatibility and Accessible Design In Archaeological Sites	• Bilgenur Ak • Öner Demirel • M. Bihter Bingül Bulut • Tuba Gizem Aydoğan	Kırıkkale University, Türkiye
Design Principles for Urban Open Parking Lots in the Climate Change Adaptation Process: The Case of Isparta	• Fatma Özkan Bayındır • Ali Öz • Atila Gül	Süleyman Demirel University, Türkiye Mehmet Akif Ersoy University, Türkiye
Urban Green Space-Sensitive Parking Lot Planning: An AI-Supported Sustainable Approach	• Fatma Özkan Bayındır • Ali Öz • Atila Gül	Süleyman Demirel University, Türkiye Mehmet Akif Ersoy University, Türkiye
Natural Carbon Sinks and Ecosystem-Based Approaches in Combating the Climate Crisis	• Mahmut Tuğluer • Mert Çakır	Kahramanmaraş Sütçü İmam University, Kahramanmaraş, Türkiye Süleyman Demirel University, Isparta, Türkiye
Citizen Science as a Tool for Urban Biodiversity Monitoring	• Mert Çakır • Mahmut Tuğluer	Süleyman Demirel University, Isparta, Türkiye Kahramanmaraş Sütçü İmam University, Kahramanmaraş-Türkiye

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 13:00-14:45 (Online)		
SESSION-22 HALL-4/ OTURUM 22, SALON-4 • MODERATOR: Dr.B. Mahadevan		
TITLE	**AUTHORS**	**AFFILIATION**
The Metaphysics of Form: Energy, Geometry, and Sphericity in Nature	• Yasin KHALILOV	Baku Engineering University, Hirdalan, Azerbaijan
A Performance Driven Generative Design Workflow for Optimizing Building Facades for Daylight and Energy Efficiency in a Mediterranean Climate	• Fahim Yar Bai • Samira Mehrafza	Ahlul Bayt International University, Tehran, Iran
Smart Irrigation System for Sustainable Farming	• Nithish Kumar R, • S Udhaya Kumar, • S Rakshith	R.M.K. Engıneering College
Information and Communication Technology Adoption Behaviour of Farmers in Thanjavur District: A Study	• B. Mahadevan	Vellalar College for Women (Autonomous), Thindal (Post), Erode, Tamilnadu, India.
Natural Farming a Sustainable Approach for Management of Soil Degradation and Climate Change Mitigation	• Ganesh Kumar, • R.Y Hiranmai, • Harshita Marwal, • Ajay Neeraj	Central University of Gujarat, Kundhela, Vadodara-391107 Gujarat, India
The Circular Memory of Hands: Circularity In The Domestic Wisdom Of Peoples	• Yasin Khalilov	Baku Engineering University, Hirdalan, Azerbaijan
Circular Bridge from East to West: The Global Dialogue of Cultures	• Yasin Khalilov	Baku Engineering University, Hirdalan, Azerbaijan

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 13:00-14:45 (Online)		
SESSION-23, HALL-5 / OTURUM 23, SALON-5 **MODERATOR: Aicha Belgacem**		
TITLE	**AUTHORS**	**AFFILIATION**
Advanced And Future Ndds Concept	• V. Hariharan, • Danish khan, • G. Madhan prasadh, • S. Punithavalli, • P. Saranya • A. Vivek, • Snehamayee mahapatra, • R. Thelshath	Bharath Institute Of Higher Education And Research
Capacity Analysis of Signalized Intersections in Oran, Algeria: A Probabilistic Model for Left-Turn Movements	• Wissem Belkheir • Zahra Bounouara • Fatima Hadjadj • Wafaa Tebboune	University of Sciences and Technology of Oran-Mohamed BOUDIAF, Algeria
Integrating Traditional and Modern Sustainable Architectural Practices for Cost-Efficiency and Climate-Responsive Buildings in Niger State, Nigeria	• Muhammad Hassan Ishaq, • Bukar Ali Kime	Ahmadu Bello University Zaria, Nigeria. University of Maiduguri, Nigeria.
Effectiveness of Land Use Planning and Zoning Regulations in Controlling Urban Development in Bauchi Metropolis	• Mustapha Umar Sa'ad, • Ibrahim Muhammad Shera, • Ibrahim Idris	Abubakar Tafawa Balewa University Bauchi, Nigeria Federal University Birnin Kebbi, Nigeria
Integrating Climate-Responsive Strategies in Environmental Design for Sustainable Urban Futures	• Jibril Jamilu, • Ibrahim Khalil Adamu	American University of Nigeria Yola, Nigeria. Federal College of Education Gidan Madi Sokoto, Nigeria
Sustainable Irrigation of an Apple Orchard Using a PV Pumping System: A Case Study from Algeria	• Aicha Belgacem, • Fatima Belgacem, • Mohamed Mostefai, • Yahia Miloud	Moulay Tahar University of Saida, Algeria

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 13:00-14:45 (Online)		
SESSION-24, HALL-6 / OTURUM 24, SALON-6 **MODERATOR: Melik Sami**		
TITLE	**AUTHORS**	**AFFILIATION**
Impact of Green Finance in Sustainable Performance: Mediating the Role of CSR	•Aqsa Farooq, •Rimsha Iqbal	Riphah International University Rawalpindi
Economic Development and Sustainable Development Goals in Africa: Challenges, Opportunities, and Policy Perspectives	•Ali Jan Sharifi, •Ahmad Farid Qasemi, •Mohammad Bashir Ashrafi, •Hamed Mohammadi, •Mohammad Yasin Rezaei	International Islamic University, Islamabad, Pakistan
The Green Waqf: Financing Eco-Architecture Through Islamic Endowments	•Melik Sami, •Khelil Sara, •Tallal Abdel Karim Bouzir	Mohamed Khider Biskra University, Biskra, Algeria. LACOMOFA Biskra laboratory. Algeria.
Economic Viability of Vertical Farming in Urban Architecture: A Sustainability Perspective	•Melik Sami, •Khelil Sara, • Tallal Abdel Karim Bouzir	Mohamed Khider Biskra University, Biskra, Algeria. LACOMOFA Biskra laboratory. Algeria.
Embedding Circular Economy Principles in Architectural Design for Sustainable Cities	•Melik Sami, •Khelil Sara, •Tallal Abdel Karim Bouzir	Mohamed Khider Biskra University, Biskra, Algeria. LACOMOFA Biskra laboratory. Algeria.
Islamic Economic Principles in Eco-Mosque Architecture: A Path to Sustainability	•Melik Sami, •Khelil Sara, •Tallal Abdel Karim Bouzir	Mohamed Khider Biskra University, Biskra, Algeria. LACOMOFA Biskra laboratory. Algeria.

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 15:00-16:45 (Online)		
SESSION-25, HALL-1/ OTURUM 25, SALON-1 MODERATOR: Prof. Dr. Sevgi Yılmaz		
TITLE	**AUTHORS**	**AFFILIATION**
Landscape Character Analysis Evaluation in Rural Settlements: Erzurum Palandöken Example	• Ahmet Koç • Sevgi Yılmaz	Dicle University, Türkiye Atatürk University, Türkiye
Climate-Sensitive Urban Design Approaches: The Case of Elazığ City	• Yaşar Menteş • Sevgi Yılmaz	Ministry of Agriculture and Forestry, Türkiye Atatürk University, Türkiye
Reducing the Urban Heat Island Effect with Water Surfaces: The Case of Lake Hazar	• Yaşar Menteş • Sevgi Yılmaz	Ministry of Agriculture and Forestry, Türkiye Atatürk University, Türkiye
Spatial Hybridization and The Transformation of Identity: A Study on Rural Settlements and Secondary Houses in The Edremit Gulf	• Aysu Çakır • Gaye Birol	İzmir Democracy University, Türkiye
Analysis of Studies on Transparent Wood and Its Potential Use in The Construction Industry	• Nilay Aykan • Esra Lakot Alemdağ	Recep Tayyip Erdoğan University, Türkiye
A Comparative Analysis of Similar Traditional Wall Construction Techniques in Different Regions	• Ayça Akkan Çavdar • Esra Lakot Alemdağ	Recep Tayyip Erdoğan University

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 15:00-16:45 (Online)		
SESSION-26, HALL-2 / OTURUM 26, SALON-2 • MODERATOR: Prof. Dr. Aybike Ayfer Karadağ		
TITLE	**AUTHORS**	**AFFILIATION**
Use of Fragrant Plants Growing in Isparta in Landscape Designs	• Emine Ağlar • Şirin Dönmez	Süleyman Demirel University, Türkiye
Natural Medicinal And Aromatic Plants Growing in Konya Climatic Conditions and Their Use in Plant Design	• Nilgül Bağcı • Şirin Dönmez	Süleyman Demirel University, Türkiye
Multi-Layered Spatial Development of Konya: A Topological Analysis of The Basin at Two Scales	• Merve Alıcı Aka • Elif Yeşim Kösten • Gülşah Üner	Kocaeli University, Türkiye
The Development of Roman Bath Architecture in the Light of the Sebastopolis Roman Baths	• Akın Temür	Ondokuz Mayıs University, Türkiye
Legal Vulnerability of Ecological Assets In the Post-Disaster Period in Turkiye	• Aybike Ayfer Karadağ • Demet Demiroğlu	Düzce University Kilis 7 Aralık University, Turkiye
Urban Open- Green Spaces Within the Framework of Turkiye's Climate Law	• Demet Demiroğlu • Aybike Ayfer Karadağ	Kilis 7 Aralık University, Turkiye Düzce University, Turkiye

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 15:00-16:45 (Online)		
SESSION-27 HALL-3/ OTURUM 27, SALON-3 **MODERATOR: Melik Sami**		
TITLE	**AUTHORS**	**AFFILIATION**
A Holıstic Conceptual Framework For Bıiophilic Desıgn in Healthcare Environments: Enhancing Elderly Well-Beıng Through Environmental Integration	• Aylar Ranjbarian, Mehrdad Karimimoshaver	Bu-Ali Sina University, Hamedan, Iran
Urban Density, Morphology, and Soundscapes: Architectural Strategıes For Sustainable Design	• Melik Sami, • Khelil Sara, • Tallal Abdel Karim Bouzir	Mohamed Khider Biskra University, Biskra, Algeria. LACOMOFA Biskra laboratory. Algeria
The Interplay of Sound and Space in Vernacular Desert Housing: Toward Sustainable Futures	• Melik Sami, • Khelil Sara, Tallal Abdel Karim Bouzir	Mohamed Khider Biskra University, Biskra, Algeria. LACOMOFA Biskra laboratory. Algeria
Soundscapes and Human Experıence: Archıtecture for the Ear in Urban Futures	• Melik Sami, • Khelil Sara, • Tallal Abdel Karim Bouzir	Mohamed Khider Biskra University, Biskra, Algeria. LACOMOFA Biskra laboratory. Algeria
Smart Soundscapes: Acoustic Technologies for Sustainable Architectural Environments	• Melik Sami, • Khelil Sara, • Tallal Abdel Karim Bouzir	Mohamed Khider Biskra University, Biskra, Algeria. LACOMOFA Biskra laboratory. Algeria
Buılding Climate Resilience Rural Settlement Design for Agricultural Communities	• Most. Mokarroma • Esita Ghosh	University of Rajshahi, Rajshahi, Bangladesh

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 15:00-16:45 (Online)		
SESSION-28 HALL-4/ OTURUM 28, SALON-4 **MODERATOR: Popescu Gh. Cristina Raluca**		
TITLE	**AUTHORS**	**AFFILIATION**
Leadership, Communication, and Cognitive Skills as Drivers of Project Performance: Prioritizing Soft Skills in the Construction Industry	• Greg Odee Ikwe	Bingham University
Dynamics of Funeral Practices Among the Haussa Muslims of the City of Zinder	• Soumana Abdoul-Wahab • Kassou Maman • Dlawali Maman Toukour	Université André Salifou, Zinder-Niger Republic
Spaces That Enhance Well-Being in Türkiye, Ireland, Netherlands, Portugal, Spain, And United States: Designing for Health as a Holistic Approach Where Human Resources Can Thrive	• Popescu Gh. • Cristina Raluca	University of Bucharest, Bucharest, Romania and The Bucharest University of Economic Studies, Bucharest, Romania
Acoustic Planning Policies: Shaping Sustainable Urban and Architectural Environments	• Melik Sami, • Khelil Sara, • Tallal Abdel Karim Bouzir	Mohamed Khider Biskra University, Biskra, Algeria. LACOMOFA Biskra laboratory. Algeria.
Biomechanically Informed and Sustainable Architectural Design in Sports Facilities: Enhancing Athlete Performance and Spectator Experience	• Shiv Kumar	Physical Education, SBV Vikas Puri, India
Climate-Responsive Architectural Strategies for Lahore: A Bioclimatic Approach Toward Sustainable Design	• Farhana Naz	Lahore College for Women University, Pakistan

FRIDAY– October 31, 2025 Antalya (Demre)-Türkiye Time 15:00-16:45 (Online)		
SESSION-29, HALL-5/ OTURUM 29, SALON-5 MODERATOR: Sándor Földvári		
TITLE	**AUTHORS**	**AFFILIATION**
Echoes of the Desert: Acoustic and Spatial Responses in Vernacular Sustainable Architecture	• Melik Sami, • Khelil Sara, • Abdel Karim Bouzir	Mohamed Khider Biskra University, Biskra, Algeria. LACOMOFA Biskra laboratory. Algeria.
Multiculturality of Lviv/Lemberg/Lwów, the Centre of West Ukraine, As Reflected in The Architectural History of the City	• Sándor Földvári	Debrecen University, Emeritus
Potential and Constraints of Beekeeping Development in Sri Lanka: A Review on Socioeconomic, Technological, And Environmental Perspectives	• Mahamarakkalage Nethmi Ayodya Perera	University of Ruhuna
Valuing The Intangible: An Integrated Economic Framework for Assessing the Cultural Capital of Heritage Architecture In Urban Regeneration	• Mohsen Mohammadi Khyareh • Mohadeseh Nezhadipour	Gonbad Kavous university, Gonbad Kavous, Iran
The Entrepreneurial City: Exploring The Impact of Zoning Regulations and Building Codes on Startup Ecosystems and Innovation Districts	• Mohsen Mohammadi Khyare • Mohadeseh Nezhadipour	
Achievements in the Temple to Moon God Nanna Built By King Ur Engur In 3 100 Bce in Ur in Mesopotamia	• Natela Borisovna Popkhadze	Head of Scholarly Information Center at Academy of Phasis in Tiflis in Gurcistan//Georgia Republic//Sakartvelo
Partial Replacement of Coarse Aggregate with Crumb Rubber Chips in Concrete Production	• N.G. Kalyani Reddy, Chayaraju BalaSai, K. Tharani	G Pulla Reddy Engineering College

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 15:00-16:45 (Online)		
SESSION-30, HALL-6/ OTURUM 30, SALON-6 MODERATOR: Kazem Golizadeh		
TITLE	**AUTHORS**	**AFFILIATION**
Assessing Global Covid-19 Recovery Roadmaps for Enhancing Resilience in Nigeria's Construction Sector: A Comparative Framework for Sustainable Adaptation	• Tasleemah Yusuf, • Peter Gangas Chindo, • Mustapha Abdulrazaq	Ahmadu Bello University Zaria, Kaduna – Nigeria
Evaluation of Biophilic Design Principles in The Design Proposal of 5-Star Hotel	• Safiya Bello Abdullahi	Federal University of Technology Minna
A Comparative Analysis of the Role of Rock-Cut Architecture in the Life Cycle of Rural Tourism: A Case Study of Kandovan, Iran, and Göreme, Türkiye	• Kazem Golizadeh	National University of Skills, Tehran, Iran
Architecture, Environmental Externalities, And Economic Policy for Sustainable Cities	• Melik Sami, • Khelil Sara, • Tallal Abdel Karim Bouzir	Mohamed Khider Biskra University, Biskra, Algeria. LACOMOFA Biskra laboratory. Algeria.
The Trade-off Between Economic Growth and Environmental Architecture in Developing Regions	• Melik Sami, Khelil Sara, Tallal Abdel Karim Bouzir	Mohamed Khider Biskra University, Biskra, Algeria. LACOMOFA Biskra laboratory. Algeria.
Effect of Material Suitability and Availability on Residents' Building Preferences in Nupe Land, Kwara State	• Kolo Vincent Mana, • Olakanbi Bolaji Abdulraheem	University of Ilorin, Kwara, Nigeria University of Abuja, FCT, Abuja, Nigeria
Iranian Art And Architecture	• Dr. Mehdi Shalchi Tousi	Ahle Beyte Internatinal University, Tehran, Iran

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 17:00-18:45 (Online)		
SESSION-31, HALL-1 / OTURUM 31 SALON-1 MODERATOR: Assist. Prof. Dr. Mert Çakır		
TITLE	**AUTHORS**	**AFFILIATION**
Integration of Advanced Building-Integrated Photovoltaic (Bipv) Systems for Sustainable Architectural Design	• Muhammad Mateen Afzal Awan	University of Management and Technology Lahore, Pakistan
Smart and Ecological Cities: Pathways to Climate-Resilient and Sustainable Urban Futures	• K. R. Padma	Sri Padmavati Mahila Visvavidyalayam (Women's University) , Tirupati, AP. India
Urban Greening Transformation of Mediterranean Cities: An Application to The City of Naples	• Floriana Zucaro	University of Naples Federico II, Italy
A Machine Learning-Driven Model to Predict Urban Outdoor Thermal Comfort	• Hüseyin Ögçe • Meltem Erdem Kaya	Istanbul Technical University, Istanbul-Türkiye
Building Envelope Strategies for Enhancing Urban Thermal Comfort: A Climate-Sensitive Perspective	• Alireza Gerami, • Mehrdad Karimimoshaver	Bu-Ali Sina University, Hamedan, Iran
Evaluating Human Impact in Urban Areas, With the Example of Sofia, Bulgaria	• Stefan Stamenov • Vanya StamenoVA	Bulgarian Academy of Sciences, Sofia - Bulgaria

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 17:00-18:45 (Online)		
SESSION-32, HALL-2 / OTURUM 32, SALON-2 • MODERATOR: Assoc. Prof.Dr. Soad Abokhamis Mousavi		
TITLE	**AUTHORS**	**AFFILIATION**
Local Material Use in Interior Architecture for Thermal Comfort in arid Climates: A Case Study of Ouarzazate, Morocco	• Chaimae Kraouch • Soad Abokhamis Mousavi	Final International University, TRNC Arkin University of Creative Arts and Design, TRNC
Societal Acceptance of Thermal Storage Wall in Buildings in Mediterranean Region	• Soad Abokhamis Mousavi	Arkin University of Creative Arts and Design, TRNC
3d Topographic and Architectural Documentation of The Multi-Functional Underground Structure at Miletus Kaletepe	• Özel Teraman Hepdinçler • Nikolai Techo • Haralambos Nikolayidi • Özlem Kaya • Hasan Ersin Güvendik • Ece Kızıldağ	Mimar Sinan Fine Arts University, Türkiye Berliner Hochschule für Technik, Germany Bilecik Şeyh Edebali University, Türkiye Yıldız Technical University, İstanbul-Türkiye
Analysis of The Impact of Urban Design on Social Inequalities and Mental Health: A Case Study of Isfahan, Iran	• Parsa Barahouei • Çilen Erçin	Eastern Mediterranean University, Northern Cyprus European University of Lefke, Northern Cyprus
Transitioning from Ifc to Linked Building Data: Semantic Simplification With Bot, Product, and Props Ontologies	• Murat Aydın	Ankara University, Türkiye
Conceptual Uncertaıntıes in Semantic BIM: Achieving Definition Clarity Through Ontology Engineering	• Murat Aydın	Ankara University, Türkiye

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 17:00-18:45 (Online)		
SESSION-33, HALL-3 / OTURUM 33, SALON-3 • MODERATOR: Assoc. Prof.Dr. Sultan Sevinc Kurt Konakoğlu		
TITLE	**AUTHORS**	**AFFILIATION**
The Role of Green Infrastructure in Improving Air Quality: A Case Study of Kocaeli Darıca Millet Garden	• Kübra Hanoğlu • Gülnur Kardan • Sultan Sevinç Kurt Konakoğlu	Amasya University, Türkiye
Assessment of Green Infrastructure Systems Based on Ecosystem Services: The Case of Amasya Unıversity	• Mustafa Taha Keskiner • Alper Kaan Kalkan • Sultan Sevinç Kurt Konakoğlu	Amasya University, Türkiye
Rural Planning Strategies: The Case of Acıpayam, Denizli	• Mine Cengiz • Murat Akten	Süleyman Demirel University, Türkiye
Hybrid Education Spaces: Spatial Strategies and Design Perspectives	• Hatice Ceylan • Ekrem Bahadır Çalışkan	Ankara Yıldırım Beyazıt University, Ankara, Türkiye
Dwelling-Street Relations in Traditional Urban Fabrics: The Case of Famagusta Walled City	• Hasan Doğan	Harran University, Türkiye
Strategic Approaches to Climate Change Adaptation and Mitigation	• İzel Meral	KTO Karatay University, Türkiye

FRIDAY – October 31, 2025 Antalya (Demre)-Türkiye Time 17:00-18:45 (Online)		
SESSION-34, HALL-4/ OTURUM 34, SALON-4 MODERATOR: M. Fathrezza Imani		
TITLE	**AUTHORS**	**AFFILIATION**
Evaluation of Users' Preferred Biophilic Design Elements in Commercial Office Buildings in Abuja, Nigeria	• Adeniji Ahmed Adeola, • Muhammad Isa Bala	Federal University of Technology Minna
Intellectual Property And Design Protection	• Aswin M Nair • Payal Shukla	Sharda University, Greater Noida, India
Pekalongan City Culture and Its Nickname as the City of Batik	• M. Fathrezza Imani	UIN KH. Abdurrahman Wahid Pekalongan

Reducing the Urban Heat Island Effect with Water Surfaces: The Case of Hazar Lake
Dr. Yaşar MENTEŞ
Ministry of Agriculture and Forestry
Provincial Directorate of Agriculture and Forestry
Elazığ, Türkiye
Email: yasarment@hotmail.com
Prof. Dr. Sevgi YILMAZ
Atatürk University
Faculty of Architecture and Design
Landscape Architecture Department
Erzurum, Türkiye
Email: sylmaz_66@hotmail.com

Material and Method
Using a qualitative case study of the Rami Barracks' transformation into Turkey's largest library, the study triangulates primary and secondary data — including historical, architectural, spatial, and sustainability sources.
These encompass archival records, 2014–2023 restoration drawings, programmatic and capacity metrics, and Biosphere certification / landscape data.
Supported by an extensive literature review on adaptive reuse, the research analytically evaluates the relationships among conservation, public space production, and cultural memory.
Stage
Description
Objective
Literature Review
Identifying fundamental concepts and research gaps on adaptive reuse.
To establish the conceptual framework and guide the case selection.
Case Selection
Selecting an example of sustainable reuse.
To ensure representativeness.
Data Collection and Analysis
Examining practices from institutional documents, projects, and reports.
To understand reuse and conservation strategies.
Evaluation and Recommendations
Evaluating the cultural, economic, and environmental impacts of historic building reuse and conservation strategies.
To assess the effectiveness of the strategies and their sustainability compliance.
Methodological Framework

ISSUED: December 15, 2025

TITLE	AUTHORS	Page No
Urban Greening Transformation of Mediterranean Cities: An Application to the City of Naples	• Floriana ZUCARO	87
Replanning Benghazi's Historic Downtown: Restoring Identity	• Fathi M. LAYAS • Ramadan E. SULEIMAN • Vail KARAKALE	88
The Sculptural Effect in Architecture: The Valencia Opera House	• Nihansu KÜCÜ • Özgü ÖZTURAN • Şebnem ERTAŞ BEŞİR	89
An Evaluation of The Restoration of Seyh Mehmet Emin Efendi Lodge to Create an Effective Protection-Use Balance by Re-Functioning	• Eyüp Salih ELMAS	90
Architectural Creativity Through Generative Ai: Evaluating Dall·E, Midjourney, and Stable Diffusion	• Minel KURTULUŞ	91
Rural Decline and Revival: Alternative Living Models for the Revitalisation of Migration-Affected Settlements	• Melike AKSAKAL • Büşra YILMAZ ERDOĞAN	92
From Cultural Memory to Contemporary Design: Traces of Nomadic Structures in Sustainability	• Rümeysa ÜZÜM • Büşra YILMAZ ERDOĞAN	93
The Lifecycle Assessment Analysis: Recycled Concrete Aggregate Incorporating Boron	• Seda Nur ALKAN • Gamze DOĞDU YÜCETÜRK • Özkan ŞENGÜL	94
A Study on Rural Resilience: The Case of Akçaabat District	• Duygu AKYOL KUYUMCUOĞLU • Tuğçe YAZICI	95
A Machine Learning-Driven Model to Predict Urban Outdoor Thermal Comfort	• Hüseyin ÖGÇE • Meltem ERDEM KAYA	96
Strategic Approaches to Climate Change Adaptation and Mitigation	• İzel MERAL	97
A Sustainable Development Allegory: *Entelköy Efeköy'e Karşı and SDGS*	• Pınar ZEĞEREK ALTUNBEY	98
Development of Hospital Garden Design	• Melike SAĞLAM • Sima POUYA	99

Assessing Soundscape Quality in Urban Open and Green Spaces	• Gizem DELİKAN • Sima POUYA	**100**
Adaptive Reuse of Dead Malls into Healthcare Facilities	• Dilara BERK COŞKUN • Kunter MANİSA	**101**
Cappadocia of Traces: Temporary and Permanent Layers	• Emine AKCAN ŞİRİN	**102**
Sick Building Syndrome and Toxicological Assessment of Construction Materials Among Workers and Residents in Dutse Metropolis, Jigawa State, Nigeria	• Bate Garba BARDE	**103**
Integration of Informal Interactive Space in A Design of Faculty of Architecture	• A. A. Muhammed • D. O. Alonge • J. A. Yusuf	**104**
Societal Acceptance of Thermal Storage Wall in Buildings in Mediterranean Region	• Soad ABOKHAMIS MOUSAVi	**105**
Local Material Use in Interior Architecture for Thermal Comfort in Arid Climates: A Case Study of Ouarzazate, Morocco	• Chaimae KRAOUCH • Soad ABOKHAMIS MOUSAVI	**106**
Voicenote: Mobile App for Taking Voice and Written Notes	• Ceydanur DUMAN • Büşra TAKGİL	**107**
Evaluation of Room Acoustics in Auditoriums in the Context of Speech Intelligibility: An Examination of a University Auditorium	• Okan ŞİMŞEK	**108**
Multi-Layered Spatial Development of Konya: A Topological Analysis of The Basin at Two Scales	• Merve ALICI AKA • Elif Yeşim KÖSTEN • Gülşah ÜNER	**109**
The Transformation of the Rami Barracks into a Library: An Evaluation Within the Context of Adaptive Reuse	• Miskine AKAR • Derya SU	**110**
IoT And Mobile Application Based Smart Environment Monitoring and Drug Deterioration Prediction System Design	• Bedirhan KORKMAZ • Büşra TAKGİL	**111**
Sinan & Zaha: Shaping the Urban Skyline Through the “Art of Structure & Geometry”	• Ürün BİÇER • Serkan Yaşar ERDİNÇ	**112**

Smart Design Solutions For University Housing: A Waste-Optimized Architectural Solution for Postgraduate Accommodation at Futminna	• OKONNAH SAMUEL David	**113**
Effect of Material Suitability and Availability on Residents' Building Preferences in Nupe Land, Kwara State	• KOLO, Vincent Mana • OLAKANBI BOLAJI Abdulraheem	**114**
Influence of Lighting Quality on Emotional and Cognitive Responses to Artworks: A Comparative Study of Prominent Art Galleries in Lagos State, Nigeria	• SA'AD Muhammad Abolakale • OLAKANBI BOLAJI Abdulraheem	**115**
A Holistic Conceptual Framework for Biophilic Design in Healthcare Environments: Enhancing Elderly Well-Being Through Environmental Integration	• Aylar RANJBARIAN • Mehrdad KARIMIMOSHAVER	**116**
Building Envelope Strategies for Enhancing Urban Thermal Comfort: A Climate-Sensitive Perspective	• Alireza GERAMI • Mehrdad KARIMIMOSHAVER	**117**
Urban Morphology and Natural Ventilation: Evaluation of Different Textures in Hot and Dry Climate Cities (Case Study: Kashan City)	• Mostafa AZAD • Mehrdad KARIMIMOSHAVER	**118**
Urban Density, Morphology, And Soundscapes: Architectural Strategies For Sustainable Design	• Melik SAMI • Khelil SARA • Tallal Abdel Karim BOUZIR	**119**
The Interplay of Sound and Space in Vernacular Desert Housing: Toward Sustainable Futures	• Melik SAMI • Khelil SARA • Tallal Abdel Karim BOUZIR	**120**
Soundscapes and Human Experience: Architecture for the Ear in Urban Futures	• Melik Sami • Khelil Sara • Tallal Abdel Karim Bouzir	**121**
Smart Soundscapes: Acoustic Technologies for Sustainable Architectural Environments	• Melik Sami • Khelil Sara • Tallal Abdel Karim Bouzir	**122**
A Performance Driven Generative Design Workflow for Optimizing Building Facades for Daylight and Energy Efficiency in a Mediterranean Climate	• Fahim Yar BAIG • Samira MEHRAFZA	**123**

Building Climate Resilience Rural Settlement Design for Agricultural Communities	• Most. MOKARROMA • Esita GHOSH	**124**
Dynamics of Funeral Practices Among the Haussa Muslims of the City of Zinder	• SOUMANA Abdoul-Wahab • KASSOU Maman • LAWALI Maman Toukour	**125**

Urban Greening Transformation of Mediterranean Cities: An Application to the City of Naples

Floriana ZUCARO [1*]

ORCID 1: 0000-0003-4171-3659
[1]PhD, University of Naples Federico II,
Civil, Building and Environmental Engineering Department (DICEA), Naples-Italy
floriana.zucaro@unina.it ***(**Responsible Author)

Abstract

Global warming increases the risks of heat stress in urban areas, endangering people's health and the ability of permeable surfaces to regenerate. The scarcity of green spaces, combined with the dense and compact structure of highly built-up cities like those in Europe and the Mediterranean, makes implementing mitigation measures especially difficult. These limitations greatly restrict opportunities to transform and renovate open spaces, necessitating careful and innovative approaches that balance climate effectiveness, heritage preservation, and urban usability.

As temperatures rise, it becomes essential to adapt and reorganize urban spaces and activities to ensure resilience against the unpredictable impacts of climate change, protect urban assets, and most importantly, enhance people's quality of life.

The methodology involves interconnected phases that provide knowledge and practical results by integrating GIS and microclimatic tools. This approach is applied in Naples, southern Italy, where the current baseline scenario is compared to a comprehensive greening and reforestation transformation of all open spaces, including planting 50 cm high grass and new trees.

The study shows that widespread conversion to green and permeable surfaces, even on a small scale, can significantly lower key summer comfort indices. It emphasises that priority interventions should focus not only on large parks but especially on small open spaces, mainly in the historic parts of the city. The benefits of increased greenery in reducing urban heat island effects and improving runoff management are evident in both central and peripheral areas, experiencing high energy use and flooding risks. These findings offer a strong foundation for local authorities, designers and residents to implement targeted adaptation strategies.

Keywords: Urban greening, urban reforestation, micro-climate simulations, GIS, urban planning

Replanning Benghazi's Historic Downtown: Restoring Identity

Fathi M. LAYAS[1*]

ORCID 1: 0009-0002-6121-6924

vail.karakale@medeniyet.edu.tr

Abstract

The historic core of Benghazi, a critical and culturally rich area, has suffered extensive damage from recent conflict. Bordered by Omar Ibn Al-Aas Street to the south, Omar Al-Mukhtar Street to the north, Ben Issa Street to the east, and Gamal Abdel Nasser Street to the west, this area is in urgent need of comprehensive reconstruction. The primary goal of this effort is to create a new vision for this part of the city, one that ensures the safe return of its residents while preserving its unique cultural and historical identity.

The initiative is built on a two-phase approach. Phase one begins with a detailed damage assessment, classifying the extent of the destruction across all buildings. This crucial step provides the data needed to inform effective rehabilitation strategies, allowing planners to determine the most suitable action for each structure—whether it requires full reconstruction or restoration.

Phase two focuses on the replanning effort itself, which aims to revitalize and protect Benghazi's identity. This includes safeguarding religious sites, historical landmarks, and other defining features of the city's character. To achieve this, we will develop separate rehabilitation schemes: one specifically for ordinary buildings to meet modern needs, and another for historic structures to preserve the city's unique architectural and cultural heritage for future generations. This dual approach ensures a balanced and thoughtful reconstruction that honors the past while building a resilient future.

Keywords: Urban replanning; cultural identity; historical identity; restoration; reconstruction.

sertasbesir@akdeniz.edu.tr

Abstract

Following the Industrial Revolution, the socio-cultural transformation accelerated the permeability between art and architecture. Within the modernist context, structure was no longer perceived merely as a load-bearing component, but rather as an aesthetic and sculptural medium. This study explores the intersection of sculpture and architecture through Santiago Calatrava's Palau de les Arts Reina Sofía (Valencia Opera House), analyzed within the framework of semiotics. The methodology relies on photographs, drawings, the architect's statements, and secondary literature. Form, the symmetrical shell structure, and the external envelope are examined as signifiers, while functional layout, circulation, and spatial experience are considered as signified.

The findings indicate that the exposed structure not only produces visual impact but also enhances spatial legibility, enriches user experience, and contributes to the building's iconization at the urban scale. The Valencia Opera House, shaped by Calatrava's biomorphic and sculptural design language, exemplifies a contemporary architectural product where engineering and art converge. The study highlights the articulation of form, structure, and meaning as key components of sculptural architecture.

Keywords: Sculptural architecture; semiotics; Santiago Calatrava; *Palau de les Arts Reina Sofía*; icon–index–symbol

An Evaluation of The Restoration of Seyh Mehmet Emin Efendi Lodge to Create an Effective Protection-Use Balance by Re-Functioning

Eyüp Salih ELMAS [1*]

ORCID 1: 0000-0002-7363-6670
[1] Dr., Provincial Manager Advisor, Ministry of Environment, Urbanization and Climate Change, Istanbul Provincial Directorate, Istanbul- Türkiye
eselmas@gmail.com

Abstract

Sufi orders which emerged alongside Sufism in the Ottoman Empire, constructed lodges to provide spiritual and moral education. Initially consisting of a single room, these lodges evolved over time to incorporate various architectural features and units.

The dervish lodge building of the subject of this study, is located in the Beykoz district of Istanbul. The lodge was established by Mehmet Emin Efendi who is a Nakşıbendi Şeyh between 1829 and 1830 and its foundation charter was drawn up between 1820 and 1821. The lodge building is a single-story, masonry structure with a mezzanine.

Following the founding of the Republic of Türkiye, the lodges considered to have completed their mission were closed in 1925. The Seyh Mehmet Emin Efendi Lodge Building which remained abandoned and neglected after the lodges were closed was demolished towards the end of the 1930's, because it was located within the section of the Bosphorus Coastal Road during the reconstruction process leaving only a portion of the main wall. The main wall traces served as an important reference point in preparing documentation and conservation projects.

Using written and visual materials (old and new buildings, aerial photographs and maps), analyses of the lodge building and its surroundings were conducted. Survey, restitution, and restoration projects were prepared by The Beykoz Municipality in 2017, during the author's tenure as a senior manager. A reconstruction decision was obtained from the relevant Cultural Heritage Preservation Board. The restoration permit and accompanying projects for the dervish lodge building deemed suitable for reuse as a cultural center were approved by the Boğaziçi Zoning Directorate. The lodge building and its surroundings were revitalized within the framework of conservation projects approved by official institutions.

Keywords: Conservation, restoration, The Seyh Mehmet Emin Efendi Lodge, re-functioning.

Architectural Creativity Through Generative Ai: Evaluating Dall·E, Midjourney, and Stable Diffusion

Minel KURTULUŞ [1*]

ORCID 1: 0000-0003-4623-0613
[1]Asst. Prof., Istanbul Gelisim University, Department of Interior Architecture, Istanbul-Türkiye
mikurtulus@gelisim.edu.tr ***(**Responsible Author)

Abstract

This study aims to examine the contributions of generative artificial intelligence (GAI) models to the processes of architectural form generation. In particular, the models DALL·E (OpenAI), Midjourney, and Stable Diffusion, which generate images from text prompts, are comparatively analyzed. The primary objective is to evaluate the potential of these models in terms of conceptual design, formal diversity, visual quality, and user control, and to determine their level of integration into the architectural design process.

A qualitative comparative methodology is adopted in this research. Architectural design prompts with identical or similar content were used with each model to generate visual outputs. These outputs were assessed based on criteria such as formal creativity, technical precision, aesthetic quality, and ease of use. Additionally, functional aspects including accessibility, controllability, and applicability in educational and research environments were analyzed.

The findings indicate that DALL·E provides a balanced approach between realistic and conceptual visualization; Midjourney stands out in producing aesthetically rich, abstract, and creative forms; while Stable Diffusion emerges as a strong alternative for experimental and research-oriented architectural productions, owing to its open-source structure and customizability. Moreover, Stable Diffusion demonstrates higher levels of prompt sensitivity and responsiveness to technical detail.

In conclusion, generative AI models can be integrated as creative and supportive tools into the architectural form-generation process. However, the choice of model should vary depending on the design objective and contextual needs.

Keywords: Artificial intelligence, architectural form generation, generative ai models, DALL·E, midjourney, stable diffusion, visualization in the design process.

ORCID 2: 0000-0002-2993-4240
[2]Res. Assist. Dr., KTO Karatay University, Faculty of Fine Arts and Design, Department of Architecture, Konya/Türkiye

Abstract

The population losses experienced in rural areas in recent years are not merely a numerical decline; they also signal the rapid disappearance of cultural heritage, traditional architecture, local production methods, and social fabric. However, villages that have experienced migration are not merely witnesses to the past; they are also potential spaces for alternative and sustainable living models. This study argues that rural settlements affected by migration are undergoing not only physical decline but also cultural, economic, and social disintegration. It examines the importance of revitalizing these areas from a multidimensional perspective. The potential of sustainable development tools such as agriculture-based development, women's labor-focused production networks, cooperatives, local production, eco/agro-tourism, and cultural routes is highlighted in terms of preserving rural heritage and sustaining local identity. Preserving and applying traditional construction techniques supports the continuity not only of architectural heritage but also of historical and cultural memory. Active participation of local communities enables more sustainable, need-based solutions rather than imposed models, while promotional opportunities such as digital platforms, films, and cultural events enhance the visibility and appeal of rural life. This study views abandoned rural areas not only as heritage sites to be preserved but also as potential spaces for productive, resilient living models oriented toward the future. Ultimately, it aims to contribute to emerging holistic conservation approaches by proposing a redefined understanding of rural conservation and encouraging an approach that integrates spatial improvement with social transformation.

Keywords: Abandoned villages, local participation, rural development, rural heritage, rural revitalization

ORCID 2: 0000-0002-2993-4240
[2]Res. Assist. Dr., KTO Karatay University, Faculty of Fine Arts and Design, Department of Architecture, Konya/Türkiye

Abstract

Nomadism is a lifestyle based on the seasonal and regular movement of communities, typically rooted in pastoral animal husbandry. This way of life requires harmony with the environment, which in turn necessitates architectural structures that are portable, lightweight, durable, and temporary. In this study, the concept of nomadism is examined from cultural, economic, and social perspectives, with attention to spatial organization and usage patterns. Through literature research, portable architectural typologies emerging in different regions are analyzed; examples such as yurts, Bedouin tents, tipis, and yak hair tents are evaluated in detail. These structures share common characteristics in terms of construction techniques, materials, spatial organization, and cultural symbols, including lightness, ease of transport, quick assembly and disassembly, climate adaptability, and sustainable use of natural and local materials. Designed as single-volume, multifunctional spaces, these sustainable structures minimize environmental impact, use resources efficiently, and support communal lifestyles by strengthening social bonds. The study investigates the typological features of architectural forms developed in relation to the nomadic way of life, revealing how they have inspired contemporary approaches centered on sustainability, modularity, and temporariness. It is determined that modern solutions such as the tiny house movement, mobile structures, container homes, and disaster shelters are directly influenced by traditional nomadic architecture. The analysis of these typologies serves as a reference not only in historical and cultural contexts but also in the development of innovative, environmentally friendly designs. The study aims to offer a concrete evaluation of how these traditional principles can be integrated into contemporary architectural practice.

Keywords: Temporary shelter, nomadic architectural forms, mobile structures, mobile architecture, sustainable architecture

Abstract

Recycling has become a critical issue considering the results of global warming, especially the depletion of natural resources. Concrete, as one of the commonly used construction materials, has been a crucial research topic in order to decrease the disadvantages of the high amount of energy consumption during the production phase and the limited recycling opportunities after destruction. After the February 6, 2023 earthquakes in Türkiye, depending on the high amount of construction and demolition waste (CDW), recycling concrete (RC) can be an efficient way in terms of preservation of natural resources and sustainability of the environment and economy. Additionally, several urban transformation projects have been planned and implemented in most of the cities of Türkiye. Accordingly, recycling CDW may play a significant role in reusing waste with an environmentally friendly approach. In this study, the equivalent CO_2 emissions of recycled concrete aggregate (RCA) incorporation of various proportions of boron were investigated by applying the Excel-based GreenConcrete LCA software developed at the University of California Berkeley Campus (UC Berkeley). Based on the analysis, it is observed that the use of RCA has a positive contribution to the environmental impacts in the LCA analysis. Furthermore, the use of concrete mixtures that contribute to the recycling of waste, boron, as admixtures contributes to reducing the environmental damage of the waste and developing material properties.

Keywords: Construction and demolition waste (CDW), boron, lifecycle assessment analysis (LCA), recycled concrete aggregate (RCA), Türkiye

Abstract

Rural resilience is defined as the capacity of rural areas to survive, adapt, and, when necessary, transform in the face of environmental, economic, and social shocks. The concept emerged from the theoretical framework developed in the 1970s on the resilience of ecological systems and has evolved over time into a multidimensional structure with a socio-ecological systems perspective. Today, rural resilience studies are based on a holistic approach that considers interrelated factors such as climate change, natural disasters, economic fluctuations, migration movements, and cultural transformations.

This paper first examines the historical development of the concept of rural resilience in the literature and its definitions across different disciplines, focusing on three main dimensions: ecological resilience economic resilience and social resilience. In the second part of the study, the Trabzon/Akçaabat district, located in the coastal-rural transition zone of the Black Sea Region, is examined as a case study. Akçaabat offers a suitable platform for multidimensional resilience discussions, with factors such as agricultural production systems (especially hazelnuts and tea) vulnerable to climate change, urbanization pressures, youth migration, and the fragility of coastal ecosystems. The theoretical framework found in the literature is linked to Akçaabat's local dynamics, and recommendations are developed to enhance resilience capacity.

Abstract

Climate change has been significantly altering both natural and built environments, leading to more frequent extreme weather events, droughts, microclimate shifts, and associated outdoor thermal comfort (OTC) challenges in urban areas. Predicting the magnitude and extent of these changes is essential for climate-responsive landscape design. However, microclimate models such as ENVI-met, while highly detailed, require substantial computational power and long simulation times, limiting their accessibility in practical decision-making.

*This study develops a machine learning (ML)-based model to predict the OTC in open and semi-open urban areas in the Tuzla district of Istanbul for the year 2100, using climate projections under the RCP8.5 scenario. ENVI-met simulations were performed for 24 grid-based urban configurations (100*100 cells, 2*2 m resolution), incorporating diverse surface covers and vegetation types. Microclimatic variables - including air temperature, mean radiant temperature, wind speed, relative humidity, shortwave radiation, and Physiological Equivalent Temperature (PET) - were collected at pedestrian height (1.4 m).*

After data cleaning, balancing, and augmentation, the final dataset comprised over 200000 cell-level records. A Random Forest Regressor was trained separately for tree shade and open conditions, using surface and tree types as primary predictors. Currently, model performance showed high prediction performance when it compares with ENVI-Met results (R^2 >= 0.8) for PET estimation. A user-friendly graphical interface enables rapid scenario evaluation without the need to operate complex simulation tools, allowing landscape architects and urban planners to assess the impact of surface and vegetation configurations on OTC under future climate conditions.

Strategic Approaches to Climate Change Adaptation and Mitigation

İzel MERAL [1*]

ORCID 1: 0000-0001-7788-7672
[1]KTO Karatay University, Faculty of Fine Arts and Design, Department of Architecture, Konya-Türkiye
izelmeral@gmail.com ***(**Responsible Author)

Abstract

Climate change is one of the major issues of the 21st century, directly or indirectly affecting the lives of all living beings. When the 2021 IPCC (Intergovernmental Panel on Climate Change) reports are evaluated alongside previous IPCC reports, it is evident that the effects of climate change are becoming more pronounced (IPCC, 2021, IPCC, 2014, and IPCC, 2007). This study examines the factors causing climate change and the possible consequences associated with these factors. Since climate change is a complex and multidimensional problem, developing effective and sustainable solutions will be of great benefit on a global scale. The attitudes and approaches of different countries towards making cities more resilient in the fight against climate change have been examined. Based on current emissions, the latest data shows that China, the US, Russia, and EU countries are responsible for 50% of global emissions. In this context, countries such as the US, the Netherlands, Japan, Austria, Denmark, China, the UK, and Scotland, which contribute significantly to the increase in global emissions related to climate change, were selected. The use of permeable materials on Chicago streets allows rainwater to seep into the ground, improving drainage. In Rotterdam, rainwater is collected in basins and used to water plants in the square. A hotel in Vienna stores rainwater to irrigate its gardens and flush its toilets. Green parking lots in Copenhagen help prevent flooding. Green roofs in Shanghai improve air quality while reducing flood risk. The selected examples examine methods for mitigating the effects of climate change and strategies for adapting to climate change. Some of the recommendations for Türkiye include strengthening infrastructure systems, creating rainwater collection areas, increasing the use of renewable energy sources, reducing roof snow loads, using permeable materials on streets, and creating climate change action plans specific to cities. By following international developments in light of these recommendations, the negative effects of climate change can be mitigated.

A Sustainable Development Allegory: *Entelköy Efeköy'e Karşı and SDGs*

Pınar ZEĞEREK ALTUNBEY[1*]

ORCID 1: 0000-0002-5855-1484
[1]Research Assistant Dr., Niğde Omer Halisdemir University, Faculty of Architecture, Department of Landscape Architecture, Niğde-Türkiye
pzegerek@ohu.edu.tr***(**Responsible Author)

Abstract

Yüksel Aksu's 2011 film Entelköy Efeköy'e Karşı humorously engages with environmental sustainability themes, which remain underexplored in Turkish cinema. This study examines the film through the lens of the United Nations Sustainable Development Goals (SDGs), aiming to understand how popular culture reflects sustainability concerns. The story of a small Aegean village resisting a proposed thermal power plant provides a compelling backdrop for exploring these issues.

Through a qualitative film analysis, the study interrogates the film's social, economic, and environmental dimensions in relation to specific SDGs. Socially, the interactions between urban environmental activists and villagers reveal both conflicts and moments of solidarity, connected to SDG 10 (Reduced Inequalities) and SDG 16 (Peace, Justice, and Strong Institutions). Economically, the film highlights the tension between short-term promises of industrial development and the long-term sustainability of traditional agriculture, relating to SDG 8 (Decent Work and Economic Growth) and SDG 12 (Responsible Consumption and Production). Environmentally, the narrative emphasizes the importance of protecting natural resources and addressing climate change, corresponding to SDG 7 (Affordable and Clean Energy), SDG 13 (Climate Action), and SDG 15 (Life on Land).

Overall, this study illustrates how Entelköy Efeköy'e Karşı not only entertains but also communicates complex sustainability principles. By weaving together social justice, environmental stewardship, and economic considerations, the film exemplifies the interconnected nature of the SDGs. The analysis presented here reflects the unique contribution of cinematic narratives to fostering awareness and critical reflection on sustainability challenges.

Abstract

Some clinical findings have been obtained regarding the effect of natural areas, which appear as hospital gardens, on the psychological well-being of patients. In the literature, the reasons for the positive contributions of being with nature to the daily lives of patients have been investigated and patients have been shown to benefit from nature internally, mentally and physically. In Türkiye, there are very limited institutions that individuals, especially those with cancer, who need hospital gardens can go to. For this reason, families and patients with cancer are helpless, hopeless, unhappy and in a difficult situation. Natural environments, such as hospital gardens, are known to positively impact patients' psychological well-being. However, these therapeutic spaces are scarce in Türkiye, causing distress for cancer patients and their families. To address this issue, this study aimed to create a design proposal for an interior garden at İnönü University's Oncology Hospital. The design's core goal was to reduce patient stress, enhance motivation, and provide a calm, welcoming space distinct from the typical hospital setting. The research methodology involved four stages: a literature review, an on-site survey, a needs assessment based on interviews and surveys with patients and doctors, and the development of a final design proposal using digital software. The study successfully identified key landscaping elements and provided concrete suggestions for designing effective therapeutic gardens for oncology patients.

Abstract

Due to rapid urban growth and unplanned development driven by technological advancements, cities have become excessively dense. This has increased the importance of open and green spaces where individuals can meet their social, cultural, and physiological needs. However, the presence of uncontrolled environmental sounds in these areas negatively impacts the user experience and reduces spatial comfort. In this context, the primary goal of this study is to move beyond the "quiet/calm areas" approach in urban open and green spaces. The aim is to explain the design principles of "soundscape," a more comprehensive, human-centered, and perceptual concept, and to raise awareness about its significance. The research also aims to determine the auditory preferences of user profiles, a topic not yet comprehensively defined in Türkiye. The study takes a human-centric approach to evaluating the phenomenon of sound in the landscape design process. To this end, soundscape analyses were conducted in four different urban open and green spaces in the city of Malatya, using both objective measurements and subjective evaluations. Based on the collected data, sound and noise maps were created. Through surveys and observations, the "symbol sounds," "background sounds," and "foreground sounds" that define the auditory identity of the study areas were identified. The findings provided a foundation for developing design and planning recommendations to improve the quality of soundscapes in urban open and green spaces.

Keywords: Soundscape, soundwalk, noise, acoustic comfort

kunter.manisa@yildiz.edu.tr

Abstract

Shopping malls have long been conceived as major urban focal points and became spaces frequently preferred by users, leading to the development of numerous projects across different regions. However, over time, many malls failed to attract the expected interest. While some with qualified design and favourable locations achieved their user targets, others were forced to operate with low occupancy rates due to poor site selection, functional shortcomings, and architectural deficiencies. Declining occupancy reduced visitor numbers, and vacant areas not only caused economic losses but also contributed to the overall obsolescence of the building.

In recent years, the acceleration of digitalization, the rise of online shopping, shifting consumption habits, and economic fluctuations have further intensified this decline, rendering many shopping malls obsolete. This phenomenon has generated challenges beyond economics, extending to social and environmental impacts. Rather than demolition, adaptive reuse and reintegration of such underutilized structures into the urban fabric present more rational solutions in terms of cost, time, and sustainability.

This study examines the causes of functional decline in shopping malls and reviews transformation examples from both global and Turkish contexts. The analyzed cases highlight malls that have been reintegrated into urban life through functions such as education, healthcare, culture, commerce, and religion. Building on these precedents, the study discusses the potential of obsolete shopping malls to be converted into healthcare facilities, particularly regarding accessibility, infrastructural capacities, opportunities linked to urban memory, sustainability, enhancement of urban life quality, and contributions to health sector.

Cappadocia of Traces: Temporary and Permanent Layers

Emine AKCAN ŞİRİN [1*]

ORCID 1: 0000-0003-1540-2427
[1]Assistant Professor, İstanbul Ticaret University, Faculty of Architecture and Design, Department of Architecture, Istanbul-Türkiye
easirin@ticaret.edu.tr *(Responsible Author)

Abstract

Cappadocia is a multi-layered spatiality produced at the intersection of nature and culture. By its very nature, it is a geography where both temporary and permanent traces coexist. On the one hand, the constant change created by weather conditions lends the space a sense of temporariness, while on the other hand, thousands of years of human settlements, both above and below ground, give the region a sense of permanence. Re-thinking this multi-layered spatiality in Cappadocia through the concept of "trace" in the context of both transience and permanence relates the "trace" to both its physical and cultural dimensions. The trace is a sign of both presence and absence. Traces that persist on the soil, landscape, and geography can be read not only as concrete reflections of natural processes but also as abstract counterparts of social memory, identity construction, and a sense of spatial belonging.

This study examines the dilemma between the temporary and permanent layers of traces in the rock-carved spaces of Cappadocia. Traces formed by nature and human hands reveal the layers of time and space; however, today, tourism pressure, spatial transformations, and lack of legal regulation leave these traces in a state of tension between erasure and preservation. In this context, traces produce a resistance against forgetting and disappearance, and traces at high risk of disappearing keep social memory and spatial continuity alive. The traces of Cappadocia reveal a plane extending from transience to permanence, allowing for questioning of the continuity between natural and cultural layers.

Keywords: Cappadocia, trace, temporary, permanent

Sick Building Syndrome and Toxicological Assessment of Construction Materials Among Workers and Residents in Dutse Metropolis, Jigawa State, Nigeria

Bate Garba BARDE [1*]

[1]Department of Environmental Sciences, Federal University Dutse, Jigawa State, Nigeria
bategarba@yahoo.com *(Responsible Author)

Abstract

The type and quality of construction materials determine to a large extent the prevalence of sick building syndrome (SBS) which puts the occupants' lives at risk. This study was conducted to assess the prevalence and risk factors of SBS stemming from construction materials among workers and residents in the study area. A total of 1765 study subjects were involved using a structured questionnaire and observational checklists in a multistage random sampling technique, covering homes, offices, classrooms and business premises. SBS symptoms were assessed using their confirmation criteria and their risk factors were determined using adjusted odds ratio (AOR) with logistic regression analysis at 95% confidence interval (CI). Results showed the general prevalence of SBS to be 58.02% while that of skin symptoms was 5.47% and mucosal symptoms was 93.46%. The most commonly reported symptoms include rhinitis (69.92%) and headache (24.02%) which were mostly observed in the construction workers (76.37%) and residents (23.63%). Type of construction materials were significantly related to SBS symptoms as risk factors which include paint (AOR=1.93, CI=0.48 to 7.77), cement (AOR=1.67, CI=0.26 to 10.06), plastic/rubber (AOR=1.38, CI=0.05 to 3.42) and iron (AOR=0.81, CI=0.17 to 3.92). It is suggested that construction materials in the study area should be standardized and regulated, the workers be provided with personal protective equipments and residents should be properly guided on how to care for themselves while occupying such structures.

Key words: Construction; sick building syndrome; adjusted odds ratio; prevalence; building materials.

J. A. YUSUF [1]

[1] Department of Architecture, Federal University of Technology Minna

Abstract

The integration of informal interactive spaces within the design of a Faculty of Architecture represents a strategic approach to fostering creativity, collaboration, and knowledge exchange among students and faculty members. Unlike traditional classroom and studio environments, informal interaction zones provide flexible, student-centered platforms for spontaneous dialogue, peer learning, and interdisciplinary engagement, which are essential in architectural education. This study explores the significance of incorporating such spaces into faculty building designs, highlighting their role in enhancing communication, social cohesion, and academic performance. Through a review of literature, case studies, and analysis of spatial qualities to identify key design parameters. Descriptive research design with a qualitative and quantitative approach was adopted as it allows for systematic exploration of existing informal interactive spaces within faculties of architecture while capturing user perceptions and spatial characteristics. The findings shows that many faculty are design with little or no consideration for user centric design idea which is the bedrock of informal interaction among users and also aligns with existing literature on the importance of informal spaces in educational environments. The study concludes that integrating informal interactive space in the design of faculty of architecture significantly shapes the students social and academic performance. It also suggests to the architects, designer and relevant authority to prioritizes its inclusion during the design stages.

Societal Acceptance of Thermal Storage Wall in Buildings in Mediterranean Region

Soad ABOKHAMIS MOUSAVI [1*]

ORCID 1: 0000-0002-5710-6565
[1]Assoc.Prof. Dr., Arkin University of Creative Arts and Design, Faculty of Design, Department of Architecture, Northern Cyprus-Türkiye
soad.mousavi@arucad.edu.tr **(**Responsible Author)

Abstract

The Thermal Storage wall, an ancient passive solar technique, continues to be recognized for its effectiveness in enhancing passive solar systems. However, its practical implementation in contemporary architecture is hindered due to concerns regarding the visual impact of Thermal Storage wall on building facades. This study aims to address two primary objectives: (1) to investigate the reasons behind the limited adoption of Thermal Storage wall in Mediterranean region buildings, and (2) to propose potential solutions to foster societal acceptance of Thermal Storage wall in architectural designs. To accomplish these objectives, the present research endeavors to develop and design alternative Thermal Storage Wall configurations using different materials and facade treatments. A qualitative research methodology was employed, utilizing a combination of observation and questionnaires administered to diverse clients and expert architects within the targeted region. The findings reveal that through innovative designs, the incorporation of Thermal Storage wall on building facades can be accomplished without compromising aesthetic appeal.

soad.mousavi@arucad.edu.tr * **(**Responsible Author)

Abstract

This research investigates the role of local materials in achieving thermal comfort through sustainable interior architecture in arid climate housing, with a case study focused on Ouarzazate, Morocco. As climate resilience becomes increasingly urgent, there is a growing need to integrate passive design principles with regionally appropriate materials that respond to environmental challenges and cultural contexts. The study aims to explore how locally sourced materials such as adobe, rammed earth, and natural stone, can enhance indoor thermal performance while supporting ecological and economic sustainability.Due to logistical constraints, the research adopts a qualitative, desk-based methodology relying on secondary data, including climate analyses, architectural documentation, and literature on passive and sustainable design. Emphasis is placed on examining how material selection, spatial configuration, and surface treatments in interior spaces contribute to indoor comfort without mechanical systems. Findings indicate that the use of high thermal mass local materials significantly reduces indoor temperature fluctuations in arid zones. The study concludes that integrating these materials into contemporary interior architecture can provide an effective, culturally grounded strategy for sustainable housing in hot, dry climates like that of Ouarzazate.

Abstract

Today, the integration of mobile devices into every aspect of life and the proliferation of AI-powered voice interaction technologies enable individuals to access information more quickly and easily. The VoiceNote application offers users a note-taking experience using both voice input and voice output, an alternative to traditional text-based note-taking methods. This application is a two-way interactive mobile application that allows users to take notes in either voice or written format and listen back to them. Designed with Flutter, the application's front-end interface offers multi-platform support, while the back-end supports voice interaction using the Whisper (ASR) and Coqui TTS (TTS) models, running under the Python-based FastAPI framework. Authentication and real-time data management are provided using the Firebase infrastructure. The application has a flexible structure for offline scenarios. VoiceNote offers a user-friendly and sustainable digital note-taking solution that aims to increase accessibility, particularly for individuals with physical disabilities, the elderly, and users who lack the ability to write on the go. This system, developed as part of the project, offers a unique and functional contribution thanks to its open-source technology-supported structure and its suitability for multiple use cases. The results demonstrate that VoiceNote offers a unique and functional contribution thanks to its accessibility, multiple use cases, and open-source technology-based architecture.

Evaluation of Room Acoustics in Auditoriums in the Context of Speech Intelligibility: An Examination of A University Auditorium

Okan ŞİMŞEK [1*]

ORCID 1: 0000-0003-3500-9438
[1] Research Assistant Dr., Adana Alparslan Türkeş Science and Technology University, Faculty of Architecture and Design, Department of Architecture, Adana-Türkiye
osimsek@atu.edu.tr ***(**Responsible Author)

Abstract

Auditoriums are spaces used for conferences, seminars, ceremonies, and educational purposes within university campuses, where ensuring a high level of speech intelligibility is of critical importance. The acoustic performance of such enclosed spaces depends on many physical variables, including volume, geometric proportions, stage design, source–listener relationship, surface material properties, and ceiling design. In this study, the auditorium of Adana Alparslan Türkeş Science and Technology University was comprehensively examined in terms of room acoustics, the current situation was analyzed, and improvement proposals were developed.

In the research process, the volume values, proportions, stage layout, and all surface materials of the space were examined in detail. Based on these data, the room acoustic parameters of reverberation time (RT), strength (G), and bass ratio (BR) were calculated. The calculated parameters were evaluated within the framework of national and international standards, and the obtained results were assessed in the context of the speech-oriented use of the space.

In the subsequent stage, design interventions were developed to improve acoustic performance. In particular, the ceiling design was reconsidered, solutions for achieving a more balanced distribution of reflections were proposed, and alternative usage scenarios for surface materials were discussed. In this context, the possible effects of different materials on absorbing, reflecting, or diffusing sound were evaluated.

The study emphasizes the necessity of providing acoustic conditions suitable for the functional uses of auditoriums in educational institutions and presents a guiding framework for the evaluation and design processes of similar spaces.

Abstract

Throughout history, Anatolia has been located at the intersection of east-west and north-south roads, hosted many civilizations; thus, a rich cultural heritage accumulated in its cities. Yet modernization and rapid urbanization have diminished its visibility in today's urban fabric and caused the fading of historical identity. Konya, in central Anatolia, is not only a transit point at the crossroads of historical routes but also a hub where cultural accumulations and socio-economic relations converge. Situated on the Royal Road, Silk Road and Pilgrimage Road, the city demonstrates a multi-layered spatial development.

This paper aims to read the historical development of Konya through transportation axes and to evaluate the layered structure of the city using the topological analysis method. This study adopts a two-scale approach: at the Anatolian scale, the physical geography of the basin and its surroundings, successive settlements/civilizations, and the historical road network shaped by geography are examined to reveal regional interactions; at the basin scale, the emergence of the first settlements following the retreat of the Ancient Lake Konya and the temporal connections of the ancient road network are assessed through the maps produced. In this context, the analysis process not only traces the historical continuity; it also focuses on identifying the cultural and spatial values that can guide future planning and design decisions for the city. Thus, it is aimed to shed light on today's urban interventions by considering the unique morphology created by transportation networks, together with urban memory and layered texture.

Keywords: Topology, Konya, route structure, urban morphology.

deryasu@fsm.edu.tr

Abstract

The reuse of buildings, also referred to as adaptive reuse, has emerged as a key design and planning strategy in contemporary architecture, combining sustainability principles with the preservation of cultural heritage. Located in Istanbul's Eyüpsultan district, the Rami Barracks was constructed in the second half of the 18th century and is one of the largest examples of Ottoman military architecture. After losing its military function in the 20th century, the complex served for decades as a storage facility and gradually fell into disuse. In 2023, following an extensive restoration and adaptive reuse project, it was reopened to the public as Türkiye's largest library.

The transformation of the Rami Barracks represents a significant example of adaptive reuse, in which the original spatial organisation, façade composition, and material character of the historic structure were preserved, while a "minimum intervention" principle guided the design. In parallel, contemporary functions such as reading halls, a children's library, exhibition spaces, event areas, and social amenities were carefully integrated into the building. The redesign of the courtyards and landscape aimed to create a public realm that harmonises with the library's new function.

This study examines the transformation of the Rami Barracks through the lenses of architectural conservation, public space production, and cultural memory. It discusses how the project goes beyond physical restoration, facilitating a symbolic shift in the urban memory from a site associated with military and commercial uses to a cultural and educational hub. The findings suggest that historic buildings can be both preserved and revitalised through adaptive reuse, thereby contributing meaningfully to the creation of high-quality public spaces.

Keywords: Adaptive reuse, architectural conservation, Rami Barracks, public space transformation, sustainable architecture, cultural heritage, reuse/repurposing.

Abstract

Storing medicines under optimal conditions is critical throughout the production and delivery process. Various environmental conditions, such as temperature and humidity, significantly impact the shelf life of medicines. This study develops an IoT-based mobile application system that continuously monitors the environmental conditions where medicines are stored, alerts users of out-of-threshold conditions, and also uses artificial intelligence to predict spoilage risk. The primary objective of the study is to instantly monitor environmental variables such as temperature, humidity, and gases, notify users of critical situations via mobile devices, and calculate the probability of spoilage based on environmental risk for drugs entered by the user using artificial intelligence. This system aims to detect improper drug storage conditions, prevent health risks, and minimize economic losses. The system transfers data obtained from DHT11 and MQ2 sensors to the Firebase database via ESP8266 and presents it to the user instantly in the mobile application interface. If the specified thresholds are exceeded, the system notifies the user with a push notification and lists critical situations within the application. The application also stores historical data and offers data export in PDF format. Users can enter medication information into the system and receive AI-powered spoilage predictions based on environmental conditions. This system offers an effective, reliable, and user-friendly solution, particularly for monitoring temperature- and humidity-sensitive medications. All functions operate in real time, and the system operates seamlessly within an integrated structure. The developed application is expected to offer an innovative and practical approach to environmental monitoring and health technologies and contribute to the foundation of more advanced systems in the future.

Keywords: Artificial Intelligence, IoT, mobile application.

Abstract

In architecture, structure and geometry play important role in shaping of artefact, safety, durability and aesthetic value of structures. Architecture cannot be fully understood without discovering the dialectical relationship between structure and geometry. Mimar Sinan and Zaha Hadid interpreted this relationship in different eras and cultural contexts, reshaping the dimensions of architecture and silhouettes of cities.

Mimar Sinan, by blending the innovative geometric order and structural knowledge that brought to Ottoman Architecture, prioritized structural integrity and aesthetics in addition to functionality in his structures. On the other hand, Zaha Hadid's bold use of fluid geometric forms has not only ensured that the structures offer a visual feast, but also provided a futuristic image and structural strength. The works of these two great architects reveal the impact of the interaction between structure and geometry on architectural design and urban image, while providing examples of how these elements can be brought together in architectural practice.

In this context, the aim of the study is to analyze the geometric and structural elements in the designs of Mimar Sinan and contemporary architect Zaha Hadid from a holistic perspective. In the study, a qualitative research approach is adopted. Using a qualitative research and comparative analysis method, their design philosophies, aesthetic preferences and their effects on urban space will be systematically addressed. The iconic structures of Sinan and the geometric and structural innovations in Zaha Hadid's contemporary structures will be focused on with case studies, and the effects of the structures on the urban silhouette will be analyzed. The study will reveal how architecture evolved over time by bringing together the architectural understanding and geometric aesthetics of two different periods in a historical and cultural context and evaluating the works of two great architects.

Keywords: Mimar Sinan & Zaha Hadid, architectural geometry, structure & materiality, futuristic vision & innovation, city image

Smart Design Solutions for University Housing: A Waste-Optimized Architectural Solution for Postgraduate Accommodation at Futminna

OKONNAH SAMUEL David [1*]

[1] Department of Architecture, Federal University of Technology, Minna
samuelokonnah@gmail.com *(Responsible Author)

Abstract

Solid waste management in university hostels is essential for environmental sustainability and public health. Inefficient systems in postgraduate hostels can lead to littering, poor sanitation, and operational challenges, highlighting the need for optimized management practices.

This study aims to optimise waste management systems in the design of postgraduate hostels, improving efficiency, reducing environmental impact, and promoting sustainable waste disposal behaviours among residents.

A qualitative approach was be employed, using unstructured interviews and non-participant observations. Participants from the interview included hostel managers, cleaners, waste collection contractors, and student residents. For the non-participant observation, purposive sampling with maximum variation was used to ensure diversity across hostels. The observations focused on three overarching themes; behavioural strategies in place, student participation behaviours, and effective indicators. The interviews explored participants' knowledge, attitudes, and perceptions of existing practices. Observational data was analysed using content analysis with deductive themes, while interview data was analysed using thematic analysis.

The study revealed that student participation in waste segregation was moderate, with higher compliance in hostels where bins were clearly labelled, awareness materials were visible, and waste collection was timely. Gaps were noted in areas with irregular collection and inconsistent behavioural strategies, like irregular waste segregation, delayed collection schedules, poor adherence to disposal guidelines, inconsistent monitoring and enforcement and limited community education indicating opportunities for improving operational efficiency and resident engagement.

Findings provided recommendations for integrating efficient waste management system into hostel design and operations, fostering sustainable practices and informing higher education environmental strategies.

Keywords: Behavioural strategies, observation, postgraduate hostels, solid waste management, thematic analysis, waste optimisation.

Effect of Material Suitability and Availability on Residents' Building Preferences in Nupe Land, Kwara State

KOLO, Vincent Mana[1*]

[1]Department of Architecture, Faculty of Environment Sciences, University of Ilorin, Kwara, Nigeria

OLAKANBI BOLAJI Abdulraheem[2]

[2]Department of Architecture, Faculty of Environment Sciences, University of Abuja, FCT, Abuja, Nigeria
abdelrahim.bola@gmail.com *(Responsible Author)

Abstract

The increasing shift toward modern construction materials has led to the gradual neglect of indigenous materials traditionally used in rural Nigerian architecture, particularly in Nupe Land, Kwara State. This study examined the effect of material suitability and availability on residents' building preferences in the Nupe-speaking region of Edu Local Government Area. The primary aim was to evaluate how perceptions of indigenous materials influence construction choices and to identify factors that sustain or hinder their continued use. Specifically, the objectives were to assess community awareness of indigenous materials, determine their perceived suitability and availability, and explore challenges, opportunities, and cost implications associated with their use.

A mixed-methods approach was adopted. Quantitative data were collected through questionnaires administered to a sample of 330 respondents, drawn from an adult population of 2,257 residents across the villages of Bokungi, Yana, and Patidzuru. A total of 280 valid responses (86.4%) were analyzed using descriptive statistics such as frequencies, percentages, and means. Qualitative insights were obtained through interviews with local architects, builders, and artisans experienced in the use of indigenous materials.

Findings revealed a high level of awareness (80%) of indigenous materials among residents, with Earth, Laterite, and Timber rated highest in both suitability and availability. Over 70% of respondents perceived indigenous materials as more cost-effective than modern alternatives. However, the study identified growing neglect and decline in traditional knowledge, even though communities recognized the environmental, cultural, and aesthetic benefits of indigenous construction practices.

The study concludes that enhancing local production, technical training, and policy support can revitalize the use of indigenous materials, promoting sustainability and cultural preservation. It contributes to knowledge by linking material suitability and availability to user preference in rural housing development. It is recommended that government agencies, NGOs, and educational institutions promote hybrid building models integrating indigenous and modern materials to achieve affordable, climate-responsive architecture in nupe land, kwara state.

Keywords: indigenous materials, vernacular architecture, Nupe land, suitability, stability, sustainable construction, hybrid architecture, earthen construction, cultural heritage, Nigeria

Influence of Lighting Quality on Emotional and Cognitive Responses to Artworks: A Comparative Study of Prominent Art Galleries in Lagos State, Nigeria

SA'AD Muhammad Abolakale[1]

[1]Department of Architecture, Faculty of Environment Sciences, University of Ilorin, Kwara Nigeria

OLAKANBI BOLAJI Abdulraheem[2]

[2]Department of Architecture, Faculty of Environment Sciences, University of Abuja, FCT, Abuja, Nigeria
abdelrahim.bola@gmail.com *(Responsible Author)

Abstract

Poor lighting design in art galleries can distort visual perception, reduce emotional engagement, and impair visitors' cognitive appreciation of artworks. In tropical contexts like Lagos State, Nigeria, where natural and artificial lighting conditions vary significantly, achieving optimal visual comfort remains a challenge. This study therefore examines the influence of lighting quality on emotional and cognitive responses to artworks across four prominent art galleries—Nike Art Gallery (Lekki), Red Door Gallery (Victoria Island), Mydrim Gallery (Ikoyi), and Thought Pyramid Art Gallery (Ikoyi). The study aimed to determine how lighting adequacy, visibility, comfort level, and shading effectiveness affect visitors' satisfaction and perceptual experiences.

A quantitative survey research design was adopted, using structured questionnaires administered to 382 visitor respondents, determined through Cochran's finite population correction method from an estimated 50,000 gallery visitors. Data were analyzed using the Satisfaction Index (SI), Mean Adequacy Score (MAS), and inferential statistical methods including Pearson correlation and multiple regression analysis to measure the relationships between lighting quality variables and visitors' emotional and cognitive responses.

Findings revealed that lighting quality significantly influenced both emotional and cognitive engagement. The overall MAS of 4.2969 indicated general satisfaction with lighting adequacy across all galleries. Comfort level (MAS = 4.4) and visibility of artworks (MAS = 4.375) ranked above the mean, confirming their positive impact on visitor experience, while shading effectiveness (MAS = 4.1875) scored slightly lower, suggesting minor improvement needs. Regression results further showed that lighting parameters collectively explained over 60% of the variance in visitors' emotional and cognitive satisfaction.

The study concludes that optimal lighting design enhances visitors' emotional connection, comfort, and interpretive depth within gallery environments. It contributes to knowledge by providing a quantitative framework for evaluating perceptual adequacy in art spaces. The study recommends that Lagos art galleries adopt adaptive daylight and artificial lighting systems, improved shading devices, and regular lighting audits to sustain visual comfort and enhance overall visitor experience.

Keywords: Lighting quality, emotional responses, cognitive responses, artworks, art galleries and Lagos State.

Abstract

Biophilic design, which integrates natural elements into built environments, offers significant potential for supporting human well-being, particularly among elderly populations who are vulnerable to environmental stressors in healthcare settings. Despite growing research, a critical gap persists: the absence of comprehensive, multisensory frameworks specifically tailored to healthcare environments for older adults. Existing studies often focus on isolated design elements, overlooking the complex interactions between environmental factors and the well-being of the elderly .This paper proposes a holistic conceptual framework that systematically integrates biophilic design principles into healthcare environments to enhance the well-being of the elderly through environmental integration. A systematic review and synthesis of interdisciplinary literature—including architecture, environmental psychology, gerontology, and healthcare design—identifies key biophilic elements and their theoretical applications in geriatric care .The framework encompasses five core dimensions: optimization of natural light to support circadian rhythms, integration of therapeutic greenery to reduce stress, incorporation of water features for visual and auditory comfort, enhancement of natural ventilation for air quality, and application of multisensory stimuli, including tactile, olfactory, and acoustic natural elements. Each dimension is analyzed with consideration of elderly-specific physiological and cognitive needs .This novel conceptual model provides guidance for architects and healthcare designers, identifies research gaps for future empirical studies, and establishes a theoretical basis for systematic implementation of biophilic principles in healthcare environments. By offering the first comprehensive, multisensory framework for elderly-focused spaces, this study advances biophilic design theory and promotes restorative, supportive healthcare settings for older adults.

Building Envelope Strategies for Enhancing Urban Thermal Comfort: A Climate-Sensitive Perspective

Alireza GERAMI[1]

[1] Department of Architecture, Faculty of Art and Architecture, Bu-Ali Sina University, Hamedan, Iran

Mehrdad KARIMIMOSHAVER[2]

ORCID 1: 0000-0001-5536-2138
[2] Professor of Architecture, Department of Architecture, Faculty of Art and Architecture, Bu-Ali Sina University, Hamedan, Iran
mkmoshaver@basu.ac.ir*(Responsible Author)

Abstract

Rapid urbanization and climate change have intensified the challenge of outdoor thermal discomfort in many cities. Among the factors that shape this condition, building envelopes and façade materials can play an important role. This study discusses how envelope materials, surface finishes, and vegetation applied to façades and roofs can mitigate outdoor overheating and contribute to more sustainable urban spaces. Insights from climate-responsive design approaches in different Iranian contexts suggest that smooth and light-colored materials are more beneficial in dry climates, while vegetation enhances outdoor livability across multiple regions, although its effectiveness is moderated by humidity. This highlights the importance of considering not only air temperature but also humidity, wind, and solar exposure when assessing the environmental impact of façades. Overall, building envelopes should be seen not just as physical boundaries but as environmental tools. By choosing materials and greening strategies suited to local conditions, designers can reduce heat stress in cities and support sustainable urban development.

Keywords: Building envelope, façade materials, outdoor comfort, vegetation, climate-responsive design

Abstract

Urban passages constitute essential public spaces within cities, accommodating a wide range of daily activities. When endowed with adequate environmental quality, these spaces support not only movement and necessary functions but also extended use and diverse social interactions, thereby reinforcing social sustainability.

Thermal comfort represents a critical dimension of environmental quality, particularly in hot and arid climates, where it strongly influences outdoor engagement. Within this climatic context, wind flow emerges as a decisive factor in shaping thermal comfort. Accordingly, this study investigates the role of urban texture in modulating natural wind flow, with the city of Kashan serving as the case study.

The research focuses on a comparative assessment of different urban textures—traditional, new, semi-traditional, regular, and irregular. By analyzing the geometric configurations of buildings and open spaces, the study elucidates how various urban forms affect wind behaviour. The findings provide insights into the effectiveness of different morphological components and offer guidance for identifying optimal urban textures capable of enhancing natural ventilation and improving outdoor thermal comfort.

Keywords: Urban morphology, Natural wind flow, Urban open space, Hot and dry climate, thermal comfort.

Abstract

This paper will examine the complex connection between morphology, soundscapes, and urban density and the ways in which the design strategies of architecture can be used to counteract noise pollution and promote sustainable urban living. The study uses a qualitative and quantitative methodology, which entails the use of sound levels data, urban design models, and surveys of residents who evaluate perceptions of noise and landscape quality. The results show substantial relationships between urban shape and soundscapes, where an effectively designed urban environment is able to properly reduce the impact of noise and improve the well-being of urban residents. In particular, the paper shows that the strategic changes in the location of buildings, choice of materials, and integration of green spaces help to reduce the level of ambient noise and enhance the auditory perception. These lessons highlight the need to view soundscapes within urban planning as a vital consideration of health in the urban population since stress reduction, improved cognitive abilities, and improved health outcomes are linked to reduced noise pollution. The wider implications of this study are given to urban planners and architects and it proposes that soundscape considerations must be incorporated into the sustainable design practice to enhance the quality of life in highly populated regions to promote healthier communities. The article is an important addition to the discussion on urban health that highlights the importance of interdisciplinary treatment of urban living complexities.

Tallal Abdel Karim BOUZIR[3]

[3] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.

Abstract

The paper explores acoustic dynamics and the physical form of vernacular desert housing with the view to inform sustainable architecture in response to the critical necessity to comprehend how acoustic qualities relate with environmental flexibility in arid environments. This study, based on a thorough qualitative study, involving case studies, acoustic measurements, and occupant experiences, demonstrates, though, that well-designed sound control and space could contribute greatly to the liveability and sustainability of desert homes. Among the major results, the finding that soundscape-friendly structures enhance comfort, along with decreasing the use of mechanical cooling systems, which, in turn, decreases the consumption of energy and leads to increased resource efficiency. The applications of the findings are not restricted to the field of architecture since it is important to note that acoustic environments play a significant role in the healthcare setting, and sound can influence patient health and recovery. This study helps to fill a wider discussion on sustainable living by showing the importance of sound dynamics in designing future housing and encouraging architects and policymakers to put the importance of acoustic design first and foremost. Finally, the research recommends the combined approach that recognizes the synergistic association among sound, space and sustainability leading to the emergence of novel architectural solutions that meet environmental and human health issues in desert areas.

Tallal Abdel Karim BOUZIR[3]

[3] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.

Abstract

The paper examines the complexity of the urban soundscapes and their effects on human experience with the aim of bridging the significant gap in architectural design with regard to auditory elements in well-being in urban settings. Through the mixed-method approach, qualitative and quantitative data in the form of surveys and acoustic measurements are analyzed, to examine the impact that various soundscapes have on perceptions and emotional reactions to build spaces. The important research results are that certain acoustic features, including sound variety and volume, largely contribute to user satisfaction and comfort whereas discordant sounds reduce the overall city experiences. These findings have been highlighted as important in the healthcare setting, as auditory environment has been shown to reduce stress and better mental health outcomes among urban populations in the context of improved auditory environment. Moreover, the study has implications in the sphere of healthcare because the study supports a more holistic approach to urban planning and architectural design, where sound is an essential factor in creating healthier urban experiences. This study helps shape solutions to the challenges of providing acoustic well-being in the environment, contributing to the evolution of solutions that would serve to improve community health and the overall quality of life in more urbanized communities, which eventually suggests that sound-aware design ethos will become a key factor in the future of urban design.

A Performance Driven Generative Design Workflow for Optimizing Building Facades for Daylight and Energy Efficiency in a Mediterranean Climate

Fahim Yar BAIG [1*]

[1] Architect
fahimyarbaig@gmail.com *(Responsible Author)

Samira MEHRAFZA [2]

[2] Assistant Professor Dr., Ahlul Bayt International University, Tehran, Iran

Abstract

The design of building facades in Mediterranean climates presents a critical challenge: reconciling the competing objectives of maximizing natural daylight ingress and minimizing solar heat gain to reduce cooling energy consumption. Traditional design methods often fail to systematically explore the vast solution space for this multi-objective problem. This research aims to develop and test a generative design workflow that leverages computational optimization to identify facade configurations that optimally balance Daylight Autonomy (DA) with Cooling Energy Use Intensity (EUI).

A parametric model of a standard office space was developed in Rhino3D. A generative algorithm was constructed using Grasshopper, incorporating variable parameters for Window-to-Wall Ratio (WWR) and horizontal shading device properties. The Ladybug and Honeybee plugins were used to conduct iterative environmental simulations, evaluating each design variant for spatial Daylight Autonomy (sDA) and annual Cooling Energy Use Intensity. The Octopus solver was employed for multi objective optimization to identify Pareto-optimal solutions.

The workflow successfully generated a Pareto front of non-dominated solutions, quantitatively illustrating the trade-off between daylight availability and energy performance. Specific optimal configurations were identified, ranging from a high-performance solution with a WWR of 45%, a shading depth of 1.0m, and a tilt of 25° (achieving an sDA of 58% and an EUI of 28 kWh/m²/yr) to a daylight-focused solution with a WWR of 60% (sDA 72%, EUI 38 kWh/m²/yr).

The study demonstrates the efficacy of a performance-driven generative workflow as a robust decision-support tool for architects. It facilitates the data-informed design of high-performance building envelopes early in the design process, significantly contributing to energy-efficient and occupant-centric sustainable architecture in Mediterranean regions.

Keywords: Generative design, building performance simulation, facade optimization, daylight autonomy, energy efficiency, parametric design, multi-objective optimization.

Esita GHOSH [2]

ORCID 2: 0009-0003-7933-2314
[2] Department: Economics, University of Rajshahi, Rajshahi, Bangladesh

Abstract

Rising temperatures, erratic rainfall, and degrading soils are not only reducing crop yields but also testing the resilience of traditional settlements. This study explores how thoughtful design and planning can help farming communities adapt linking the spaces where people live with the systems that sustain their crops. Based on surveys of 80 farming households in the Rajshahi region, convenience sampling was applied and the data were analyzed using SPSS. Results showed that 43.2% of farmers were experienced very high climate impacts on their crops, driven mainly by pest outbreaks (56%), rising input costs (43%), and increasing irrigation demands (19%). Yet, adaptation was visible in action: many farmers rely on resilient crop varieties such as BR-32 and BARI Gom-33 for wheat, and experiment with maize hybrids like C.P-988 and BARI maize. Regarding actions taken to address the climate crisis, most respondents reported focusing on improving food security (24.00%), reducing fertilizer use (21.00%), and ensuring adequate water supplies for crops (18.00%). Architectural responses mirror this resilience. Traditional building forms, shaded courtyards, and rainwater harvesting systems—combined with modern environmental design—reduce heat stress, improve water use, and support productive land use. The study argues that real climate resilience lies not in isolated interventions but in designing entire rural environments that sustain both people and their livelihoods. By blending indigenous wisdom with practical innovation, this research offers a grounded, low-cost framework for climate-sensitive rural development—one that honors the deep link between shelter, soil, and survival.

Keywords: Climate resilience, rural architecture, agricultural adaptation, sustainable settlement design, agro eco-system planning

LAWALI Maman Toukour [3]

[3]Dr., Lecturer at the English Department of Université André Salifou, Zinder-Niger Republic

Abstract

Funerals are essential sociocultural events in all societies. This study investigates the dynamics of funeral practices Hausa Muslims of Zinder. To do so, the paper attempts to answer the research question how can changes occur in funeral practices among the Hausa Muslims of the city of Zinder. In conducting this research, a qualitative approach is used, with 50 people being interviewed as well as participant observation sessions during the funerals. The investigations led to several results. Funerals are not only an expression of mourning, but also fulfill sociocultural, religious, and symbolic functions in the Hausa Muslim societies of the city of Zinder. These results made it possible to understand that these rites strengthen family and community ties, cultural identity, and active solidarity. The results also show that significant socio-cultural, religious and economic changes, with multiple and varied factors, are observed in funeral rites.

Keywords: Zinder, funeral practice, dynamics, Hausa of Muslim faith, mutation.

Spaces That Enhance Well-Being in Türkiye, Ireland, Netherlands, Portugal, Spain, and United States: Designing for Health as a Holistic Approach Where Human Resources Can Thrive

Habil. Cristina Raluca Gh. POPESCU[1]

ORCID 1: 0000-0002-5876-0550

[1] Full-Professor PhD., University of Bucharest, Bucharest, Romania and The Bucharest University of Economic Studies, Bucharest, Romania.
popescu_cr@yahoo.com *(Responsible Author)

Abstract

Nowadays the Sustainable Development Goals have a profound impact on all domains, including on the architectural, engineering and cultural studies, environmental studies, urban studies which have to adapt in order to create spaces that enhance users' well-being. The current research has the objective of highlighting the characteristics of the spaces that promote and enhance well-being, while creating valuable connections with the social, environmental, and economic fields. The paper argues that by incorporating nature, providing ample natural light and fresh air spaces are expected to become functional and comfortable, offering, in turn, significant opportunities for social connection or quiet retreat. Also, by including biophilic design with key elements such as plants and water features, clear air, diverse and adaptable layouts intended to meet different needs, and access to communal and private areas, individuals can thrive, feel happier, and work with more dedication. The study starts with a literature review on this important topic, where the accent is positioned on the importance and role of incorporating nature. Additionally, valuable explanations and examples are provided so that a better understanding of the following elements is facilitated: promoting mental and emotional health; encouraging social well-being; and, fostering physical well-being. The benefits and opportunities of inclusivity in space design in the form described by the European Environment Agency (EEA) initiatives are presented together with several case studies from countries such as Türkiye, Ireland, Netherlands, Portugal, Spain, and United States. The current work demonstrates that designing for health is essential in developing a holistic approach where human resources can thrive. In essence, those spaces that promote and enhance well-being incorporate successfully biophilic design, natural light, and ventilation so that mental and physical health are considered accordingly.

Keywords: Sustainable development goals; architectural studies; engineering and cultural studies; environmental studies; urban studies; employee experience; change management; biophilic design; green and blue spaces; indoor elements; functionality; comfort.

Tallal Abdel Karim BOUZIR[3]

[3] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.

Abstract

This paper analyses how acoustic planning policies can help achieve sustainable urban and architectural environments, especially how noise pollution can be managed and its effects on the sustainability of the urban environment. This study uses a mixed-method design that combines qualitative and quantitative data and examines the case studies of existing acoustic policy, urban noise level measurements and resident satisfaction survey in terms of auditory comfort. Results show that there is a strong relationship between positive acoustic planning and optimized resident well-being and that lower noise levels may result in better healthcare outcomes such as lower stress and anxiety. These findings indicate the importance of sound management in the larger framework of urban health and that cities with effective acoustic policies are in a better position to support programs in the enhancement of the public health and to improve the living conditions of the citizenry. This research has added value to the discipline of healthcare by illustrating the importance of considering the auditory setting within the urban planning systems and this is why this research proposes an interdisciplinary methodology that has to integrate environmental sustainability with promoting health. This study has implications on policymakers, urban planners, and professionals working in healthcare and therefore there is a necessity to embrace sound as an important element of sustainable urban development policies, and it is possible that future policies on these areas and create healthier cities.

Keywords: Acoustic planning; sustainable urban environments; soundscape assessment; noise management policies; urban design strategies.

Biomechanically Informed and Sustainable Architectural Design in Sports Facilities: Enhancing Athlete Performance and Spectator Experience

Shiv KUMAR [1]*

ORCID 1: 0009-0009-6196-2063
[1]Lecturer Physical Education, SBV Vikas Puri, India

shiv.kmr1986@gmail.com *(Responsible Author)

Abstract

The architecture of sports facilities is evolving into a multidisciplinary field that integrates human performance science, environmental sustainability, and smart technology. This study examines how advanced architectural strategies—such as parametric design, computational fluid dynamics (CFD)-optimized airflow, and adaptive day lighting—improve athletic performance, recovery, and spectator comfort across multiple sports. By incorporating evidence from biomechanical analyses and environmental simulations, the research highlights the critical role of spatial geometry, thermal comfort, and acoustics in influencing athlete efficiency and psychological well-being. Case studies of next-generation multi-sport complexes and LEED-certified stadiums demonstrate how green roofs, passive ventilation, high-albedo surfaces, and renewable energy systems can reduce operational energy demands by up to 35% while maintaining high-performance standards. Additionally, the paper explores the use of AI-driven crowd management, digital twin modelling, and modular designs for adaptable, cost-effective, and inclusive sports infrastructures. The findings underscore that athlete-centric and eco-responsive architectural innovations foster not only superior sports performance but also resilient, community-oriented urban development.

Keywords: Sports architecture, sustainable design, biomechanics, adaptive facilities, smart infrastructure, environmental innovation.

Climate-Responsive Architectural Strategies for Lahore: A Bioclimatic Approach Toward Sustainable Design

Farhana NAZ [1*]

ORCID 1: 0009-0000-9495-5489

[1]Assistant Professor, Lahore College for Women University, Faculty of Arts and Social Sciences, Interior Design Department, Lahore, Pakistan
farhana.naz@lcwu.edu.pk *(Responsible Author)

Abstract

This study examines Lahore's climatic conditions to derive a comprehensive framework of design strategies that can significantly reduce reliance on artificial systems and promote thermal comfort through passive, climate-responsive architecture. By analyzing interrelated climatic parameters (temperature, humidity, solar radiation, daylight levels, and wind velocity), the research establishes a bioclimatic design approach tailored to Lahore's hot semi-arid climate with monsoon influence.

The results reveal that Lahore experiences substantial temperature extremes, ranging from low winter temperatures below comfort levels to summer peaks exceeding 40°C. Consequently, winter design strategies emphasize compact layouts, south-facing openings for solar gain, thermal insulation, and controlled wind exposure to retain heat. In contrast, summer conditions necessitate intensive passive cooling through cross-ventilation, evaporative cooling systems, shaded courtyards, reflective materials, and vegetative buffers to mitigate solar gain. Spring and Autumn, being naturally comfortable periods, allow for open, flexible, and naturally ventilated spaces requiring minimal mechanical intervention.

Solar radiation analysis confirms Lahore's strong year-round solar potential, advocating dual use, passive solar heating in winter and photovoltaic integration for energy generation in summer. The daylight availability (averaging 6,000–8,500 footcandles annually) supports the use of daylight harvesting systems, light shelves, and adjustable shading to balance illumination with thermal comfort. Wind analysis indicates low average speeds (5–6 mph), limiting wind energy utilization but emphasizing architectural ventilation strategies through orientation and spatial permeability. Temperature–humidity correlation highlights the need for hybrid HVAC systems that can adapt to dry summers and humid monsoon months while maintaining indoor air quality and moisture control.

In conclusion, the study establishes a dual-seasonal, bioclimatic design model for Lahore, promoting energy efficiency through contextual strategies, integrating insulation, shading, orientation, ventilation, and renewable energy systems, to ensure sustainable, adaptive, and human-centered built environments.

Keywords: Climate-responsive design, bioclimatic architecture, passive cooling and heating, thermal comfort, sustainable building strategies

Echoes of The Desert: Acoustic and Spatial Responses in Vernacular Sustainable Architecture

Melik SAMI [1]*

[1] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.
[2]LACOMOFA Biskra laboratory. Algeria.
sami.melik@univ-biskra.dz *(Responsible Author)

Khelil SARA[2]

[2] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.

Tallal Abdel Karim BOUZIR[3]

[3] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.

Abstract

This study examines the interactions between acoustic attributes and spatial designs in vernacular sustainable architecture in desert settings in order to optimize architectural designs to increase the acoustic comfort and ecological stability. The results of the thorough analysis based on the synthesis of the qualitative information obtained through acoustic measurements, spatial reviews, and interviews with users show that certain architectural qualities, including the choice of materials, design, and orientation, have a strong impact on the auditory experience and affect the emotional condition of the residents. It is worth noting that buildings constructed using natural sound management systems do not only support a healthier acoustic surrounding but also social interactions and cohesion of the community, which underlines the importance of these designs in improving the general standard of life. The implications of the findings to healthcare are that stress can be alleviated and mental health outcomes are improved through environments that support acoustic comfort, and this may provide new avenues to integrate architecture with the wellness-oriented healthcare practices. The general implication of this research is the promotion of acoustic and spatial concerns as part of sustainable architecture as a support towards better health and environmental performance in desert environments that may influence future building policies and standards towards enhancing holistic health in such environmental settings.

Keywords: Vernacular architecture; acoustic environment; desert architecture; traditional building techniques; cultural sustainability.

Multiculturality of Lviv/Lemberg/Lwów, The Centre of West Ukraine, as Reflected in the Architectural History of The City

Sándor FÖLDVÁRI [1*]

ORCID 1: 0000-0002-7825-0531
[1]Debrecen University, Faculty of Humanities, Baltic Program, Debrecen, Hungary; Emeritus.
alexfoldvari@gmail.com *(Responsible Author)

Abstract

Lviv's architectural legacy is a fusion of various styles that reflect the city's rich history. These include Gothic, Renaissance, Baroque, Classical, Art Nouveau and Modernist features. A notable example is the Hutsul Art Nouveau style, which attempts to create a distinct Ukrainian design by combining folk motifs with Art Nouveau elements. This style is characterised by its decorative features and is a unique Ukrainian style that combines elements of the Viennese Secession with local folk architecture. It is characterised by the use of bold colours and geometric patterns, particularly the prominent sun motif.

Lviv was an important centre for the Hutsul Secession movement, where architects like Ivan Levynsky incorporated local folk elements into the broader Secessionist trend. The historic centre of Lviv, designated as a UNESCO World Heritage Site, showcases a diverse range of European and local architectural styles through its narrow streets. These elements combine to create a unique and distinctive look that represents Lviv's rich cultural heritage and history. This paper focuses on Hutsul art as a significant Ukrainian cultural phenomenon, providing an overview of the various peoples who have inhabited the region over the centuries.

Keywords: Lviv, Ukraine, Polish-Lithuanian commonwealth, hutsul_architecture, cultural_heritage.

Potential And Constraints of Beekeeping Development in Sri Lanka: A Review on Socioeconomic, Technological, and Environmental Perspectives

Mahamarakkalage NETHMI AYODYA PERERA [1*]

[1]Department of Agricultural Biology, Faculty of Agriculture, University of Ruhuna
ayodyanethmi99@gmail.com *(Responsible Author)

Abstract

Beekeeping, or apiculture, represents an increasingly important component of sustainable agricultural development and rural livelihoods in Sri Lanka. As a tropical and high bio diversified country, Sri Lanka also has very good climatic conditions and environmental conditions for beekeeping. This review explores the potential and constraints of beekeeping development from socioeconomic, technological, and environmental perspectives. Beekeeping provides a viable income-generating opportunity, particularly for unemployed and low-income rural populations, while contributing to crop pollination and biodiversity conservation. The native species Apis cerana indica remains the primary honeybee used for commercial honey production, supported by Sri Lanka's diverse floral resources. However, the national honey yield and consumption remain relatively low compared to global averages, indicating underutilized potential. Adoption of precision apiculture technologies offers opportunities to enhance productivity, quality assurance, and colony management efficiency. How ever, challenges such as inadequate training, limited access to modern equipment, high initial costs, and low youth engagement limit the progress. Environmental constraints, including pesticide exposure, drought, deforestation, and bee diseases, further limit colony survival and honey yield. The review also identifies positive market prospects through value addition, including the use of wax, propolis, royal jelly, and venom, which can improve profitability and export potential. Strengthening institutional support, expanding training and extension programs, and integrating technology into apiculture practices are essential for realizing the industry's full potential. Therefore, beekeeping in Sri Lanka constitutes a viable pathway for enhancing rural livelihoods, food security and contribute to environmental sustainability despite existing challenges.

Valuing the Intangible: An Integrated Economic Framework for Assessing the Cultural Capital of Heritage Architecture in Urban Regeneration

Mohsen Mohammadi KHYAREH [1*]

[1]Gonbad Kavous university, Gonbad Kavous, Iran
m.mohamadi@gonbad.ac.ir *(Responsible Author)

Mohadeseh NEZHADIPOUR [2]

[2]BA in Economics, Gonbad Kavous university, Gonbad Kavous, Iran
m.nejadipour@gmail.com

Abstract

This paper addresses the central challenge of quantifying the economic value of cultural capital embedded in heritage architecture within urban regeneration projects. Urban development often prioritizes new structures due to the perceived intangible nature of cultural assets, resulting in a loss of historical heritage and undermined sustainable economic growth. The core research question is: How can the economic value of cultural capital from heritage architecture be quantified, and how can these assessments influence urban policy? To answer this, we propose an integrated, mixed-methods approach combining the Hedonic Pricing Model (HPM), the Contingent Valuation Method (CVM), and the Social Return on Investment (SROI) framework to capture both market and non-market values. Through case study analysis, the framework is demonstrated to robustly quantify cultural capital via indicators such as a heritage premium on property values and tourism multipliers. Expected results, supported by empirical models, suggest that preservation can yield a 10-20% increase in adjacent property values and significant social returns. The findings advocate for the inclusion of standardized, measurable metrics in cost-benefit analyses, ensuring that cultural preservation is effectively integrated as an economic asset in urban planning and policy decisions.

m.mohamadi@gonbad.ac.ir *(Responsible Author)

Mohadeseh NEZHADIPOUR [2]

[2]BA in Econmics, Gonbad Kavous university, Gonbad Kavous, Iran
m.nejadipour@gmail.com

Abstract

This paper examines the critical role of urban regulatory frameworks—specifically zoning regulations and building codes—in shaping the development and success of startup ecosystems and innovation districts. In an era where cities increasingly compete to become hubs of economic innovation, understanding the impact of land-use and building policies is paramount. Drawing on theories from urban economics and entrepreneurship, we argue that flexible zoning, such as mixed-use designations and density bonuses, and adaptive building codes that accommodate modern work styles are critical enablers of innovation. This study employs a mixed-methods approach, combining a comparative case study analysis of San Francisco, Berlin, and Singapore with regression modelling of startup and regulatory data. Our key findings reveal that cities with more permissive and adaptable regulatory environments exhibit significantly higher startup density and venture capital investment. Conversely, restrictive and outdated regulations are found to stifle the clustering, collaboration, and scalability essential for entrepreneurial growth. The paper concludes with a proposed policy toolkit for cities aiming to cultivate robust entrepreneurial hubs by strategically reforming their foundational land-use and building policies.

Abstract

The release of synthetic dyes into aquatic environments poses serious environmental and health challenges due to their toxicity, high chemical stability, and resistance to biodegradation. Widely used in various industrial sectors such as textiles, plastics, paper production, and pharmaceuticals, these dyes persist in wastewater and contribute significantly to surface and groundwater contamination. Developing effective, low-cost, and sustainable materials for their efficient removal is therefore of critical importance to protect ecosystems and human health.

In this study, a naturally abundant clay was chemically modified to enhance its adsorption performance toward dye pollutants in aqueous media. The modification process aimed to improve the clay's surface functionality, porosity, and overall interaction with organic molecules responsible for coloration in wastewater.

Structural and morphological characterization of both raw and modified clays was carried out using Fourier-transform infrared spectroscopy (FTIR), X-ray diffraction (XRD), and scanning electron microscopy (SEM). These analyses confirmed significant structural transformations and improved surface properties following the modification process.

Batch adsorption experiments were conducted to evaluate the effect of key operational parameters, including pH, initial dye concentration, adsorbent dosage, and contact time. The modified clay exhibited a significantly enhanced adsorption capacity and faster kinetics compared to the unmodified raw clay.

Overall, the results highlight the potential of the modified clay as a cost-effective, eco-friendly, and efficient adsorbent for the treatment of dye-contaminated wastewater. This study contributes valuable knowledge to the development of advanced clay-based materials for environmental remediation and industrial wastewater management.

Keywords: Modified clay, synthetic dyes, adsorption, environmental remediation.

Achievements in the Temple to Moon God Nanna Built By Kıng Ur Engur in 3 100 Bce in Ur in Mesopotamıa

Natela Borisovna POPKHADZE [1*]

ORCID 1: 0000-0003-1552-7860

[1] Dr., Head of Scholarly Information Center at Academy of Phasis in Tiflis in Gurcistan//Georgia Republic//Sakartvelo
Aiakolkhetikardugeorgia@gmail.com *(Responsible Author)

Abstract

My aim is to talk about the architectural achievement of ancient kings of Sumer//Khaldaea. I have used the method of learning the ancient languages made in cuneiform script, searching as much publications in Sumerian and modern languages Kartuli//Georgian, English, Italian, Latin, Graek, Russian , French, Turkish and Gearman as I could find in libraries in various towns and on the Internet websites. I have noticed that several authors made geographical names changed with words that were not in the texts and I am against tose changes because they distort the true geography and history of ethnicities. liI shall overview a brief history of the building of the Great Ziggurat of Ur built by king Ur-Engur. After his death he was succeeded by his son that was called Tungy by schollars a century ago, but is called now Shulgy. Shulgy continued building the ziggurat of Nanna. It was a religious, cultural, political and economic center. The corners were directed to North , South, East and West. The staircase in front of the building was directed towards the summer solstice sunrise direction. King Nabonidus of Khaldea made restoration of this building in 650 BCE and his son that became king of Khaldea after his death continued the rebuilding and restauration of this building. This king of Khaldea was called Nabu-Kudurru-Uzzur II. His namesake king Nabu-Kudurru-Uzzur I was king in 1100 BCE. Both were very patriotic caring for their kingdom and their compatriots the Khaldaeans. Nabu-Kudurru-Uzzur II was a very handsome person as revealed by his portrait embroidered on the cloth of his clothes when he was a young man of 17. Both kings are praised very much by ancient authors and our contemporary authors and researchers. Nabu-Kudduru-Uzzur II had a political friendship with the king of Media called Cyaksar and even married his daughter to strengthen their friendship. The bride was very sad about the landscape defence with the area from where she arrived to Ur in Khaldaea and she liked it very much when her husband arranged the garden of trees and flowers on the terraces of their palace where they lived in Ur.It was considered to be a marvel and called the Hanging Gardens.

A bit later Enheduana was the Great Priestess of god Nanna and she became the first female poetess in the woorld. The text is signed by her as Enheduana. She was the king's daughter. Her father was the king of Khaldaea. I have learned ancient languages written in the cuneiform Sumerian and cuneiform Akkadyan shrift with professors in my home town Tiflis at the Ivane Javakhishvili University a decade ago and I enjoyed this teaching and learning process very much. It enabled me to notice several facts in the ancient history that my professors did not notice. One of the facts that I noticed was that the king Ur Engur was later mentioned by professors by the different name Ur-Namu. I am against the change.

I think it is important that I have noticed that the song to god Nanna is preserved in my Sakartvelo//Gurcistan//Georgia among my ethnicity that is called Kardu/Katveli/Gurci/Georgians and it is still very popular nowadays in 21th century. I shall demonstrate videos of persons singing this hymn/song to Nanna.

Keywords: God Nanna, a temple, a hymn to God Nanna, Khaldaea.

Evaluation of Biophilic Design Principles in the Design Proposal of 5-Star Hotel

Safiya Bello ABDULLAHI [1*]

[1]Department of Architecture, Federal University of Technology Minna
safiyabello100@gmail.com *(Responsible Author)

Abstract

The growing concern for sustainability and occupant well-being has increased the adoption of biophilic design plans in hospitality architecture. The innovative practice of biophilic design incorporates natural features like plants, water, and natural lighting into constructed spaces to highlight the relationship between humans and the natural world. This study evaluates the integration of the biophilic principles (Terrapin 14 Patterns) into the design proposal of a 5-star hotel in Minna, Niger State, Nigeria, with the aim of identifying patterns suitable for the region's tropical savannah climate. Data were collected from case studies of hotels in Abuja and Minna, and questionnaires administered to architects, hotel managers, and users. Findings show that patterns such as Visual Connection with Nature, Thermal & Airflow Variability, Natural Materials, Prospect & Refuge, and Diffuse & Dynamic Light align strongly with Minna's climate, while Presence of Water and Risk/Peril is less proper and right due to water shortage and cultural restrictions. The study concludes that biophilic design can enhance guest comfort, environmental performance, and cultural identity in luxury hotels if modified to local climate and resources.

Keywords: Biophilic design; hospitality architecture; terrapin 14 Patterns; environmental sustainability; climate-responsive design.

Abstract

Artificial Intelligence (AI) has become an essential element in technological innovation across various sectors in the United States, Europe, and Asia. This research explores the evolving role of AI in 3D printing technology within the construction industry. Findings indicate that a 3D digital model forms the foundation of every 3D printing process, while Building Information Modelling (BIM) integrated with AI enables automation and precision in construction activities. The incorporation of AI-driven 3D printing improves efficiency, accuracy, and productivity while reducing costs and reliance on manual labor. Nevertheless, this integration also raises ethical and technical challenges, including unemployment, data security, intellectual property disputes, AI bias, and cybersecurity concerns.

Omadachi Ogbodo UGBABE[4]

[4]Department of Agricultural Economics, Ahmadu Bello University Zaria, Kaduna State.

Abstract

The study examined the perceived effects of fuelwood energy exploitation on livelihood of farming households in Bauchi and Gombe States, Nigeria. Primary data were collected using structured questionnaire and interview scheduled among 400 respondents. Percentage and factor analysis were used in analysing the data. The result showed that, there is higher reliance on non-sustainable fuelwood energy exploitation practices, this led to directly felling of green tree, this account for 77.80% of the respondents and the use of chainsaw in cutting down trees accounted for 62% of the respondents in the study area. The result of Principal Component Analysis (PCA) shows the perception items rated on a 5-point Likert scale with mean response varying from 4.34 to 4.81, signifying a very high level of respondent's consensus that fuelwood energy exploitation has negative effects on farming household's livelihood in different ways. The respondents strongly agreed that, fuelwood exploitation lowers food crop output with a mean value of 4.81 and lowers livestock feed availability with a mean value of 4.67. These high mean scores with very low standard deviations of (0.555) for low food crops and (0.528) for livestock feeds availability suggest that, households share a very strong agreement concerning fuelwood energy exploitation activities and its effects on the productivity of farming households. There is need for Government to intensify awareness campaigns on the negative environmental and health effects of unsustainable fuelwood energy exploitation and it use, and also the need for Government and community leaders to collaborate to enforce stringent rules and penalties for illegal green tree cutting especially using chain saw. Inconclusion, there is need for Government to introduce and promote community-based forest guard with improved surveillance equipment and law enforceability. Finally, the need for extension agents to collaborate with local leaders to educate community on sustainable practices and the use of climate smart alternative energy technologies.

Keywords: Fuelwood energy exploitation, livelihood, farming households.

A Comparative Analysis of The Role of Rock-Cut Architecture in The Life Cycle of Rural Tourism: A Case Study of Kandovan, Iran, and Göreme, Türkiye

Kazem GOLIZADEH [1*]

ORCID 1: 0000-0002-0381-2667
[1]Department of Architecture and Urban Planning, National University of Skills, Tehran, Iran
K-gholizadeh@nus.ac.ir *(Responsible Author)

Abstract

Rock-cut architecture, as one of the most authentic manifestations of vernacular architecture, plays a crucial role in shaping cultural identity and attracting tourists. This study aims to provide a comparative analysis of the tourism life cycle in two rock-cut settlements—Kandovan in Iran and Göreme in Türkiye—using Butler's Tourism Area Life Cycle (TALC) model. It analyzes the role of rock-cut architecture in sustaining or eroding tourism in these regions. Kandovan, as one of the few living rock-cut settlements in the world, remains in the early stages of tourism development despite its physical and cultural richness. In contrast, Göreme, benefiting from UNESCO World Heritage registration, infrastructural diversity, and cultural branding, has reached a consolidation phase and is recognized as a prominent destination in cultural and experiential tourism. Using a descriptive–analytical approach and Butler's model, this study examines the current status of these two destinations from physical, managerial, and community participation perspectives, and employs the SWOT matrix to propose strategies for Kandovan's transition toward sustainable development. Findings indicate that rock-cut architecture, beyond its visual appeal, serves as a foundation for a cultural ecosystem and, if properly managed, can act as a driver for balanced development. In this regard, physical restoration, prevention of unprincipled interventions, architecture-centered branding, and local community education for the wise use of this heritage are essential steps toward achieving sustainable tourism in Kandovan

Keywords: Rock-cut architecture; butler model; rural tourism; Kandovan; Göreme; sustainable development

Faculty of Interior Design Department, Lahore College for Women University, Lahore, Pakistan.

Abstract

Old train carriages are often left to rust and decay, even though they're built to last and could be repurposed in creative ways. This project repurposes these forgotten carriages into immersive escape rooms, creating interactive environments that engage visitors both intellectually and physically. By building on the existing structure, the design reduces environmental impact and revives forgotten infrastructure with a fresh purpose. The "Threads of Escape" concept links several carriages into one seamless journey, creating a stronger sense of exploration and keeping the experience engaging throughout. Preserving the original form of the trains, the project blends history with innovation, offering a unique recreational attraction that local tourism and public engagement. It demonstrates how adaptive reuse can turn outdated spaces into vibrant, experience-focused destinations, reimagining abandonment as a chance for creativity and innovation.

Keywords: Abandoned trains, adaptive use, adventure, escape, environments, experiential design, interactive space.

Greasing The Gears of Innovation: The Role of Petroleum Chemistry in Architectural Design And Engineering

Ibrahim Khalil ADAMU[1*]

[1]Department of Petroleum Chemistry, American University of Nigeria Yola, Nigeria.
Department of Chemistry, Federal College of Education Gidan Madi Sokoto, Nigeria.
ibrahimkhaliladamu@yahoo.com *(Responsible Author)

Abdullahi ALIYU[2]

[2]Department of Pure and Industrial Chemistry, Federal University, Birnin Kebbi, Nigeria.

Abstract

Petroleum chemistry is a branch of chemistry concerned with the transformation of crude oil and natural gas into valuable products. It plays a fundamental role in the development of materials and technologies used in engineering, construction, design and modern architectural development. The petrochemical industry provides essential building blocks for plastics, resins, adhesives, insulation materials, paints, synthetic rubbers etc. which are integral to modern construction, design, infrastructure and architectural development projects. As architecture and engineering increasingly emphasize efficiency, durability, and sustainability, the relationship between petroleum-derived materials and design innovation becomes more compound and critical. Petroleum chemistry has been a foundational asset behind the contemporary built environment, it influenced both the engineering and architectural realms. While it has aided outstanding improvements in materials science and construction techniques, the environmental cost is substantial particularly the greenhouse gases, oil spills and marine degradation. The future lies in complementing functionality and sustainability through innovation, circular economy models, and integration of greener alternatives for effective service delivery.

Keywords: Petroleum chemistry, architectural design and engineering

Tallal Abdel Karim BOUZIR[3]

[3] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.

Abstract

This paper explores the complex correlation of architectural practices, environmental externalities and economic policy in urban environments which center around the critical role of sustainable urban development. It fills a gap that is very important on current research because it presents empirical information that links architectural strategies to their environmental effects and financial results by gathering and analyzing case studies, thorough statistical data about urban environmental indicators, and analysis of contemporary economic policies. The results indicate that particular design options and construction materials have a considerable impact on urban thermal trapping, air quality, and resource use, and the evaluation of the economic policies indicates the flaws in the incentivization of eco-friendly architectural innovation. The study highlights the importance of combining architectural decision-making with environmental health factors, which might imply that better architectural work could result in a dramatic increase in urban public health conditions, including the number of respiratory diseases solved and the quality of life. Also, the implications go beyond personal health gains; by educating policy-makers and city planners, the study proposes a synergist action plan that creates an equilibrium between the architectural design solution and the environmental sustainability and economic benefits, which will generate the resiliency in the healthcare systems of the city. The findings highlight why the interdisciplinary work of the architects, environmental scientists, and economists is needed to facilitate one holistic approach to urban development that would lead to the long-term sustainability and the benefits of urban development to the population.

Keywords: Environmental externalities; economic policy; sustainable cities; urban sustainability governance; green building design.

The Trade-Off Between Economic Growth and Environmental Architecture in Developing Regions

Melik SAMI [1]*

[1] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.
[2]LACOMOFA Biskra laboratory. Algeria.
sami.melik@univ-biskra.dz *(Responsible Author)

Khelil SARA[2]

[2] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.

Tallal Abdel Karim BOUZIR[3]

[3] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.

Abstract

This paper examines the compound relationship between economic growth and environmental architecture in the developing world with main emphasis on the frantic conflict between the fast rate of economic growth and the need to follow sustainable environmental practices. The study involves qualitative and quantitative approaches and includes an in-depth examination of economic indicators, environmental impact evaluation, and multiple case-studies of development initiatives in a number of geographic settings. Important findings include the fact that economic growth is a necessary process that improves the standards of living, but it tends to compromise the environmental integrity, which translates to increased pollution and degradation of natural resources. Notably, the research study finds a strong relationship between sustainable architecture and better public health outcomes, which suggests that areas that consider the environmental factor in their developmental policies have improved healthcare profiles, including a lower rate of respiratory diseases and an overall increase in the well-being of the communities. The implications of these results are not limited to the context of urban planning and population health but are vital in policy-making and stakeholders in the healthcare industry, who need to take into consideration the need to ensure that environmental sustainability is part of the economic planning to enhance a holistic development. Finally, the study can be described as part of a more sophisticated perception of the trade-offs inherent in the practice of development, which is why the need to promote the adoption of policies that will encourage economic growth and the preservation of the environmental health are justified, which is also directly connected to the main goal of ensuring that the healthcare systems of emerging economies become more sustainable.

Keywords: Economic growth; environmental architecture; green building design; socio-economic trade-offs; sustainability challenges.

From Farm to Cup: The Interplay of Sustainability and Governance in Ethiopia's Coffee Value Chain for Sustainable Development

Sintayehu Assefa YIRGA

[1] Ph.D., Hawassa University, Department of Management
sintayehuassefa58@yahoo.com * (Responsible Author)

Abstract

Coffee, Ethiopia's leading export and the livelihood of millions of smallholder farmers, faces mounting challenges from volatile prices, environmental stress, and social inequities. This study explores how economic, social, and environmental sustainability, alongside governance, influence development outcomes in the Sidama coffee value chain. Using survey data from farmers analyzed through Partial Least Squares Structural Equation Modelling (PLS-SEM), the findings reveal that all three sustainability dimensions significantly foster development, with social sustainability exerting the strongest influence, followed by environmental and economic aspects. Governance not only directly drives development but also strengthens the impact of sustainability practices, especially social sustainability, on developmental outcomes. These results underscore that long-term resilience in Ethiopia's coffee sector requires more than economic viability it depends on socially inclusive practices, ecological stewardship, and effective governance frameworks. By grounding the analysis in Sustainable Development Theory and Institutional Theory, this study offers fresh empirical evidence on how governance amplifies sustainability's role in advancing development within Ethiopia's coffee sector.

Keywords: Coffee value chain, sustainability, governance, development, Sidama, Ethiopia, institutional theory, sustainable development theory

Abstract

Artificial Intelligence (AI) is gaining remarkable momentum in the modern era, influencing nearly every domain—from automated design systems to intelligent urban planning and sustainable environmental solutions. Its impact and adaptability are particularly critical in architecture and engineering, where AI-driven tools directly influence human living environments, structural safety, and ecological balance. The AI revolution has introduced new dimensions in addressing complex design challenges, optimizing building performance, and preserving cultural heritage through intelligent data analysis and predictive modelling.

Recent advancements have shown how AI algorithms can simulate structural behavior, predict material degradation, and even reconstruct historical sites with unprecedented precision, thereby transforming both design and conservation practices. The growing complexity of global environmental challenges poses a major test for urban planners and architects, demanding innovative, data-driven, and interdisciplinary approaches. Researchers and professionals are now integrating AI not only as a computational aid but also as a creative partner capable of generating sustainable and culturally sensitive design solutions.

The Information technology-based era further demonstrated the transformative potential of AI and digital collaboration tools in maintaining continuity of architectural research, design education, and project coordination. Platforms powered by AI enhanced virtual modelling, simulation, and cultural documentation processes, bridging physical gaps across disciplines. Overall, the integration of AI across architecture, engineering, cultural studies, and environmental sciences is redefining the way humanity conceives, designs, and sustains its built and natural environments—fostering innovation while supporting economic and ecological resilience.

Smart and Ecological Cities: Pathways to Climate-Resilient and Sustainable Urban Futures

K. R. PADMA [1*]

ORCID 1: 0000-0002-6783-3248
[1]Assistant Professor, Department of Biotechnology, Sri Padmavati Mahila Visvavidyalayam (Women's University), Tirupati, AP.
thulasipadi@gmail.com *(Responsible Author)

Abstract

Smart and Ecological Cities is the vision of a new way of building cities, which combines the innovative technology with the environmentally-friendly policy. Due to the rapidly increasing urbanization of the world, cities are increasingly challenged by the lack of resources, pollution, climate change, and social inequality. The idea of smart and ecological cities is suggested to overcome these problems using the digital innovations, green infrastructure, and data-driven governance in order to make living in cities more liveable and resilient. The core idea here is the convergence of information and communication technologies (ICT) and urban systems in order to maximize the consumption of energy, transportation, waste management, and services to the population. Meanwhile, the principles of the ecological design focus on renewable energy, protection of biodiversity, efficient use of water resources, and development of green areas that help people live better and maintain the natural state. A combination of clever technologies and environmentally friendly planning will allow cities to reduce the ecological footprint, but also support economic development and social integration. As case studies in different countries show, such cities do not only contribute to the quality of the environment, but also to the quality of life of citizens, due to participatory form of governance and feedback of data in real-time. The shift to smart and ecological cities needs the cooperation of policymakers and technologists, urban planners, and citizens to guarantee equity and sustainability in the long run. The future studies in the field should be aimed at creating quantifiable sustainability indicators, how citizens use digital ecosystems, and how technology innovation can be consistent with ecological and ethical norms. Finally, smart and ecological cities represent a comprehensive view of the expected urban environment in the future- efficient, adaptable and friendly to the environment.

Keywords: Smart cities, Ecological cities, sustainable development, urban planning, green infrastructure, renewable energy, internet of things (IoT), artificial intelligence (AI), climate resilience, circular economy.

Sustainable Urban Planning and Development

S. SHAKTHI SREE[1*]

[1]Bharath Institute of Higher Education and Research, Selaiyur, Chennai-73.
shreesshakthi@gmail.com *(Responsible Author)

Abstract

Sustainable urban planning and development aim to create cities that balance environmental protection, economic growth, and social equity while ensuring long-term resilience. As rapid urbanization accelerates worldwide, cities face growing challenges such as resource depletion, pollution, inadequate housing, and climate change. Sustainable planning provides a strategic approach to address these issues by integrating land use, transportation, housing, and infrastructure in a manner that minimizes environmental impact and promotes efficient resource utilization. Key principles include compact city design, green infrastructure, renewable energy adoption, waste reduction, and participatory governance. Innovative models such as smart cities, transit-oriented development, and eco-friendly urban systems demonstrate how technology and policy can work together for sustainable outcomes. Case studies from cities like Copenhagen, Singapore, and Curitiba highlight the effectiveness of sustainable practices in enhancing liveability, resilience, and economic vitality. However, achieving sustainability requires inclusive policies, community engagement, and strong institutional support. Overall, sustainable urban planning and development are essential for building resilient, equitable, and environmentally responsible urban futures.

Keywords: Urban planning, urbanization, resource depletion, pollution, inadequate housing, climate change.

The Urban Landscape of Western Europe: Impact of the Decline of the Western Roman Empire on Urbanization from AD 400 to the 17th Century

Ananda MAJUMDAR[1*]

ORCID 1: 0000-0003-3045-0056
[1]Ananda Majumdar - Harvard University
anandamajumdar2@gmail.com *(Responsible Author)

Abstract

This study looks at how the decline of the Western Roman Empire affected urban development in Western Europe. It focuses on the social and economic changes that occurred from AD 400 to the 17th century. The main goal is to understand why urban life stagnated during the medieval period and how cities eventually started to recover. The study uses historical analysis, reviewing existing literature and archaeological findings to explore changes in city layouts, population shifts, and the impact of invasions by Germanic tribes and Norsemen. It identifies three types of urban forms during this time: rectangular layouts, spontaneous irregular designs, and planned towns, each representing different historical backgrounds and environmental factors. The findings show that urbanization nearly stopped after the fall of the Roman Empire due to isolation, declining agriculture, and the dominance of farming societies. Trade disruptions, particularly during the rise of Islam and Norse raids, worsened city life in Europe. However, the 10th century marked a turning point, leading to a gradual revival of commerce with the reopening of trade routes and the growth of fortified settlements, signalling the beginning of urban renewal. In conclusion, the research highlights how various factors shaped the medieval urban landscape, leading to limited city growth characterized by small populations and a lack of large urban centers. This study offers valuable insights into the political, economic, and social changes during a key period in European history, emphasizing the importance of understanding urban development in a broader context.

Keywords: Decline, isolation, cities, revival.

Sustainable Urban Farming in India: Pathways to Achıevıng the Sustainable Development Goals (Sdgs)

Hari Prasad AGARWAL[1*]
[1]Dr., Royal School of Architecture, The Assam Royal Global University, Guwahati
hari_architect94@yahoo.com *(Responsible Author)

Abstract

In areas that are rapidly urbanizing, Urban farming (UF) is becoming a crucial tactic for improving social justice, environmental sustainability, and food security. In the context of Indian cities, where urban expansion, resource scarcity, and socioeconomic inequality pose issues, incorporating UF into the built environment provides a holistic approach that is consistent with the United Nations Sustainable Development Goals. This study investigates the spatial and architectural aspects of sustainable Urban farming in India, looking at how community involvement, land-use regulations, and design interventions may turn underutilized urban areas into resilient, productive ecosystems.

The paper emphasizes key success factors and challenges in implementing UF on a scale through a review of the literature, investigating urban farming projects in cities like Bengaluru, Hyderabad, Delhi, and Mumbai, Kolkata, Bhubaneswar, Guwahati, Jaipur, Udaipur, and case studies of rooftop farms, vertical gardens, and community plots. To promote local food systems and achieve SDG targets like Zero Hunger (SDG 2), Sustainable Cities and Communities (SDG 11), and Climate Action (SDG 13), the study highlights the role that architects and urban designers play to establish inclusive, climate-responsive contexts.

According to key findings, UF may enhance ecological balance and urban resilience when integrated into architectural frameworks such modular farming systems, mixed-use zoning, and green roof typologies. To find ways to incorporate sustainable agriculture into urban planning practices, the investigation proposes a variety of design concepts and regulatory recommendations. This study positions urban farming as an essential tool in India's sustainable urban development by emphasizing the importance that the built environment contributes to establishing food systems.

Keywords: Urban farming, sustainable development goals (SDGs), architectural integration, urban resilience, food security

Mohammad Yasin REZAEI [1]

[1]International Islamic University, Pakistan

Abstract

The integration of digital technologies in landscape design is transforming the way agricultural and ecological systems are managed, modelled, and optimized. This chapter explores the intersection of physics-based models, technological innovations, and agricultural landscapes, highlighting how emerging tools can address the pressing challenges of sustainability, climate change, and resource management. Using principles from physics, such as energy balance, fluid dynamics, and soil-water interactions, advanced computational models can simulate environmental processes with greater accuracy, enabling designers and planners to make data-driven decisions in landscape architecture. At the same time, technologies such as Geographic Information Systems (GIS), remote sensing, drones, Internet of Things (IoT) sensors, and virtual reality (VR) applications are providing new dimensions for monitoring, visualization, and design.

This chapter discusses how digital tools contribute to sustainable agriculture through precision farming, smart irrigation, and climate-resilient landscape planning. Furthermore, it emphasizes the role of digital simulations in predicting the impacts of climate change on agricultural and ecological landscapes, and how these predictions can be integrated into adaptive design strategies. Case studies from recent applications in precision agriculture and ecological restoration illustrate the potential for combining traditional landscape knowledge with technological innovation.

By bridging agriculture, physics, and technology, this work contributes to a deeper understanding of how interdisciplinary approaches can transform landscape design into a more resilient, efficient, and sustainable practice. Ultimately, the chapter argues that the integration of physics-based models with digital technologies is not only advancing landscape architecture but also reshaping agricultural systems to meet the global demands of food security, sustainability, and climate adaptation.

Keywords: Digital technologies, landscape design, agriculture systems, sustainable agriculture, remote sensing, resource management.

Capitalizing on Local Knowledge of Tetraclinis articulata in Morocco's Central Plateau: Challenges for Conservation of an Endangered Medicinal Heritage

Jaayefar FATIMA-EZZAHRA[1*]

[1] Ibn Tofail University, Laboratory of Plant, Animal Productions and Agro-Industry, Kenitra, Morocco
Fatima-ezzahra.jaayefar@uit.ac.ma*(Responsible Author)

et Dahmani JAMILA [2]

[2] Ibn Tofail University, Laboratory of Plant, Animal Productions and Agro-Industry, Kenitra, Morocco

Abstract

Tetraclinis articulata also known as Barbary Thuya or Aarar, is a conifer native to North Africa and belongs to the Cupressaceae family. This well-known conifer of Mediterranean landscape is mainly distributed in Morocco, Algeria, and Tunisia with relict populations in Spain and Malta. Morocco is home to the largest sites, and the species occurs particularly in the valleys of the Central Plateau. This study is aimed at gathering and synthesizing recent scientific research regarding this important plant resource. Data was derived from scientific databases (pubmed, science direct, web of science) primarily dealing with phytochemicals and pharmacology. The Barbary Thuya is a thermophilic and xerophilic species common in semi-arid bioclimatic stage (300-500mm in annual rain). This species has high edaphic plasticity, and grows in well-drained calcareous, siliceous, or gypsum soils. It forms pure populations, or it can co-inhabit with Aleppo Pine, Holm Oak or different matorral species. Its role in the ecosystem is highlighted by its importance in soil protection against erosion and in its admirable abilities in regeneration via stump sprouting after fires. Its socio-economic role is multifaceted: its precious wood (notably the burl) is exploited for marquetry or fine cabinet work, service wood, sandarac gum and the production of a honey classified as premium quality. The leaves and the twigs have been used in traditional medicine, particularly for their diuretic, anti-rheumatic effects or against respiratory conditions. Yet, although it is resilient, over the past decades the Barbary Thuya has been facing strident anthropogenic pressures (fires, over-exploitation, and over-grazing), resulting in an alarming regression of its stands. Thus, the conservation and valorisation through an adapted silviculture is required for the Barbary Thuya, and the development of the rural territories of the Maghreb.

Keywords: Tetraclinis articulata, barbary thuya, central plateau, biodiversity, ecology, valorisation, Morocco

Contribution of Rural Infrastructure Development Fund (RIDF) in rural prosperity in India

Bhawana PAL [1*]

[1] Dr., Faculty Member, Bankers Institute of Rural Development, Kolkata
bhawana.banjare@nabard.org *(Responsible Author)

Abstract

The Rural Infrastructure Development Fund (RIDF) was established by NABARD in 1996 to provide financing to state governments and state-owned corporations for infrastructure development in sectors such as irrigation, rural roads and bridges, health, education, and agriculture-related infrastructure. Through targeted investments, the RIDF plays a crucial role in strengthening rural resilience, promoting inclusive growth, advancing rural development, and improving the quality of life in underserved areas.

Rural infrastructure development is a critical driver of inclusive and sustainable growth in rural areas. This entails mobilising and allocating financial resources for the creation and maintenance of essential physical and social infrastructure such as roads, irrigation systems, bridges, drinking water supply and sanitation, power supply, health facilities, and digital connectivity. Adequate and timely investment in rural infrastructure not only stimulates economic activity by improving access to markets and services but also plays a pivotal role in narrowing the urban–rural divide.

Through the provision of low-cost loans to state governments and local bodies, NABARD facilitates the creation of durable infrastructure assets that improve agricultural productivity, enhance connectivity, and expand market access. This support aims to bridge the rural infrastructure gap, thereby strengthening the resilience and long-term development potential of rural communities. As on FY2025, cumulative sanctions under infrastructure financing from NABARD stood at ₹8.9 lakh crore, with disbursements amounting to ₹6.8 lakh crore. For rural produce to reach market connectivity is of vital importance.

Keywords: RIDF, NABARD, agricultural productivity and digital connectivity.

D. O ALONGE[2]

[2]Department of Architecture, School of Architectural Technology, Federal University of Technology, Minna, Nigeria

E. UDOKO [3]

[3]Department of Architecture, School of Architectural Technology, Federal University of Technology, Minna, Nigeria

Abstract

The trajectory of sustainable urban development in Nigeria is intrinsically linked to the quality of its architectural education. However, existing educational facilities often lack the environmental and spatial qualities necessary to train future architects in sustainable design, hindering progress toward resilient urban futures. This study addresses this critical gap by exploring the intersection of environmental studies, cultural relevance, and architectural design within an educational framework. It puts forward a new design proposal for the School of Architectural Technology at the Federal University of Technology, Minna (FUT Minna), that serves as a model for green and sustainable infrastructure. The proposal is grounded in evidence-based principles to foster a learning environment that enhances productivity, well-being, and ecological consciousness.

Employing a mixed-methods case study, the research integrates a comprehensive review of biophilic design, environmental psychology, and sustainable architectural pedagogy with an analysis of existing architectural faculties. This is complemented by qualitative surveys and interviews with students to ensure the design is culturally and contextually responsive.

The findings reveal a significant disconnect between current facilities and the needs of a modern, environmentally focused curriculum, identifying issues such as sub-optimal lighting, inadequate ventilation, and a lack of adaptable, collaborative spaces. In response, our proposed design champions flexible, technology-rich, and biophilic learning environments that are climate-responsive and utilize local, sustainable materials.

This work contributes a contextually grounded model for transforming architectural education infrastructure in Nigeria and beyond. It offers a blueprint for purpose-built facilities that not only enhance student learning but also function as pedagogical tools for sustainable urbanism, construction innovation, and environmental stewardship.

Keywords: Architectural education, biophilic design, Nigeria, spatial needs, sustainable infrastructure.

Pekalongan City Culture and its Nickname as the City of Batik

M. Fathrezza IMANI [1]

ORCID 1: 0000-0001-6071-2390

[1]Magister of Islamic Economics of UIN KH. Abdurrahman Wahid Pekalongan
rezaimani82@gmail.com *(Responsible Author)

Abstract

Pekalongan City is a city that borders the Java Sea in the north, Pekalongan Regency in the south and west and Batang Regency in the east. Since tens and hundreds of years ago until now, most of the production process of Pekalongan batik is done at home. As a result, Pekalongan batik is closely integrated with the life of the Pekalongan people. Batik has become the lifeblood of the Pekalongan people and is proven to still exist and not give up on the times, as well as show the tenacity and flexibility of its people to adopt new ideas. Finally, in 2011, Pekalongan City was dubbed the "World City of Batik" which was carried by Pekalongan City because of the branding that Pekalongan City launched itself. This research was conducted to explain the origin of the nickname Pekalongan city as the world city of batik. The method in this research is an empirical study of phenomenology in the form of library research using a qualitative approach. This study used secondary data obtained from previous studies and other literature with similar research topics. The results of the study explain that in 2011, Pekalongan City was dubbed the "World City of Batik" which was carried by Pekalongan City because of the branding that Pekalongan City launched itself, in order to welcome the city's 105th anniversary. And Batik is designated by UNESCO as a Humanitarian Heritage for Oral and Intangible Culture on October 2, 2009. Since then, every October 2 is always celebrated as National Batik Day.

Keywords: Pekalongan city, motif, and batik.

Abstract

Smart buildings integrate networked sensors, building automation systems (BAS), IoT devices, and cloud-based analytics to deliver energy efficiency, occupant comfort, and operational cost savings. However, the IT-OT convergence that enables such benefits also expands the cyberattack surface: unencrypted IoT endpoints, legacy building controllers, and sub segmented networks create routes for attackers to insert physical disruption or exfiltrate sensitive data. This study investigates cybersecurity risks in smart building infrastructure using a mixed-methods design. The key findings illustrate runaway growth of IoT endpoints (tens of billions globally), high and rising percentage of devices with critical vulnerabilities (industry sources report substantial year-over-year increases), and common architectural vulnerabilities such as flat network topologies, default passwords, and unpatched firmware that persist across deployments. From data-driven risk metrics that draw on NIST guidance and industry threat intelligence reports, we show that 10–100 networked BAS/IOT devices in building infrastructure can create numerous high-severity vulnerabilities if proper practices are not being practiced and that attacks can disable HVAC, access control and energy systems with real physical and economic impact. We bring together robust mitigations segmentation, device lifecycle and inventory management, zero trust principles, secure procurement and recommend a research agenda that includes federated intrusion detection for building automation systems and standardized security certification for IoT building infrastructure.

Keyword: Smart buildings, BAS, IoT, cybersecurity, NIST, vulnerability metrics.

Historic Monument Buildings – European Union Perspectives on Their Protection

Voroneanu-Popa Rareș-VASILE[1*]

[1]Grigore T. Popa University of Medicine and Pharmacy of Iași
raresvoroneanu95@gmail.com *(Responsible Author)

Richard CONSTANTINESCU[2]

[2]Grigore T. Popa University of Medicine and Pharmacy of Iași

Abstract

In principle, buildings that are part of the cultural sphere are designated as monuments. In most national legislations, they benefit from a special legal status. Lawmakers have understood that their protection must be ensured through specific legal instruments that set out how such buildings are to be preserved, restored, and maintained.

State authorities have shaped their legislation in ways that highlight and enhance historic buildings. These structures not only demonstrate the historical importance of nations but also preserve the architectural style of their times—an aspect that influences how cities are maintained and developed.

The protection of cultural heritage is primarily the responsibility of national authorities; however, the European Union provides significant support in this area. The most common actions take the form of funding, recommendations, and policy initiatives, though additional strategies are needed to further encourage member states to conserve historical buildings.

Abstract

Algerian desert cities, particularly Biskra, are experiencing rapid socio-economic and urban transformations driven by agricultural expansion, tourism development, and demographic change. These dynamics are reshaping traditional spatial organization and architectural identity, resulting in both opportunities and challenges for sustainable urban planning.

This paper explores the interaction between socio-economic change and urban morphology in Biskra, focusing on how agricultural investment and social mobility influence housing patterns and architectural forms. Using a socio-economic analytical approach, field observations, and statistical data, the study highlights the mismatch between official urban policies and local practices.

Findings reveal that the accelerated urbanization process often neglects the social and cultural specificities of desert environments, leading to spatial fragmentation and environmental stress. The paper concludes by recommending the integration of socio-cultural dimensions into urban planning and architectural design, promoting inclusive and sustainable development for desert cities.

Keywords: Biskra, socio-economic transformation, urban change, desert architecture, sustainable development.

Abstract

Various theoretical and empirical studies tried to underline that the current rate of economic expansion is unsustainable due to the major environmental issues it causes. In the light of these environmental problems, many policy-makers looked for strategies aimed to enhance sustainable development. Thus, in 2012, GreenInvest was established at the G20 Leaders' Summit, in order to accelerate the investment in green priorities in developing countries. In this context, foreign investors became more tempted to contribute to the environmentally sustainable projects. These investments, named Green FDI, are made especially in sectors such as renewable energy, clean technology and sustainable infrastructure. Taking into account all these aspects, the purpose of the present paper is to analyse the role of eco-friendly foreign investment in promoting sustainable development in developing and emerging economies that face the dual challenge of fostering economic growth while mitigating the environmental degradation. Our results indicate a statistically significant and negative correlation between Green FDI and CO_2 emissions, suggesting that higher Green FDI inflows are associated with improved environmental outcomes. Moreover, we noticed that countries with targeted green investment policies, such as feed-in tariffs, green bonds and tax incentives, have seen stronger positive impacts on renewable energy adoption and green employment rates.

Keywords: Green FDI, sustainable development, developing countries, CO_2 emissions, environment

An Analytical Study of AI-Enabled Tourism and Global Integration

Deepanjali MISHRA[1*]

[1]Associate Professor, School of Liberal Studies, KIIT University, India
deepanjalimishra2008@gmail.com * (Responsible Author)

Abstract

Tourism is one of the major industries which was affected the most during the COVID-19 lockdown. It was in the month of December 2019 when the world came to a catastrophe halt in one of the most devastating pandemic, Covid -19. Looking into the urgence of the situation the governments of all the countries imposed a nationwide lockdown due to which it was impossible for people to go out of their homes except a few hours relaxation to get their necessary daily needs for survival. Tourism, which was one of those sectors that yielded maximum revenues for a country, started to decline at an alarming rate as people were left confined to their homes and aircrafts, trains and other mode of transportation didn't ply from one place to another. However, after 2021, when the situation improved and normalcy returned, people started to travel and aircrafts also took off carrying tourists on board. Tourism has been one of the most developed sectors and technology plays a major impact on it. The basic objective of this paper is to bring out a narrative on the role of Artificial Intelligence in connecting the world through tourism.

The Energy Affordability Crisis: Fuel Price Shocks, Urban-Rural Disparities, and the Climate Mitigation Paradox in Northern Nigeria

Sabiu Bello YUSUF [1*]

Umar SHAMSUDEEN[3]

[3]Umaru Ali Shinkafi Polytechnic, Sokoto[3]

Abstract

This research examines the critical conflict between climate mitigation goals and socio-economic reality in Northern Nigeria, focusing on the impact of recent fuel and electricity price hikes. Building on longitudinal data from Sokoto, we analyse the limited success of national energy policies like the National Gas Policy. Our findings reveal a severe energy affordability crisis: low-income urban households spend over 12% of their income on electricity under conservative estimates, tripling the World Bank's affordability threshold. The recent removal of the petrol subsidy and increased electricity tariffs have intensified this crisis, forcing a regression to polluting biomass fuels like firewood and charcoal despite growing LPG infrastructure. This creates a critical climate mitigation paradox; well-intentioned policies designed to create sustainable energy markets effectively price out the population, thereby perpetuating reliance on GHG-intensive energy sources. Analysis of household energy choices shows that availability, not cost, remains the primary driver, underscoring profound infrastructural deficits. The crisis manifests differently across settlements: urban households face crippling costs, while rural communities, largely off grid, experience deepened energy poverty and accelerated deforestation. The study concludes that without integrated pro-poor energy strategies, targeted subsidies, and decentralized renewable systems, climate policies will continue to undermine their own objectives. The findings offer crucial insights for sustainable architecture and urban planning, emphasizing the need for housing designs and settlement strategies that integrate passive environmental controls and affordable clean energy systems. This will help to build resilience against both energy poverty and climate change.

Keywords: Energy poverty, climate mitigation, fuel pricing, urban-rural disparities, Nigeria, sustainable housing.

Legal Implications of Building Collapse in Nigeria: A Case Study Approach

Samuel Akpadiagha ETUK, Esq[1*]

[1]Department of Paralegal Studies , Akwa Ibom State Polytechnic, Ikot Osurua
harrieslawpartners@gmail.com *(Responsible Author)

Udeme E. ETTENTUK, Esq[2]

[2]Faculty of Law, University of Uyo

Abstract

The frequent occurrence of building collapses in Nigeria has raised serious legal, ethical, and professional concerns within the construction and architectural sectors. This study examines the legal implications of building collapse in Nigeria through a case study approach, focusing on the interplay between negligence, regulatory failures, and enforcement gaps in the nation's building and construction industry. Using notable incidents such as the Synagogue Church of All Nations (SCOAN) building collapse and the Ikoyi high-rise tragedy as case references, the paper analyses the extent of legal accountability borne by architects, engineers, builders, and regulatory agencies. It explores relevant statutory frameworks including the Building Code of Nigeria, the Architects Registration Council of Nigeria (ARCON) Act, and tort principles of duty of care, breach, and liability for professional negligence. The study also highlights the challenges of weak institutional oversight, corruption, and non-compliance with approved standards, which collectively undermine public safety. Furthermore, it evaluates judicial responses to building collapse cases and the limitations of existing legal remedies in providing justice for victims. By adopting a doctrinal and empirical analysis, the paper underscores the urgent need for stricter enforcement of building regulations, professional accountability, and legal reform to deter future occurrences. Ultimately, the research advocates for a more robust integration of law, architecture, and engineering ethics as a foundation for sustainable and safe urban development in Nigeria.

Keywords: Building collapse, legal liability, architecture, negligence, regulation, Nigeria.

The Architectural Philosophy of Southern Albania (15th Century – Early 20th Century)

Vivian MUKLI[1*]

[1]Universiteti POLIS, Tirana, Albania
vivian_mukli@universitetipolis.edu.al *(Responsible Author)

Abstract

The traditional architecture of southern Albania (Labëria, Vlora) is characterized by a functional and defensive approach, deeply connected to the natural environment. Vernacular architecture represents regional identity, founded not only on family and social customs but also on the internal functional organization of the dwelling. Houses typically include a courtyard, multiple stories, and gender-based divisions of space. Within the same clan, family houses were built close to each other, forming compact residential clusters. The buildings were generally two-story structures: the ground floor was used for storing work tools and sheltering animals, while the upper floor served as the living space. Each house possessed its own oven. Researcher E. Riza, who has extensively studied the settlements and vernacular constructions of Labëria, emphasizes: "The inhabited centers of this region, mostly villages, are located on the western slopes of the highlands that stretch almost parallel to the Ionian coast, at an altitude of 300–600 meters. The settlements along the coastal zone are built on rugged rocky terrain, never directly by the seaside." A key feature of southern Albanian architecture is the use of local materials—stone, wood, and roof tiles. The stone houses have thick walls, simple floor plans, and high defensive functionality. Traditional dwellings express self-sufficiency, safety, and harmony with nature. The architecture possesses an organic character, as every element is interrelated with the terrain and the lifestyle of the inhabitants.

Keywords: Traditional architecture, architectural philosophy, settlements.

Sustainable Concrete Design Using Low-Volume Fly Ash: Experimental Evaluation of Strength and Durability

Marjuka MEHJABIN[1*]

[1]Department of Civil Engineering, Hajee Mohammad Danesh Science & Technology University, Dinajpur, Bangladesh
marjukamehjabin.ce@gmail.com *(Responsible Author)

Abstract

Concrete is used extensively in modern building; however, sustainability issues are raised by the high carbon footprint of cement manufacturing. Since concrete cannot be made without cement, it is imperative for us to find alternatives that will minimize environmental damage. One such alternative could be fly ash, which is a byproduct of coal-fired power plants, as it can sustainably replace a portion of cement. This research experimentally studies the mechanical as well as durability properties of concrete containing Class C fly ash at replacement levels of 10%, 20%, 30%, 40%, and 50%, comparing it to a control mix without fly ash. Superplasticizer gave early-age strength and workability; therefore, it was added into the water cement ratio of 1:2.1:2.4, with a constant water cement ratio of 0.48. At 7, 14, and 28 days, 72 cylindrical specimens measuring 100 x 200 mm were prepared and tested for water absorption, splitting tensile strength, and compressive strength. The specimens' mechanical strength decreased as the amount of fly ash increased. However, workability and durability improved and water absorption was reduced. The results indicate that low-volume fly ash can successfully produce concrete that is both environmentally friendly and meets strength performance requirements while having improved durability. By reducing the quantity of cement used and the amount of waste generated by industries, this method helps to create more sustainable construction practices.

Keywords: Low-volume fly ash, sustainable concrete, mechanical properties, durability properties

Abstract

Diabetes mellitus is one of the most prevalent metabolic disorders globally, requiring continuous monitoring of blood glucose levels. Traditional glucose measurement techniques often involve invasive sampling and delayed results. The emergence of smart biosensors has revolutionized glucose monitoring by enabling non-invasive, real-time detection. These biosensors integrate nanotechnology, biocompatible materials, and microelectronics to detect glucose concentrations with high sensitivity and specificity. Enzyme-based biosensors using glucose oxidase (GOx) have demonstrated reliable electrochemical performance, while novel approaches involving graphene-based nanomaterials and wearable technologies have enhanced signal transduction efficiency and patient comfort. Recent advancements include flexible, skin-mounted biosensors capable of transmitting data to mobile applications for continuous tracking and predictive analytics. These systems not only improve patient adherence but also support precision medicine through personalized treatment plans. Despite progress, challenges such as calibration accuracy, sensor stability, and biofouling remain significant. Future developments in biosensor technology are expected to focus on multi-analyte detection and full integration with artificial intelligence for predictive health management.

sami.melik@univ-biskra.dz *(Responsible Author)

Abstract

This paper explores the introduction of Islamic economic values to eco-mosque buildings to help develop sustainability to meet the urgent intersection of religious practice and environmental care. The study using a mixed-methods approach includes both qualitative data (case studies of currently existing eco-mosques), interviews with architects and community leaders, and the examination of a quantitative data on the environmental effects of these buildings. The results demonstrate that the design of eco-mosques that demonstrates Islamic values helps to decrease carbon footprints and increase community interactions with sustainability programs. Moreover, the structures show how the faith in religious principles can guide the proper management of the resources, thus creating the holistic perspective that would solve the spiritual satisfaction and environmental protection issue. The implications of these results can be conveyed to the healthcare industry as a sustainable environment is associated with better population health results; thus, the introduction of environmentally-friendly construction of mosques may influence a wider change in society towards healthier constructions. Finally, this research has deep implications, proposing that green architecture which incorporates Islamic economic principles not only facilitates environment sustainability but also can serve as an example of establishing health-aware communities, which should trigger a massive reconsideration of how religious environments can be used to the forefront of communal health and environmental robustness.

Keywords: Eco-mosque architecture; Islamic economic principles; sustainable architecture; religious buildings; community-oriented design.

sami.melik@univ-biskra.dz *(Responsible Author)

Abstract

This paper examines the plausibility of Green Waqf as a sustainable financing tool to fund eco-architecture by Islamic communities with a particular emphasis on whether the traditional Islamic endowments can be modified to favourably fund environmentally friendly building practices. The study indicates that current Green Waqf practices have the potential to finance eco-architecture projects, thus showing that Waqf can be used to tackle the current environmental issues. The study comes up with essential insights through qualitative data collected in different case studies and interviews with stakeholders in the fields of Islamic finance and architectural realms, which reveal the significance of implementing sustainability in urban development in these societies. The results of the study show the importance of Green Waqf in the creation of health promoting environment and indicate that investment in eco-architecture is not just in line with Islamic, but also leads to the well being of the people by improving the air quality, lessening energy use, and providing habitable spaces. The present study provides meaningful implications to the health field, as it shows that building environmentally friendly infrastructure can bring significant improvement in health outcomes and community resilience. This study, by providing an example of how conventional Waqf can be redefined to serve as a dynamic environmental sustainability tool, can be added to the larger discussion on the intersection of Islamic finance, architecture and community health, indicating avenues of future initiatives that reimburse cultural values to promote sustainable development.

[3] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.

Khelil SARA[2]

[2] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.

Abstract

This paper explores the economic feasibility of vertical farming in urban architecture, in terms of how it would contribute to food production sustainability, as well as environmental impact reduction. The research design combines both quantitative analysis of the initial investment expenses, operating costs, yields as well as revenue and qualitative analysis of consumer attitudes and policy frameworks that are in place to influence urban farming projects. Highlighted in the findings include that initial expenses are high, but vertical farming can provide competitive yield benefits and operational efficiency, thus it is a viable alternative to an urban setting with space constraints and food supply issues. Moreover, the work emphasizes an increasing tendency of the consumers towards locally sourced food which is important in terms of urban agricultural policy and the ability to maintain a healthier diet. These findings are important to the healthcare sector because they highlight the importance of sustainable urban food systems in overcoming food insecurity, enhancing both nutritional quality and reducing the population health hazards related to environmental degradation. Finally, the study adds to the discussion of urban sustainability, causing policymakers and urban planners to reconsider how urban agriculture can not only increase the efficiency of food production, but also rebuild the community health outcomes, which can make urban environments more sustainable.

Keywords: Vertical farming; urban architecture; food security; agri-architecture; sustainability assessment.

Embedding Circular Economy Principles in Architectural Design for Sustainable Cities

Khelil SARA[2]

[2] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.

Melik SAMI [1]*

[1] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.
[2]LACOMOFA Biskra laboratory. Algeria.
sami.melik@univ-biskra.dz *(Responsible Author)

Tallal Abdel Karim BOUZIR[3]

[3] Department of architecture, Mohamed Khider Biskra University, Biskra, Algeria.

Abstract

This paper explores how the concepts of circular economy can be incorporated into architectural design as a measure to improve the sustainability of urban areas in this context; that is, the current challenges of resource depletion and waste generation common in the modern-day architectural design practices. The study, conducted on the basis of a detailed examination of qualitative case studies of the available sustainable buildings and quantitative evaluation of resource utilization and waste reduction indicators, shows that effective implementation of the practice of the circular economy can significantly reduce material waste and make the use of resources in cities more efficient. The main conclusions are that the principle of circles is used not only to ensure the minimum impact on the environment, but also to create a healthier urban habitat due to the positive effect on the air quality and the overall well-being of the community. These results go beyond the profession of architecture since they emphasize the importance of sustainable urban settings on overall population health outcomes indicating that environmentally more sustainable architectural endeavors can achieve an improved health of urban populations. Furthermore, the paper puts forward the possible implication to the healthcare industry, including the need to use the concept of sustainable buildings that may offer a paradigm of healthier environments, lower healthcare-related expenditures in connection with environmental pollution, and enhance the comprehensive perspective on community health. Presenting the architectural design in the framework of the circular economy, the current research study helps to continue the existing discussion of sustainable urban development and its applicability to areas of public health, thus stimulating future investigations and implementation of these principles into different sectors.

Keywords: Circular economy; sustainable architecture; urban sustainability; zero-waste design; resilient urban development.

ORCID 2: 0000-0001-6773-8219

[2]Assoc. Prof., PhD., Head of the Department of Multicultural Education and Translation, Faculty of History and International Relations, Uzhhorod National University, Ukraine

Abstract

Zakarpattia region, despite being one of Ukraine's smallest regions by area (13.0 thousand km²), holds a unique economic and political-geographical position at the intersection of four European Union countries: Hungary, Slovakia, Romania, and Poland. This geographical configuration shapes a specific development vector for the region, focused not only on tourism and recreation but also on logistical integration into European transport and trade networks [1]. The region's economy remains relatively small in the national context, and prior to the full-scale Russian invasion in 2022, Zakarpattia accounted for only 1.5% of the country's Gross Regional Product (GRP) [4]. At the same time, the GRP per capita was approximately 48.9 thousand UAH, which was 52% of the national average. In addition, the GRP's physical volume index demonstrated a stable upward trend, indicating the area's potential for economic development [4]. Zakarpattia is characterized by a high degree of foreign economic dependence. In 2024, the region's goods exports totalled $1,446.2 million, while imports amounted to $1,620.4 million, resulting in a negative trade balance of $174.2 million [2,5]. The scale and direction of this foreign trade underscore that transport and logistics infrastructure are a critical factor in regional development.

A significant socio-economic factor is border traffic, which is regulated by EU Regulation No. 1931/2006 [6]. Thanks to local border traffic agreements (with Hungary in 2007, Slovakia and Poland in 2008, and Romania in 2015), residents of the border zone gained simplified access to crossing the state border, which facilitated the intensification of cross-border connections and the formation of local logistics flows [6].

As of 2025, the number of checkpoints in Zakarpattia Oblast exceeds 19 (including the recently opened Velyka Palad–Nagyhódos crossing) and continues to expand. However, only a few of them have infrastructure that meets modern logistics standards, such as automated customs services, sufficient vehicle lanes, and multimodal connections [3, 7]. A milestone was the opening of the new Velyka Palad–Nagyhódos crossing on the border with Hungary in 2025, which was the first new checkpoint to open in two decades [7]. This partially alleviated congestion at other crossings and optimize cross-border flows. There are also plans to open the Bila Tserkva–Sighetu Marmației crossing on the border with Romania [8], which would significantly strengthen the southern logistics corridor. Overall, low throughput capacity, limited number of traffic lanes, insufficient automation of customs procedures, and the lack of multimodal hubs remain key barriers to the development of the border infrastructure. Despite positive developments, the region's logistics faces several challenges: a low level of road network development, absence of modern logistics hubs, congestion at main crossings, limited development of railway infrastructure, and poor integration into the European TEN-T transport corridors. The key directions for the development of transport logistics in Zakarpattia by 2030 are defined by the following priorities: modernization of the road network; integration into TEN-T; establishment of multimodal logistics centers; increasing the number of border checkpoints and digitizing customs control; development of "green logistics"; and cross-border cooperation within the framework of Interreg NEXT 2021–2027.

Keywords: Logistical integration, logistics infrastructure, foreign economic dependence, multimodal hubs, cross-border cooperation

Abstract
The Sustainable Development Goals (SDGs) provide a universal framework designed to address interconnected social, economic, and environmental challenges while promoting long-term prosperity. In Africa, the pursuit of these goals is shaped by distinctive demographic dynamics, economic structures, and environmental realities, which present both formidable obstacles and transformative opportunities. Despite progress in selected areas, the continent continues to face persistent poverty, inequality, weak governance systems, limited financing, climate change vulnerabilities, youth unemployment, inadequate infrastructure, regional disparities, public health crises, and data constraints. These challenges hinder the pace of implementation and highlight the urgent need for integrated and context-sensitive approaches. At the same time, Africa holds significant potential to accelerate SDG achievement through technology adoption, renewable energy transitions, regional integration, human capital development, governance reforms, and strengthened multi-stakeholder partnerships. Case studies from Kenya, Rwanda, Ghana, South Africa, Ethiopia, Senegal, Botswana, Nigeria, Tanzania, and Morocco illustrate innovative interventions and successful practices that offer valuable lessons adaptable across the continent. The analysis emphasizes the importance of inclusive governance, innovative financing, and policy coherence in overcoming structural barriers. Ultimately, Africa can leverage its demographic dividend, natural resources, and innovation capacity to achieve sustainable, inclusive, and resilient development by 2030. Meeting the SDGs will not only foster economic prosperity and social equity but also safeguard environmental sustainability for future generations.

Yahia MILOUD[4]

[4]Pr. Moulay Tahar University of Saida, Algeria, Geometry, Analysis, Control and Applications Laboratory.

Abstract

This study focuses on the design of a solar-powered water pumping system for irrigating a 10-hectare apple orchard during the growing season, which extends from March to September. The orchard is irrigated for 8 hours per day and is divided into two equal parts, with each part receiving 4 hours of irrigation between 10 a.m. and 6 p.m. This schedule aligns well with solar availability, enabling the solar pump to operate efficiently during daylight hours. The motor (IM) drives a water pump that extracts water from a well with a depth of 20 meters, delivering it to a drip irrigation system. The water requirement is estimated at 2 m³/h per hectare for land planted with 1000 trees. Therefore, for 5 hectares irrigated at a time, the system must provide 10 m³/h. To accurately simulate the proposed PV pumping system under real climatic conditions, MATLAB and its Simulink environment are utilized to develop a comprehensive simulation model. The suggested system is constructed in such a way that it always performs satisfactorily regardless of the insolation variation. In order to assess whether the proposed PVPS satisfies the orchard's water requirements and to evaluate its dynamic behaviour, a case study based on a typical day of solar irradiance in August is conducted. The corresponding results are presented. The simulation results confirm that the proposed PVPS is sufficient to adequately irrigate the apple trees through direct solar operation without battery storage, demonstrating the soundness of the system's design and the relevance of the proposed concept.

Ibrahim Khalil Adamu[3]

[3]Department of Chemistry, Federal College of Education Gidan Madi Sokoto, Nigeria.

Abstract

As climate variability intensifies across urban regions, the need for climate-responsive design has become a fundamental concern in environmental architecture. This study explores how adaptive design strategies can mitigate the impact of extreme temperatures, enhance thermal comfort, and reduce energy dependency in built environments. The research adopts a mixed-method approach, combining field observation, simulation analysis, and stakeholder interviews within selected urban neighborhoods in semi-arid zones. Findings indicate that integrating passive cooling systems, locally sourced materials, and landscape-based shading significantly improves building performance while maintaining cultural relevance. The study also highlights the gap between design intention and user adaptation, emphasizing the importance of community engagement in the design process. Results suggest that climate-responsive principles are most effective when contextualized within social and environmental realities rather than applied as standardized technical models. The paper concludes that sustainable urban futures depend on locally informed, climate-responsive environmental design capable of bridging ecological efficiency with human comfort.

Abstract

Advanced and future concepts in Novel Drug Delivery Systems (NDDS) are revolutionizing the way therapeutic agents are delivered to specific sites in the body, enhancing efficacy and minimizing side effects. Traditional drug delivery methods often suffer from poor bioavailability, systemic toxicity, and lack of target specificity. Emerging NDDS technologies aim to overcome these barriers through intelligent, controlled, and personalized drug delivery approaches. Advanced systems such as nanocarriers, liposomes, dendrimers, micelles, and polymeric nanoparticles are being engineered to provide site-specific and sustained release of drugs. Smart delivery systems responsive to stimuli like pH, temperature, enzymes, or magnetic fields offer precise control over drug release profiles. Furthermore, the integration of biotechnology and nanomedicine has led to the development of gene and peptide-based delivery platforms, opening new horizons for treating chronic and genetic disorders. Future NDDS research is focused on combining artificial intelligence (AI), 3D printing, and biomaterials to design patient-specific drug delivery systems with predictive release patterns. These innovations promise to transform modern therapeutics by improving patient compliance, reducing dosing frequency, and ensuring optimal therapeutic outcomes.

Keywords: Advanced NDDS, targeted drug delivery, nanocarriers, smart drug delivery, controlled release, gene delivery, nanotechnology, personalized medicine, 3D printing, artificial intelligence.

Abstract

The increasing use of synthetic antioxidants such as tert-butylhydroquinone (TBHQ) in food, cosmetics, and pharmaceuticals has raised concern due to dose-dependent toxicological effects on vital organs. Although TBHQ is permitted at low concentrations, evidence of hepatotoxicity, nephrotoxicity, and metabolic disturbances at higher doses underscores the need for experimental validation of its physiological consequences.

This study aimed to evaluate the effects of graded TBHQ supplementation on growth performance, hematological and biochemical indices, lipid profile, glucose regulation, and histopathological changes in Swiss albino mice (Mus musculus).

Forty mice were randomly assigned to one control and four treatment groups (T1–T4), each receiving escalating TBHQ doses for the experimental period. Growth indices, including relative body weight (RBW%), average weekly weight gain (AWWG%), and specific growth rate (SGR%), were monitored. Hematological parameters, serum biochemical markers (SGPT, SGOT, urea, creatinine, uric acid), glucose levels, and lipid fractions (HDL, LDL, TG, TC, VLDL, atherogenic index) were analyzed, alongside histopathological examinations of liver and kidney tissues.

It demonstrated a dose-dependent decline in growth indices, with the most pronounced reduction in T4. Elevated SGPT, SGOT, urea, creatinine, and uric acid indicated progressive hepatic and renal dysfunction. Moderate doses (T2, T3) improved glucose tolerance, while higher supplementation reduced this benefit. Lipid analysis revealed reductions in triglycerides, total cholesterol, VLDL, and atherogenic index, particularly in T3 and T4, suggesting paradoxical lipid-lowering effects. Histopathology confirmed dose-dependent damage, including hepatocyte swelling, fatty degeneration, necrosis, and renal tubular injury.

TBHQ demonstrated dualistic effects, exerting lipid- and glucose-modulating potential at moderate doses but severe hepatotoxic and nephrotoxic outcomes at higher levels. These findings highlight the importance of strict dose regulation in food and pharmaceutical use and call for further research on oxidative stress–mediated mechanisms of toxicity.

Keywords: Tert-Butylhydroquinone (TBHQ), Swiss albino mice, hepatotoxicity, nephrotoxicity, and lipid profile

Abstract

Agricultural production is continuously declining due to environmental contamination, groundwater depletion, shrinkage in agricultural land and cost of production. With changing time agricultural practices were practiced using modern technology. This advanced approach of agriculture served many opportunities but also posed several challenges for long term use in crop production. Continuous use of modern chemicals in agricultural system seriously impacted soil health and productivity. Excessive use of synthetic fertilizers polluted soil and water ultimately leading to ecosystem degradation. The agricultural land gets converted into barren land in due course of time as the soil fertility declines. The present study explores the role of natural farming a chemical free crop production strategy as an agroecological approach and excludes the use of chemical fertilizers. Natural farming is a holistic approach integrating the use of available diversity on farm such as livestock, trees, crops. Natural farming have the potential to increase yield and income of farmers, offers various benefits such as restoration of soil quality, mitigates greenhouse gas emission and improves the overall health of environment. Furthermore as a substitute of chemical fertilizers biocultures like Beejamrit, Ghanjeevamrit and Jeevamrit are used to increase floral population in soil. Different farm made pesticides such as Neem Astra, Dashparni Ark, Brahmastra and Agni Astra are applied in fields to control diseases and pest in sustainable manner. Organic matter decomposition by microbes occurs directly on surface of soil and enhances nutrients uptake. Natural farming involves multiple cropping strategy that promotes agricultural system in sustainable manner. Natural farming addresses issues of food insecurity, health problems associated with fertilizers, pesticides, climate change, global warming and other calamities. This strategy of farming blends traditional wisdom with modern science helps in the conservation of biodiversity,reduces greenhouse gases emission and maintains proper balance with nature. Natural farming also plays important role in achieving the targets of sustainable development goals.

Abstract

The growing demand for sustainable farming has led to the creation of smart systems that improve the use of water and fertilizers. This paper presents a Smart Irrigation System that combines a soil moisture sensor and an NPK (Nitrogen, Phosphorus, Potassium) sensor for precise irrigation and nutrient management. The system constantly checks the soil's moisture level and nutrient content using real-time data. A microcontroller, like Arduino or Node MCU, processes these sensor readings and automatically adjusts water and fertilizer pumps based on the soil's needs.

Using Internet of Things (IoT) technology, the system allows for remote monitoring and control through mobile apps or cloud platforms. Data can be viewed, stored, and studied to spot trends and improve irrigation schedules. By tracking both water and nutrient levels, the system ensures crops get enough water and balanced nutrients, which boosts growth efficiency and cuts down on manual work.

Compared to traditional irrigation methods, this system offers significant advantages, including conserving up to 40% of water, improving soil fertility, and increasing crop yield. Its modular design allows it to scale and fit various agricultural settings, from small gardens to large farms. Additionally, solar power operation enhances energy efficiency and supports environmental sustainability.

In summary, the Smart Irrigation System provides a practical and affordable way to embrace modern precision farming. It supports global goals for sustainable agriculture by promoting smart water management, reducing waste, and giving farmers real-time, data-driven decision-making tools.

Keywords: Smart irrigation system; soil moisture sensor; NPK sensor; precision agriculture; IoT-based irrigation; sustainable farming; water conservation; soil nutrient management; automation; embedded systems.

Iranian Art and Architecture

Mehdi Shalchi Tousi[1*]

ORCID 1: 0000-0003-4601-1082
[1] Dr. Engineer, Department of Engineering Faculty of Ahle Beyte International University, Tehran, Iran

Abstract

The art and architecture of Iran stand as a profound testament to centuries of cultural synthesis, innovation, and spiritual expression. From the early vernacular traditions to the sophisticated urban ensembles of the Islamic period, Iranian artistic practice has consistently fused form, function, and symbolism. Architecture in Iran has uniquely integrated climatic adaptation, geometric rigor, and intricate ornamentation, producing spaces that are both meticulously crafted and deeply experiential. The visual language—characterized by domes, iwans, muqarnas, and tilework—reflects a continuous dialogue between secular dynasties and religious authorities, guiding daily life while elevating collective memory. Iranian art transcends regional boundaries, influencing and being influenced by neighbouring civilizations along the Silk Roads, thereby shaping a distinct Mediterranean-Asian continuum. This scholarly inquiry interrogates the epistemologies of Iranian aesthetics, examining how material choices, technological innovations, and patronage networks cohere into a cohesive artistic panorama. By analyzing monuments, furniture, metalwork, and manuscript illumination, we uncover patterns of continuity and rupture that illuminate identity construction over time. The study also engages with contemporary reinterpretations of traditional motifs, assessing how modern architectural practice negotiates heritage, modernity, and sustainability. Ultimately, this article seeks to contribute a nuanced understanding of how Iranian art and architecture articulate space, memory, and meaning within broader regional and global contexts.

Information And Communication Technology Adoption Behaviour of Farmers in Thanjavur District: A Study

B. MAHADEVAN[1*]

[1]Assistant Professor and Head, PG Department of Library and Information Science, Vellalar College for Women (Autonomous), Thindal (Post), Erode, Tamilnadu, India.

dmaha32@gmail.com ***(**Responsible Author)

Abstract

The study examines the adoption behaviour of Information and Communication Technology (ICT) among farmers in Thanjavur District, Tamil Nadu. It aims to understand the extent of ICT awareness, accessibility, and utilization in agricultural practices. A descriptive survey method was employed, and data were collected from a representative sample of farmers using a structured questionnaire. The findings reveal that most farmers are aware of ICT tools such as mobile phones, the internet, and agricultural information portals. However, the level of adoption varies based on factors such as age, education, farm size, and income. The study highlights that while ICT has significantly improved access to agricultural information, barriers such as inadequate training, poor connectivity, and lack of technical knowledge persist. Recommendations are made to strengthen ICT infrastructure and promote digital literacy among farmers to enhance productivity and sustainable agricultural development.

Keywords: Information and communication technology, ICT adoption, farmers, agricultural information, thanjavur district, digital literacy.

Abstract

The aim of this study was to determine the effect of silicon and nanosilicon supplementation on the growth and development of Lycium chinense Mill. shoot cultures under in vitro conditions. This species, commonly known as goji, is valued for its health-promoting properties and has long been used in traditional Asian medicine. Due to its antioxidant, anti-inflammatory, and metabolism-regulating properties, it represents a valuable pharmacological and dietary resource. Stabilized shoot cultures were propagated on Murashige and Skoog (MS) media supplemented with silicon in the form of Actisil (200 mg/L) and nanosilicon (nSi) at concentrations of 200, 400, and 600 mg/L. Key morphological parameters were analysed, including shoot and root length, number of shoots, fresh and dry biomass, and relative water content (RWC).

The obtained results demonstrated that nanosilicon supplementation significantly stimulated vegetative growth. The most favourable effects were observed at 600 mg/L nSi, which increased root length by 47%, fresh biomass by 83%, and dry biomass by 66% compared to the control. The addition of Actisil also promoted growth, though to a lesser extent than nanosilicon.

The results confirm the potential of silicon nanoparticles as effective biostimulators in plant tissue cultures. These findings may serve as a foundation for further research on the use of nanosilicon to optimize micropropagation and enhance plant tolerance to environmental stress.

Keywords: Nanosilicon, actisil, goji berry, biomass, relative water content (RWC)

"Nature is the greatest artist of all time".

Dante Alighieri

Abstract

The principle of prevention in environmental policy provides a conceptual basis for the argument that the best environmental strategy is to prevent pollution and environmental damage of any kind from occurring, rather than trying to remedy its effects. Prevention involves, on the one hand, risk assessment to avoid hazards and, on the other hand, actions based on knowledge of the present situation to avoid environmental degradation.

The purpose of the article is to approach the principle of prevention in a conceptual-applicative way, which aims to study the field, the development of regulation, case law and the difficulties that may arise in its application, as well as the interaction of the principle of prevention with other principles in environmental law. Thus, the article states that the most appropriate and effective environmental strategy is to prevent pollution and environmental damage of any kind, rather than to repair its effects.

Esayas SHEGAW [2]

[2] Debre Tabor University, Department of Medical Laboratory, Ethiopia

Abstract

The leather business is an essential part of economic development and the job market; however, it is among the most harmful manufacturing industries in terms of the environment and workplace health and safety. This paper explores the two-fold effects of the leather manufacturing industry on the environment and human health with specific reference to an in-depth examination of the tanning process, which involves the intensive use of toxic substances like chromium salts, sulphides, and acids. The study determines the level of environmental pollution in terms of air emissions, wastewater discharge, and solid waste production, which tend to pollute soil, surface water, and groundwater resources. Moreover, it raises the occupational health hazards for tannery workers, which include respiratory illnesses, skin diseases, and prolonged exposure to carcinogenic substances. The case studies of the developing world indicate that poor treatment of waste, bad ventilation of the working space, and the shortage of protective equipment aggravate these problems. The article goes further to discuss the emerging green options, including vegetable tanning, enzyme processing, and closed-loop water, as the ways forward in the journey of making production sustainable. This paper will focus on the importance of more stringent regulatory implementation, technological development, and worker protection schemes through an integrated environmental and health analysis framework.

Abstract

Rice (Oryza sativa), the global staple food, is increasingly vulnerable to the economic and agronomic pressures of climate change. Rising temperatures, erratic rainfall, and extreme events are reshaping production conditions and farmer livelihoods. This study explores how rice farmers in Rajshahi and Naogaon districts of Bangladesh perceive these changes and adapt their practices, with an emphasis on economic sustainability. Data were collected through convenience sampling and analyzed using SPSS. Farmers reported sharp increases in production costs, water demand, and pest infestations, particularly cutworm and stem borer. Nearly half adopted resistant varieties such as BRRI 11, BRRI 81, and BRRI 71, while about three-quarters depended on motorized irrigation to secure adequate water. Yields ranged from 7–10 tons/ha using 14-21 kg seed inputs, yet rising costs continue to squeeze profit margins. These findings show that climate change not only disrupts agronomy but also reshapes the economic landscape of rice farming. Ensuring sustainability will require integrated approaches that link genetics, agronomic innovation, and socioeconomic strategies. Such measures can strengthen both productivity and resilience, helping farmers maintain their livelihoods in the face of growing climate stress.

Wafaa TEBBOUNE[4]

[4]University of Sciences and Technology of Oran-Mohamed BOUDIAF, Faculty of Architecture and civil engineering, Department of civil engineering. Oran-Algeria.

Abstract

Signalized intersections constitute a critical component of urban road networks, and their operational efficiency significantly dictates overall network performance. This study addresses the need for detailed, context-specific analysis by investigating the impact of key operational parameters—specifically left-turn movements—on the capacity of signal-controlled intersections.

Empirical data were gathered from several intersections within the metropolitan area of Oran, Algeria. An initial evaluation, utilizing established international capacity methodologies, revealed notable shortcomings in their applicability to the local traffic environment. Specifically, the estimated flow rates for left-turn movements exhibited statistically significant discrepancies from observed values.

To rectify these inconsistencies, we developed a novel probabilistic model designed to accurately represent the evacuation dynamics of left-turning vehicles from a shared lane. This model was rigorously validated against field data collected under diverse operational regimes, including: varying left-turn storage capacities (1 to 5 vehicles), fixed-time signal control, a wide range of left-turn proportions (9% to 100%), and opposing traffic saturation levels (38% to 99%).

The results demonstrate that the proposed probabilistic model achieves a strong alignment with observed capacities, effectively capturing the complex dynamics of mixed-lane operations under opposing flows. Statistical validation, performed using a paired t-test, confirmed that the residual differences between predicted and observed values were not statistically significant at the 95% confidence level. This supports the model's accuracy and establishes its suitability for enhanced traffic planning and operational analysis within Algerian urban settings.

Bukar Ali KIME[2]

[2] Department of Architecture, University of Maiduguri, Nigeria.

Abstract

Niger State, Nigeria, characterized by its hot-dry and tropical wet-dry climates, faces significant challenges in creating affordable and climate-responsive housing. This study examines how traditional vernacular architectural practices in Niger State, Nigeria, can be integrated with modern sustainable building strategies to deliver cost-efficient, climate-responsive buildings. For generations, traditional architectural techniques—courtyard layouts, thick masonry walls, and systems for natural ventilation—have served efficiently in adapting to the humid tropical climate of the region. Yet, as urbanization accelerates and modern influences grow, many of these methods are being replaced by modern contemporary styles that often fail to accommodate local climatic demands coupled with the urgency to reduce energy consumption, improve indoor thermal comfort and lower construction and lifecycle costs. Through a comparative analysis of vernacular and contemporary case studies in Minna and surrounding areas, the study demonstrates how hybrid approaches can reduce construction costs by up to 40% while enhancing thermal comfort and energy efficiency. Key findings show the importance of integrating both traditional and modern approaches to enhance climate responsiveness and cost efficiency in buildings in Niger state. The paper proposes a hybrid design framework, cost comparisons, and guidelines for integrating vernacular and modern strategies in Niger State, with implications for more sustainable housing policy contributing to Nigeria's sustainable development goals.

Keywords: Niger State, traditional architecture, sustainable design, climate-responsive buildings, cost efficiency.

Abstract

The public spaces located on Didouche Mourad Street in Skikda are symbolic places where social life, architectural heritage, and significant movements in the city intersect. Formerly named Georges Clemenceau Street, this historic thoroughfare, established during the French colonial period, is an extension of the cardo maximus of the ancient Roman city.

This study examines the evolution of these spaces, initially designed as places of representation, encounter, and transition, in light of urban changes and contemporary practices.

The study is based on a comparative visual approach that contrasts old postcards with recent photographs taken at the same locations. The aim is to highlight, through visual representations, the transitions and discontinuities observed in the development of the structures, uses, and ambiances of urban areas. The analysis is structured around three complementary axes: the first axis concerns morphology (including spatial organization, built environment, and landscaping), the second axis concerns functionality (encompassing uses, mobility, and social interactions), and finally, the third axis concerns perception (including light, sounds, materials, and visual depth).

In addition to its documentary nature, the research questions the function of public spaces as vectors of collective memory and their impact on the urban and sensory identity of the street. The results highlight the coexistence of structures inherited from colonization and the emergence of new social practices that are constantly redefining the quality of the experience of these spaces.

Keywords: Public spaces - urban heritage - visual interpretation - urban ambiance - Didouche Mourad Street (Skikda).

Choosing a Slope-Stability Method under Groundwater Conditions: A Decision-Oriented Reframing of an Inter-Software Comparison

Hachimi DAHHAOUI [1*]

ORCID 1: 0000-0002-6603-1411
[1]Department of Civil Engineering /EOLE Laboratory, University of Tlemcen, Algeria

Abdeldjalil ZADJAOUI, Mohammed BEKHTI, Naima BELKADI[2]

[2]Department of Civil Engineering /EOLE Laboratory, University of Tlemcen, Algeria

Abstract

Evaluating slope stability in the presence of groundwater is highly sensitive to the chosen calculation method and to modeling assumptions. Building on unchanged analyses performed with GeoStudio and cross-checked against PETAL-LCPC, this paper reframes prior findings into a decision-oriented framework for method selection under hydrological effects. The original results—kept intact—show a marked influence of groundwater on deformation and displacement patterns, shifting the locus of maximum movement toward the slope toe, as well as systematic differences among widely used limit-equilibrium methods (Bishop, Perturbation, Fellenius, Janbu, Sarma). In dry and wet scenarios, several methods yield lower factors of safety by a few percent, with Janbu commonly returning the most conservative values under groundwater; in one comparison, a discrepancy of about 20% is observed for Sarma versus PETAL-LCPC, attributable to methodological assumptions and thus warranting verification rather than dismissal. We translate these discrepancies into actionable rules aligned with design objectives and consequence of failure: (i) state the objective (ULS/ELS) and risk posture; (ii) select a primary method consistent with the hydraulic regime; and (iii) cross-check when inter-method or inter-software deltas exceed preset thresholds (e.g., 5–10% near ULS) or when pore-pressure modelling is critical. A concise checklist—covering boundary conditions, mesh density, slip-surface search, and documentation of assumptions—supports reproducibility. The proposed framework preserves scientific rigor while improving day-to-day decision-making for geotechnical design and slope-risk management under groundwater conditions.

Rapid Estimation of Secondary Creep in Soft Clays Using Machine Learning

Hachimi DAHHAOUI [1*]

ORCID 1: 0000-0002-6603-1411
[1]Department of Civil Engineering /EOLE Laboratory, University of Tlemcen, Algeria

Abstract

The long-term performance of embankments and foundations on soft clays is governed by the secondary compression coefficient (Cαε,max), yet measuring this parameter currently demands multi-day creep tests that are rarely scheduled in routine site investigations because of their cost and programme impact. This study investigates whether Cαεmax can be estimated at the end of a conventional oedometer test by exploiting an open dataset comprising 282 Finnish clay and gyttja samples. The input features are restricted to index properties already collected as standard practice: initial void ratio, natural water content, compression index, pre-consolidation stress and over-consolidation ratio, thereby avoiding any additional laboratory effort or expense. Using a non-linear machine-learning workflow with rigorous cross-validation, we obtain predictions with a coefficient of determination R^2 higher than 0.60 and a substantial reduction in error compared with classical empirical correlations. Training and inference are completed in less than one second on a standard laptop, highlighting the method's suitability for rapid decision-making. The talk will describe the data curation, the feature-engineering strategy and the safeguards adopted to prevent over-fitting, before illustrating how the resulting "day-0" estimate can shorten design programmes and support low-carbon construction choices. Finally, we outline how the same framework could be transferred to other regional databases and packaged in an open-source web application for geotechnical practitioners.

Keywords: Soft clays; secondary creep; oedometer; machine learning; predictive modelling; open data

Abstract

This study examines the universal role of spherical and circular shapes in the daily lives of people worldwide through a multidisciplinary approach. The article systematically analyzes the manifestations of circularity in household utensils, domestic objects, and everyday items across various cultures.

The work demonstrates that circular and spherical shapes are not merely an aesthetic preference but also a result of practical necessity, ergonomic advantage, material efficiency, and profound cultural symbolism. From African basketry to Asian porcelain, from Indigenous American grinding stones to European pottery, and from traditional Azerbaijani and Turkish cauldrons to modern smart home appliances, circularity functions as a universal design language across all cultures.

The article scientifically explains the compatibility of spherical shapes with human anatomy, the optimization of stress distribution, material economy, and production efficiency. It also explores the cultural meanings of circular shapes as symbols of social unity, cosmic harmony, and spiritual perfection. The findings indicate that the principle of circularity has been an integral part of human life from ancient traditions to modern technology and will maintain its importance in future design solutions. This universal form provides both practical functionality and aesthetic harmony, reflecting intercultural understanding and the deep needs of human nature.

Keywords: Circularity, round shapes, household items, domestic tools, cultural anthropology, ergonomics, traditional craftsmanship, universal design, practical aesthetics, cross-cultural research

Circular Bridge from East to West: The Global Dialogue of Cultures

Yasin KHALILOV[1*]

ORCID 1: 0000-0001-6251-7556
[1]Associate Professor, PhD in Technical Sciences, Department of Design, Faculty of Architecture and Construction, Baku Engineering University, Hirdalan, Azerbaijan
*yxalilov@bmu.edu.az **(**Responsible Author)

Abstract

This study examines the phenomenon of sphericality in music through a multidisciplinary approach, analyzing the manifestations of these principles across various dimensions of the musical art. The article investigates the role of sphericality in music on physical, acoustic, structural, cultural, and psychological levels. The research reveals that spherical and circular forms constitute one of the fundamental building blocks of music. The physical nature of sound propagates in spherical waves, and this principle finds extensive application—from the design of musical instruments to the architecture of concert halls. In nearly all world cultures, circular musical instruments—frame drums, tambourines, gongs, tabla, tar, saz, kamancha, zurna, balaban, and others—rely on this form to achieve optimal acoustic properties. In harmonic theory, fundamental concepts such as the "Circle of Fifths," cyclical structures in musical composition, and loop techniques in minimalist music are abstract expressions of circularity. Circular dances in folk music, ritual ceremonies, and community-unifying practices are universal.

The study concludes that sphericality in music is not merely an aesthetic or technical issue, but a universal principle that plays a significant role in human psychology, social interaction, and the formation of cultural identity. These principles are also expected to play an important role in the development of future technologies such as quantum music, holographic sound, and neuro-musical interfaces.

Keywords: Sphericality, circular forms, musical acoustics, harmonic circles, cyclical structures, musical instruments, interdisciplinary research, cultural symbolism**.**

The Metaphysics of Form: Energy, Geometry, and Sphericity in Nature

Yasin KHALILOV[1*]

ORCID 1: 0000-0001-6251-7556
[1]Associate Professor, PhD in Technical Sciences, Department of Design, Faculty of Architecture and Construction, Baku Engineering University, Hirdalan, Azerbaijan
*yxalilov@bmu.edu.az **(**Responsible Author)

Abstract

This paper analyzes the energy efficiency of various geometric shapes (sphere, cube, and pyramid) under the same volume conditions. The study was conducted based on two main physical models: surface tension energy for liquids and internal elastic energy for solids.

Theoretical calculations and finite element method (FEM) results show that the spherical shape is the most suitable geometric shape in terms of minimizing both surface energy and internal elastic energy. Stress concentration factor (SCF) and internal energy calculations prove that the geometric structures of shapes directly affect stress distribution and total energy consumption.

The research results explain the widespread use of spherical shapes in nature (cells, droplets, planets), engineering (pressure vessels, aerodynamic capsules), architecture and design (domed structures, circular planning, spherical buildings), and also in symbolic and cultural fields using basic laws of physics.

This multidisciplinary approach demonstrates that the form-function relationship is universal at the technical, architectural, design, and symbolic levels. It has been determined that the dominant role of globality in nature, technology, architecture, and culture is guided by the principles of energy optimization.

Keywords: Spherical shape, energy efficiency, surface tension, internal elastic energy, stress concentration (SCF), FEM analysis, form-function relationship, nature and design, engineering geometry, symbolic structures

Eco-Colonialism or Climate Justice? Reassessing Global Environmental Agreements from the Global South Perspective

Astitva Kumar RAO[1*]

[1]Dr. B.R. Ambedkar National Law University, Sonepat, Haryana, India

Anamika PRASAD[2]

[2]Amity University, Gwalior, Madhya Pradesh, India

Abstract

The discourse on global environmental governance has increasingly highlighted the tensions between climate action and socio-economic equity, giving rise to debates on eco-colonialism and climate justice. Eco-colonialism critiques the imposition of environmental norms and policies by the Global North on the Global South, often disregarding local contexts, developmental imperatives, and historical responsibilities. Climate justice, conversely, emphasizes equity, fairness, and accountability, advocating that nations most responsible for environmental degradation bear the primary burden of mitigation, while vulnerable countries receive support to adapt and sustain development. This paper critically reassesses major global environmental agreements—including the Paris Agreement, Kyoto Protocol, and UN Framework Convention on Climate Change—from the perspective of the Global South. It examines whether these frameworks perpetuate structural inequalities or meaningfully address the disproportionate vulnerabilities faced by developing nations. Drawing upon case studies, policy analyses, and historical data, the study highlights the persistent gap between global commitments and local realities, revealing instances where well-intentioned climate policies inadvertently reinforce economic dependence and technological asymmetry. Furthermore, it explores alternative models of environmental governance, rooted in the principles of sovereignty, equity, and indigenous knowledge systems, that prioritize justice alongside ecological sustainability. By reframing global environmental discourse through the lens of the Global South, this paper argues for a recalibration of climate negotiations, emphasizing inclusive decision-making, differentiated responsibilities, and transnational solidarity. Ultimately, the research contributes to a nuanced understanding of how global environmental agreements can evolve from instruments of hegemonic imposition to platforms of cooperative climate justice, enabling equitable pathways for sustainable development.

Keywords: Eco-colonialism, climate justice, global south, environmental agreements, sustainable development

Abstract

Understanding, interpreting, and disseminating geoscientific data requires the modelling and representation of geological events. A complementary method that combines scientific accuracy and visual quality is made possible by the integration of digital technologies like ArcGIS, ENVI, and Adobe Illustrator. Geological data management, geographical analysis, and cartographic representation are made easier by the robust geographic information system (GIS) ArcGIS. It makes it possible to create accurate and dynamic thematic maps by superimposing several layers of data (lithology, tectonics, geomorphology, mineral resources, etc.). In contrast, ENVI, which specializes in processing satellite and aerial images, provides sophisticated spectral analysis and classification tools that enable the identification of tectonic structures, changed regions, and geological formations from multispectral or hyperspectral data. In the last stage of formatting and illustration, Adobe Illustrator steps in. It is used to improve the readability, aesthetics, and graphic consistency of maps, geological sections, and interpretive diagrams produced by scientific software in preparation for publishing or presentation. As a consequence, the integration of these three technologies facilitates comprehensive geological modelling: Adobe Illustrator for graphic enhancement and results distribution, ArcGIS for information structure and spatialization, and ENVI for raw data analysis. The scientific and aesthetic value of contemporary geological works is strengthened by this integrated approach.

Keywords: Geological events, modelling, illustration, ArcGIS, ENVI, adobe illustrator

Abstract

The development of eco-building materials has become a key priority in sustainable construction, aiming to reduce environmental impact while maintaining structural performance. This review investigates the potential of sewage sludge ash (SSA), a residue from wastewater treatment plants, as an alternative raw material in mortar production. The incorporation of SSA aligns with circular economy principles by transforming waste into a valuable component for eco-friendly construction.

This paper compiles and analyzes recent research on the physical, chemical, and mechanical properties of mortars containing SSA. Findings reveal that replacing SSA can lead to improved sustainability outcomes, including reduced carbon emissions, resource conservation, and enhanced durability under thermal and chemical exposure. The review also examines microstructural developments that contribute to improved bonding and densification in SSA-based mortars.

However, the variability of SSA composition and the need for standardized processing techniques remain key challenges to large-scale implementation. Overall, this study highlights the promising role of SSA in the production of eco-building mortars, reinforcing its potential to support greener and more resilient infrastructure.

Keywords: Eco-building mortar, sewage sludge ash, sustainability, circular economy, construction.

Thermal Stability of Composite Materials Using a Refined Higher Order Shear Deformation Theory

Tebboune WAFA[1*]

[1]Department of Civil Engineering, Faculty of Architecture and Civil Engineering, University of Sciences and Technology Mohamed Boudiaf, Oran, Algeria

*(Responsible Author)

Belkheir WISSEM, Bounouara ZAHRA, Hadjaj Fatima ZOHRA[2]

[2]LMST Laboratory, Department of Civil Engineering, Faculty of Architecture and Civil Engineering, University of Sciences and Technology Mohamed Boudiaf, Oran, Algeria.

Abstract

In this paper, a sinusoidal shear deformation theory is presented for thermal buckling analysis of composites plates. It is assumed that the plate is in contact with elastic foundation during deformation. This refined plate theory contains only four unknowns. It is assumed that the mechanical and thermal non-homogeneous properties of functionally graded plate vary smoothly by distribution of power law across the plate thickness. Using the non-linear strain-displacement relations, the equilibrium and stability equations of composites plates made of functionally graded materials are derived. The boundary conditions for the plate are assumed to be simply supported on all edges. The elastic foundation is modelled by two-parameters Pasternak model, which is obtained by adding a shear layer to the Winkler model. The effects of thermal loading types and variations of power of functionally graded material, aspect ratio, and thickness ratio on the critical buckling temperature of functionally graded plates are discussed.

Keywords: Refined plate theory; thermal buckling analysis; FGM plates

Fire-Adaptive Architecture: Integrating Indigenous Fire Stewardship for Climate-Resilient and Regenerative Design

B. S. Abdur RAHMAN CRESCENT[1*]

[1]Department of EEE, B. S. Abdur Rahman Crescent Institute of Science and Technology, a Private deemed university, Chennai, India

Professor, Institute of Science and Technology, a Private deemed university, Chennai, India

Abstract

The escalating frequency and intensity of global wildfires, exacerbated by climate change and unsustainable land management practices, demand a fundamental paradigm shift in architectural and urban design approaches. This paper introduces Fire-Adaptive Architecture as a transformative framework that reconceptualizes fire from an adversarial force to an ecological partner in regenerative design. Grounded in the ancient Indian philosophy of Panchabhutas, where fire (Agni) represents transformation and renewal, this approach integrates millennia-old Indigenous fire stewardship wisdom with cutting-edge material science and contemporary architectural innovation. Through comprehensive analysis of case studies from Australia, North America, Africa, and the Mediterranean, we demonstrate how spatial configuration, sacrificial design elements, landscape integration, and community-scale planning can create settlements that not only survive but thrive in fire-prone environments. The framework directly contributes to Sustainable Development Goals (SDGs) 11, 13, and 15, offering scalable solutions for climate adaptation and ecosystem regeneration. Our findings reveal that fire-adaptive strategies reduce structural vulnerability by up to 75% while enhancing biodiversity and community resilience, providing a blueprint for sustainable coexistence with natural fire regimes.

Green by Design: The Role of Urban Farming in Achieving Sustainable Cities

Astitva KUMAR RAO[1*]

[1]Dr. B.R. Ambedkar National Law University, Sonepat, Haryana – 131029 (India)

Anamika PRASAD[2]

[2]Amity University, Gwalior, Madhya Pradesh – 474005 (India)

Abstract

The accelerating pace of urbanization has intensified pressure on natural resources, food systems, and urban sustainability. The study explores how integrating agriculture into urban environments can foster ecological balance, social well-being, and economic resilience. Urban farming—ranging from rooftop gardens and vertical farms to community plots and hydroponic systems—represents a transformative approach to rethinking food production and urban planning. By localizing food systems, cities can significantly reduce carbon footprints associated with food transport, minimize waste through circular resource use, and enhance food security for urban populations. Moreover, urban green spaces contribute to improved air quality, biodiversity restoration, and temperature regulation, thereby mitigating the urban heat island effect. Beyond environmental benefits, urban agriculture promotes community engagement, provides livelihood opportunities, and enhances mental health through interaction with nature. This paper analyses global best practices, policy frameworks, and design strategies that facilitate the integration of green farming infrastructures within urban landscapes. It also addresses challenges such as land scarcity, water management, and institutional support, proposing policy-driven solutions to scale sustainable urban farming models. The study concludes that urban farming, when embedded in city planning and governance, is not merely an environmental initiative but a multidimensional tool for achieving the United Nations' Sustainable Development Goals (SDGs), particularly SDG 2 (Zero Hunger), SDG 11 (Sustainable Cities and Communities), and SDG 13 (Climate Action).

Keywords: Urban farming, sustainable cities, green infrastructure, food security, climate resilience

Abstract

This work focuses on the preparation of Zn(II), Co(II), and Cu(II) complexes from the Schiff base ligand bidentate. The molecular structures of the synthesized compounds were elucidated using various spectroscopic analysis methods such as mass spectroscopy IR, UV-vis, NMR (^{1}H, ^{13}C), and DTA, TGA. In addition, the antibacterial, antifungal, and antioxidant activity of the ligand and their metal complexes were examined in vitro. Results showed that Cu (II) complexes exhibited very strong free radical scavenging activity against the DPPH free radical, while antibacterial activity using the disk diffusion method and the micro-dilution method against Gram-positive and Gram-negative bacteria enabled us to conclude that antibacterial activity varies according to compound structure and strain sensitivity. The results for antifungal activity revealed that transition metal complexes showed good activity against the fungus Candida.

Key words: Schiff base; complexes; antibacterial activity; antioxidant activity; antifungal activity; DPPH.

Abstract

To expand the range of plants recommended for the creation and reconstruction of parks and squares in the Steppe Dnipro region, we conducted studies on representatives of the genus Berberis L., which are undergoing the process of introduction under the conditions of the Oles Honchar Dnipro National University Botanical Garden. The assessment of plant vitality was determined by the activity levels of antioxidant system enzymes.

Studies were conducted on the activity of catalase, peroxidase, and SOD, which catalyze the two-electron reduction of H_2O_2 to water while using hydrogen peroxide as an electron donor in catalase and various reductants in peroxidase. The highest peroxidase activity was observed in Berberis koreana and B. rotundifolia, while the lowest was in B. lyceum. Catalase activity in all studied species varied depending on changes in climatic conditions. The obtained results regarding SOD indicate that the highest activity was observed in B. koreana, B. lyceum, and B. rotundifolia, while the lowest was in B. canadensis and B. vulgaris.

The analysis of changes in the activity of all studied antioxidant enzymes in the leaves of the introduced species relative to the changes in enzyme activity in the local species B. vulgaris showed a decrease in catalase activity in August, while the activity of other enzymes increased.

A high correlation was established between the activity of antioxidant enzymes in the leaves of introduced species of the genus Berberis compared to the local species B. vulgaris in terms of catalase activity, as one of the key enzymes of the adaptive antioxidant system. The specific changes in the activity of all the studied enzymes indicate the balance of the defense system in the leaves of Berberis species and allow recommending B. koreana for broader introduction in the creation and reconstruction of parks and squares in the steppe Dnipro region, as one of the species most adapted to local conditions.

Keywords: Representatives of the genus *Berberis*, introduction, adaptation, parks and squares, Dnipro steppe region.

Rima BOUKERMA[2]

[2]Phd student in Architecture, Department of Architecture, University of Algiers 1

Leila SRITI[3]

[3]Professor of Architecture, LACOMOFA Laboratory, Department of Architecture, Mohamed Khider University Biskra

Abstract

The ksour of the Ksour Mountains region represent an architectural and cultural heritage of outstanding value. These fortified settlements, built from local materials and seamlessly integrated into their mountainous and oasis environments, demonstrate a remarkable adaptation to arid climatic conditions and to a long-standing communal way of life. Their urban layouts, irrigation systems, and social structures reflect a sustainable balance between human settlement, nature, and architectural design. Despite their exceptional heritage significance, the ksour remain vulnerable due to rural depopulation, material degradation, and the lack of appropriate protection and promotion measures. Their recognition and potential inscription on the UNESCO World Heritage List are key steps toward ensuring their preservation and transmission to future generations.

This paper aims to highlight the outstanding universal value of the ksour of the Ksour Mountains, assess their conservation status, and propose an integrated approach to their management and valorisation. This approach combines scientific documentation, community involvement, and sustainable development strategies to strengthen their visibility and guarantee their long-term protection.

Keywords: Ksour, Ksour Mountains, world heritage, popular architecture, preservation, cultural identity.

Green Spaces: Restoring Mind and Body in Urban Life

Maryam MOSLEHI [1*]

ORCID 1: 0000-0003-2065-5234

[1]Associate Prof, Natural Resources Research Department, Agricultural and Natural Resources Research and Education Center, Hormozgan, I.R. Iran

*(Responsible Author)

Abstract

Modern urban living has distanced humans from nature, increasing stress, anxiety, and chronic health conditions. Research shows that green spaces can serve as a natural remedy for high-stress urban environments. Presence in parks, tree-lined streets, and hospital green areas activates the parasympathetic nervous system while reducing sympathetic activity, lowering stress hormones and psychological tension, and accelerating mental and physical recovery. Observing natural landscapes and engaging in activities such as walking, cycling, and exercise in these spaces improves cardiovascular health and immune function. In hospitals, access to green spaces reduces patient anxiety and pain, decreases the need for pain medication, and shortens recovery time. In urban streets, trees and natural scenery lower environmental stressors, enhance driver focus, and reduce accident rates. Moreover, green spaces foster social interaction, enhance collective well-being, and improve overall urban quality of life. These findings indicate that the development and preservation of green spaces are not only an ethical and economic necessity but also a natural, cost-effective investment for promoting physical, mental, and social health in urban populations.

Effects of Organic Mulch and Natural Methods on Soil Moisture Retention and Growth of *Ziziphus spina* Christi Seedlings in Afforestation

Maryam MOSLEHI [1*]

ORCID 1: 0000-0003-2065-5234

[1]Associate Prof, Natural Resources Research Department, Agricultural and Natural Resources Research and Education Center, Hormozgan, I.R. Iran.

Abstract

Proper soil moisture management and the use of natural methods play a key role in the success of seedling planting in afforestation and the restoration of vegetation in dry and semi-arid areas. In this study, 12 Ziziphus spina seedlings were planted in two experimental groups: the first group was mulched with organic material derived from local plant residues, while the second group was left without mulch. Mulch was applied to a depth of 20 cm in the planting holes and 5 cm on the soil surface. Irrigation was provided during the first year and was stopped whenever rainfall occurred. Soil moisture was measured 24 hours after rainfall to assess the effect of mulch on moisture retention under realistic field conditions. After three years, measurements showed that mulched seedlings exhibited significantly greater growth in both height and crown area compared to unmulched seedlings (crown height: 70.2 cm vs. 55.2 cm; crown area: 2032 cm² vs. 1311 cm²). Additionally, annual height growth (73.76 cm vs. 55.23 cm) and soil moisture around mulched seedlings were higher (soil moisture: 23.95% vs. 18.83%). These findings indicate that organic mulch, by conserving moisture, reducing environmental stress, and enhancing root access to nutrients, accelerates growth and improves seedling health. The use of organic mulch and natural methods represents a cost-effective, sustainable, and efficient approach to improving seedling survival and growth in afforestation and ecosystem restoration projects in dry regions.

Keywords: Organic mulch, soil moisture, plant growth, natural methods

Strength Characteristics of M40 Grade Concrete as Partial Replacement of Cement by GGBS and Fine Aggregate by Crusher Dust

Subhashish Dey[1*]

[1]Department of Civil Engineering, Gudlavalleru Engineering College, Andhra Pradesh, India

Abstract

Concrete is the most widely used material in the construction industry. The cement required in the concrete leaves enormous carbon which shows an alarming impact on the global environmental conditions. Hence, there is a requirement of some material which can be effective in supporting cement when added along with it shows similar characteristics. Ground granulated blast furnace slag (GGBS) is found to be one such material which has similar characteristics when mixed with cement. GGBS is a by-product of steel manufacturing industry which is disposed. Quarry dust is a waste from the stone crushing unit. This quarry dust can be used as partial replacement for fine aggregates in concrete. The principle objective is to study the strength properties. Concrete cubes, cylinders and beams for M40 grade are prepared initially by replacing the sand with quarry dust by increasing proportions as 10%, 20%, 30% and so on until an optimum is obtained. After with the optimum percentage of fine aggregate, the cement is replaced with GGBS by 10%, 20%, 30%, and 40%. According to the results, the quarry dust increases the strength for 20% replacement of fine aggregate and GGBS with 30% replacement of cement.

Keywords: Concrete, quarry dust, cement, ground granulated blast furnace slag, M40 grade and global environmental

Durability of Vegetable Fiber-Reinforced Concrete Under External Sulfate Attack

Imane MIHOUB[1*]

[1] Department of Civil Engineering, Faculty of Science and Technology, University Center of Morsli Abdellah Tipaza, Algeria.

Sif Allah MEGHZILI[2]

[2] Department of Civil Engineering, Faculty of Science and Technology, University Center of Morsli Abdellah Tipaza, Algeria.

Abderraouf ACHOUR[3]

[3] Department of Civil Engineering, Faculty of Science and Technology, University Center of Morsli Abdellah Tipaza, Algeria.

Abstract

The durability of cementitious materials is a major concern in civil engineering, especially when exposed to aggressive environments. This study focuses on the behaviour of concrete reinforced with natural plant fibers under external sulphate attack. The incorporation of vegetable fibers, aims to improve the mechanical performance and sustainability of concrete through enhanced crack control and toughness. However, the interaction between these organic fibers and a sulphate-rich environment raises questions regarding their long-term stability and the microstructural integrity of the cement matrix. Laboratory tests were conducted to evaluate the physical and mechanical properties of fiber-reinforced concretes after exposure to sodium sulphate (Na_2SO_4) solutions over several curing periods.

Results indicate that while fiber addition improves flexural strength and reduces crack propagation at early ages, prolonged sulphate exposure leads to gradual degradation due to ettringite and gypsum formation, which affects both matrix integrity and fiber-matrix adhesion.

Nevertheless, the use of suitable fiber treatments and optimized mix designs can mitigate these effects and extend the service life of sustainable, eco-friendly concrete materials

Keywords: Durability, vegetable fibers, sulphate attack, fiber-reinforced concrete, eco-friendly concrete materials.

Mapping Albania's Cultural Heritage: A Spatial and Typological Analysis of Tangible and Intangible Assets

Mishela RAPO[1*]

ORCID 1: 0009-0000-9263-0146
[1]Assistant Lecturer, PhD Student, Department of Management and Marketing, European University of Tirana

Abstract

This study analyzes the spatial distribution and typological composition of Albania's cultural heritage, drawing on data from the national inventory of tangible and intangible assets. Using a descriptive-analytical approach supported by Excel-based data processing, the research provides a comparative overview of heritage representation across the country. Findings reveal that tangible heritage constitutes the most comprehensively documented component of Albania's cultural landscape. Monuments, archaeological sites, historical architecture, and religious structures collectively account for more than two-thirds of all recorded elements. These assets are widely represented across regions, with the highest concentrations in Gjirokastër, Berat, Vlorë, Tirana, and Korçë, reflecting their enduring historical and architectural significance and their potential for heritage-based tourism development. In contrast, intangible heritage appears significantly underrepresented in the national register. The recorded data include only three regions, Gjirokastër, Korçë, and Shkodër, where traditional crafts, polyphonic music, rituals, and gastronomy are officially recognized as cultural assets. This limited spatial scope highlights major gaps in the systematic documentation and territorial integration of living heritage. The resulting imbalance between tangible and intangible heritage underscores the need for a more comprehensive and geographically inclusive inventorying framework. The study recommends the development of an integrated geo-information system that would enable more accurate mapping, monitoring, and policy coordination of cultural assets. Such an approach would strengthen Albania's capacity to preserve, promote, and manage its diverse heritage, ensuring that both material monuments and living traditions contribute to sustainable regional development and cultural identity preservation.

Keywords: Albania; cultural heritage; cultural categories; spatial distribution; geo-information system; heritage documentation.

Abstract

The colonial period in Bengal (1757–1947) profoundly transformed the architectural landscape, introducing hybrid typologies that reflected a dialogue between European grandeur and indigenous spatial sensibilities. This study explores the form, space, and spatial organization of three exemplary colonial-era houses in Narayanganj, a prominent river port and industrial hub during British rule. Through architectural documentation, spatial mapping, and morphological analysis, the paper examines how colonial domestic architecture in this region negotiated climatic adaptation, social hierarchy, and cultural identity. The selected houses—representing distinct socio-economic and stylistic backgrounds—illustrate variations in planning concepts, façade articulation, and functional zoning. While the external expressions reveal neoclassical and Indo-Saracenic influences, the internal arrangements reflect a nuanced response to Bengali lifestyle and environmental demands, such as cross-ventilation, verandah transitions, and courtyard-centric planning. The study identifies a spatial duality—the coexistence of formality and intimacy, where the imported ideals of order and symmetry were localized through vernacular materiality and living patterns. By analyzing these architectural configurations, the paper contributes to understanding the colonial negotiation between power, culture, and space, offering insight into the evolution of domestic architecture in Bengal. The findings not only emphasize the architectural significance of Narayanganj's colonial heritage but also underscore the urgent need for heritage conservation and adaptive reuse to safeguard these endangered cultural assets for future generations.

Keywords: Colonial architecture, Narayanganj, spatial organization, domestic heritage, form and space, Bengal

Chayaraju BALASAI[2]

[2]Assistant Professor in Civil Engineering, G Pulla Reddy Engineering College, (Autonomous), Kurnool-518002 (A.P)

K. THARANI[3]

[3]Assistant Professor in Civil Engineering, G Pulla Reddy Engineering College, (Autonomous), Kurnool-518002 (A.P)

Abstract

This research aims to examine the performance of concrete where a portion of the coarse aggregate is replaced by crumb rubber derived from used tires. Globally, over 270 million discarded tires are generated annually. In India, improper disposal of these non-biodegradable wastes poses major environmental, fire, and health challenges. Beyond their use as tire-derived fuel, recycled rubber finds promising applications in civil engineering, such as artificial reefs, erosion prevention, and as aggregate substitutes in concrete. This study evaluates M30-grade concrete where scrap tire chips are introduced as partial replacements for natural coarse aggregates at 5%, 10%, and 15% substitution levels. Workability and compressive strength tests were conducted to determine the most efficient proportion of crumb rubber that can be incorporated without significantly compromising concrete performance.

Keywords: Coarse aggregate, crumb rubber, tires

Abstract

This study examined the environmental impact of artisanal gold mining in Minna Metropolis, Niger State. The study was guided by three research objectives which was translated into three research questions. The study adopted survey research design. The population of this study was 1000 artisan gold miners in mining sites in Minna Metropolis, Niger State. Krejcie and Morgan table was utilized in determining the sample size of the study which was 278. The instrument used in collecting data was a structured questionnaire State College of Education Minna, The data collected was analyzed using simple percentage, frequency table, mean and standard deviation in order provide answers to the research questions. Based on the findings, this research concluded that that activities of artisanal gold miners have significantly alter land use patterns, leading to deforestation, farmland loss, health hazards, and socio-economic challenges for local communities. It was therefore, recommended that Government should develop and implement awareness programmes to educate artisanal miners and local communities about existing laws and regulations related to land use and environmental protection. This should include information on the legal consequences of illegal mining activities and the importance of sustainable practices.

Keywords: Environmental impact, artisanal, gold mining, land use pattern

Assessment of Aquifer Protective Capacity and Corrosivity Around Solid Waste Dumpsites in Parts of Minna Metropolis, North-Central, Nigeria

BALARABE, J. J., RAFIU, A. A., ADETONA, A., SHEHU, J., SALIHU, Y.L. [1]

[1]Department of Physics, Federal University of Technology Minna, Niger State, Nigeria

Abstract

This study investigates the aquifer protective capacity and soil corrosivity of subsurface layers around solid waste dumpsites in Chanchaga and Maitumbi, Minna metropolis, Niger State, Nigeria, using the Vertical Electrical Sounding (VES) geophysical method with the Wenner configuration. The research aims to delineate subsurface layers, assess aquifer potential, evaluate aquifer protective capacity, determine soil corrosivity, and identify suitable sites for productive boreholes. A total of 60 VES points were surveyed across the two dumpsites, revealing three to four geoelectric layers, including topsoil, weathered/fractured basement, and fresh basement. Results indicate that 77% of the study area has medium groundwater potential, with aquifer thicknesses ranging from 10–25 m and resistivity values between 80–100 Ωm. In Chanchaga, 27% of the area exhibits moderate to good aquifer protective capacity, while 73% shows weak to poor capacity. In Maitumbi, 44% has excellent to very good protective capacity, and 56% is weak to poor. Soil corrosivity analysis shows 7% moderately corrosive, 26% slightly corrosive, 19% very strongly corrosive, and 48% practically non-corrosive areas. The findings highlight vulnerable zones susceptible to contamination and recommend avoiding borehole development in areas with weak protective capacity, using electrical resistivity tomography for further contamination assessment, and preferring plastic pipes in corrosive zones to prevent infrastructure deterioration. This study provides critical insights for groundwater protection, site remediation, and sustainable waste management strategies in Minna metropolis, Niger State.

Keywords: Vertical electrical sounding, aquifer potential, corrosivity, aquifer protective capacity and good/moderate rating.

The Role of Artificial Intelligence in Creating Public Value in Local Government: Evidence from Hyderabad City, Pakistan

Liaquat Ali RAHOO[1*]

[1]IT Officer, Mehran University of Engineering and Technology, Jamshoro

Muhammad Nawaz TUNIO[2]

[2]Assistant Professor, University of Sufism and Modern Sciences, Bhitshah

Abstract

Objective: the purpose of this research is evaluating the effects of artificial intelligence on generating public value, with the focus on government employees and citizens in the Hyderabad City, Pakistan. Theoretical framework: This study builds on the theory of digital governance, which argues that digital technologies can transform public administration by improving transparency, efficiency, accountability, and service delivery. This study explores how these technological interventions can promote participatory governance models by facilitating better interactions between citizens and government. Methods: The study uses structural equation modelling (SEM) to explore key aspects of digital governance, including transparency, cost-effectiveness, data-driven policymaking, accountability, and service quality. Results: The analysis shows a strong positive correlation between various elements of digital governance and increased citizen engagement. These findings highlight the power of digitalization in public administration to increase public engagement and trust. The findings suggest a close relationship between the role of AI in local government and the building of public values. This suggests that integrating AI into local governance can deliver significant public benefits, enhancing its importance in policymaking and service delivery. Implications: The study provides important insights for policymakers on the impact of digital initiatives on urban governance. It highlights the importance of continued investment in technological advancement and data security to improve urban governance and increase citizen engagement. Originality: This study makes a unique contribution to the understanding of how digital government initiatives can create public value by enhancing citizen engagement. It critically examines the components of digital governance and their effectiveness in promoting public engagement and trust, and provides valuable recommendations for policymakers concerned with urban governance and digital transformation.

Keywords: Artificial intelligence, local government, public service delivery, citizens, transparency, saves costs, and e-governance.

The Role of Mosques and Shrines in the Socio-Political Life of Settlements and Their Influence on Urban Formation

Mahammad BAYRAMOV[1*]

ORCID 1: 0009-0009-2074-58-71
[1]PhD Candidate, Lecturer at the Department of Architecture Nakhchivan State University
*mehemmedbayramli996@gmail.com (Responsible Author)

Abstract

Mosques and shrines have played a fundamental role in the socio-political life of settlements for centuries. The Juma Mosque in the city of Nakhchivan *and the congregational mosque located in the city of Ordubad are among the most prominent examples of such institutions. These structures have not only served as places of religious worship but have also evolved into central hubs for social, cultural, and political processes. Mosques have significantly contributed to the development of urban and rural communities through educational, charitable, and other public activities. Although the structure of society has changed over time, mosques and shrines have preserved their significance, becoming centers that unite people, shape the cultural environment, and influence regional development. In modern times, they also serve as important monuments that offer insights into the historical and social life of societies. Therefore, the study of mosques and shrines provides a deeper understanding of both the historical and contemporary structures of communities, as well as the processes shaping their socio-political life.*

Abstract

Concrete that contains recycled aggregate may help protect the environment. The materials of the future are recycled aggregates. Large-scale construction projects in numerous European, American, Russian, and Asian nations have begun to use recycled aggregate. In order to increase the usage of recycled aggregate, many nations are relaxing their infrastructure regulations. The fundamental characteristics of recycled coarse and fine aggregate are described in this work along with a comparison to natural aggregates. The implications of basic changes in all aggregate qualities on concreting work are extensively examined. In a similar manner, recycled aggregate concrete's characteristics are also established. Here are explanations of basic concrete attributes for various combinations, such as workability, flexural strength, and compressive strength. Codal guidelines of recycled aggregates concrete in various countries are stated here with their effects, on concreting work. In general, present status of recycled aggregate in India along with its future need and its successful utilization are discussed here.

[2]BALL B student, Sharda School of Law, Sharda University, Greater Noida, India

Abstract

Intellectual Property (IP) plays a pivotal role in safeguarding creativity, innovation, and the commercial value derived from original works. Within this framework, design protection occupies a distinctive space as it bridges the gap between artistic creativity and industrial applicability. Design law ensures that the aesthetic aspects of products such as shape, configuration, pattern, or ornamentation, receive legal recognition and protection from unauthorized reproduction. In architecture and industrial design, where artistic expression meets functional utility, IP protection becomes crucial to preserve the creator's moral and economic rights. This paper examines the legal framework governing design protection, with a special focus on the Designs Act, 2000 in India, and its alignment with international instruments such as the TRIPS Agreement and the Hague System. It explores how intellectual property rights, particularly copyrights, design rights, and patents, interact and sometimes overlap in the domain of design and architecture. Further, the study analyses issues related to plagiarism, infringement, and moral rights, which often arise due to technological advancements and easy replication methods. The research highlights recent judicial interpretations and landmark cases that have shaped the understanding of design protection in India. It also evaluates the challenges faced by designers in enforcing their rights and proposes measures to strengthen the existing legal regime. Ultimately, the paper underscores the need for a balanced approach that encourages innovation while maintaining fair competition in creative industries.

Keywords: Intellectual property rights, design protection, copyright, innovation, architecture, TRIPS Agreement, Designs Act 2000

Exploring Evidence Based Design Strategies to Foster Healing in the Design of a Paediatric Hospital in Rigasa, Kaduna State

Amira ABDUL-AZEEZ[1*]

Department of Architecture Faculty of environmental Design Ahmadu bello university, Zaria Nigeria

Abstract

Architecture can significantly become part of the healing process through the creation of spaces that foster and provide meaning to those activities utilized to achieve gradual rehabilitation through a therapeutic environment. In recent years, design for health care environments have begun to include proven enhancements in an attempt to reduce stress and anxiety, increase patient satisfaction, and promote health and healing. This concept is referred to as Evidence Based Design. Despite the numerous proven ways in which Evidence-based healthcare design can provide favourable clinical outcomes, few hospitals have incorporated this concept within the Nigerian context. On this account, we embarked on local and international case studies to assess the level of application of the concept in Kaduna State. Local cases were chosen using a criterion that will represent variety of hospital types in the study area. Comparative analyses using visual survey and checklist methods were used during the case-studies. Comparative analyses, using the designated framework helped to explore the design elements that were employed in the hospital designs. Qualitative analyses in the form of semi-structured interviews were conducted among hospital users to gain useful insight on user experience within the hospitals. Findings show that the paediatric hospital cases assessed through visual observations in Kaduna have a very low level of application of evidence-based design approaches with the following indices: environmental factors 30%, patients' sustainability 46.6%, support spaces 43% and wayfinding strategies 40%. This was demonstrated in a design proposal of a paediatric hospital in Rigasa, Kaduna State using evidence-based design strategies to promote healing. This research finally recommends that when designing paediatric hospitals in the North Western region of Nigeria, architects should try to consider Evidence Based Design strategies as they make the hospital achieve optimum functionality.

Gorla LALITHA[2]

[2]Student, Dept. of Electronics and Communication Engineering, G. Pulla Reddy Engineering College (Autonomous), Kurnool, Andhra Pradesh, India

Abstract

This paper explores the role of Artificial Intelligence (AI) in transforming various aspects of the transport sector for rural development. It reviews recent developments in AI applications in traffic management, public transport planning, autonomous vehicles, maintenance, and safety systems. Through a systematic literature review, the paper identifies key methodologies, current results, and gaps in research. It also presents a methodology for evaluating AI-based systems in transport using case studies and simulation experiments. The findings show that AI has significant potential for reducing congestion, improving safety, lowering emissions, and optimizing operations, but challenges related to data quality, ethical issues, interpretability, and deployment remain. The paper concludes with recommendations for future research and policy considerations.

Abstract

This paper reviews how alkaline activators (type, concentration, and silica modulus) and other mix/processing factors influence the mechanical and durability properties of geopolymer concrete (GPC) produced from industrial wastes such as fly ash, GGBS, and rice husk ash. The study also presents a Gene Expression Programming (GEP)-based modelling framework to predict key properties such as compressive strength and chloride penetration resistance. The methodology is aimed at researchers and engineers interested in optimizing activator usage while enhancing waste valorization.

Forest Carbon Assessment and Modelling in Bangladesh: Pathways for Sustainable Forest Management and Climate Mitigation

Sadid SHAHRIYAR[1*]

[1]Faculty of Agriculture, Sher-e-Bangla Agricultural University

Abstract

Bangladesh's forests are critical carbon sinks, yet they face significant threats from deforestation, degradation, and unsustainable land-use practices. This study synthesizes secondary data from the Food and Agriculture Organization (FAO), Bangladesh Bureau of Statistics (BBS), Intergovernmental Panel on Climate Change (IPCC), and peer-reviewed publications to provide updated estimates of forest carbon stocks and evaluate management scenarios. Remote sensing products (Landsat, MODIS, Sentinel) and biomass models were analyzed to determine

sequestration status. Findings indicate that the Sundarbans (~110–120 Mg C ha−1), Chittagong Hill Tracts (~80–100 Mg C ha−1), and Sal forests (~70–85 Mg C ha−1) store substantial carbon, although annual losses of 0.5–1% persist. Scenario modeling predicts that REDD+ strategies could improve sequestration by 15–20%, while afforestation and community forestry programs could enhance storage by up to

25% compared to Business-as-Usual (BAU). However, limitations in standardized methodologies, national inventories, and institutional frameworks restrict accurate assessments. This study proposes the integration of GIS-based MRV systems, localized allometric equations, and REDD+ financing to strengthen forest carbon management in Bangladesh.

Impact of Green Finance in Sustainable Performance: Mediating the Role of CSR

Aqsa FAROOQ[1*]

[1]Department of Business Administration, Riphah International University Rawalpindi

Rimsha IQBAL

[2]Department of Business Administration, Riphah International University Rawalpindi

Abstract

Purpose: This study aims to examine the impact of Green Finance on sustainable organization performance, assessing how financial sustainability drives environmental and social outcomes. It also explores the mediating role of Corporate Social Responsibility who influence the relationship of both variables. By analyzing financial strategies and CSR practices, the research seeks to identify how businesses balance profitability with sustainable growth.

Design: By using deductive approach, Applying established scale theories to test the relationship between green finance, CSR and sustainable performance. A survey-based methodology is used, incorporating the all three variables scale to measure key constructs. we take data from university students and corporate sectors to capture diverse perspectives specifically in Pakistan. The findings aim to validate theoretical assumptions and provide practical insights into financial sustainability and responsible corporate practices. through questionnaire form using the scale of three variables.

Finding: Our analysis confirms that green finance exerts a significant direct influence on sustainable performance, while also positively driving Corporate Social Responsibility (CSR) initiatives. Correlation and regression analyses reveal robust relationships between these variables—green finance is strongly associated with both CSR ($r = 0.824$; $p < 0.05$) and sustainable performance ($r = 0.588$; $p < 0.05$). Furthermore, CSR markedly mediates the relationship between green finance and sustainable performance (indirect effect $B = 0.2380$ with a 95% confidence interval that excludes zero), underscoring the dual pathway through which financial strategies both directly and indirectly enhance long-term organizational outcomes.

Originality: In my limited knowledge. I haven't found any study that examines the impact of green finance on sustainable performance within this specific population in Pakistan also this research incorporates the mediating role of CSR which the the best of my understanding, has not been widely explored in this context. By addressing this gap, the study provides unique insights

into financial sustainability and responsible business practices in Pakistan's corporate and entrepreneurial landscape.

Keywords: Green finance, CSR, developing countries, decision making, sustainable performance

Abstract

The evolution of Advanced Fabrication and Construction Technologies is redefining the future of architecture and engineering, enabling faster, smarter, and more sustainable building processes. This emerging field integrates digital design, automation, robotics, and additive manufacturing to enhance precision, efficiency, and environmental performance. Techniques such as 3D printing, robotic assembly, prefabrication, and modular construction are revolutionizing how structures are conceived and realized — reducing material waste, labor intensity, and on-site disruptions. Additionally, parametric modelling and Building Information Modelling (BIM) allow real-time collaboration and optimization across design and construction phases. Innovations in smart materials, including self-healing concrete and responsive composites, further expand the scope of adaptive and resilient structures. These advancements not only streamline complex fabrication but also support circular design principles and energy efficiency goals. Ultimately, advanced fabrication and construction technologies represent a paradigm shift from traditional craftsmanship to data-driven, automated precision — bridging creativity, technology, and sustainability in the built environment.

Abstract

Acylhydrazones represent a distinctive class of Schiff bases that have attracted considerable attention due to their wide range of applications. These compounds serve as valuable intermediates in organic synthesis and coordination chemistry. Notably, N-acylhydrazones act as key precursors for various heterocyclic frameworks and exhibit strong coordinating abilities with metal cations. Several N-acylhydrazones and their metal complexes have demonstrated remarkable sensitivity and selectivity toward specific metals, as well as significant bioactive properties in medicinal chemistry.
In this study, we report the synthesis and characterization of two N-acylhydrazones prepared through simple and cost-effective methods using salicylic acid as a starting material. The target molecules were obtained via condensation of hydrazide intermediates with different natural and/or synthetic aldehydes, affording the desired products in good yields.
Furthermore, we investigated the photoisomerization behavior of the synthesized N-acylhydrazones under UV irradiation. UV–visible spectral analysis revealed a reversible E/Z isomerization around the C=N bond, whose kinetics were strongly influenced by the solvent polarity. In methanol, the trans-to-cis conversion occurred within approximately 30 minutes, whereas in DMSO it required about 45 minutes. These observations demonstrate the solvent's role in stabilizing the photoinduced transition states and confirm the reversible photoresponsive nature of these compounds, making them promising candidates for use as molecular photoswitches or photoactive materials.

Assist. Prof., University of Management and Technology Lahore, Sialkot Campus, Pakistan
mateenafzalawan@gmail.com

Abstract:

The global demand for sustainable and energy-efficient buildings has accelerated the adoption of Building-Integrated Photovoltaic (BIPV) systems that seamlessly merge architectural aesthetics with renewable energy generation. This paper presents an interdisciplinary approach combining architectural design principles with advanced electronics engineering to optimize photovoltaic performance within building structures. The study emphasizes the role of semiconductor materials, power electronics, and maximum power point tracking (MPPT) algorithms in enhancing the efficiency and reliability of BIPV installations. Various integration strategies are analyzed, including façade, rooftop, and window-based PV modules, with a focus on their electrical modeling, energy yield, and thermal management. The work also explores the potential of emerging thin-film and organic PV technologies for flexible and transparent surfaces, enabling novel design possibilities for modern architecture. The proposed framework aims to establish an efficient synergy between aesthetic design and functional energy conversion, contributing toward the development of self-sustaining smart buildings.

The Role of Design Strategy in Creating Resilient Historic Cities within the Framework of Sustainable Development Goals

Kağan GÜNÇE

ORCID: 0000-0003-1557-2987
[1]Prof. Dr., Eastern Mediterranean University, Faculty of Architecture, Famagusta – North Cyprus
kagan.gunce@emu.edu.tr

Abstract

Historic cities are comprised of tangible and intangible elements. Tangible elements encompass, in addition to the city's structure, architectural elements, the urban landscape, archaeological remains, panoramas, silhouettes, vantage points, and monumental sites. Intangible elements involve the activities, symbolic and historical functions, customs, traditions, memories, and cultural resources that constitute the essence of historical value. Historic cities are living proof of the past that shaped them and, at the same time, important settlements reflecting cultural identity. Historic cities and urban areas should be a part of daily life.

In our changing and evolving world, historic cities, which hold heritage value, must be preserved and passed on to future generations. Rapid population growth, unplanned urbanization, climate change, disaster risks, and socio-cultural, socio-economic, and technological changes and transformations make it increasingly difficult to preserve historical structures (texture) and carry them into the future. Sustainable and resilient redesign of historic cities is essential for their preservation.

This study has two primary objectives. The first one is to demonstrate how urban models can be created within the framework of the Sustainable Development Goals for historic cities that hold heritage value and require preservation. The second is to discuss how such cities can be made more resilient to potential physical, social, and cultural risks.

In the study, recommendations are also presented for safeguarding the cultural heritage values of historic cities by bringing these values to the forefront and for advancing progress toward the Sustainable Development Goals. These recommendations particularly underscore the significance of "resilience" in the preservation of historic cities. Furthermore, the study emphasizes the need to develop holistic strategies in conservation efforts concerning historic urban areas to foster sustainable and resilient cities, and it proposes design strategies aimed at creating durable historic urban environments within the framework of the Sustainable Development Goals.

Keywords: Historical Cities, Cultural Heritage, Preservation, Urbanism, Resilience, Sustainable Development Goals (SDGs), Design Strategies

1. Introduction

Historic cities and urban areas are living testimonies to the past that has shaped them. Historic or traditional districts form an integral part of everyday life, and their preservation and integration with contemporary society constitute a fundamental basis of urban planning and development initiatives. Rich in both tangible and intangible cultural heritage, historic cities not only embody the identities of their respective settlements but also safeguard their collective memory. International organizations such as UNESCO and ICOMOS approach cultural heritage as a multifaceted set of values encompassing both its tangible and intangible dimensions.

Historic cities, which contain both tangible and intangible heritage values, face numerous threats, including population growth, infrastructure projects, tourism pressure, commercialization, migration movements, disasters, climate crises, and inadequate conservation policies. While these threats physically deteriorate historic cities, they also weaken and undermine local identity, historical continuity, and social memory.

The concept of urban resilience, which has become increasingly prominent in recent years, offers a significant framework for countering these challenges. Resilient historic cities stand out not only for their physical robustness but also for their social inclusivity, cultural continuity, and environmental adaptability. Similarly, the United Nations Sustainable Development Goals, which have gained considerable attention in recent years, encompass a wide range of global priorities, including poverty reduction, environmental protection, and the promotion of well-being for all. Resilience is defined as the capacity of cities to recover, adapt, and reorganize in the face of diverse threats and the Sustainable Development Goals together provide important strategic insights for the conservation of historic cities.

The principal aim of this study is to examine the relationship between cultural heritage conservation, urban resilience, and the Sustainable Development Goals within the context of historic urban fabric. Exploring how architectural and urban design strategies can be developed in line with resilience and the Sustainable Development Goals constitutes the core purpose of this research.

2. Materials and Methods

The study began with an examination of themes such as historic cities, cultural heritage, conservation, urbanism, resilience, the Sustainable Development Goals, and design strategies. Subsequently, a theoretical framework was established to elucidate the role of design strategies in creating resilient historic cities within the framework of the Sustainable Development Goals. In this process, policy documents prepared by international organizations and the relevant academic literature were reviewed. Good practices in the field were also identified and analyzed. All research activities, reviews, and analyses conducted for this study were carried out from a holistic perspective.

The theoretical foundation of the study draws on documents published by international organizations such as the United Nations, UNESCO, ICOMOS, and the OECD. Academic publications addressing concepts such as sustainable development, cultural heritage conservation, climate change mitigation, and resilient cities were examined with a particular focus on these themes. Additionally, policy documents issued by the Council of Europe and other international actors were evaluated within the scope of the study, with an effort to understand how these documents approach the multilayered structure of historic environments.

The data collection process was conducted using documentary analysis. UNESCO World Heritage reports concerning cities, strategic documents of local administrations, urban planning materials, and scientific publications served as the principal sources. Through these documents, the implementation of sustainability and resilience policies in the historic fabrics of the selected cities Amsterdam and Fez was systematically analysed, and the outcomes were identified.

The collected data and information were evaluated using descriptive analysis. During the analysis, particular attention was given to establishing a conceptual alignment between the United Nations' 2030 Sustainable Development Goals and the strategies implemented in cities, thereby revealing how the sustainable development perspective is integrated into historic environment planning. Ultimately, the study emphasizes the importance of design strategies in creating resilient historic cities within the framework of the Sustainable Development Goals and offers recommendations in this direction.

3. Cultural Heritage in Historical Cities - Preservation and Possible Threats

Cultural heritage is a treasure that tells the members of a society about their shared past and strengthens their sense of solidarity and unity. It ensures the continuity of the experiences and traditions people have accumulated throughout history and the proper construction of the future. Cultural heritage should be protected not only because of the universal values that give it its heritage status, but also because it offers new learning and development opportunities for young people, evokes beautiful emotions and warm memories, fosters creativity and the drive for discovery, adds depth to our perspective on the world and life, and because we all have much to learn from our past. Cultural heritage encompasses all tangible and intangible values related to our identity, culture, and history. Historical cities and textures, cultural landscapes, monumental structures, archaeological sites, as well as living but intangible values such as language, traditions, dance, music, and rituals constitute cultural heritage.

Based on definitions provided by internationally respected organizations such as UNESCO and ICOMOS, cultural heritage can be classified into four main categories (ICOMOS, 1999; UNESCO 1972, 2001, 2003):

- Tangible Cultural Heritage: Movable items (artifacts, objects) and immovable assets (monuments, historic buildings).
- Underwater Cultural Heritage: Cultural properties located beneath the sea, including shipwrecks and submerged remains.
- Intangible Cultural Heritage: Living cultural expressions such as oral traditions, rituals, and folk dances.
- Natural Heritage: Natural areas and landscapes that possess cultural value.

Under the four main cultural heritage categories mentioned above, memory and memento should also be considered as an important part of heritage protection efforts. Naturally, in the context of the memory of historical cities, the phenomenon of memory is considered an integral element of cultural heritage protection efforts. While the architectural structures, monuments, squares, streets, and roads that make historical urban areas valuable and important, the textures, colors, memories, oral narratives, traditions, and all folkloric elements belonging to that place (Turangil & Ertuğrul, 2024).

The first efforts to protect tangible cultural heritage in the international arena were aimed at preventing damage to cultural assets caused by war and physical conflict. The Hague Convention No. 4 of 1907 prohibited attacks on structures used for religious, scientific, artistic, and humanitarian purposes, as well as on tangible cultural assets (Abbenhuis, 2017). As awareness in this area increased after 1950, the awareness that cultural heritage is the ‘common heritage of humanity’ came to the front. The Hague Convention of 1954 emphasized that an attack on the cultural property of any nation is considered an attack on the culture of all humanity (Toman, 2017). The 1972 World Heritage Convention stated that the degradation of cultural and natural heritage is a loss for all humanity, and the understanding that the protection of cultural heritage is a shared responsibility of the international community was officially accepted (Gruber, 1972). Since the 2000s, the Council of Europe has viewed cultural heritage as a resource for strengthening cultural diversity and promoting intercultural dialogue. With this understanding, UNESCO’s 2001 Declaration on Cultural Diversity defined cultural heritage as a source of creativity. This declaration also stated that tangible and intangible

cultural heritage must be protected, enriched, and passed on to future generations (Kitaplar, 2014).

Unfortunately, official documents published by international organizations are often not sufficiently considered or effectively implemented. Processes of change and transformation expose cultural heritage sites and historic cities to a wide range of physical, technological, economic, political, cultural, and social risks. These risks include:

- Dense construction
- Uncontrolled urban development
- Large-scale infrastructure projects
- Population pressure and migration
- Tourism pressure
- Commercialization
- Loss of identity
- Inadequate protection
- Insufficient oversight

Such challenges threaten the sustainability of cultural heritage and may result in the degradation or even the loss of the cultural identity and collective memory of historic cities.

Physical, technological, cultural, social, political, and economic pressures, as well as disasters, heighten the vulnerability of historic cities and urban areas. This growing fragility brings the need for urban resilience to the forefront. Urban resilience refers to the capacity of the urban fabric to remain flexible in the face of various risks, threats, and pressures, while also possessing the ability to recover rapidly in moments of crisis.

4. From Resilience to Sustainability: New Paradigms in Urban Design

The concept of resilience denotes the capacity to survive, endure, and remain functional in the face of complex, unexpected, and challenging events (Davoudi et al., 2013). Viewed more broadly, resilience may be defined as the ability of individuals, communities, and both natural and built environments to respond to and adapt in the face of sudden and unforeseen shocks (Büyüközkan et al., 2022; Klein et al., 2003; Norris et al., 2008).

Resilience represents an effort to cope with the challenges arising from climate change, uncontrolled urbanization, and socio-cultural, socio-economic, and socio-political instability. It has therefore emerged as a significant concept in architectural and urban design research (Cimellaro, 2016; Zengin & Yamaçlı, 2023). Research on resilience in architecture and historic urban design intersects with global sustainability frameworks such as the United Nations Sustainable Development Goals, the Sendai Framework for Disaster Risk Reduction, and the Paris Climate Agreement. These global initiatives highlight resilience as a fundamental strategy for addressing climate change, reducing disaster risks, confronting physical, technological, cultural, social, and economic pressures, and promoting sustainable urbanization.

Urban resilience is more than a reactive response to immediate threats. In this regard, questions concerning how urban resilience aligns with sustainability and how it contributes to the achievement of sustainable development goals gain critical importance (Coaffee, 2008; Sharifi et al., 2017).

5. Design Strategies in Historical Cities in the Context of Resilience and Sustainable Development

The concepts of urban resilience and sustainability must be addressed together, encompassing their social, economic, and environmental dimensions. Both aim to foster safe living environments, strong community structures, and settlements characterized by a high quality of life.

The United Nations Commission on Sustainable Development (UN, 2022) emphasizes that sustainable development must adopt a more resilient structure by focusing on the resolution of social, cultural, and environmental challenges. Similarly, Marchese et al. (2018) argue that achieving sustainable development requires the explicit consideration of resilience. In this context, sustainable development in historic cities may be attained by balancing cultural heritage conservation with economic and social advancement (Appendino, 2017; Moazzeni Khorasgani, 2024). Sustainability, urban resilience, and sustainable development together offer holistic solutions to the social, cultural, structural, environmental, and economic issues confronting contemporary cities. These three concepts are inherently complementary.

In 2015, the United Nations formally announced the Sustainable Development Goals (SDGs) (European Commission, n.d.). Intended to be achieved by 2030, these goals apply to all countries. The SDGs consist of 17 core objectives / goals and 169 indicators (Bexell & Jönsson, 2017; European Commission, n.d.; Opoku, 2016). Relevant UN bodies prepare an annual SDG Progress Report, and nations publish Voluntary National Review (VNR) reports every two years (United Nations Department of Economic and Social Affairs, n.d.).

The Sustainable Development Goals cover broad themes such as ending poverty, protecting the planet, and ensuring prosperity for all. The 17 goals are listed as follows (European Commission, n.d.):

- Goal 1 - No Poverty
- Goal 2 - Zero Hunger
- Goal 3 - Good Health and Well-Being
- Goal 4 - Quality Education
- Goal 5 - Gender Equality
- Goal 6 - Clean Water and Sanitation
- Goal 7 - Affordable and Clean Energy
- Goal 8 - Decent Work and Economic Growth
- Goal 9 - Industry, Innovation, and Infrastructure
- Goal 10 - Reduced Inequalities
- Goal 11 - Sustainable Cities and Communities
- Goal 12 - Responsible Consumption and Production
- Goal 13 - Climate Action
- Goal 14 - Life Below Water
- Goal 15 - Life on Land
- Goal 16 - Peace, Justice, and Strong Institutions
- Goal 17 - Partnerships for the Goals

Figure 1. Visual representations of the 17 SDGs (European Commission, n.d.).

When developing design strategies for the survival and vitality of historic cities, the SDGs must be considered. Considering all 17 goals is essential for ensuring the sustainability and resilience of historic settlements (Mrak et al., 2022). Goal 3, Goal 4, Goal 7, Goal 8, Goal 9, Goal 13, and Goal 17 and particularly Goal 11 - Sustainable Cities and Communities directly support discussions on sustainability and resilience in design strategies (European Commission, n.d.; Lerario, 2022).

For a historic city to be considered resilient, it must possess qualities such as adaptability, robustness, redundancy, flexibility, resourcefulness, inclusiveness, and the ability to integrate and adjust (OECD, 2016). The relationship between the SDGs and resilience in historic cities should converge toward creating sustainable, inclusive, and adaptive urban environments (Lerario, 2022; Mrak et al., 2022). The concept of historic urban resilience should be regarded not as a tool to achieve goals such as sustainable development but as a goal (Pearson et al., 2014).

Fez and Amsterdam are historical cities with high cultural heritage value and are among the cities where the concepts of Sustainable Development Goals (SDGs) and resilience in historical texture are kept alive.

A. The Historic City of Fez - Morocco

The historic city of Fez, established in the late eighth and early ninth centuries CE, has served as a home to numerous civilizations. Fez reached its zenith in the 13th and 14th centuries during the Marinid period, when it replaced Marrakesh as the kingdom's capital. The urban fabric of the medina and its principal monuments such as madrasas, fountains, palaces, mansions, mosques, and public fountains, largely date from this era. Although Morocco's political capital

was moved to Rabat in 1912, Fez has retained its status as the country's cultural and spiritual centre. Each civilization that left its mark on the city enriched it with new historical layers, both tangible and intangible, traces of which remain visible today.

The historic city of Fez contains numerous significant examples of traditional Moroccan architecture. This architectural style, which developed during the Islamic period, formed part of a broader cultural and artistic complex often referred to as *Moorish* architecture characteristic of Fez, al-Andalus (Muslim Spain and Portugal), and the regions of present-day Algeria and Tunisia.

Located in Morocco on the African continent, Fez stands out as one of the most notable examples of alignment with the Sustainable Development Goals (SDGs) and the cultivation of resilience within a historic urban context. Fez is among the oldest Islamic city centres inscribed on the UNESCO World Heritage List. For centuries, its narrow, intact streets, artisan workshops, traditional architecture, and living intangible cultural practices have made it an important historic centre. Through the initiatives of international and local authorities, conservation projects were undertaken in Fez in the late twentieth century to sustain both its tangible and intangible heritage. Alongside physical restorations, these projects addressed environmental challenges such as water management, waste system operation, and energy efficiency. As a result, Fez constitutes a resilient and sustainable historic city model aligned with both Goal 11 (Sustainable Cities and Communities) and Goal 6 (Clean Water and Sanitation).

Images from the historical city of Fez (SDG Morocco, n.d; T. Experience n.d.).

Figure 2. The historical city of Fes, which still carries tangible and intangible cultural heritage, is also an exemplary city in terms of resilience and the SDGs.

B. The Historic City of Amsterdam - The Netherlands

Amsterdam is situated at the mouth of the Amstel River, which was dammed to control floods. Originally a small fishing village in the 12th century, Amsterdam became a major world port during the Dutch Golden Age in the 17th century, when the Netherlands became an economic powerhouse. Amsterdam became a leading centre of finance and trade, as well as a centre for secular artistic production. In the 19th and 20th centuries, the city expanded, and new neighbourhoods and suburbs were built. The city has a long tradition of openness, liberalism, and tolerance. Cycling is key to the city's modern character, and numerous bike paths and lanes are spread throughout.

Numerous buildings and structures are protected by national and municipal heritage lists. While the status of conservation appears complex within the context of the Amsterdam Central District (the heart of the city), the procedures governing conservation are being adhered to. The keen awareness of those responsible means that the excesses of urban growth, which were sometimes difficult to control in the recent past, particularly the visual impact of advertising within the property and high-rise buildings on the property's urban landscape, are being increasingly managed. All management measures form an effective and coherent system under the responsibility of the Amsterdam Central Municipality and the assurance of the Monuments Office. The Amsterdam World Heritage Office has now been established as a horizontal management and monitoring body for the property. Amsterdam, one of the most distinguished historical cities in Europe, is one of the examples of a city that demonstrates strong resilience and is aligned with the Sustainable Development Goals.

Images from Amsterdam (SDG House, n.d; Understand Amsterdam, n.d.).

Figure 3. The historical city of Amsterdam, which still carries tangible and intangible cultural heritage, is also an exemplary city in terms of resilience and the SDGs.

Amsterdam stands as one of Europe's leading historic cities in terms of cultural heritage preservation and climate resilience. Its canal system, bridges, well-preserved architecture, and planned urban development are complemented by effective water management strategies that address rising sea levels, making the city a model of climate adaptation. During restoration projects, both tangible and intangible cultural values have been carefully preserved. The city has also introduced systems aimed at improving energy efficiency and reducing carbon emissions, directly aligning with Goal 13 (Climate Action). Furthermore, the active participation of residents in decision-making processes provides strong examples related to Goal 16 (Peace, Justice and Strong Institutions) and Goal 17 (Partnerships for the Goals). Collectively, these initiatives position Amsterdam as a resilient and sustainable historic city aligned with Goal 13, Goal 16, Goal 17, and Goal 11 (Sustainable Cities and Communities) (Figure 3).

6. Conclusion and Recommendations

Historic cities not only represent the environments of the past but also embody tangible and intangible values that must be safeguarded for the future. Shaped by tradition and collective experience, historic urban settlements offer essential reference points for sustainability and resilience. As in every city undergoing change and transformation, similar processes take place both within and around historic urban areas. Rapidly developing new urban segments are often inserted beside or within historic fabrics, posing serious threats to the authenticity and integrity of the original urban identity. For this reason, the conservation of historic cities must be planned in harmony with emerging development areas, and integration processes should be approached holistically. Design strategies for historic cities should be developed in alignment with the United Nations Sustainable Development Goals (SDGs), and resilience-oriented planning must be incorporated. The historic fabric needs to coexist with new urban components without conflict and within a framework of mutual compatibility.

Active participation from all segments of society is a key factor in strengthening this integration. Participatory planning methods make it possible both to preserve historic urban fabrics and to ensure that new urban developments evolve within socially acceptable and sustainable parameters. Within this framework, the following recommendations are highlighted:

• *Conservation and Integration*: Historic urban fabrics should not be confined to designated 'protected zones'. Where necessary, new urban segments that emerge beside or within these areas should be integrated at functional, spatial, and cultural levels in line with contemporary needs.

• *Architectural Strategies*: New urban developments must not appear alien or disconnected from the historic environment. Insertions beside or within historic fabrics should meet contemporary requirements while adhering to design principles that support, rather than overshadow, the historic character and identity.

• *Alignment with the Sustainable Development Goals*: The relationship between historic environments and new urban development should be structured according to the 17 SDGs. Historic cities should be reassessed through the lens of all SDGs, with particular emphasis on Goal 11 (Sustainable Cities and Communities), as well as Goals 6 (Clean Water and Sanitation), Goal 13 (Climate Action), Goal 15 (Life on Land), 16 (Peace, Justice and Strong Institutions), and 17 (Partnerships for the Goals).

• *Community Participation*: For every strategy and design related to the historic city and its newly developing segments, contributions from local residents, civil society organizations, academic circles, and local and national authorities should be ensured. A societal consciousness that embraces the historic environment must be cultivated, and pathways must be opened for all segments of society to participate as stakeholders in decision-making processes.

• *Adaptive Planning*: New developments within or around historic cities should be planned according to principles of flexibility and adaptability, ensuring that no conflict arises with the historic environment. Such an approach facilitates urban resilience, continuity of identity and memory, and planning aligned with the SDGs.

In conclusion, the preservation of historic cities must be approached beyond their aesthetic or touristic value. Conservation strategies should be accompanied by considerations of social continuity, cultural identity, safety, environmental compatibility, and physical and economic livability. The presence of resilient historic cities is only possible through holistic approaches that respect these values. In this way, urban fabrics can maintain their connection to the past while evolving into sustainable and resilient environments for the future.

Abstract

The existence of water resources is a vital necessity for all living things. It is the basic substance of life, especially for humans, plants and animals. Water is needed for all vital and utilisation activities. Current environmental problems, increase in production and consumption tendencies with population growth, construction tendencies, wrong and unconscious land uses, climate change effects, negative human activities, etc. factors lead to the decrease, pollution and deterioration of the quality of potable water resources. This situation brings great risks and threats for natural and urban life. Demre (Myros) Stream, located in the west of Antalya, in the Demre district of Antalya, carries its waters to the Mediterranean Sea, reaches the sea from the Demre Plain, east of the Demre district centre. In this context, Demre Stream, which is an important water source for Demre district, has a critical importance for the coastal ecosystems of the Mediterranean Region. However, in recent years, rapidly developing agricultural and other activities in the region have disrupted the ecosystem and ecological balance in and around Demre Stream and Demre Stream has dried up completely today. This study analyses the pressures created by mining enterprises, industrial areas and greenhouse activities due to intensive agricultural production in the Demre Stream region from a holistic perspective. In the study, the current problems on Demre Stream were evaluated by using the findings obtained from land use data, field observations and local stakeholder interviews. The data obtained show that especially intensive greenhouse cultivation increases agricultural pressure, and the lack of waste management of mining sites and industrial facilities negatively affects aquatic ecosystems. However, Demre Stream is a vital connection line for the continuity of coastal ecosystems. The study emphasises that in order to protect the ecological value of the region, sustainable land use, monitoring of water resources and ecologically based planning decisions should be taken by local administrations.

Keywords: Demre Stream, Water resources, Land use/Land cover (LULC), Intensive agriculture, Ecological balance

1.Introduction

Rapid urbanisation, agricultural expansion and tourism activities are transforming land use and cover, particularly in coastal and river basin areas, threatening ecosystem integrity. Global studies have revealed that aquatic and coastal ecosystems are among the most vulnerable systems to anthropogenic pressures (Foley et al., 2005; Ellis & Ramankutty, 2008). Rivers and deltas are constantly changing areas where geomorphological processes intersect with human activities, possessing a complex structure where agricultural production, settlement and ecological sensitivities coexist. Rapid land use changes in these areas bring with them numerous environmental problems such as habitat loss, coastal erosion, increased flood risk and loss of

biodiversity (MEA, 2005; Turner et al., 1998). Irregular settlement, uncontrolled agricultural practices, increased sedimentation, and deterioration of surface water quality in river basins make the need for sustainable management of these areas even more important (Vörösmarty et al., 2010; Allan, 2004).

In Turkey, rivers and wetlands are under intense pressure, particularly due to the expansion of agricultural production areas, the spread of settlements towards river corridors, and infrastructure interventions. These pressures lead to the degradation of the natural structure of river corridors, disruption of habitat continuity, and weakening of ecosystem functions. Changes in land use and land cover around rivers have decisive effects not only on water quality and biodiversity, but also on flood regimes, sediment transport, and landscape integrity. This situation highlights the necessity of ecologically based approaches and comprehensive landscape restoration strategies in the planning and management processes of river corridors (Şahin et al., 2014).

Studies conducted at the scale of river valleys in Turkey reveal that human-induced activities such as settlement, tourism, and energy investments disrupt the natural functioning of river ecosystems, creating serious pressures on ecosystem integrity (Selim, 2011). Particularly in the Mediterranean Basin, increasing temperatures, decreasing flow regimes and drought trends associated with climate change are further straining the carrying capacity of river ecosystems and threatening ecosystem sustainability (Giorgi & Lionello, 2008; IPCC, 2014). Therefore, land use planning in coastal and river ecosystems should include not only spatial arrangements but also ecological resilience, water management, and comprehensive protection strategies at the landscape scale (Ahern, 2011).

The Demre Stream and its immediate surroundings are highly sensitive to these pressures, as they are an area where intensive agricultural activities and natural and cultural values are intertwined. The geomorphological development of the Demre Stream, the valley changes that occurred during palaeogeographic periods, and the delta-lagoon system shaped by the alluvium it carries reveal that the region's natural structure is highly sensitive to tectonic and climatic processes (Keser, 2012). Despite its rich conservation status, the region is at the centre of intensive agricultural activities and tourism pressure. In particular, the uncontrolled expansion of greenhouse agriculture, which constitutes a large part of the district's economy, and the increasing demand for construction pose a serious threat to existing natural and cultural conservation areas. Recent studies conducted in the region reveal that increasing agricultural land use and urban growth trends threaten the sustainability of protected areas, disrupt spatial integrity, and cause fundamental changes in landscape character (Dündar et al., 2024). In intensively farmed areas such as Demre, the transport of human-induced chemical use into watercourses also has a decisive impact on water quality and ecosystem health (Carpenter et al., 1998).

In this context, identifying the land use and land cover characteristics of the Demre Stream and its immediate surroundings and spatially assessing existing problems is of critical importance for the sustainability of the region. The study will contribute to the development of sustainable planning decisions, conservation and management approaches for the region by establishing a 1.5 km buffer zone around the Demre Stream and revealing the interaction between land use and land cover classes, ecological damage and human-induced pressures in this area. Accordingly, this study aims to analyze the spatial distribution of land use/land cover (LULC)

patterns and associated anthropogenic pressures within a 1.5 km buffer zone along the Demre Stream corridor using GIS-based analyses.

2.Materials and Methods

This study was conducted using Geographic Information Systems (GIS)-based analyses to determine land use and land cover characteristics in the Demre Stream and its surrounding area and to spatially assess human-induced pressures. The analyses were performed using ArcGIS Pro 3.5 software.

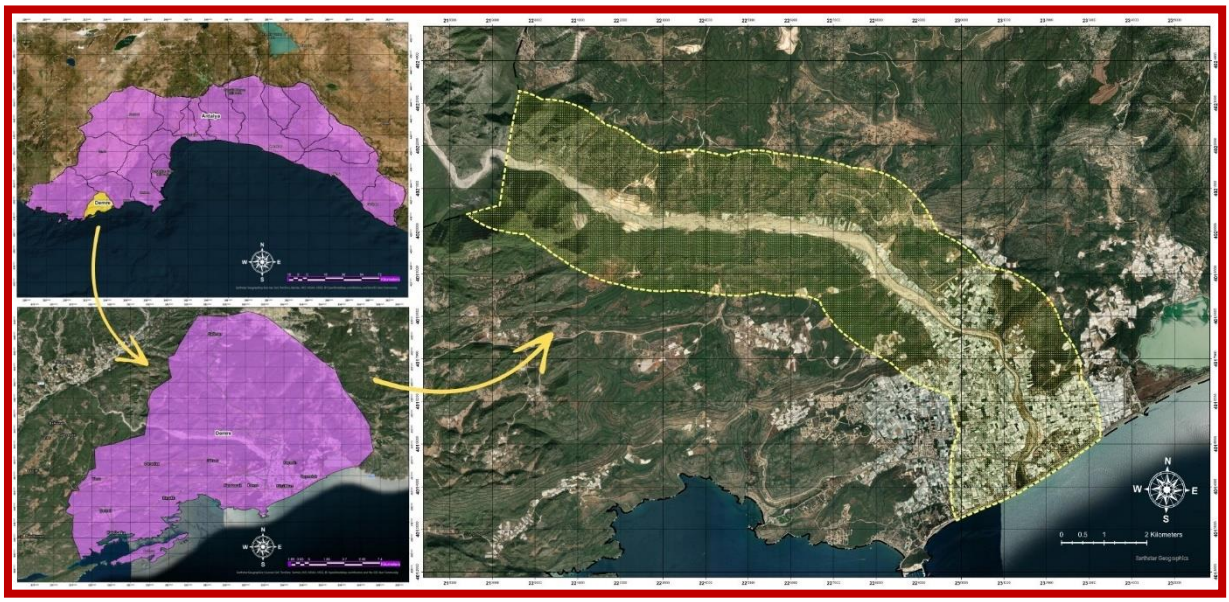

Figure 1. Research area boundary (From the authors' archive, 2025)

The district boundary of Demre district was obtained from the Antalya-Isparta-Burdur 1/100,000 Environmental Planning Map; the section of the Demre Stream included in the scope of the study is defined as the river section within the environmental planning boundaries at coordinates 36°17′3.07″ N – 29°58′1.48″ E (Figure 1.). Due to the absence of surface water within the study area and the inability to identify a continuous water surface, the stream boundaries were determined using a screen digitisation method based on current satellite imagery. Using this method, the river course was produced as vector data, taking into account the morphological traces of the Demre Stream within the boundaries of the environmental planning map.

In the assessment of the topographic structure, Digital Elevation Model (DEM) data obtained from the USGS EarthExplorer platform was utilised; contour lines and stream network data for the study area were generated using this data. In order to spatially reveal anthropogenic pressure around the stream, a 1.5 km wide buffer zone was created using the stream boundaries produced as vector data as a reference, and analyses were performed within this area. The spatial findings obtained were analysed and interpreted in comparison with the visual materials obtained.

Within the scope of the study, land use and land cover were evaluated under 7 classes, and the spatial pressures around the Demre Stream were revealed by calculating the spatial sizes and percentage distributions of each class. Planning and management recommendations were made based on the findings obtained. The current land use and land cover data are from 2024. The

LULC classes were determined based on dominant land use patterns observed in the study area and their potential ecological impacts on stream systems.

3.Findings and Discussion

Within the scope of this study, a total area of 5,325.53 hectares located within the 1.5 km wide buffer zone established around the Demre Stream and its immediate surroundings was evaluated. The findings were obtained through the combined interpretation of GIS-based land use and land cover analyses, spatial statistics, stream network assessments, and field and aerial photographs obtained from the Demre Municipality Press, Publication and Public Relations Directorate. Within this framework, the spatial distribution of land use classes and anthropogenic pressures on the stream ecosystem were comprehensively presented, taking into account the upper, middle, and lower sections along the Demre Stream.

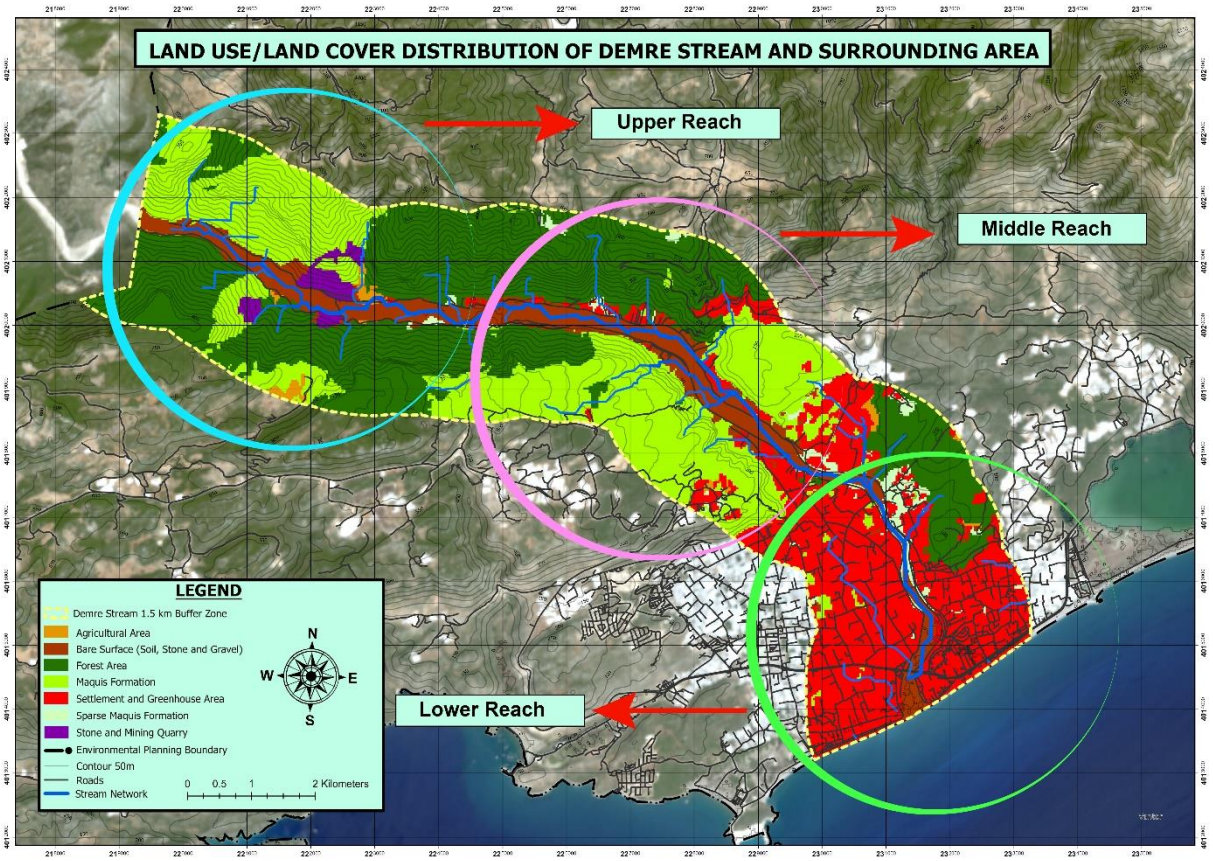

Figure 2. Land use/land cover (LULC) distribution of Demre Stream and its surroundings (From the authors' archive, 2025)

When examining the spatial distribution of land use and land cover classes, forest areas, which constitute 36.1% (1,921.13 ha) of the study area, are largely concentrated in the upper reaches of the Demre Stream. These areas play a critical role in the stream system in terms of regulating surface runoff, sediment retention and ecological continuity, and exhibit a relatively more holistic distribution. Maki formations follow forest areas with 27.4% (1,456.85 ha). These areas are particularly widespread in the middle sections and form transition zones between natural areas and human uses (Figure 2).

In contrast, settlement and greenhouse areas show a significant distribution in the study area, accounting for 23.4% (1,247.55 ha). They are particularly concentrated in the lower reaches of the Demre Stream, in areas close to the coast and delta plain. It has been determined that these areas are in direct contact with the riverbed and have largely eliminated the natural coastal zones. The spatial concentration of settlement and greenhouse areas constitutes the most pronounced anthropogenic pressure on the stream ecosystem. In particular, the covering of natural ground by large areas of greenhouses directly affects the quality of the flow reaching the stream by altering the amount and direction of surface runoff (Figure 2.).

Bare surfaces (soil, rock and gravel areas) are concentrated particularly in the stream corridor and surrounding areas where the slope increases, accounting for 8.7% (462.11 ha). These areas stand out as potential risk areas that cause accelerated surface runoff, increased sedimentation and heightened erosion risk. Stream network analyses show that some tributaries connected to the Demre Stream pass through stone and quarry areas, while others pass through or directly adjacent to residential and greenhouse areas (Figure 2). This situation leads to surface runoff reaching the stream being deprived of natural infiltration processes and an increase in the load of transported sediment and pollutants.

Sparse maquis formations cover a limited area of 2.4% (126.97 ha) within the study area, mostly located in transition zones between natural and human uses. Although quarry and mine areas cover only 1.2% (67.14 ha), they are considered areas with high ecological damage impacts due to their location near tributaries feeding the stream. Although agricultural areas account for a low percentage of 0.8% (43.79 ha), when considered together with greenhouse areas and taking into account human-induced chemical use, this becomes a significant factor increasing the pressure on the stream ecosystem (Figure 2.).

Table 1. Area and percentage of land use/land cover (LULC) classes

LULC Class No	Land Use and Land Cover	Area (Ha)	Percentage (%)
1	Forest Area	1921.13	36.1
2	Settlement and Greenhouse Area	1247.55	23.4
3	Stone and Mining Quarry	67.14	1.2
4	Agricultural Area	43.79	0.8
5	Bare Surface (Soil, Stone and Gravel)	462.11	8.7
6	Maquis Formation	1456.85	27.4
7	Sparse Maquis Formation	126.97	2.4
TOTAL		5325.53	100

Field and aerial photographs, along with spatial analyses, strongly support these findings with the current situation on the ground. Upon examination of the images, it is evident that the natural morphological structure of the Demre Stream bed has been significantly altered, particularly in its middle and lower sections, due to excavation, filling, and bed regulation works. Areas where the streambed has been widened, levelled, and the natural vegetation cover largely removed are noteworthy. Furthermore, the pressure exerted by settlement and greenhouse areas on the stream ecosystem is clearly evident in these images.

Figure 3. Field and aerial photographs of demre stream and ıts surroundings (Demre Belediyesi Basın Yayın ve Halkla İlişkiler Müdürlüğü, 2025)

Overall, the land use and land cover distribution of the Demre Stream and its surroundings reveal a distinct spatial differentiation: natural areas are relatively well preserved in the upper reaches, maquis formations dominate in the middle reaches, and settlement, greenhouse, and infrastructure interventions intensify in the lower reaches. The varying land use and land cover classes along the stream corridor directly affect the quantity and quality of surface runoff; tributaries passing through mining sites, greenhouse areas, and settlement areas, in particular, increase the intensity of pressure on the Demre Stream ecosystem. The findings reveal that the current land use pattern not only points to today's ecological problems but also to the risks of flooding, erosion and ecosystem degradation that may increase in the future. The construction of dams and reservoirs in the upper reaches of the Western Mediterranean Basin, the intense anthropogenic pressure on land use and land cover, and the resulting significant interruption of surface runoff are the main factors contributing to the lack of continuous water flow in the Demre Stream today.

4.Conclusions and Recommendations

Within the scope of this study, spatial analyses conducted within the 1.5 km buffer zone established around the Demre Stream and its immediate surroundings revealed that land use and land cover distribution exert pressures on the Demre Stream ecosystem. The findings clearly show that natural areas are relatively well preserved in the upper reaches, maquis formations dominate in the middle reaches, and settlement and greenhouse infrastructure interventions are concentrated in the lower reaches. The varying land use and land cover classes along the stream corridor directly affect the quantity and quality of surface runoff; tributary routes feeding the stream, particularly in mining areas, greenhouse areas, and settlement areas, increase the ecological pressure on the Demre Stream. The construction of dams and reservoirs in the upper basin sections, the exposure of land use and land cover to intense anthropogenic pressure, and the significant obstruction of surface runoff associated with this play an effective role in the lack of continuous water flow observed in the Demre Stream today. This situation clearly demonstrates the necessity of comprehensive, basin-scale planning approaches for the sustainability of the Demre Stream and its surroundings.

In this regard, the following conclusions and recommendations have been developed based on the findings of the study:

- A comprehensive planning approach should be adopted at the basin scale; all natural and anthropogenic factors affecting the Demre Stream should be addressed at the scale of the upper basin system (Western Mediterranean Basin) that feeds the Demre Stream, and the basin, which includes the river, should be considered within the boundaries of the Western Mediterranean-Transition Micro-Basin, located at 36.29410°N, 29.91917°E, with an area of 16,972.2 ha, (Çölleşme ve Erozyonla Mücadele Genel Müdürlüğü, n.d.).
- For the settlements and greenhouse areas concentrated in the lower reaches of the Demre Stream, ecological corridor solutions should be implemented along the stream corridor to create buffer zones, and uses in direct contact with the stream bed should be gradually restricted.
- Within the stream network, tributary routes feeding the stream that pass through mines and greenhouse areas should be identified as priority risk areas; measures to regulate surface runoff and reduce pollutant loads should be developed for these sections.
- Nature-based solutions should be implemented to reduce erosion and sedimentation risks in areas with concentrated bare surfaces and excavation/fill areas.
- The hydrological and ecological impacts of dams and reservoirs located in the upper reaches of the Western Mediterranean basin on the Demre Stream should be comprehensively assessed, and management strategies should be developed to ensure the continuity of environmental flow in areas where possible.
- Bed regulation and engineering interventions carried out along the riverbed should be approached in line with ecosystem-based approaches; practices that support natural morphology and ensure coastal zone continuity should be encouraged.
- Considering the concentration of subsurface agricultural activities in the lower reaches of the Demre Stream, controls and practices should be developed for agricultural pesticides and chemical inputs used in these areas, targeting groundwater sources that feed the stream through irrigation processes or are located within the stream corridor.
- GIS and remote sensing-based monitoring studies should be carried out periodically in and around the Demre Stream; land use changes and anthropogenic pressures should be tracked over time.
- A multi-stakeholder management model should be established between local authorities, relevant public institutions and producer stakeholders to develop a joint decision-making mechanism for the protection and sustainable management of the Demre Stream.

In conclusion, the land use and anthropogenic pressures identified in the Demre Stream and its surroundings indicate not only existing ecological problems but also potential future hydrological and environmental risks. Therefore, the sustainability of the Demre Stream depends on the implementation of long-term, basin-scale strategies that integrate ecological protection, land use planning, and water management.

Abstract

The controlled integration of daylight into interior spaces has become a significant design issue in contemporary architecture, as it relates directly to both energy efficiency and user comfort. In this context, light shelves, which are passive systems developed to redirect and evenly distribute daylight, are elements that must be carefully considered within the architectural design process. The performance of light shelves is determined by factors such as latitude, sky conditions, window characteristics, dimensional proportions, and ceiling surface properties. Proper consideration of these parameters enhances the functionality of light shelves and their contribution to indoor lighting quality. Beyond being merely a technical system, light shelves make a direct contribution to visual comfort, glare control, balanced illumination, and energy efficiency. In this way, they reduce the need for artificial lighting, promote energy savings, and support sustainable design goals. This study addresses the role of light shelves in the architectural design process from a theoretical perspective, demonstrating that they should not be regarded solely as daylight-directing elements but as important design tools that integrate visual comfort, reduced energy consumption, and sustainability principles. In this framework, subsequent sections will provide a detailed discussion of the definition of light shelves, their relationship with visual comfort and energy efficiency, and the key approaches emphasized in the literature.

Keywords: Visual comfort, energy efficiency, light shelf, sustainable

1.Introduction

In architectural practice, natural daylight is regarded not only as a source of illumination but also as a fundamental design element that enriches spatial experience, reduces energy consumption, and enhances user comfort. Throughout history, daylight has been introduced into interior spaces through windows, courtyards, skylights, and various types of openings; however, with the widespread adoption of deep-plan spatial typologies in modern architecture, the controlled distribution of daylight within interior spaces has become a critical design challenge. In this context, light shelf systems have gained a significant place in architectural literature as innovative passive elements that homogenize daylight distribution and reduce glare.

Daylight emerges as an effective strategy for optimizing building energy performance. The use of advanced daylighting design systems not only significantly reduces electrical energy consumption but also improves the quality of interior lighting. Although daylight is primarily introduced into spaces through window openings, the presence of windows alone is not sufficient; additional systems that direct and control daylight are required (Moazzeni & Ghiabaklou, 2016).

A light shelf installed at a window is a typical daylight-control system that reduces lighting energy consumption by delivering natural light from outside into the deeper areas of a room through the use of a reflective surface and the ceiling plane. By preventing direct entry of daylight into the room through windows, light shelves can improve illuminance uniformity (Lee et al., 2019).

This study aims to reconsider the role of light shelves within the architectural design process and to discuss them within a theoretical framework in the context of sustainable and comfortable interior environments. Consequently, the light shelf should be regarded not only as a daylight-control element but also as an architectural design tool positioned at the intersection of visual comfort, energy efficiency, and sustainability objectives. In the subsequent sections of this study, the definition of light shelves, their historical development, their relationship with visual comfort and energy efficiency, and the key findings highlighted in the literature will be examined in detail.

2.Materials and Methods

This study examines light shelf systems within the context of the architectural design process and evaluates them in terms of visual comfort and energy efficiency. Research on light shelf typologies, dimensional characteristics, and their performance under different sky conditions has been systematically reviewed. Findings from various studies have been compared in terms of shelf dimensions, orientations, surface reflectance properties, glass types, and ceiling geometries. In this way, the critical factors influencing the effectiveness of light shelves in achieving a homogeneous distribution of daylight within interior spaces have been identified. The obtained data were interpreted within the framework of sustainable architectural design. The study emphasizes that light shelves are not only systems that contribute to energy savings but also design tools that enhance visual comfort.

2.1. Emergence of the Light Shelf System

In buildings with fully glazed façades, the distribution of daylight within interior spaces is often not homogeneous. This condition becomes particularly evident in areas located farther from the façade, where daylight alone is frequently insufficient, making the use of artificial lighting unavoidable. As a solution to this problem, it is recommended to integrate systems into façade design that can collect daylight, redirect it into interior spaces, and, if possible, provide adequate daylight even to areas farthest from openings.

In this context, various studies have been conducted with the aim of protecting users from glare caused by direct sunlight while ensuring a more uniform distribution of daylight within interior spaces. As a result of these studies, light shelf systems have been developed to both reduce glare and distribute daylight more evenly (Kontadakis et al., 2017). These systems, designed to enhance daylight performance, have become prominent in contemporary architectural designs that focus on the effective use of natural lighting.

Today, light shelves are among the passive daylighting elements frequently preferred in modern buildings and are described in the literature as effective systems due to their ability to improve lighting quality and contribute to energy savings when combined with appropriate daylight control strategies (Kontadakis et al., 2017). These relatively simple systems operate through a horizontal or inclined surface installed above eye level, either on the interior or exterior side of a window, reflecting incident daylight and redistributing it into the interior space. In this

respect, light shelves divide the window into upper (clerestory) and lower (view) sections and can perform both shading and light-redirecting functions (Littlefair, 1995).

The system primarily directs a large portion of incoming daylight toward the ceiling, from where it is reflected into the space, thereby reducing glare near the window and increasing illuminance levels in deeper areas of the room. While the lower window section maintains visual connection to the exterior and supports natural ventilation, the upper section functions to deliver daylight into the interior space (Masoud, 2024). With this dual functionality, light shelves are considered an important architectural component that enhances user comfort and energy efficiency.

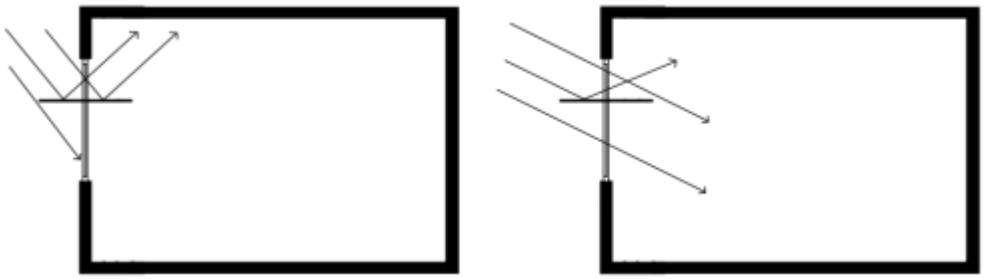

Figure 1. Summer (left) and winter (right) light shelf performance (Masoud, 2024)

Light shelves are classified into three main groups according to their placement configurations: interior, exterior, and combined interior–exterior systems. Light shelves positioned on the exterior provide shading, particularly during summer months, thereby reducing the building's cooling load, while interior light shelves have been shown to achieve higher average illuminance levels (Masoud, 2024).

2.2. Factors Affecting Performance in Light Shelf Design

2.2.1. Latitude and sky conditions

The performance of light shelves is directly influenced by latitude and sky conditions, which vary according to geographical location. In particular, under overcast sky conditions, the efficiency of light shelves is significantly reduced compared to clear sky conditions. For example, in climates characterized by predominantly overcast skies, such as the United Kingdom, light shelves have been observed to exhibit relatively low performance. Nevertheless, they can still offer advantages such as providing shading during summer months and enhancing daylight penetration into interior spaces during winter (Masoud, 2024).

Some studies have shown that under 'intermediate sky' conditions where the sky alternates between sunny and cloudy light shelves yield more effective results in terms of daylight availability and interior light distribution. While performance decreases on fully overcast days, intermittently sunny conditions allow for more homogeneous and deeper daylight penetration within interior spaces (Lim & Ahmad, 2014).

Another study reported that simulations conducted at latitudes of 30° and 45° indicated the suitability of interior light shelves, and that shelf efficiency increased significantly in conjunction with space height (Kurtay & Esen, 2019).

2.2.2 Window components

Since light shelves operate in direct integration with window systems, the physical and optical properties of window components have a direct impact on light shelf performance. As one of the main components of a light shelf system, the window must be carefully evaluated in terms of its characteristics—particularly size, position, and glazing type—for the efficient use of daylight (Uyduran & Yağmur, 2020). While the position and size of the window affect the distance daylight can penetrate into the interior space, the transmittance and reflectance of the glazing in the upper window zone directly influence the amount of light reaching the shelf surface (Rezaei et al., 2024). The type of window glazing (e.g., low-E coated, tinted, or electrochromic glass) determines not only the indoor illuminance levels but also the associated heat gains.

The mere physical presence of a window is not sufficient; daylight must be distributed into the space in a controlled manner. In this regard, the light shelf—one of the systems responsible for directing and redistributing daylight—contributes to both visual comfort and thermal comfort (Rezaei et al., 2024; Nageib et al., 2020).

2.2.3. Dimensions, types, and proportions of light shelves

The performance of a light shelf is determined by variables such as width, angle, height, and surface reflectance. Light shelves can be located either inside or outside the space (Lee, 2020). The dimensions of light shelves should be defined in relation to interior geometry and ceiling height. It is generally recommended that the depth of interior light shelves be equal to the height of the upper window. Exterior shelves, on the other hand, should be shorter than the vertical distance between the top of the window and the work plane (Kontadakis et al., 2017). The shelf length is typically designed to match the width of the window. However, in some cases, the shelf length may exceed the window width or vertical side elements may be added to prevent direct sunlight from entering from the sides. The installation height of light shelves is a critical factor for visual comfort; shelves are recommended to be positioned above eye level, at approximately 2 meters above the floor (Masoud, 2024).

Light shelves are generally classified into four main categories: horizontal, tilted, curved, and active (motorized or adjustable) systems (Kontadakis et al., 2017). The main difference among these types lies in how they modify the reflection and distribution of incoming light. Horizontal shelves are commonly preferred in standard window designs, while tilted shelves offer the advantage of delivering daylight deeper into the space. Curved shelves provide a more homogeneous light distribution and stand out in terms of energy efficiency during summer months. However, the risk of glare should also be considered in angled designs. For instance, it has been noted that a 30° reflector angle used in flat shelves may cause discomfort by reflecting light directly into the user's eye level (Kontadakis et al., 2017; Lee et al., 2019).

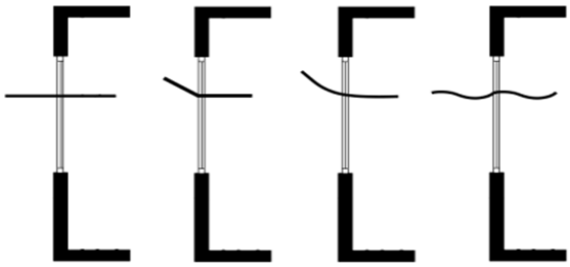

Figure 2. Shelf types (flat, angled, curved, and wavy) (Masoud, 2024)

The dimensions and types of light shelves are key factors in directing daylight into interior spaces in a homogeneous manner and ensuring visual comfort. During the design process, the shelf's angle, height, and reflectance properties should be selected in accordance with the spatial geometry and sustainability criteria, in a way that minimizes the risk of glare.

2.2.4. Effect of ceiling surfaces

The functionality of light shelves largely depends on their interaction with the ceiling surface. The distribution of reflected light into the interior space is directly related to the ceiling's form and reflectance. In a study conducted by Freewan, it was found that ceiling curvature can improve the uniform distribution of light by up to 10% (Freewan, 2010). In another study, three different ceiling types—sloped, pitched, and curved—were examined, and it was determined that curved ceilings, followed by pitched ceilings, performed better than flat ceilings (Freewan et al., 2008).

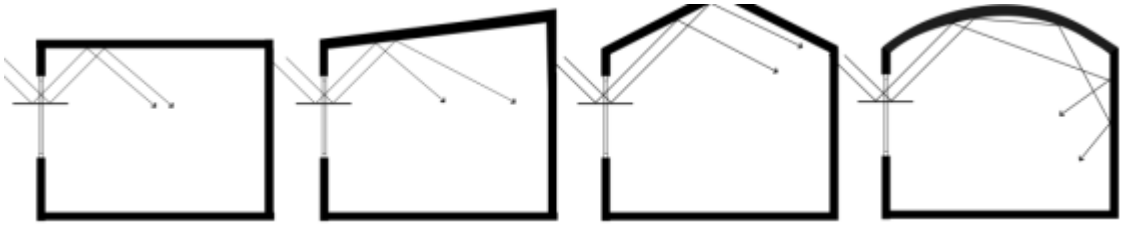

Figure 3. Effect of various ceiling surfaces on daylight penetration depth (Masoud, 2024)

The color and surface texture of the ceiling are also important factors affecting performance. Although glossy surfaces can reflect more light, they may cause undesirable effects such as light patches. Therefore, matte white ceiling surfaces are recommended to achieve a more homogeneous illumination level (Masoud, 2024).

2.3. Light Shelves in the Context of Visual Comfort

Visual comfort is an important factor that directly affects not only the spatial experience but also individuals' psychological well-being and productivity. Daylight, in particular, plays a critical role in regulating the circadian rhythm, which is fundamental to human biology. Research has shown that daylight synchronizes individuals' internal clocks with the 24-hour cycle, thereby improving overall health conditions (Tabadkani, 2021).

Ensuring visual comfort is not limited to providing adequate light levels alone. It also involves offering glare-free viewing angles, achieving a homogeneous distribution of illumination within the interior, and providing sufficient visual connection to the outdoors, all of which are critical for user satisfaction. Otherwise, limited outdoor views or sudden changes in brightness may cause visual discomfort. High luminance contrasts or distracting light sources can lead to discomfort glare, while unevenly illuminated task areas may result in visual fatigue, disability glare, and concentration problems (Tabadkani, 2021).

Numerous studies have emphasized that the presence of windows has positive effects on individuals' psychological well-being, stress levels, job satisfaction, and overall performance. However, the mere physical presence of a window is not sufficient; daylight must be distributed into the space in a controlled manner. In this context, light shelves—one of the systems designed to redirect and distribute daylight—emerge as an important tool for achieving visual comfort (Tabadkani, 2021).

Light shelves are among the most common passive system solutions developed to use daylight more effectively. Particularly preferred in side-lit spaces to control daylight, light shelves can be produced in fixed or dynamic forms and can be designed with flat, inclined, or curved surfaces. These systems, which can be easily installed on both the interior and exterior sides of windows, provide shading by blocking direct sunlight while simultaneously directing a significant portion of the light flux toward the ceiling, resulting in a more homogeneous illumination that reaches deeper into the space (Kontadakis et al., 2017).

One of the most important advantages of these systems is their ability to reduce negative effects associated with solar radiation, such as excessive brightness, heat gain, and glare. By redirecting daylight toward the ceiling, light shelves balance excessively high illumination levels near windows, thereby enhancing visual comfort and ensuring a more even distribution of daylight throughout the space (Kontadakis et al., 2017).

In conclusion, light shelves not only improve lighting quality but also create an interior experience that responds to users' psychological and physiological needs. As a significant element in achieving visual comfort, these systems play a critical role in the design of healthy, productive, and sustainable living environments through the efficient use of natural light.

2.4. Energy Efficiency in the Use of Light Shelves

In recent years, climate change resulting from the intensive consumption of fossil fuels has made it necessary to reconsider energy production and consumption patterns. In this context, the integration of renewable and sustainable energy sources, such as solar energy, in place of non-renewable resources has become increasingly important. With the aim of reducing energy consumption while maintaining spatial quality, the effective use of daylight has emerged as a strategic approach (Masoud, 2024).

Especially in buildings with deep floor plans, daylight cannot be distributed evenly throughout the interior space. This condition necessitates either the support of artificial lighting or the use of light shelves to achieve adequate illumination levels indoors. Light shelves are regarded as an effective solution for redirecting daylight and optimizing its distribution in side-lit spaces. These systems not only provide shading but also contribute to energy savings by enhancing daylight uniformity, thereby improving the overall lighting quality of the space. Light shelves are daylight-redirecting elements consisting of a horizontal or inclined surface positioned above the window. Owing to these characteristics, they perform a shading function by blocking excessive sunlight and, when installed on the exterior, help reduce solar gains, thereby lowering both lighting and cooling loads (Ghalati & Ahmadian, 2024).

In conclusion, light shelves offer an effective solution for both energy conservation and improving indoor lighting quality. Through proper design and positioning, a homogeneous distribution of daylight can be achieved while minimizing the negative effects of excessive solar radiation. Therefore, particularly for buildings with deep floor plans, the use of light shelves is considered an important component of sustainable and efficient lighting strategies.

3. Findings and Discussion

The literature review conducted reveals that light shelves are an effective passive system for delivering daylight deeper into interior spaces and ensuring a homogeneous distribution of light. The studies examined indicate that shelf dimensions, surface reflectance, installation configuration (interior, exterior, or combined), and sky conditions are decisive factors

influencing performance. In particular, high-reflectance surfaces and designs integrated with the ceiling enhance visual comfort and reduce the risk of glare.

However, the effectiveness of light shelves varies depending on different climatic conditions and orientations. Under overcast or partly cloudy sky conditions, the contribution of light shelves remains limited, whereas under sunny conditions they significantly increase illumination levels in deep spaces. Excessive enlargement of shelf dimensions may negatively affect shadow distribution within the interior and disrupt the aesthetic integrity of the design.

The discussions demonstrate that light shelves are not merely a technical system aimed at energy savings, but also a design element that directly influences user comfort and spatial perception. Therefore, approaches aimed at enhancing the performance of light shelves should be evaluated holistically within the architectural design process.

4.Conclusion and Recommendations

This study examined light shelf systems within the context of the architectural design process, evaluating them in terms of visual comfort and energy efficiency. Findings from the literature indicate that light shelves are particularly effective in providing a homogeneous distribution of daylight in interior spaces and reducing the need for artificial lighting, especially in sunny climates. Shelf dimensions, surface reflectance, installation configuration, and the geometric characteristics of the space are determining factors influencing performance.
The results demonstrate that light shelves are not merely technical lighting elements, but also architectural components that enhance user comfort and contribute to sustainable design goals. Therefore, during the design process, light shelves should be considered holistically, addressing their aesthetic, functional, and energy efficiency aspects together.
However, the present study is a theoretical review, and future experimental and simulation-based research may yield more concrete results regarding the performance of light shelves under different climatic conditions and across various spatial typologies.

Abstract

Mitigating the effects of climate change, one of the foremost global issues, and ensuring the spatial quality and sustainability of educational institutions in particular during the adaptation process is becoming increasingly important. A sustainable school is defined as a school designed and managed taking into account the social, environmental and economic sustainability issues that must be addressed for sustainable development. The fundamental idea of a sustainable school is to integrate sustainability into every aspect of school life. This approach envisages the use of environmentally friendly and renewable materials in the construction of buildings, ensuring energy efficiency, reducing waste production, and designing buildings in accordance with local living conditions. These structures reduce operating costs by saving energy, while also offering solutions to significant problems such as environmental pollution and climate change. In school spaces, landscape areas in particular provide multifunctional services and contributions. In order to make decisions on climate change in school spaces and reflect them in spatial design, it is necessary to consider the educational building and landscape spaces holistically and design them accordingly. This study will discuss the current situation and possible strategic actions required for the adaptation process of secondary school landscape spaces to climate change, using the example of Isparta Secondary School.

Keywords: Climate change, school landscape spaces, strategic actions.

1. Introduction

Global climate change is one of the most critical environmental issues transforming the physical, ecological, and socio-economic structure of urban life. Rising temperatures, irregular rainfall patterns, extreme weather events, and the urban heat island effect negatively impact the quality of life, particularly in urban areas. In this process, educational structures, which are an integral part of the urban fabric, and their open spaces are also directly exposed to the effects of climate change. Therefore, mitigating the negative effects of climate change on urban life is only possible through a transformation at the societal level, not just through technical or infrastructural interventions.

Sustainable development is a long-term transformation process that requires the holistic balancing of environmental, economic, and social dimensions. The success of this transformation is possible not only through technological or political measures, but also through the development of individuals' knowledge, awareness, and value systems. In this context, education is seen as a fundamental tool for achieving sustainable development. As stated by the United Nations Educational, Scientific and Cultural Organization (UNESCO, 2017), prioritizing education is indispensable for a sustainable future because education fosters environmental sensitivity, ecological literacy, and sustainable living habits in individuals. Similarly, Tilbury (2011) emphasizes that sustainability awareness through education

transforms not only environmental protection behaviors but also social values and lifestyles. Therefore, aligning education systems with sustainability principles is considered a long-term strategic necessity in the processes of combating and adapting to climate change. A sustainable school is defined as an educational institution designed and managed by comprehensively addressing the social, environmental, and economic dimensions required for sustainable development (Kalaitzidis, 2012). These schools are important not only in terms of energy and resource efficiency but also in terms of developing students' awareness of climate change adaptation and environmental responsibility.

The fundamental approach of a sustainable school is to integrate the principle of sustainability into all areas of school life, management processes, teaching programs, building and landscape management, transportation arrangements, and relationships established with school management (Huckle, 2010). Papadimitriou (2010), on the other hand, defines the concept of a sustainable school through three main components (pedagogical, social-organizational, and environmental-technical-economic components). These components represent fundamental areas corresponding to different aspects of school life and requiring the holistic application of sustainability. Failure to consider climate change adaptation and sustainability principles in the planning and design processes of school landscape spaces leads to serious problems, particularly in terms of energy efficiency and student comfort. Therefore, educational buildings and their surrounding landscape spaces must be reevaluated with a climate-sensitive approach.

School landscape spaces are not merely spaces serving aesthetic functions; they are also critical environmental systems in terms of regulating the microclimate, contributing to ecological balance, and protecting user health. Open and green spaces, plant designs, and permeable surfaces in school landscape spaces reduce the urban heat island effect, improve air quality, and support biodiversity. These areas are also important learning environments where students can interact with nature, observe environmental processes, and develop their ecological awareness. Therefore, designing school landscapes in line with sustainability principles provides long-term benefits from both an environmental and pedagogical perspective.

Secondary school represents a critical developmental period during which individuals acquire environmental awareness, a sense of responsibility, and sustainable living habits. Creating nature-based and participatory learning environments that enable students in this age group to interact with the environment contributes to the permanent establishment of sustainability awareness. Therefore, evaluating secondary school landscape spaces from the perspective of climate change adaptation not only enhances the quality of the physical environment but also carries social value in terms of raising future environmentally conscious individuals.

Measuring and evaluating climate change adaptation characteristics at the school level enables institutions to identify their strengths and weaknesses in this area and develop strategies for improvement accordingly. This process contributes to the development of a comprehensive perspective that will support the transformation of schools in line with sustainability principles. In this context, the development of measurement tools to determine schools' adaptation to climate change will enable the systematic evaluation and improvement of sustainable school practices.

In this regard, the primary objective of the research is to develop a valid and reliable measurement tool that can assess sustainable school characteristics in the context of the climate change adaptation process. Such a tool will contribute to objectively evaluating schools'

sustainability and climate adaptation performance, identifying areas for improvement, and promoting the dissemination of the sustainable school model.

The research seeks to answer the following fundamental question: “How can a measurement tool be developed that can validly and reliably assess sustainable school characteristics in the context of secondary schools' adaptation process to climate change?”

2. Materials and Methods

The study aims to evaluate sustainable school characteristics within the context of the adaptation process to the effects of climate change using a holistic approach. In this regard, the measurement tool to be developed is intended to cover the fundamental components of the sustainable school concept and enable the evaluation of schools across different dimensions. The sub-objectives of the research are outlined below:

1. Determining the Physical–Environmental Dimension: Assessing the level of physical arrangements (use of open and green spaces, energy efficiency, water management, etc.) that adapt to climate change in the design of the school's indoor and outdoor spaces,

2. Examination of the Pedagogical Dimension: Determine the extent to which education and learning environments are integrated with the principles of sustainability and climate change adaptation,

3. Assessment of the Social and Administrative Dimension: Analyzing the level to which school administration, teacher, student, and parent interactions support a culture of sustainability; examining participation, awareness, and collaboration processes,

4. Examination of the Economic and Technical Dimension: Evaluate the school's efficiency in terms of resource use, maintenance and repair processes, waste management, and economic sustainability,

5. Development of a Measurement Tool: Develop a scientific tool that can measure sustainable school characteristics in the context of climate adaptation.

This research is based on a scale development model conducted within the framework of a quantitative research approach. In order to develop a valid and reliable measurement tool for assessing schools' sustainability and climate change adaptation characteristics, the research process includes the stages of (1) literature review, (2) determining performance criteria, (3) obtaining expert opinion, and (4) model creation. The original “MEBPERMOD” model, designed to determine the performance status of school facilities in the climate change adaptation process, will enable the prioritization of strategic actions by revealing the strengths and weaknesses of schools.

The study utilized descriptive and correlational survey methods. The descriptive dimension aimed to reveal the current sustainability levels of schools, while the correlational dimension focused on the relationships between the scale's sub-dimensions and the overall construct validity. The data collection tool used in the study was rated on a five-point Likert scale as “1-Equally important,” “3-Moderately important,” “5-Strongly important,” “7-Very strongly important,” and “9-Definitely important,” based on literature review and expert opinions, and weight coefficients and importance rankings were determined.

The content validity of the scale will be ensured by obtaining opinions from academic experts in the field and school administrators. The results obtained have been interpreted to represent the adaptation dimension of the sustainable school concept to climate change.

3. Findings and Discussion

In line with Türkiye's net zero carbon target by 2053, the commitment made at the 28th Conference of the Parties (COP28) requires the inclusion of school buildings, which constitute a significant portion of the public building stock, in this transformation process. In this context, efforts to develop green school buildings, zero-energy school buildings, and carbon-neutral or carbon-positive school buildings are of strategic importance in line with sustainable development goals.

The development of zero-energy school strategic plans for school facilities serves as an institutional roadmap for both mitigating the effects of climate change and supporting climate change adaptation processes. Such plans not only increase energy efficiency but also contribute to the creation of healthy, high-performance learning and working environments. This supports students in gaining environmental awareness and conservation consciousness during their development processes, while enabling school users to be more productive while saving energy and resources.

In the process of adapting to climate change, it is crucial to set measurable targets to objectively evaluate the sustainability performance of educational structures. These targets ensure that improvement and development processes in key areas such as energy, water, materials, carbon, transportation, waste, ecology, and maintenance in existing and potential school buildings become trackable. In this context, in the design and operation processes of school landscape spaces;

1. Energy use and efficiency,
2. Efficient use of water,
3. Sustainable material status and use,
4. Carbon emissions and storage capacity,
5. Environmental location and transportation relationship,
6. Waste and residue management and recycling,
7. Ecological contributions,
8. Building maintenance and repair level,
9. User perception and awareness performance-based criteria must be developed for these topics.

In determining these criteria, globally recognized green building certification systems that are also widely used in Türkiye have been taken as a basis. These include LEED (Leadership in Energy and Environmental Design), BREEAM (Building Research Establishment Environmental Assessment Method), DGNB (Deutsche Gesellschaft für Nachhaltiges Bauen), CASBEE (Comprehensive Assessment System for Built Environment Efficiency), GREEN STAR, SBTool, IISBE, Green Globe, B.E.S.T., and the YeS-TR system specific to Türkiye (Çapkın, 2010).

The evaluation criteria derived from these certification systems have been classified within a framework of 15 basic criteria to determine the sustainability and climate change adaptation performance of school buildings (Table 1). These criteria enable a holistic approach to both physical environmental conditions (energy, water, materials, carbon management) and socio-pedagogical components (awareness, ecological contribution, sustainable behavior). The criteria developed in this direction provide a strategic framework for the design of climate-resilient, energy-efficient, and environmentally sustainable green school buildings and the improvement of existing structures.

Table 1. Performance criteria for secondary school spaces

Criteria	LEED	Breeam	DGNB	IISBE	Greenstar	Casbee	Green Globe	SBTool	B.E.S.T	YeS-Tr	Frekans	Weight Score
1-Energy use and efficiency	X	X		X	X	X	X	X	X	X	9	**0,13**
2-Exterior, interior quality and comfort	X			X	X	X	X	X	X	X	8	**0,12**
3-Effective use and efficiency of water	X	X			X		X		X	X	6	**0,09**
4- Sustainable material status and use	X	X			X				X	X	5	**0,07**
5- Carbon emissions and storage capacity	X		X	X	X		X				5	**0,07**
6-Innovation in spatial design	X	X	X						X	X	5	**0,07**
7-Environmental impacts and pollution	X	X	X			X		X			5	**0,07**
8-Environmental location and transportation	X	X			X	X	X				5	**0,07**
9-Evaluation of waste and residues		X					X			X	4	**0,06**
10-Ecological contributions		X	X		X						3	**0,04**
11-Building management and governance		X			X					X	3	**0,04**
12-Service and service quality				X		X		X			3	**0,04**
13-Social, cultural perception and awareness			X	X				X			3	**0,04**
14-Economic capacity			X	X							2	**0,03**
15-Level of maintenance and repair of school premises									X		1	**0,01**
										67		**1,00**

The criteria were evaluated by experts using a 5-point Likert scale: “Equally important” 1 point, “Moderately important” 3 points, “Strongly important” 5 points, “Very strongly important” 7 points, and “Definitely important” 9 points, thereby establishing the priority and weight coefficient of the criteria (Table 2). When weighing up, the opinions of 20 experts in the fields of Landscape Architecture, Architecture, Civil Engineering, Agricultural Engineering, Food Engineering, and Environmental Engineering were consulted.

Table 2. Evaluation of performance criteria for secondary school spaces

Criteria	Total Points	Total Weight
Energy use and efficiency	160	0,10
Ecological contributions	146	0,08
Effective use and efficiency of water	144	0,08
Environmental impacts and pollution	140	0,08
Exterior, interior quality and comfort	132	0,07
Sustainable material status and use	128	0,07
Carbon emissions and storage capacity	124	0,07
Evaluation of waste and residues	120	0,07
Social, cultural perception and awareness	110	0,06
Building management and governance	110	0,06
Environmental location and transportation	102	0,06
Innovation in spatial design	96	0,05
Service and service quality	94	0,05
Economic capacity	92	0,05
Level of maintenance and repair of school premises	82	0,05
TOTAL	**1780**	**1,00**

Weight scores were determined by calculating the ratio of the scores obtained by 15 basic criteria, which were scored by experts according to their importance. Accordingly, the basic criteria are ranked as follows: first, “Energy use and efficiency (0.10)”, followed by “Ecological contributions (0.08)”, “Effective use and efficiency of water (0.08)”, “Environmental impacts and pollution (0.08)”, “Exterior, interior environment quality and comfort (0.07)”, “Sustainable material status and use (0.07)”, “Carbon emissions and storage capacity (0.07)”, and “Evaluation of waste and residues (0.07)”. Thus, it is envisaged that strategic action plan decisions for school landscape spaces will be developed using holistic performance benchmarks for school spaces.

In this context, the "MEBPERMOD" model has been developed to evaluate each school's performance in adapting to climate change by scoring sub-criteria and indicators based on 15 basic criteria. In schools where performance evaluation will be conducted, the goal is to obtain the school's total performance score by multiplying the weight score of each basic criterion, which includes the sub-criteria, by 5 points for "Yes" and 1 point for "No" for each of the 69 sub-criteria (Table 3).

Table 3. Approach to evaluating the performance status of secondary school spaces with the MEBPERMOD model

Number	Basic Criteria (BC)	Sub-Criteria (SC)	Total Indicator Score (TIS)	Basic Criteria Weight Score (BWS)
1	Energy use and efficiency	1-Availability of a low-energy appliance system 2-Conversion of the heating boiler system (conversion to natural gas) 3-Reduction of capacity load during holiday periods 4-Building interior and exterior thermal insulation 5-Daylight usage 6-Renewable energy generation from solar, wind, etc. 7-Awareness training on energy consumption and conscious use 8-Availability of electricity generation with piezoelectric systems (pressurized)	Yes 5 Point No 1 Point	**0,10**
2	Exterior, interior quality and comfort	1-Ventilation environments 2-Air circulation status 3-Presence of ventilation shafts 4-Indoor acoustics 5-Natural lighting status 6-Geothermal heating availability 7-Presence of light shelves on windows 8-Sufficient space capacity 9-Cleaning frequency 10-Accessibility of space	Yes 5 Point No 1 Point	**0,07**
3	Effective use and efficiency of water	1-Presence of water conservation measures 2-Current greywater usage status 3-Photocell batteries 4-Presence of time relay batteries 5-Rainwater storage and use for garden irrigation 6-Presence of an artesian water source 7-Monitoring of water usage	Yes 5 Point No 1 Point	**0,08**
4	Sustainable material status and use	1-Use of natural materials in interior and exterior spaces 2-Use of recycled materials 3-Use of materials that do not pose a cancer risk 4-Use of natural water-based emulsion paints	Yes 5 Point No 1 Point	**0,07**
5	Carbon emissions and storage capacity	1-Indoor carbon content 2-Tree carbon storage in landscaped spaces 3-Per capita carbon content	Yes 5 Point No 1 Point	**0,07**

6	Innovation in spatial design	1-Technologies for the efficient use of renewable energy resources 2-Availability of building automation systems 3-Use of innovative construction techniques	Yes 5 Point No 1 Point	**0,05**
7	Environmental impacts and pollution	1- Presence of air pollution 2- Vehicle traffic density and noise 3- Dust density 4- Prevailing wind influence level	Yes 5 Point No 1 Point	**0,08**
8	Environmental location and	1-Availability of public transportation 2-Bicycle density 3-Parking capacity 4-Shuttle availability	Yes 5 Point No 1 Point	**0,06**
9	Evaluation of waste and residues	1-Availability of separation systems for waste and residues 2-The status of food waste utilization 3-The status of compost fertilizer made from plant residue 4-The status of waste paper utilization 5-The availability of recycled materials 6-The status of producing new materials from waste	Yes 5 Point No 1 Point	**0,07**
10	Ecological contributions	1-Indoor planting 2-Roof and terrace planting 3-Vertical planting on the building facade 4-Presence and number of trees and shrubs in the school landscape spaces 5-Presence of fruit trees in the school landscape spaces 6-Presence of plant production and cultivation areas	Yes 5 Point No 1 Point	**0,08**
11	Building management and governance	1-Awareness level of school administrators 2-Administrators' prioritization of maintenance and repair 3-Landscape planting activities 4-Green building project development 5-Support for student activities 6-Participation level in decision-making processes	Yes 5 Point No 1 Point	**0,06**
12	Service and service quality	1-The healthiness of school canteen products	Yes 5 Point No 1 Point	**0,05**
13	Social, cultural perception and awareness	1-Number of educational and cultural events 2-Number of student clubs 3-Number of activities	Yes 5 Point No 1 Point	**0,06**

14	Economic capacity	1-Prioritizing the school budget 2-Allocating funds for maintenance and repair	Yes 5 Point No 1 Point	**0,05**
15	Level of maintenance and repair of school	1-Existence of a periodic maintenance and repair program 2-Availability of support personnel	Yes 5 Point No 1 Point	**0,05**

The MEBPERMOD (Ministry of National Education Performance Model), developed to determine the sustainability and climate change adaptation levels of secondary school facilities, enables the evaluation of the physical, environmental, social, and economic dimensions of educational structures through a holistic approach (Akten, 2024).

The MEBPERMOD model is formulated as follows:

BCS: Basic criterion score

TSCS: Total sub-criterion score

n: Number of criteria

BWS: Basic criterion weight score

TPS: School's total performance score

$BCS = TSCS_n \times BWS_n$

$TPS = BCS_1 (TSCS \times BWS_1) + BCS_2 (TSCS \times BWS_2) + \ldots BCS_{15} (TSCS \times BWS_{15})$

The total performance score (TPS) has been grouped in three different ways to determine performance status. This scoring system quantifies the school's sustainability performance and its capacity to adapt to climate change.

$TSCS_{max}$ 69x5 = 345

$TSCS_{min}$ 69x1 = 69

$TSCS_{max} - TSCS_{min}$ = 345-69 =276/3 =92

- **Low Performance Schools:** 69 to 161 points
- **Medium Performance Schools:** 162 to 253 points
- **High Performance Schools:** 254 to 345 points

Based on the total performance score obtained from the model, school facilities are classified into three main groups:

1. High-Performance Schools (Green Schools):

These are schools that implement sustainability principles at a high level, provide energy and resource efficiency, and have effectively integrated climate change adaptation strategies. This group represents the highest level in the MEBPERMOD score range.

2. Medium-Performance Schools (Developing Schools):

These are schools that meet some sustainability criteria but need improvement in certain areas. These schools have made certain progress in environmental awareness and resource management and have the potential to achieve sustainable school status.

3. Low-Performing Schools (Schools Requiring Improvement):

These are schools that fail to meet most sustainability criteria and demonstrate low efficiency in areas such as energy, water, and material management. Schools in this group have the weakest capacity to adapt to climate change and require comprehensive physical and administrative improvements.

This three-tier classification enables the objective assessment of schools' current status and allows each school to develop sustainability strategies according to its own development potential. Thus, the MEBPERMOD model serves as a measurable tool that guides decision-makers in the process of transforming secondary schools into climate-resilient, sustainable, and healthy spaces.

4. Conclusion and Recommendations

The selection and evaluation of performance criteria in secondary school settings requires a process based on multiple data sources. This is important not only for increasing the reliability of results related to institutions but also for contributing to information access and decision-making processes. Indeed, approaches aimed at improving the performance measurement and management of public institutions also support this understanding (Lettieri et al., 2004).

According to Fındıkçı (2002), Barutçugil (2004), and Döngel (2006), evaluation based on multiple data sources increases measurement reliability and serves as an effective tool for analytical thinking, forecasting the future, managerial improvement, and organizational development. The evaluation process conducted within this scope enables the organization to conduct a self-assessment of its own performance. Thus, the findings obtained allow for the identification of existing deficiencies and problem areas, thereby enabling the development of targeted improvement strategies for these areas.

Based on the evaluation results, schools can define their own change and development goals by prioritizing areas with low performance. This process is an important part of sustainable school transformation and contributes to the continuous development cycle of institutions.

Schools play an important role as institutions that present a comprehensive vision by raising awareness among all stakeholders on climate change and sustainability issues. However, the effective continuation of this vision depends on the implementation of regular monitoring, auditing, and improvement processes. In this regard, “MEBPERMOD” has been developed to assess the performance status of schools' climate change adaptation processes.

The MEBPERMOD model enables the quantitative assessment of schools' effectiveness in adapting to climate change. Within the scope of the model, 15 basic criteria and 69 sub-criteria and indicators linked to these criteria are scored using specific weights to generate a total performance score for each school.

The total scores obtained categorize schools' climate change adaptation performance levels into three categories:

- 69–161 point range: Low-performing schools

- 162–253 point range: Medium-performing schools
- 254–345 point range: High-performing schools

This classification enables schools to objectively analyze their current status, identify their strengths and weaknesses, and define strategic areas for improvement in terms of sustainability. Thus, the MEBPERMOD model can be used as a scientifically based assessment tool for monitoring and managing adaptation to climate change in educational institutions.

The MEBPERMOD model serves as an important guide for identifying the current status and shortcomings of schools based on their performance scores, enabling the formulation and prioritization of strategic action decisions in the process of adapting to climate change. By highlighting the areas where each institution excels and those open to improvement, the model provides a data-driven approach to sustainability-based school management.

Additionally, by comparing schools' evaluation results, it is possible to monitor the temporal development of institutions and assess the effectiveness of improvement processes. In this respect, the MEBPERMOD model covers not only the evaluation process but also the stages of analyzing, interpreting, and translating the results into action. Therefore, the model offers a comprehensive framework that can be used both as a decision support tool and as a monitoring and evaluation mechanism in the process of developing sustainable school policies.

This study was conducted to improve the adaptation process to climate change in secondary school landscape spaces. The MEBPERMOD model developed for this purpose has a structure that can be applied not only to secondary schools but also to educational institutions at different levels. This feature of the model allows for reaching a broader sample group and obtaining generalizable results.

During the evaluation process, institutions can adapt, develop, or redefine the criteria that affect their performance, taking into account the structural, environmental, and pedagogical characteristics of their own school levels. Thus, the model provides a flexible framework for different types of schools and contributes to improving sustainability performance.

Furthermore, it is possible to conduct a comparative analysis of climate change adaptation performance outcomes by examining the model's relationships with school facilities in different cities. Such comparative studies can serve as an important reference source for evaluating both regional differences and the impact of local government policies on school sustainability.

Abstract

Bicycle tourism, which is a significant transportation alternative in urban and rural areas at national, regional, and local scales, is increasingly recognized as a development tool. It can also contribute significantly to the economic, socio-cultural, psychological, health, sports, recreational, technological, and environmental aspects of diversifying sustainable tourism. In this context, determining and organizing bicycle routes for bicycle tourism has become a necessity. This study aims to determine the importance and contribution of bicycle routes that will contribute to the diversification of cultural tourism, as well as the criteria and indicators for the location selection of short, medium, and long-distance bicycle routes. In this context, the opinions of decision-makers, academics, and bicycle users were gathered through a survey, and three basic criteria (physical, environmental, and visual/functional criteria) and 21 sub-criteria and indicators that could be considered in the creation of bicycle routes were determined. Thus, the most suitable bicycle paths within the scope of location selection criteria in urban and suburban tourism destination areas will provide easy and enjoyable access to cultural and natural tourism focal points. Ultimately, it will provide an alternative and economical means of access while also offering visitors the experience of using bicycles for sports, recreation, and health purposes.

Keywords: Cultural tourism, bicycle route, bicycle tourism, bicycle route selection criteria.

1.Introduction

The increase in motor vehicle use observed in recent years has led to a rise in fossil fuel consumption, seriously triggering environmental pollution and climate change at the global, national, and local levels. This situation has made the importance of sustainable transportation policies more apparent. According to the World Health Organization (WHO, 2004), sustainable transportation should be economically, safely, and socially acceptable, contribute to quality of life, operate without disrupting environmental balance, and demonstrate a solution-oriented approach to environmental issues. In this context, transportation planning plays an important role not only in the physical formation of cities but also in improving the quality of urban life. Indeed, sustainable transportation is defined as a system that meets today's transportation needs without threatening the right to life of future generations and other living species (Black, 1996).

One of the leading solutions for achieving sustainable transportation goals is to carry out travel using public transportation and non-motorized transportation modes. Urban sustainable

transportation systems are based on principles such as ensuring safe and fast transportation, planned approaches to land use, prioritizing the use of renewable energy sources, being economically low-cost, and providing quality transportation services to the community (Crawford, 2002). In this context, bicycle transportation, one of the non-motorized modes of transportation, fully complies with the definition of sustainable transportation and offers an effective alternative solution to the problems encountered in urban transportation. Compared to motorized vehicles, bicycle use significantly reduces energy consumption in the transportation sector and contributes significantly to environmental sustainability (Pucher & Buehler, 2012). In this regard, the role of bicycle use in reducing the carbon footprint caused by transportation is becoming increasingly important and is leading governments to reevaluate their policies on urban transportation systems. However, bicycles are used not only as a means of transportation but also for various purposes such as amateur and professional sports, entertainment, recreation, health, and tourism. When used for transportation, bicycles stand out as an effective alternative mode of transportation that facilitates movement between two points, is low-cost, environmentally friendly, and offers practical solutions for short distances.

Bicycles, a healthy, economical, environmentally friendly, and enjoyable mode of transportation, are considered a strong alternative to motor vehicles, especially for short and medium-distance journeys. Therefore, integrating bicycle transportation into the urban transportation system, increasing its usage rate, and promoting its widespread adoption are of great importance. As a fundamental component of sustainable and integrated transportation systems, bicycles stand out as the most effective solution capable of covering all short-distance trips (5–8 km) in cities and providing a complementary transportation alternative between the starting and ending points of public transportation systems for longer trips. Bicycle trips in cities, where the majority of the population lives, are generally considered short trips. While commuting to work and school takes place every weekday, some trips (such as for health or visits) are less frequent, and recreational, sports, and leisure trips within the city increase on weekends.

Trips between rural settlements or between the city and surrounding rural settlements share similar characteristics with urban trips, but are generally considered longer bicycle trips or bicycle trips involving public transport transfers. Long bicycle trips are typically for sports, recreation, and tourism purposes and involve cycling throughout the day. These types of bicycle rides, usually planned in advance and organized by groups of varying sizes, can take the form of nature and cultural tours on easy routes outside the city, or they can be organized on challenging trails or in rugged topography where there is no bicycle infrastructure. This diversity demonstrates that bicycles serve not only as a means of transportation but also have multifaceted functions such as physical endurance, exploration, cultural interaction, and integration with nature.

Today, the contribution of bicycles to global sustainability goals has led many countries to consider bicycles as a strategic element in their transportation and environmental policies. Accordingly, countries are developing comprehensive policies to encourage bicycle use at the national, regional, and local levels; they are preparing and implementing national bicycle strategies and regional and urban bicycle master plans. These plans aim to support sustainable transportation, reduce environmental impacts, and improve the quality of urban life. However, when evaluated specifically in Türkiye, it is observed that there is no comprehensive legal or technical framework defining the approaches, methods, and processes related to urban and rural bicycle planning.

The increasing transportation problems in our cities and the short-term effects of the solutions developed, along with growing environmental problems and economic losses on a national scale, increase the need for efforts to promote bicycle transportation. Although there are some limited technical regulations in urban areas with high bicycle usage, there is no clear, binding, and mandatory legislation on bicycle planning. As stated in the "Bicycle Paths Regulation" published in the Official Gazette, issue number 30976, dated December 12, 2019, bicycle path projects can be prepared by professionals from different disciplines, such as architects, landscape architects, cartographers, urban planners, or civil engineers. However, implementing these projects without considering the natural, cultural, and socio-economic characteristics of cities can lead to various problems. This situation creates a structural obstacle to increasing the share of bicycle transportation in the urban transportation system. Therefore, in order to make sustainable and effective decisions regarding the selection of bicycle paths, the characteristics of the region must be analyzed based on specific criteria.

The sustainable tourism approach is not only the most important economic driver at the national, regional, and local levels, but also a development tool that can make significant contributions in socio-cultural, psychological, health, sports, recreational, technological, and environmental dimensions. In developed countries, the use of bicycles, an alternative, easy, economical, and sustainable environmentally friendly transportation option, is becoming increasingly widespread (EESC, 2019). At the same time, it has brought bicycle tourism to the forefront in terms of diversifying sustainable tourism at the local level and increasing added value. In this context, determining and organizing routes for bicycle tourism has become a necessity.

This study aims to determine the importance and contribution of bicycle paths in diversifying cultural tourism, as well as the criteria and indicators for selecting locations for short, medium, and long-distance bicycle paths. Thus, the most suitable bicycle paths within the scope of location selection criteria in urban and suburban tourism destination areas will provide easy and enjoyable access to cultural and natural tourism focal points. Ultimately, this will provide an alternative and economic means of access while also offering visitors the experience of using bicycles for sports, recreation, and health purposes.

1.1. The Role of Bicycle Routes as a Sustainable Means of Transportation in Cultural Tourism

The bicycle was invented in Germany in 1818 by Baron Karl Von Drais and has evolved over approximately two hundred years to reach its current form. Today, bicycles are produced and used in various shapes and sizes depending on their intended use. The widespread use of bicycles began in England, then spread to Europe, and from there to the rest of the world (Ankaya & Aslan, 2020). During the economic crisis of the 1930s, when automobiles were not yet widespread in urban transportation, bicycle use increased in European cities, reaching a share of 80% as the most important means of transportation in some cities. Bicycle transportation continued to be important during World War II. Due to limited fuel, spare parts, and repair facilities, bicycles played a significant role in urban and rural areas when cars and buses could not provide adequate service. After the war, with the improvement of the economy and the increase in car ownership and use, the share of bicycle transportation in cities declined rapidly. This decline continued until the global oil crises of 1973 and 1978. The hardships caused by the global oil crisis, combined with growing environmental awareness and concerns, led to bicycles regaining importance as a sustainable alternative in transportation.

Bicycle transportation in Türkiye began approximately a century after the invention of the bicycle. At the beginning of the 20th century, during the Ottoman period, bicycles were used in the postal service and the military (Yılmaz, 2015). In 1940, when bicycles were widely used throughout the world, the rate of bicycle use also increased in Türkiye. The bicycle license, bicycle permit, and bicycle license plate that were implemented in Türkiye for a period demonstrate that bicycles were used as a means of transportation (Mert & Öcalır, 2010). However, in recent years, steps have been taken to increase the use of bicycles in urban transportation, both due to environmental concerns and efforts to comply with international sustainability goals. The promotion of bicycles as an environmentally friendly means of transportation is at the center of strategic efforts being made on a global scale to reduce the share of fossil fuel-powered vehicles in transportation and, consequently, minimize environmental impacts.

Bicycle transportation, being entirely powered by biological energy, does not produce harmful emissions or contribute to air pollution, unlike motor vehicles that consume fossil fuels. This feature makes it an environmentally friendly and sustainable transportation option. Additionally, bicycle use provides a high degree of flexibility in terms of time planning. While offering the same individual freedom of use as cars, it is independent of the fixed schedules that public transportation vehicles are bound to. Users can start, stop, or pause their journeys whenever they wish.

Route flexibility is also one of the important advantages of bicycles. Bicycle users have the opportunity to choose the shortest, safest, flattest, or most aesthetically pleasing route according to their personal preferences, without being tied to predetermined fixed routes. In this sense, bicycles are superior to both public transportation and cars in terms of route flexibility. In addition, the physical space occupied by bicycles while in motion, during stops, or when parked is quite small. This provides a significant advantage in terms of urban space utilization. Unlike cars, bicycles offer more efficient use of space without excessively consuming roads and other urban spaces. Therefore, bicycle transportation is of strategic importance not only for environmental sustainability but also for spatial sustainability.

Bicycle transportation stands out not only for its environmental and economic benefits, but also for the advantages it offers in terms of social and safety aspects. Since the speed of bicycles is lower than that of motor vehicles, the number of accidents they are involved in and the rates of material damage, injury, and death in these accidents are quite low. In this respect, bicycle transportation is considered a safer alternative for urban transportation. Furthermore, bicycle trips allow for more social interaction between individuals, increasing personal relationships and social solidarity within the community (Küster & Blondel, 2013). Being accessible to everyone regardless of income level makes bicycles a fair and inclusive form of transportation that reduces inequalities between income and social groups. Increasing the mobility of low-income individuals in particular makes it possible to consider cycling as a strategic tool in terms of social justice. At the same time, by supporting the mobility of women, children, young people, and the elderly within cities, cycling facilitates their participation in public life and urban activities, enabling them to be more effectively included in city life.

Today's evolving and diversifying tourism sector, driven by supply and demand and aimed at fostering economic, social, and environmental development, is transforming investments into action to support various types of activities. This is done by decision-makers (managers, political will, planners/designers etc.) in order to adapt to constantly changing conditions.

In this context, within the types of tourism, we can define bicycle tourism as trips made by bicycle by people whose main motivations are seeing the natural environment, physical fitness, experiencing adventure, seeking excitement and change, escaping routine, and feeling independence. Cycling tourism is recognized as a new market that continues to grow worldwide. In this context, it is accepted that cycling tourism has great potential in terms of tourism and that tourism regions that provide the necessary infrastructure and superstructure for cycling tourists stand out more in a competitive environment (Türkay & Atasoy, 2021).

Bicycle tourism can generally take place in nature, urban and rural areas, that is, in any location. Bicycles, which can also be described as a form of vacation transportation, are still considered a niche market in the tourism sector (Sheng, 2015). However, bicycle tourism provides opportunities to diversify and develop tourism at the national and regional levels. The creation of bicycle routes aims to attract tourists traveling in nature by providing them with a different activity (Ünüyar et al., 2017). Thus, visiting tourists contribute economically, socially, and environmentally to tourism destinations (Ritchie et al., 2010).

In the EU, it is acknowledged that the meaning attributed to and importance given to cycling, particularly in terms of environmentally conscious options, has been effective in meeting the demand for environmentally conscious tourism that aims to foster dialogue between communities at both urban and rural scales, as well as other policy approaches (Blondiau & Zeebroeck, 2014; Transport and Tourism Policy, 2019; Türkay & Atasoy, 2021).

Bicycle tourism creates certain advantages and disadvantages for tourism regions. The availability of e-bikes, the existence of different routes, and natural attractions are opportunities that tourism regions have in terms of bicycle tourism. On the other hand, the fact that it can only be carried out during certain periods of the year due to unsuitable weather conditions, the cost of creating bicycle routes, the difficulty of establishing technological infrastructure, and safety issues are cited as disadvantages that bicycle tourism brings to countries or regions (Innovation Norway, 2016).

However, there are also some physical, environmental, and individual limitations that hinder the widespread use of bicycles. Firstly, bicycles are sensitive to topographical features; cycling becomes difficult on sloping terrain, which directs users towards public transportation. However, electric bicycles (e-bikes), which have become widespread in recent years, significantly eliminate this difficulty, enabling bicycle transportation to be sustainable in different geographical conditions. Bicycles are also highly sensitive to climatic conditions. Adverse weather conditions such as rainfall, extreme heat, or cold reduce bicycle usage rates. However, even in Northern European countries with unfavorable climatic conditions, bicycle transportation does not disappear entirely; despite seasonal declines, it continues to be an important part of urban transportation systems (Türkay & Atasoy, 2021). In addition, travel distance is also an important factor affecting bicycle use. As distance increases, bicycle use becomes more difficult, especially for individuals with limited physical capacity, the elderly, or those with physical disabilities, leading to a decline in usage rates. Therefore, for bicycles to be used effectively as a means of transportation, urban planning must take these physical and environmental limitations into account, and infrastructure and supportive policies must be shaped accordingly.

For bicycle tourism to develop to the desired level in a region, infrastructure and well-defined bicycle routes are required. These conditions, in turn, require significant political power. Similarly, when discussing bicycle tourism, other important factors include natural attractions,

scenery, as well as accommodation facilities offering quality services, bicycle rental and transfer companies (luggage transport). At this point, providing the infrastructure and superstructure needed by tourism regions brings the political environment to the fore. For this reason, the EU supports bicycle tourism in the political environment. In this context, the German Cyclists' Association (ADFC) is one of the official organizations established to secure the political environment's support for bicycle tourism (Innovation Norway & NCE Tourism Fjord Norway, 1998).

2.Materials and Methods

The criteria considered in the creation of bicycle routes in this study were determined through a literature review. During the process of establishing the criteria for the research topic, the "Bicycle Paths Regulation" published in the Official Gazette dated December 12, 2019, with the number 30976, and the relevant TSE standards were examined. In addition, international standards such as AASHTO, 2012; CROW, 2017; ECF, 2019 were taken into consideration. In this context, the opinions of decision-makers, academics, and bicycle users were collected through a survey, and three basic criteria (physical, environmental, and visual/functional criteria) and 21 sub-criteria and indicators that could be taken into account in the creation of the bicycle route were determined. The criteria identified in the study include: Bicycle path types, vehicle and pedestrian lane width, slope, road surface material quality and condition, land use type, usage intensity, transportation system integration, property status, traffic density, traffic speed, building density, building layout, network continuity, integration with open and green spaces, landscape and user experience, lighting conditions, visibility distance, road traffic signs and signage, bicycle parking facilities, noise and safety level.

One of the most important factors in ensuring that CBS-based bicycle path selection is sustainable and understandable is the ranking of criteria according to their importance levels using the analytic hierarchy process. Therefore, the defined criteria were ranked in order of priority by a total of 30 people, including decision-makers, academics, and bicycle users, using a 9-point Saaty scale via a survey. The weighted scores for the criteria obtained as a result of the priority ranking were calculated. Thus, the basic/sub-criteria and indicators for determining the location of bicycle routes and their prioritization were established.

3.Findings and Discussion

3.1.Bicycle Path Location Selection Criteria

Bicycle users can be divided into different groups based on various criteria such as purpose of use, experience level, comfort expectations, and behavior patterns in traffic. These classifications play an important role in the development of bicycle transportation policies, infrastructure design, and determining the target audience for awareness campaigns.

The size and characteristics of user groups should be taken into account when developing bicycle strategies and plans. To increase bicycle usage rates, the lines between groups should be lowered to increase the number of users and the proportion of bicycle trips. The literature shows that bicycle users are classified in different ways according to their travel purposes (e.g., commuting to work, school, shopping, recreation), frequency of use (regular users, occasional users), or individual characteristics (age, gender, physical ability, etc.). Defining user groups is important because it is necessary to determine the needs of bicycle users within the city and to plan and design accordingly.

In our country, the criteria set forth in the 2017 Urban Bicycle Paths Guide issued by the Ministry of Environment, Urbanization, and Climate Change are applied. Bicycle paths should be planned with the minimum criteria necessary for cyclists to move around in mind and in a way that does not disrupt vehicle traffic. There are numerous factors that influence whether a bicycle is used or not, as well as the number, route, speed, distance, and frequency of bicycle trips, apart from personal characteristics.

Three basic criteria and 21 sub-criteria have been identified that should be considered in the planning and design of bicycle use, including physical, environmental, and visual/functional criteria. The identified criteria are shown in Table 1.

Table 1. Proposed bicycle path design criteria

Physical Criteria	Environmental Criteria	Visual/Functional Criteria
Bicycle path types	Land use type	Integration with open and green spaces
Road widths	Usage intensity	Landscape and user experience
Slope	Transportation system integration	Lighting
Road Surface Material Quality and Condition	Property status	Visibility distance
	Traffic density	Traffic signs and signage
	Traffic speed	Bicycle parking facilities
	Building density	Noise level
	Building layout	Safety level
	Network continuity	

a. Physical criteria

Bicycle path types; Bicycle transportation is one of the fundamental components of sustainable urban mobility strategies. Effective bicycle path planning depends not only on the existence of infrastructure but also on the quality and condition of this infrastructure, including path types, path width, slope, road surface material quality and condition, visibility distance, lighting, network integrity, traffic signs and directional signage, bicycle parking facilities, noise level, traffic density, usage density, land use type, building layout, building density, property status, traffic speed, and transportation system integration. In this context, the correct determination of road types plays a critical role in the safety, comfort, continuity, and attractiveness of bicycle transportation.

Bicycle paths are generally divided into three main types (AASHTO, 2012; ECF, 2019):

• Segregated Cycle Tracks: These are paths physically separated from motor vehicle traffic and designed exclusively for cyclists.

• Shared Lanes: Local roads where cyclists and motor vehicles share the same lane, typically with low speed limits.

• Bike Lanes: Special bicycle lanes on motor vehicle roads, separated by paint or markings.

This classification directly affects cyclists' perception of safety, speed preferences, and route choices (Parkin, 2018). The choice of road type is decisive for cyclists' safety. Studies show that physically separated bicycle lanes reduce the risk of traffic accidents by 30–50% compared to roads shared with motor vehicles (Pucher & Buehler, 2016). Furthermore, separated lanes provide visual and psychological comfort for cyclists, which increases bicycle use, especially among vulnerable user groups such as women, children, and the elderly. The choice of road type should be consistent with the characteristics of the urban fabric. For example, physically separated bicycle lanes are preferred in high-density city centers, while shared lanes may be more appropriate in low-density residential areas. This approach optimizes land use and ensures cost-effectiveness, in line with urban design principles (Litman, 2020).

Road widths; Road width on bicycle paths is a decisive design criterion in terms of user safety, mutual passage, comfort level, and capacity. Recommended bicycle lane widths in international standards (Table 2) vary depending on the type of use (AASHTO, 2012; CROW, 2017; ECF, 2019);

When planning road width, existing urban area constraints must also be taken into account. Buehler & Pucher (2012) stated that there is a significant relationship between the physical characteristics of roads (length, width, etc.) and the number of users. Furthermore, width directly affects not only safety but also user comfort. Sufficient width facilitates cyclists passing each other, riding side by side, and maintaining a steady speed, which makes bicycle traffic flow smoothly (Parkin, 2018).

Table 2. Width values according to international standards

Road Type	Recommended Minimum Width (m)	Suitable Width (m)	Description
One-way separated bike path	1.50	1.75–2.00	Suitable for low-density, short-distance routes.
Two-way separate bicycle path	2.50	3.00–3.50	It provides mutual passage and safe maneuvering area.
Bicycle lane (on the road)	1.25	1.50–1.80	It is applied on main arteries shared with motor vehicle traffic.
Shared road	—	—	Suitable for local roads where vehicle speed is ≤30 km/h.
Pedestrian-bicycle shared path	3.00	3.50–4.00	Visual or structural separation is recommended to avoid user conflicts.

Slope; Slope on bicycle paths is one of the fundamental physical design variables that determine the comfort, energy requirements, and speed of bicycle transportation (Table 3). Maintaining appropriate slope values encourages bicycle transportation by reducing the physical effort required by users. Excessively steep routes, however, have a deterrent effect, particularly for children, the elderly, and everyday users (AASHTO, 2012; CROW, 2017).

Table 3. Recommended slope values according to international standards

Slope Type	Maximum Slope (%)	Description
Ideal slope	0–2	Provides comfortable riding on flat terrain.
Acceptable slope	3–5	Acceptable for short distances (≤150 m).
Maximum short-term slope	6–8	Applicable only in cases of topographic necessity.
Downward slopes (maximum)	10	Requires safe braking distance and speed control.

The topography's long-distance steep inclines and descents negatively affect the number and length of bicycle trips. The gradient value directly affects the rider's required pedaling power and energy expenditure. According to CROW (2017), a cyclist's comfort level begins to decrease on gradients above 3%; gradients above 5% are acceptable for short climbs but are not sustainable over long distances. Broach et al. (2012) illustrate the slope-distance relationship by citing a 1-mile (1.6 km) route with a gentle slope (2-4%) uphill as an example of a route where cyclists would be willing to pedal.

Road surface material quality and condition; The quality of road surface material used on bicycle paths is a critical factor in terms of riding comfort, safety, maintenance costs, and the longevity of the road. Appropriate material selection determines not only structural durability but also skid resistance, vibration levels, and water drainage performance (CROW, 2017; Parkin, 2018).

The skid resistance of the material used on bicycle paths is particularly important in wet conditions. A longitudinal slope of at least 0.5–1% should be provided to prevent water accumulation on the surface (ECF, 2019). For proper drainage, the bicycle path surface should have a 2% cross slope. If the bicycle path level is above the vehicle road level, it is constructed in the direction of vehicle traffic (TS 7249). Providing cross slope on one side generally facilitates longitudinal drainage design and surface construction. If there are points where channels and grates intersect with the bicycle path for water drainage, they must be placed crosswise for driving safety.

b. Environmental Criteria

Land use type; In bicycle route planning, land use type is one of the key determinants in terms of route selection, user density, safety level, and accessibility. Different land use types (residential, commercial, industrial, educational, recreational, etc.) directly influence cyclists' travel motivations and routes (Pucher & Buehler, 2012).

Therefore, in the bicycle path planning process, not only the physical infrastructure but also the spatial distribution of urban functions must be taken into account. One of the most important factors determining the effectiveness of bicycle paths is the land use type of the surrounding area along the route. Land use type forms the spatial backbone of bicycle path planning. The relationships between different functional areas determine route selection, capacity, and design decisions. Planning bicycle paths to connect residential, commercial, educational, and

recreational areas both increase usage rates and supports sustainable urban mobility. Therefore, land use analysis should be considered a strategic guiding element in bicycle planning.

Usage intensity; Usage intensity on bicycle paths is defined as the number of cyclists passing through a unit width in a unit of time and is usually expressed in the unit of bicycle/hour/meter (b/h/m). Usage intensity is a decisive indicator in terms of bicycle infrastructure capacity planning, comfort level, safety requirements, and maintenance policies (CROW, 2017). Studies show that overcrowding on bicycle lanes reduces user riding comfort, increases stress levels, and encourages a shift to alternative modes of transportation in the long term (Kaparias et al., 2015). The maximum comfortable capacity on bicycle lanes is the density level at which cyclists can comfortably pass each other and maintain a steady speed. Table 4 shows the recommended capacity values based on road width:

Table 4. Relationship between capacity and comfort

Bicycle Facility Types	Average Width (m)	Comfortable Capacity (bicycles/hour)	Peak Capacity (bicycles/hour)
One-way path	1.5 – 2.0	600 – 800	1000 – 1200
Two-way path	2.5 – 3.0	1000 – 1500	2000 – 2500
Shared path	—	< 300	< 500

Transportation system integration; The integration of bicycle lanes into the physical environment should be evaluated not only in terms of user safety and comfort, but also in terms of urban integrity and their relationship with transportation systems. In this context, the Bicycle Lanes Regulation (2019) Article 4(27) states that bicycle lanes may be constructed on pedestrianized streets to allow bicycle use during certain hours. This regulation is an important planning principle that enables the integration of pedestrian and bicycle transportation in city centers. In this regard, one-way roads and pedestrianized streets are considered suitable areas for bicycle lane applications, while two-way roads are highlighted as areas with limited suitability. This classification is based on the impact of factors such as road width and traffic density on bicycle transportation. The integration of bicycle lanes into the transportation system plays a key role in creating flexible and sustainable transportation infrastructure in cities. McBain & Coulfield (2017) stated that in the city of Cork (Ireland), bicycle stations connected to buses or rail systems were used more frequently for transfers. This integration transforms bicycle use into a natural part of daily life while also making urban mobility more efficient, accessible, and environmentally friendly.

Property status; In bicycle path planning, property status is a fundamental planning component that determines the type of property areas (public, private, foundation, or mixed) through which the route passes, directly affecting implementation processes and investment costs (Litman, 2020). Failure to accurately analyze the property structure can lead to significant problems in bicycle network projects, such as fragmented connections, expropriation issues, access restrictions, and implementation delays. Therefore, property status must be addressed in detail in bicycle path planning, along with land use decisions. Furthermore, it is important for the sustainability of the implementation that the corridors allocated for bicycle paths in zoning

plans remain within public property boundaries. Although the Bicycle Paths Regulation (2019) does not contain detailed provisions directly related to property status, it adopts a general planning principle that local governments should take the property structure into account in design and route planning.

Traffic density; Traffic density on bike paths is a key performance indicator representing the number of bicycles passing through a section in a given time period and is typically measured in units of bicycles per hour. Accurately determining traffic density is critical for both assessing infrastructure capacity and improving user safety and comfort. Approaching capacity on bike paths during peak hours can lead to negative consequences, such as reduced speeds, reduced following distances, increased collision risk, and increased user stress levels. Therefore, density management is closely linked to urban design components such as the width of separated bike paths, intersection designs, signaling arrangements, and alternative route planning.

Traffic speed; The speed of bicycle transportation varies depending on numerous factors, including the type and technical adequacy of the bicycle used, the purpose of the journey, the physical and geometric condition of the bicycle path, its topography, slope, regional wind conditions, traffic density, and the physical condition of the rider. As traffic speed increases, the risk of accidents and the severity of collisions rise exponentially.

Research shows that speeds of 30 km/h and below are a safe threshold for cyclists (OECD, 2020).

≤ 30 km/h: Safe speed, suitable for mixed-use areas.

30–50 km/h: Separated bicycle lanes are recommended.

> 50 km/h: Physical barriers are mandatory.

Therefore, instead of a fixed speed limit, design speeds that can vary according to different conditions should be considered. The maximum cruising speed generally preferred by bicycle users should be taken as the basis for determining the design speed. However, in areas where the longitudinal gradient exceeds 4% or where strong prevailing winds are effective, a design speed of 50 km/h is recommended. This recommendation is particularly important in terms of controlling bicycle traffic and speed increases on downhill sections.

Building density, directly affects physical space usage, traffic load, microclimate, and user safety in bicycle path planning (Litman, 2020). At the urban planning scale, building density determines the prioritization of bicycle paths and investment strategies. This strategic approach increases both infrastructure efficiency and sustainable transportation rates. In urban areas with high building density, especially in central areas, the intensity of motor vehicle traffic poses a threat to bicycle transportation; at the same time, it becomes difficult to allocate sufficient physical space for bicycle lanes. However, medium-density residential areas offer more favorable physical conditions for bicycle lanes, providing advantages in terms of both road safety and user accessibility (Pucher et al., 2010). Therefore, bicycle lanes should have width and design standards that are compatible with the surrounding building density.

Building layout; A concept that defines the arrangement of buildings, facade layout, building approach distances, and height relationships. This element, which determines the physical character of the urban space, has a direct impact on the spatial continuity, safety, and user experience of bicycle paths (Gehl, 2010). Building layout (detached, attached, block, etc.) plays a decisive role in planning bicycle lane routes and crossing areas. Taking these physical

differences into account, decisions must be made during the planning process regarding the layout of bicycle lanes and how they will be constructed with protection or lane separation.

Since bicycle lanes generally extend along urban street corridors, the surrounding building layout shapes both the physical environment quality and psychological perception. The distance and layout of buildings relative to bicycle lanes also affect the field of view and sense of safety. The Bicycle Paths Regulation (2019) emphasizes that physical barriers and environmental development conditions must be taken into account in route planning; however, it does not provide a specific classification regarding building layout.

Network continuity; refers to the level at which bicycle paths form a seamless, safe, and connected system. An effective bicycle transportation system is based on the principles of continuity, connectivity, and integration not only in specific corridors but throughout the city (ECF, 2019; Pucher & Buehler, 2016). A bicycle network is a consistent route system that provides users with seamless transportation between home, work, education, commerce, and recreation areas, supported by safe crossing points. In cities with weak network continuity, bicycle paths remain fragmented, and users avoid these areas. Research shows that bicycle usage rates increase by up to 30% in cities with high network integrity (Hull & O'Holleran, 2014).

c. Visual/Functional Criteria

Integration with open and green spaces; The integration of bicycle paths with open and green spaces ensures that sustainable transportation systems become not only a means of transportation but also an ecological and recreational connecting element. This integration supports the holistic structure of the city's green infrastructure system, producing both environmental and social benefits (Beatley, 2011; ECF, 2019). This reduces the carbon footprint and mitigates the urban heat island effect (Jim & Chen, 2009). Furthermore, it positively impacts physical and psychological health by increasing users' interaction with nature.

Landscape and user experience; Bicycle paths are also experiential spaces that enable users to interact with the natural and urban environment. In this context, “landscape and user experience” is a fundamental design component that determines the spatial quality, visual continuity, and psychological comfort of bicycle paths. Cyclists' perception of their surroundings is shaped by changing perspectives while in motion. Therefore, the quality of the scenery along bicycle routes is not only an aesthetic element but also important in terms of orientation and spatial memory (Appleyard, 2013).

Lighting; Lighting on bicycle paths is a factor that directly affects user safety, visual comfort, and encourages nighttime use. Inadequate lighting limits visibility for both cyclists and pedestrians, increasing the risk of accidents. Therefore, the appropriate lighting level for bicycle paths should be planned within the framework of traffic safety, perceptual comfort, and urban safety principles (CROW, 2017; ECF, 2019).

Visibility distance; is the minimum field of vision required for cyclists to maneuver safely, detect sudden obstacles, and stop. On bicycle paths, factors such as slope, curve radius, environmental obstacles, and landscaping directly affect sight distance. Insufficient sight distance increases the risk of collisions both between cyclists and in cyclist-vehicle interactions (AASHTO, 2012).

Traffic signs and signage; Traffic signs and signage systems on bicycle paths are a fundamental component for enabling users to move safely, comfortably, and consciously. These elements provide cyclists with right-of-way, route information, hazard warnings, and guidance support. An effective signage system not only enhances safety but also strengthens the perceived integrity of the bicycle network (CROW, 2017; AASHTO, 2012). Today, smart guidance systems are being integrated into bicycle infrastructure alongside traditional signs.

Bicycle parking facilities; Bicycle parking facilities are an integral part of the bicycle transportation system. Planning areas where cyclists can safely and conveniently leave their bicycles at their destinations directly increases bicycle usage rates (Pucher & Buehler, 2012). The Bicycle Paths Regulation (2019) in force in Türkiye also supports these requirements. According to the provisions of Article 4(4) and Article 17(3) of the Regulation, bicycle parking areas must be connected to bicycle paths. These regulations reflect the structural planning principles aimed at encouraging the adoption of bicycles as a daily means of transportation. In recent years, bicycle parking systems have gained importance in terms of efficient space utilization and security optimization by being integrated with smart technologies.

Noise level; Noise level on bicycle paths is a design parameter that directly affects both user comfort and environmental sustainability. Noise is not only a physical nuisance; it is also an important environmental factor that determines cyclists' perceived safety, psychological comfort, and riding satisfaction levels (Basner et al., 2014). When planning urban bicycle networks, factors such as traffic density, motor vehicle speed, road surface material quality, and environmental sound reflections should be considered for their impact on noise during route selection. Quiet, comfortable, and safe bicycle paths are among the most important components that strengthen cities' sustainable transportation vision.

Safety level; Traffic speed is one of the most critical parameters determining the safety level of bicycle lanes, user comfort, and route preferences. In the planning and design of bicycle lanes, specific speed criteria must be adhered to, based on user safety, comfort, and transportation efficiency. The legal basis for the minimum speed limit to be applied on bicycle lanes is set out in the “Bicycle Lanes Regulation” (Official Gazette, November 3, 2020, Number: 31293), which specifies a minimum design speed of 15 km/h and a maximum design speed of 30 km/h. These speed limits have been established to ensure that bicycle users can travel in a safe, comfortable, and continuous transportation environment. The regulation also requires that speed limits be reassessed and necessary safety measures taken when the road gradient exceeds 4% (ÇŞB, 2020).

Within the scope of the study, a route recommendation for bicycle paths was made using an analysis tool based on the results obtained by ranking the criteria sets according to their importance (Table 5).

Table 5. Order of importance of criteria

Criteria number	Basic criteria	Sub-criteria	Criterion weighted score	Criteria importance order
1	**Physical Criteria**	Bicycle path types	5,51	5
2		Road widths	5,37	9
3		Slope	6,12	2
4		Road Surface Material Quality and Condition	5,61	4
5	**Environmental Criteria**	Land use type	4,96	15
6		Usage intensity	4,83	17
7		Transportation system integration	5,33	10
8		Property status	5,09	13
9		Traffic density	4,61	19
10		Traffic speed	5,46	7
11		Building density	5,06	14
12		Building layout	5,45	8
13		Network continuity	5,75	3
14	**Visual/Functional Criteria**	Integration with open and green spaces	5,26	11
15		Landscape and user experience	5,16	12
16		Lighting	4,93	16
17		Visibility distance	5,49	6
18		Traffic signs and signage	6,30	1
19		Bicycle parking facilities	4,73	18
20		Noise level	4,16	20
21		Safety level	4,15	21

4.Conclusion and Recommendations

In recent years, there has been a need for modern and innovative approaches based on planning to solve the most important transportation problem in cities. Cities with bicycle transportation networks are healthier and more livable.

The first regulation on bicycle lanes in Türkiye was issued in 2015 and updated in 2019. Another development regarding bicycle lanes in Türkiye is the requirement for bicycle lanes to be included in the zoning plans of newly developed areas. The requirement for bicycle lanes in zoning plans is only valid for newly developed areas and has been in effect since June 2019. This requirement does not apply to existing built-up areas or areas without zoning plans. This situation prevents the continuity of bicycle use and discourages the choice of bicycles as a means of transportation (ÇŞB, 2015; ÇŞB, 2019). As individuals' incomes increase, it is crucial to raise public awareness by highlighting the positive effects of bicycle use on human health, the environment, and family budgets as an alternative to the preference for automobiles for transportation.

In terms of Türkiye's sustainable tourism potential, promoting bicycle transportation between destinations and integrating it with other types of tourism is of great importance. Organizing bicycle routes in such a way that they integrate not only within cities but also with tourist areas in the surrounding rural and natural areas is one of the top priorities. Cycling tourism, especially in tourist destinations, requires well-equipped infrastructure (safety, technological maps, well-defined signs and markings) and superstructure (shops selling first aid supplies, accommodation and food and beverage facilities, etc.). To provide the infrastructure and superstructure required for bicycle tourism in urban and rural/natural areas, relevant stakeholders must act in unison within the scope of national and local government tourism and transportation policies.

As a result, the approach of conducting evaluations based on local criteria sets in determining the bicycle route, bringing together different stakeholders in this process, and using an analysis tool highlights the original aspect of the study. The parallelism between the criteria and the recommendations in the final outcome and the fact that the recommendations are based on cause-and-effect relationships within the criteria sets are also important issues. From this perspective, unlike the observation-based bicycle path selection studies found in the literature, the study must demonstrate a comprehensive and scientific approach.

On the other hand, it is anticipated that the approach presented can be replicated across different regions and sample groups using different sets of criteria, thereby contributing to the selection and implementation of sustainable bicycle routes. Since this process can be shaped according to the dynamics specific to each region, it is anticipated that this approach will also provide flexible spatial planning and design opportunities.

Abstract

This study examines the spatial effects of material in architectural design approaches adopting a minimalist attitude through a comparative analysis based on user perception. In minimalist architectural approaches, material is regarded not merely as a technical or structural element but as a determinant of spatial atmosphere, a shaper of sensory experience, and a carrier of conceptual simplicity. Within the scope of the research, eight architectural examples constructed between 1950 and 2000 were analyzed: Chapel of Notre Dame du Haut, Ronchamp (Le Corbusier, 1954); Taliesin West (Frank Lloyd Wright, 1959); Indian Institute of Management Building (Louis Kahn, 1974); Thorncrown Chapel (E. Fay Jones, 1980); Koshino House (Tadao Ando, 1984); Vitra Fire Station (Zaha Hadid, 1993); Church of Light and Sunday School (Tadao Ando, 1999); De Blas House (Alberto Campo Baeza, 2000). The findings were systematically evaluated through comparative tables. To strengthen the reliability of the study, a survey was conducted with a group of 50 architects. The survey consisted of 17 questions structured into four sections: spatial atmosphere perception, material authenticity, sensory perception, and minimalist attitude perception. The responses revealed the effects of material on spatial unity, simplicity, authenticity, sensory qualities, and the capacity to reflect minimalist principles. The findings demonstrate that in minimalist architecture, material is not solely an aesthetic element but a fundamental component shaping atmosphere, user experience, and conceptual integrity. Accordingly, the study concludes that considering user perception in material selection can provide significant contributions to the discipline of architecture.

Keywords: Minimalism, architecture, material, spatial atmosphere, user perception, material authenticity

1.Introduction

In recent years, minimalist approaches that have gained prominence in architectural theory and practice have brought forward a profound design understanding constructed through the use of materials, extending beyond mere formal simplicity of space. Within this approach, building materials are not considered solely as structural or cladding elements; rather, they are regarded as fundamental components that actively contribute to the formation of spatial atmosphere, guide user perception, and add a conceptual layer to architectural design (Cheng, 2006).

In minimalist architecture, material selection, together with principles such as simplicity, clarity, and the elimination of superfluous elements, becomes one of the primary factors shaping the sensory qualities of space. In this context, the texture, color, interaction with light, and the explicit expression of the inherent properties of materials play a decisive role in the formation of spatial experience (Islakoğlu, 2006). However, existing literature reveals a limited number of studies that address these multi-layered effects of material use in minimalist architecture through measurable and comparable systematic frameworks (Ramussen, 2021).

The aim of this paper is to evaluate the effects of building materials on spatial atmosphere and user perception through selected architectural examples that adopt a minimalist design approach. Within the scope of the study, the relationship between material, space, and user is examined through the lenses of spatial atmosphere perception, material honesty, sensory perception, and minimalist design attitude, thereby offering a holistic evaluation framework.

Accordingly, this paper focuses on two main objectives:

1. to analytically reveal how materials shape spatial experience in selected minimalist architectural examples, and
2. to propose an applicable evaluation approach for designers by addressing the meaning of material in the architectural design process from both theoretical and experiential perspectives.

2.Materials and Methods

This study was conducted within the framework of qualitative research methods and aims to investigate the role of building materials in shaping spatial atmosphere in minimalist architectural design. Rather than addressing materials solely through their technical or structural properties, the research adopts a perception-oriented approach, focusing on their experiential, sensory, and conceptual impacts within architectural space.

2.1. Research Design

The research was structured in three main stages:

1. Selection and analysis of architectural case studies,
2. Development of an analytical evaluation framework,
3. Validation of the proposed framework through a questionnaire survey applied to professional architects.

This multi-layered methodological structure enabled both qualitative interpretation and comparative evaluation of material-related spatial effects.

2.2. Selection of Case Studies

The material scope of the study consists of eight architectural works that explicitly reflect a minimalist design attitude. The selected buildings were constructed between 1954 and 2000 and represent different decades of modernist and postmodern architectural production. The temporal distribution of the cases allows for observing variations in material use and spatial expression across distinct periods while maintaining a consistent minimalist approach.

The selected case studies are as follows:

- Chapel of Notre Dame du Haut, Ronchamp – Le Corbusier (1954)
- Taliesin West – Frank Lloyd Wright (1959)
- Indian Institute of Management – Louis Kahn (1974)
- Thorncrown Chapel – E. Fay Jones (1980)
- Koshino House – Tadao Ando (1984)
- Vitra Fire Station – Zaha Hadid (1993)

- Church of Light and Sunday School – Tadao Ando (1999)
- De Blas House – Alberto Campo Baeza (2000)

These buildings were selected based on their clear material expression, architectural significance, and their contribution to minimalist spatial discourse.

2.3. Analytical Framework

In order to systematically evaluate the relationship between building materials and spatial atmosphere, an original analytical framework was developed. The framework is structured around four main evaluation categories:

- Spatial Atmosphere Perception
- Material Honesty Perception
- Sensory Perception
- Minimalist Design Attitude

Each case study was qualitatively examined through these categories, focusing on how material properties such as texture, surface continuity, light interaction, and structural expression contribute to spatial experience and atmospheric quality.

2.4. Questionnaire Survey and Data Analysis

To test and support the findings derived from the case study analyses, a questionnaire survey was conducted with 36 architects. The survey consists of 17 statements organized under the same four evaluation categories defined in the analytical framework. Responses were collected using a Likert-scale format, enabling the quantification of professional perceptions regarding the role of materials in minimalist architecture. The collected data were analyzed comparatively to identify patterns, similarities, and differences among the case studies. This process allowed the qualitative observations obtained from architectural analysis to be supported by quantitative data derived from user and expert perception.

2.5. Methodological Contribution

By combining qualitative architectural analysis with perception-based survey data, the study proposes a transferable and applicable evaluation model for assessing material-driven spatial atmosphere in minimalist architecture (Deniz, 2016). The methodology not only enables the measurement of otherwise abstract concepts such as atmosphere and material honesty, but also provides a structured assessment tool that can be utilized in future architectural research and design practice.

3. Findings and Discussion

The findings of this study demonstrate that, in architectural designs adopting a minimalist attitude, building materials function not merely as structural necessities but as primary agents that shape spatial atmosphere, construct architectural meaning, and guide user perception. Although the eight selected case study buildingsRonchamp Chapel, Taliesin West, Indian Institute of Management, Thorncrown Chapel, Koshino House, Vitra Fire Station, Church of Light, and De Blas House belong to different periods, geographies, and tectonic traditions, the analysis reveals a set of shared perceptual patterns through which minimalist atmosphere is consistently produced and interpreted by users.

The evaluation framework of the study is based on four main criteria derived from an extensive literature review and qualitative analysis of the case studies: Spatial Atmosphere Perception, Material Honesty Perception, Sensory Perception, and Minimalist Attitude Perception. A total of 17 statements corresponding to these criteria were developed and assessed by 36 professional architects using a five-point Likert scale (1 = Strongly Disagree, 5 = Strongly Agree). This approach enabled the transformation of subjective spatial experiences into systematic, comparable, and measurable data, allowing minimalist architectural effects to be evaluated quantitatively rather than solely through interpretive discourse.

3.1. Spatial Atmosphere Perception

Findings related to spatial atmosphere perception indicate that most case study buildings successfully generate a calm, legible, and low-stimulus environment, while simultaneously providing a sense of openness and spatial coherence. These results suggest that minimalist atmosphere does not emerge solely from formal reduction or geometric simplicity, but rather from the interaction between material presence, light, texture, and spatial continuity.

In Ronchamp Chapel, the sculptural use of exposed concrete establishes a strong relationship between materiality and spiritual atmosphere (Deniz, 2016). The whitewashed concrete walls, combined with carefully controlled natural light, create a perceptual depth that transcends structural function. Similarly, Taliesin West demonstrates how spatial atmosphere is strengthened through the direct use of locally sourced stone, whose rough texture and layered arrangement reinforce the building's integration with the surrounding landscape. In De Blas House, the contrast between the heavy stereotomic concrete base and the lightweight tectonic upper structure generates a dual atmospheric reading simultaneously introverted and expansive thereby enriching spatial perception through material opposition.

Figure 1. Ronchamp by Le Courbusier (URL5)

These findings confirm that spatial atmosphere in minimalist architecture is not a byproduct of visual economy alone, but a result of material-driven spatial articulation that engages users at both perceptual and experiential levels.

3.2. Material Honesty Perception

Material honesty constitutes the conceptual core of this research. The findings clearly indicate that buildings in which materials are used without concealment, imitation, or surface masking are perceived as more authentic, coherent, and convincingly minimalist by users. Material honesty emerges as a measurable determinant in the perception of minimalist architectural identity. At the Indian Institute of Management, brick is not employed as a superficial finish

but as a structural and conceptual generator of architectural form. Kahn's approach often summarized by his metaphor of "asking the brick what it wants to be" positions material as an active participant in design rather than a passive construction element (Deniz, 2016). Likewise, in Koshino House and Church of Light, Tadao Ando's exposed concrete surfaces retain formwork traces and construction joints, allowing the production process itself to become part of the architectural expression.

Figure 2. Indian Institute of Mana Gemenet Building by Louis Kahn, 1974 (URL3)

Taliesin West exemplifies material honesty through the untreated surfaces of stone, wood, and plaster, while Thorncrown Chapel achieves transparency and tectonic clarity by exposing timber and glass in their natural states. In De Blas House, the monolithic concrete mass functions as an extension of the ground, reinforcing the perception of material as both spatial and conceptual substance (Öncan, 2023). Although Vitra Fire Station also employs exposed concrete, its dramatic and dynamic formal language differentiates it from the contemplative minimalism observed in other examples, highlighting that material honesty alone does not automatically result in a calm minimalist atmosphere. Overall, these findings confirm that material honesty is a critical, perceivable parameter through which users assess the authenticity and minimalist quality of architectural space.

Figure 3. Taliesin West by Frank Lloyd Wright, 1959 (URL2)

3.3. Sensory Perception

The sensory perception findings reveal that tactile qualities, surface textures, and thermal associations of materials significantly influence users' spatial experience. In many cases, high material honesty corresponds with heightened sensory awareness; however, sensory intensity

varies depending on scale, accessibility, light conditions, and material continuity (Şimşek, 2011).

Thorncrown Chapel exhibits the strongest sensory engagement, where timber surfaces, transparency, and constantly changing daylight conditions foster a direct bodily relationship between the user and the environment. In Ronchamp and Church of Light, sensory perception is shaped through the contrast between the cold, massive character of concrete and the immaterial presence of light, transforming physical materiality into an abstract spatial experience (Bektaş, 2024).

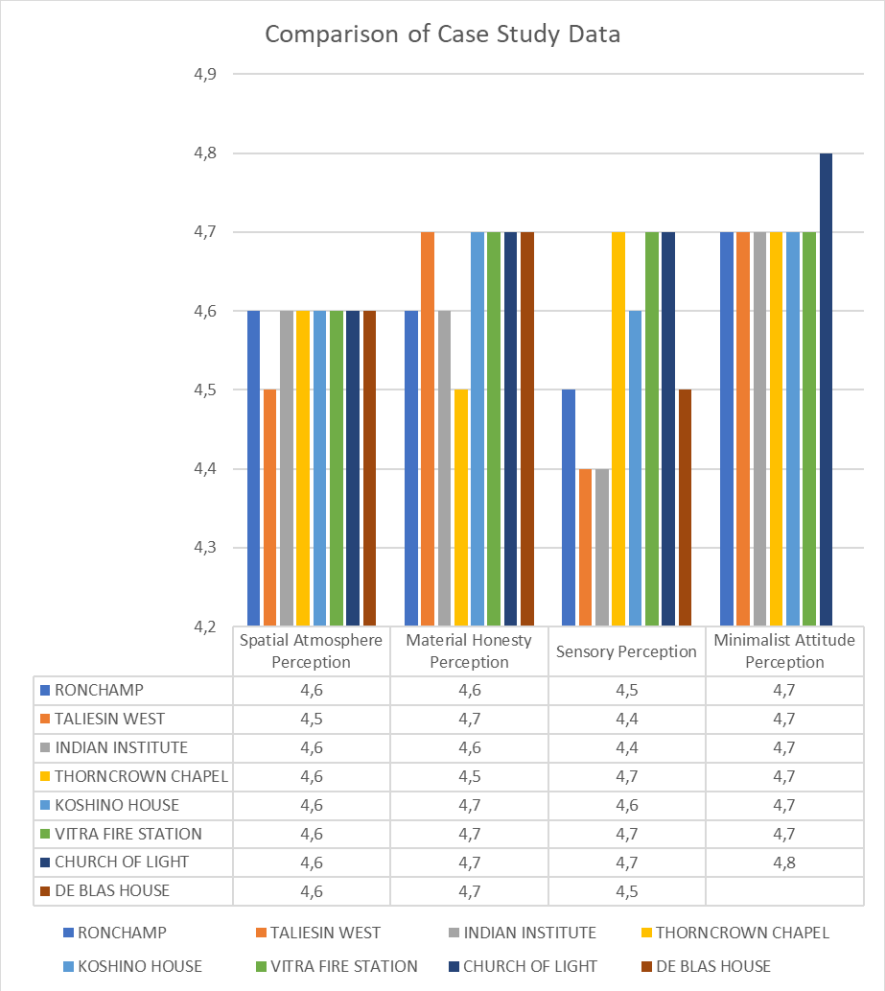
Figure 4. Church of Light and Sunday Scool by Tadao,1999 (URL1)

In De Blas House, the contrast between the heavy, enclosed concrete base and the luminous interior surfaces produces a tactile and atmospheric duality that enhances user perception. These results support the hypothesis that sensory perception is not solely dependent on material selection, but on the way material properties are spatially articulated and perceptually accessible (Şimşek, 2011).

Figure 5. De Blas House by Alberto Campo Baeza, 2000 (URL4)

3.4. Minimalist Attitude Perception

Minimalist attitude perception defined through the absence of unnecessary ornamentation, clarity of spatial organization, and the dominance of material as a primary design element received consistently high evaluations across all case studies. This outcome confirms that the selected examples successfully represent minimalist architectural principles.



Church of Light and De Blas House achieved the highest minimalist attitude scores, indicating that users strongly associate minimalism with conceptual clarity, material restraint, and expressive reduction rather than with stylistic uniformity. The results demonstrate that minimalist architecture is perceived not as a singular visual language, but as a holistic experiential condition formed through the integration of material honesty, sensory engagement, and spatial atmosphere (Özçam, 2022).

3.5. Discussion Based on the Comparative Analysis

The comparative analysis table reveals a consistent pattern across the evaluated buildings: while spatial atmosphere perception remains relatively balanced across cases, material honesty and minimalist attitude perception emerge as the most influential variables in shaping users' overall evaluation of minimalist architecture. Despite variations in material type concrete, brick, timber, glass, or steel the findings indicate that minimalist atmosphere is reinforced when materials are used in direct relation to their intrinsic properties and contextual conditions, rather than through decorative or representational strategies. The case studies demonstrate that minimalist architecture can accommodate different emotional registers, ranging from contemplative calmness (Church of Light, De Blas House) to sensory immersion (Thorncrown Chapel) and dynamic tension (Vitra Fire Station).

These results support the main hypothesis of the study: in minimalist architecture, building materials operate as measurable agents that shape spatial atmosphere through their inherent physical, sensory, and conceptual qualities. The integration of qualitative architectural analysis with quantitative user-based data confirms the applicability of the proposed evaluation model for both academic research and architectural design practice.

Table 1. Comparison of the Table and Graphical Representation of Interaction Scores Across All Case Studies by Categories

	Spatial Atmosphere Perception	Material Honesty Perception	Sensory Perception	Minimalist Attitude Perception
RONCHAMP	4,6	4,6	4,5	4,7
TALIESIN WEST	4,5	4,7	4,4	4,7
INDIAN INSTITUTE	4,6	4,6	4,4	4,7
THORNCROWN CHAPEL	4,6	4,5	4,7	4,7
KOSHINO HOUSE	4,6	4,7	4,6	4,7
VITRA FIRE STATION	4,6	4,7	4,7	4,7
CHURCH OF LIGHT	4,6	4,7	4,7	4,8
DE BLAS HOUSE	4,6	4,7	4,5	

4. Conclusion and Recommendations

This study demonstrates that, within the framework of minimalist architecture, building materials cannot be reduced to purely technical or structural components, but function as determinative and measurable agents in the formation of spatial atmosphere. While minimalist architecture has frequently been discussed in the literature through the lens of formal reduction and visual simplicity, systematic investigations that examine the relationship between materiality and spatial experience through an analytical evaluation model remain limited. In this respect, the present study contributes to the field by proposing an original framework that enables the assessment of material use in minimalist architecture through the dimensions of spatial atmosphere perception, material honesty perception, sensory perception, and minimalist attitude perception.

Through the evaluation model developed in this research, selected architectural examples from different periods and employing diverse material palettes were analyzed based on expert assessments. The resulting data were translated into weighted interaction scores, allowing the relationship between material choice and spatial experience to be examined not only qualitatively, but also within a measurable and comparable analytical structure. This approach offers a methodological contribution by bridging subjective architectural experience with structured evaluation criteria.

The findings reveal that material selection plays a central role in shaping spatial experience in minimalist architecture. Moreover, the results indicate that a minimalist atmosphere is not dependent on a specific material type; rather, it emerges when materials are used in accordance with their intrinsic physical, sensory, and contextual properties. In this sense, material honesty appears as a key parameter through which minimalist identity is perceived and evaluated, reinforcing the idea that minimalism is produced through material authenticity rather than formal abstraction alone.

Overall, the findings confirm the main hypothesis of the study, which argues that materials in minimalist architecture actively determine spatial experience and can be systematically examined at a measurable level. The subsidiary hypotheses that minimalist attitude is generated not solely through formal simplicity but through the inherent qualities of materials, and that material honesty constitutes one of the fundamental criteria of minimalist design are also supported by the results.

The evaluation model proposed in this study is not limited to the analyzed cases; it offers a transferable framework that may be applied to different building typologies and architectural movements. In this regard, the study can be considered a prototype for analytically examining the material–space relationship, contributing to both architectural research and design practice by providing a structured tool for assessing the experiential impact of material use.

Abstract

Forest fires in our country are becoming increasingly frequent and difficult to combat. Climate change has a significant impact on this trend. An increase in the number of extremely hot and dry days and above-average wind speeds can cause a fire that has just started to spread very quickly, turning into large or even mega forest fires. This process is clearly evident when looking at forest fires in previous periods. For example, between 1987 and 1996, the annual number of forest fires was 1,881, and the area burned was 12,446 ha. For the period 2015-2024, the same figures are 2,733 and 25,762 ha, respectively. While the fire that burned approximately 10,000 hectares in Marmaris in 1997 is considered the largest fire in the history of the Republic, the Serik-Taşağıl fire in 2008, which burned 15,000 hectares of forest, took first place. On the other hand, 2021 has overturned all statistics. During this period, approximately 60,000 ha burned within the Manavgat Forest Management Directorate alone, and 145,000 ha of forest area burned nationwide, and the fires of this period have been called "Mega Forest Fires."

The first step in restoration work to be carried out in large burned forest areas is planning the area. The first step in planning is to decide which production-marketing and silvicultural regimes should be applied in which areas. This requires examining the entire area. However, just driving around the terrain to see the mega forest fire areas takes a week or two. The forest fires of 2025 have revealed a different dimension in terms of their nature. As of September, the number of fires exceeds 4,000. The amount of burned area has not yet been reflected in the statistics. It is observed that forest fires in this period have spread not only in the Mediterranean climate belt areas but also towards other ecosystem types. In particular, the forest fires in Eskişehir and Karabük involve not only red pine forest types but also black pine forest types. It is emphasized that some forest fires in the Antalya Forest Regional Directorate have also shifted towards the black pine belt. This situation reveals that we need to adapt ourselves to restoration efforts in a new and relatively unfamiliar area, different from the usual red pine forest belt restoration. This study presents and discusses various approaches for the restoration of the forest fire that broke out in Karabük province on July 22, 2025, affecting approximately 6-7 thousand hectares of forest area and three forest management offices affiliated with the Forest Management Directorate. In this context, fundamental approaches are presented for issues such as the production and marketing of the area's resources, determining the intensity of the fire, identifying the stands, analyzing fine and coarse material, identifying the species that make up the stands, and discussing the appropriate silvicultural regime.

Keywords: Forest fires, restoration of burned forest areas, restoration planning

1-Introduction

Forest fires are increasingly affecting our country in a destructive manner, as they do worldwide. The rapid destruction of forest ecosystems leads to a decrease in carbon sink areas, thereby contributing to the progression of climate change effects. Climate change, in turn, causes forest fires to spread and advance rapidly. Thus, a vicious cycle is created.

In Mediterranean-type ecosystems, the number of forest fires is rapidly increasing, and the amount of area burned is also on the rise. Human factors are the primary cause of these fires. Humans fundamentally alter fire regimes in three ways: by changing the distribution and intensity of fires, by altering the seasonality of fires, or by changing the available fuel (Balch, 2017).

There is a large body of research on restoration efforts in forest ecosystems following wildfires. Since wildfires are more common in Mediterranean-type ecosystems, studies have concentrated on these areas. Post-fire biological diversity, the development of vegetation processes, success rates, the development processes of red pine and other species in the ecosystem along with it in burned areas, etc. (Barrett et al., 2024; Becker and Lutz, 2023; Blanco-Rodríguez et al., 2023; Calda, 2020).

With climate change, forest ecosystems are becoming more sensitive, and even the smallest unnoticed action can start a forest fire. The increase in the number of hot days, the decrease in relative humidity, and high wind speeds encourage an existing forest fire to rapidly escalate into a mega forest fire. Forest rangers fighting fires in the Mediterranean region have adapted to these conditions over time, but in recent years, they have been helpless in combating forest fires that have become mega fires due to the effects of climate change.

On the other hand, they have gained considerable experience in the rehabilitation of red pine ecosystems. This is because a wide variety of scientific studies have been conducted in these areas, namely Mediterranean-type ecosystems (Güney and Gülsoy, 2023; Kaniewski et al., 2008; Keeley, 2009; Keeley et al., 2005; Keeley et al, 2012; Tavşanoğlu and Gürkan, 2009; Tavşanoğlu, 2009; Tavşanoğlu and Gürkan, 2014; Tavşanoğlu, 2021a; Tavşanoğlu 2021b).

Climate change is increasingly causing forest fires to spread to higher elevations in the Mediterranean coastal region. This belt can be described as the 600m-900m elevation areas of the Central Anatolia Region, the Eskişehir province area, and the interior of the Western Black Sea region, such as the Karabük province. This change and development indicate that there are also changes in forest ecosystems. These areas appear as mixed black pine-red pine forests and pure black pine forests. Scientific studies on the restoration of black pine ecosystems after forest fires in these areas are limited (Karadağ, 1999; Keleş and Kavgacı, 2025; Bricca, 2025; Ertekin et al., 2011).

Therefore, scientific field studies should be conducted to quickly address the lack of information on these areas. In this study, the amount of burned forest areas was determined using Sentinel satellite imagery. By classifying these areas according to slope and burn intensity, various information was generated for post-fire restoration efforts. It is also known that a wide variety of studies have been conducted in this direction (Iverson et al., 19889, Jaafar and Mourad, 2021).

The data obtained were overlaid with digital forest management plans to identify compartments and forest types in the burned areas. The values of these forest compartments according to the plan data were compared with the standing sale value data for the same compartments obtained from the Forest Management Directorate. The results obtained were quite promising. Some recommendations were also made based on these results.

2- Materials and Methods

The study material consisted of the following stages.

1- Sentinel satellite images of the burned forest areas were obtained in this stage.

2- The satellite images were down sampled to the local area.

3- The burned forest areas were grouped according to burn intensity classes (Table 1).

Table 1. Fire severity classification for burned forest areas

Burn Severity Class	ΔNBR
Enhanced Regrowth, High	< -0.25
Enhanced Regrowth, Low	- 0.25 to -0.10
Unburned	- 0.10 to 0.10
Low Severity	0.10 to 0.27
Moderate-low Severity	0.27 to 0.44
Moderate-high Severity	0.44 to 0.66
High Severity	> 0.66

4- Using digital elevation maps of the four regions, slope groups for burned forest areas were created (Table 2).

Table 2. Slope classes and slope groups for burned forest areas

Slope Class	Slope Group
1	%0-%20
2	%21-%40
3	%41-%60
4	%61 +

5- The aim was to access forest management plan data for forest management units located within forest fire boundaries. To this end, the amount of burned area and the ranking of burn intensity classes were created at the compartment and forest type levels from digital forest management plan data (Table 3).

6- The tree wealth in the compartments was determined using forest management plan data. For this purpose, the total wealth was calculated by multiplying the area and wealth value of each forest type in the compartments by the total area of forest types and forest wealth values and the total burned forest areas.

7-. The total wealth in the burned forest areas was compared with the wealth in the compartments auctioned by the Karabük Forest Management Directorate through open bidding (Figure 2).

The aim is to determine the total amount of forest area burned in the forest areas affected by the fire that broke out in Karabük province on July 22, 2025, affecting approximately 6-7 thousand hectares of forest area.

At this stage of the study, knowing the intensity of the fire will help in deciding which sections and what type of application will be used for silvicultural intervention according to forest types. Slope Groups: The aim is to use this information to decide up to which slope groups production work will be carried out in the burned forest areas. For this reason, the slope groups used in forestry afforestation studies were used in the classification (Table 2).

After obtaining the maps of the burned forest areas, burn intensity, and slope groups in the studied area, the tables of these maps were organized to obtain the burn intensity and slope group values of the burned forest areas based on compartments and forest types (Figure 1).

The distribution of forest areas affected by the forest fire that occurred in July 2025 according to Forest Management Directorates and Forest Management Departments was determined by practitioners who physically visited the burned areas and made markings at the compartment and stand levels.

The comparison of the area data obtained by the field units with the area information obtained from satellite imagery was also carried out within the scope of this study (Table 4).

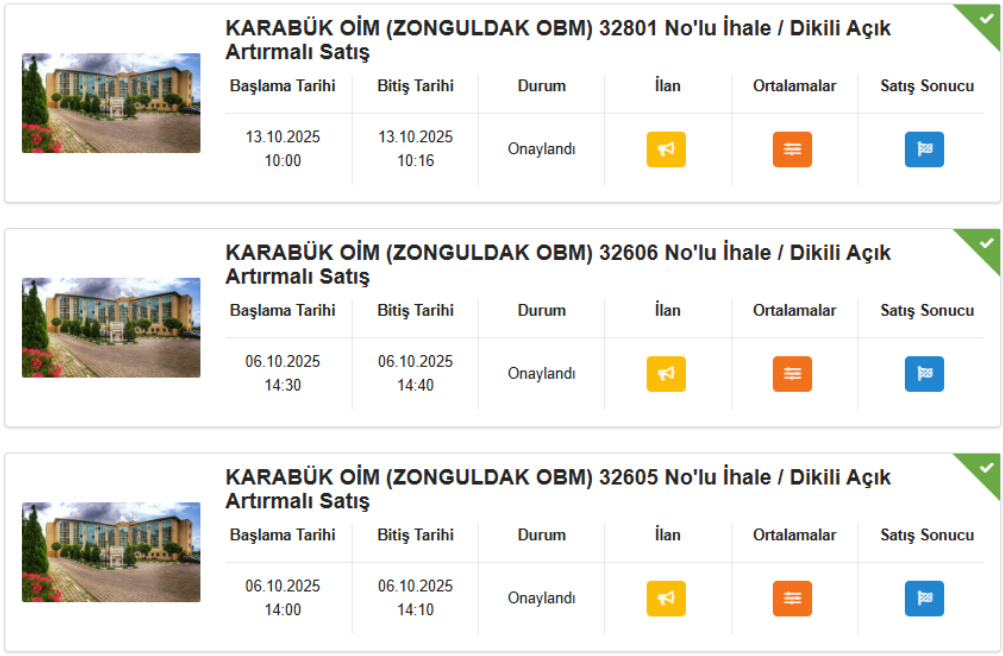

Figure 2. Burning wood raw material standing sale applications

3.Findings and Discussion

3.1. Presence of Burning Forest Areas

When the data on burning areas obtained by processing Sentinel satellite images is overlaid with digital forest management plan data, the areas affected by forest fires in the July 2025 period are revealed (Table 4).

Table 4: Distribution of Forest Areas Burned in Karabük Province in July 2025

Forest Enterprise Chef	Sentinel Data		Forest Enterprise Directorate Data	Change Rate (%)
	Bolme Total Area Hectare	Burned Area Hectare		
Karatepe Cemaller	9.940,42145	4.046,0804	3966,51448	-1,97
Kışla	1.043,66609	239,42334	238,5000	-0,38
Soğanlıçay	1.684,74310	338,9872	333,8581	-1,51
Ovacık	3.125,00285	1.083,3847	1096,9000	1,25
Toplam	15.793,83349	5.707,8755	5635,772533	-2,61

The data on burned areas obtained by cross-referencing the assessments made by forest management offices in forest management directorates for burned forest areas in the field with Sentinel satellite imagery and management plans are shown in Table 4. These data indicate that there are no significant discrepancies. What is important here is the consistency of the assets identified for the forest types in the forest management plans. This consistency is crucial for the rapid and reliable marketing of timber raw materials for post-fire restoration work by estimating the assets.

3.2. Wealth of Burned Forest Areas

In order to determine the wealth of burned forest areas, it is necessary to identify the forest types in the burned compartments and their wealth according to the forest types in the forest management plans. This study used the standing sale application data compiled by the Karabük Forest Management Directorate. This is because all trees with a diameter of 8 mm or more in the compartments of all burned areas were measured. The measurements taken were recorded in the “measurement report.”

Table 5. Standing sales and forest management plan data

Bölme No	Meşçere Type	Quantity of Wood Raw Material Sold by Standing Sale (m^3)	Forest Management Plan Data (m^3)
37	Çkbc3	1.051,251	1.608,045
43	ÇkÇzc2	2.624,932	2.240,713
35	Çkbc3/Çkcd1/ÇkGnab3	1.998,932	3.187,613
63	KDA/ÇkÇzc2/ÇzÇkbc2	2.103,691	1.184,455
56	BçzM/Çzab3/Çzbc2/T/Çzc1	1.745,159	2.099,631
31/34/33/32	ÇkMbc2/Çkbc3/Çzab	3.703,668	3.694,5149
38	Çkbc3	6.497,526	7.056,3021
	TOPLAM	19.725,159	21.071,234

Calculations were made based on the wealth amount according to forest types in the compartments of burned areas in forest management plans using standing sales marketing (Table 5). Plan data was found to be 6.82% higher than actual sales data. This forest management unit covers a 20-year planning period. The final year of the planning period is currently underway. A new management plan will be developed in 2006. A significant reason for the higher plan data may be the positive results of silvicultural practices implemented in the compartments in previous years or increases resulting from illegal logging in earlier periods.

3.3. Restoration Planning Principles

Forest fires cause enormous damage, partly due to the effects of climate change. The amount of burned area is rapidly increasing. In addition, it has been observed that fires are not only occurring in low-altitude Mediterranean ecosystems but are increasingly spreading to higher Mediterranean ecosystems. Therefore, forest fires have begun to affect not only red pine ecosystems but also black pine ecosystems. A significant portion of the forest fires that occurred in Türkiye in 2025 took place in mixed red pine-black pine forests and mixed black pine-red pine or pure black pine forests. Satisfactory scientific studies have been conducted on the adaptation of the red pine species to fire and the restoration of burned red pine forests in Türkiye (Ulus et al., 2025; Güney et al., 2024; Kavgacı et al., 2011; Viedma et al., 2017; Blanco-Rodríguez, 2024; Öztürk, 2025). Turkish foresters do not experience difficulties in rejuvenating burned red pine forests. Except for very large mega red pine forest fires. However, experience in the rehabilitation of burned black pine forests is quite limited (Karadağ, 1999; Keleş and Kavgacı, 2025; Bricca, 2025; Ertekin et al., 2011).

Rehabilitation plans should be developed with the priority of restoring black pine seedlings in pure black pine and mixed black pine-red pine stands affected by forest fires. The amount of seed required per unit area in burned areas is crucial (Alan, 2025). The methods for black pine seed sowing and the appropriate techniques for different terrain types must be determined. At this stage, it is necessary to consider the slope group classification used in Türkiye's afforestation efforts. Areas with a slope of 60% or more should be left to nature, and the progress of the ecosystem in these areas should be observed. As these areas will be very steep, no timber production should be carried out in them. This is because there will be a very serious risk of erosion with rainfall. On land with a slope of 0-20%, full-area medium-depth plowing can be carried out, followed by covering the soil and continuing the work. On land with a slope of 21-40%, taking into account the stoniness of the land, strip tillage should be carried out in large strips (6m-8m) with staggered spacing and rows, and the tillage should reach a soil depth of 8-10 cm. On land with a slope of 41-60%, small strips (2m-3m) and small spacing should be used for line planting at approximately 1.5m-2m. In restoration work, trial applications should be created using other planting methods, taking into account elevation, slope, and aspect, and scientific studies including success and economic analyses should be conducted.

4. Conclusion and Recommendations

As is the case worldwide, forest fires in Türkiye are evolving due to the effects of climate change. They are no longer confined to the Mediterranean coastal belt but have also begun to occur in mid-elevation areas. A progression from the Mediterranean belt towards the inland regions of Central Anatolia and the Western Black Sea is being observed. This situation means that forest fires are also affecting different key components of the ecosystem. Not only red pine ecosystems but also black pine ecosystems are now facing forest fires. Forest fires occurring in Türkiye in 2025 are giving us serious warnings.

While fighting Mediterranean-type forest fires, Turkish forestry is forced to combat large mega forest fires rather than small or medium-sized ones. While trying to adapt to this change, new developments show that different ecosystems will also be greatly affected by forest fires. In this context, black pine ecosystems are in serious danger. Forest fires that occurred this year in the provinces of Eskişehir and Karabük in these ecosystems show that black pine ecosystems are also at risk. Restoration efforts after forest fires are the most important way to ensure that destroyed ecosystems can return to their natural state. In this context, based on restoration experiences with Mediterranean-type red pine forest fires, forestry units that lack sufficient experience in black pine ecosystems must establish principles and guidelines that will enable them to succeed. It is essential to adhere to basic principles such as complying with seed transfer zones, paying attention to seed collection from selected seed orchards, and creating seed stocks to be prepared for large fire areas. The forest fires that occurred in black pine ecosystems in 2025 have created an opportunity to fill various information gaps for these areas. In these ecosystems, it is crucial to conduct research on which natural regeneration methods will be successful under which slope and soil conditions, which aspects and elevations, and which topographic structure conditions, as well as to perform economic analyses of all these factors. This is because it is necessary to quickly restore the burned forest areas.

In this study, the area affected by the forest fire that occurred in Karabük province in July 2025, the compartments and forest types where it occurred were estimated using Sentinel satellite imagery. Classifications were made according to slope, elevation, and fire intensity. These data are presented in comparison with the data obtained in the application (Table 4). This comparison showed a high degree of consistency in the areas. A second finding was the comparison of the wealth of the stands created by processing Sentinel satellite data with the wealth in the forest management plans, as determined by the Forest Management Directorate (Table 5). Here, too, a difference of approximately 7% in favor of the state was observed. This difference is also acceptable.

With this study, instead of labor-intensive work in the field for days or even weeks in large burned areas, it will be possible to carry out restoration work in these areas within a few days by obtaining more detailed satellite imagery. The draft restoration plan to be made can be completed in a short time, supported by rapid field assessment. Completing this planning quickly will save a significant amount of time and labor, especially when considering that it is being done for mega fire areas. Determining the wealth in the burned forest area in a short time will enable production for restoration purposes, i.e., clearing the area. In this context, time will be saved for restoration work, which will increase the chances of success of the restoration work.

Abstract

Urban green areas are one of the most important vital components of the city and are considered as a fundamental element in terms of sustainability of the urban ecosystem, protection of biological diversity and supporting the physical and mental health of urban residents. Demre district was first mentioned in historical documents in 1904 when it gained village status under the name of Eynihal. Later on, a municipality was established in 1968 with the merger of four villages, it became a district on 4 July 1987 under the name of Kale, and in 2005 it took its current name Demre. The district, which is 147 km away from the centre of Antalya, consists of 17 neighbourhoods today. This study was carried out to reveal the current status of urban green areas in Demre district and to evaluate their ecological, social and aesthetic values with a holistic approach. Within the scope of the research, parks, recreation areas, street afforestation and coastal green corridors were analysed by using municipal inventory data, satellite images and on-site observations. The results of the analysis show that there are significant differences between neighbourhoods in the amount and spatial distribution of green areas, and in some regions, the amount of green space per capita is below the minimum values recommended by the World Health Organization. However, plant species specific to the Mediterranean climate and landscape elements integrated with the historical-cultural texture have a high potential in terms of the ecological identity of the city. The study emphasises that planned growth principles, planting strategies that adapt to climate change and sustainable urban green space management models will play a critical role in improving the urban life quality of Demre.

Keywords: Urban green areas, Demre (Antalya), sustainability, climate change adaptation

1. Introduction

According to the UN, 55% of the world's population currently lives in urban areas. This figure is expected to rise to 68% by 2050. According to TUIK (February 6, 2025), 67.2% of Türkiye's population lives in densely populated cities, 15.5% in moderately populated cities, and 17.2% in rural areas (Türkiye İstatistik Kurumu, 2025).

Parallel to the increase in the world population, rapid migration from rural to urban areas has led to an increase in urbanization and the number and spatial size of urban areas. The growing

and diversifying need and demand for resources in rapidly growing cities has accelerated urbanization and construction activities. Today, the increase in production-consumption trends has further increased the pressure and damage of global capital actors and sectors on natural resources. However, it is accepted that the excessive use and destruction of natural resources, urbanization trends, misuse and misappropriation of land, and other physical interventions lead to environmental problems, primarily climate change and carbon emissions, a decline in biological diversity, an increase in natural disasters, and a growth in waste and residue problems.

Urban areas are responsible for 80% of global production and 70% of total greenhouse gas emissions, and they are also the living spaces most intensely exposed to the effects of climate change, such as heat waves, floods, water scarcity, rising sea levels, food crises, and environmental pollution (The Global Comission on the Economy and Climate, 2014). Urban areas are extremely important priority areas in combating and adapting to climate change. Cities are considered both the primary source of the problem and the target of climate disasters, and at the same time, the most important actors in the solution (Balaban, 2017).

The rapid growth of the urban population, coupled with changes in social, economic, political, and cultural conditions, has led to an increase in horizontal and vertical urbanization and speculative tendencies in land use, particularly due to the demand and dominance of residential, industrial, and other sectors in cities. This has resulted in a decrease in green spaces in both horizontal and vertical dimensions. Green areas are gradually decreasing or becoming insufficient in both horizontal and vertical directions (Gezer & Gül, 2009).

Urban green spaces are one of the most important vital components of a city. They are considered a fundamental element, particularly in terms of the sustainability of the urban ecosystem, the preservation of biological diversity, and the support of the physical, mental, and psychological health of city residents. (Gül & Küçük, 2001; Gül et al., 2020; Gezer & Gül, 2009).

The physical structure of a city is shaped by the ecological, economic, social, and cultural characteristics of the people living in that city and their interactions with each other. However, regardless of the founding purpose of today's cities, almost all of them contain sections or spaces that enable the community to engage in activities related to living, working, entertainment, and recreation. These spaces can be classified according to their functions as residential areas, open and green spaces, commercial and business areas, industrial areas, transportation areas, social facilities, and natural areas (Gül & Küçük, 2001; Gül et al., 2020; Gezer & Gül, 2009).

The overall character of a city emerges from the relationship and interaction between architectural structures, open and green spaces, and transportation areas. Open and green spaces play an important role in balancing the disrupted relationship between humans and nature and improving urban living conditions. Therefore, in developed countries, the quality and quantity of open-green spaces are considered an indicator of civilization and quality of life (Gül & Küçük, 2001; Gül et al., 2020; Gezer & Gül, 2009).

In this context, many developed countries are striving to plan and create urban spaces or ecosystems suitable for human life, taking into account people's physical, intellectual, and mental needs. Urban green spaces are public, semi-private, or private physical spaces covered with natural and cultivated plants, which provide multifaceted biological, climatic, physical,

social, psychological, economic, and aesthetic services and contributions to the city's ecosystem and its inhabitants within and around the city. They are organized according to different green space typologies at the level of the city unit they serve. (Gül et al., 2020; Gezer & Gül, 2009; Türker & Gül, 2022).

In this context, in order to realize the multifaceted services and contributions of open and green spaces, urban planning, design, and management processes must be organized holistically according to certain standards in terms of quality and quantity. In our country, issues such as the conceptual framework, typologies, functionalities, and standards of urban green spaces are addressed in academic circles in both discourse and action. However, it is observed that there are differences and uncertainties in legislation and practice on this issue. In our country, spatial planning and design processes are attempted to be implemented as defined in the relevant legislation. In the Spatial Plans Construction Regulation No. 29030 dated 14.06.2014, open and green spaces are included under the title of urban "Social Infrastructure Areas." Green spaces are defined as Parks, Picnic and Entertainment (Recreation) areas, Children's Gardens, and Public Gardens (Added: RG-01/03/2019-30701) According to the same Regulation (Article 11 and Annex-2 Table); for a population between 0 and 501 thousand, the area for children's playgrounds, parks, botanical parks, zoos, recreation areas, and recreation areas is 10 m^2 per person. In provincial plans, a minimum of 15 m^2 per person is envisaged, including 5 m^2 per person for zoos, urban forests, afforestation areas, fair, fair and festival areas, and hippodromes in settlements with a population between 0 and 501 thousand (Gül et al., 2020; Türker & Gül, 2022).

Urban green spaces are an important part of social infrastructure and public spaces. They provide important services and contributions to the health of society and individuals, as well as to a comfortable and healthy spatial environment. Therefore, public urban green spaces must be easily accessible to all population groups and distributed equitably and fairly at the urban and neighborhood scale (WHO, 2017). It is widely accepted that the urban green space system in Türkiye is addressed solely in terms of quantity, and that green spaces, in particular, are not distributed evenly and evenly throughout the urban area, lack organic connections between green spaces, lack accessibility, and exhibit fragmented distribution within the city (Bilgili et al., 2011; Gül et al., 2020). In this context, legislation needs to address not only quantity but also quality (e.g., green space quality, multifaceted functionality, accessibility, services and contributions, and equitable and fair distribution across the neighborhood and city scales, taking into account the relationship with the population, etc.) as a holistic system. In this context, it is of great importance to integrate the existing urban open and green space inventory into zoning plans, urban design and management processes in detail and to analyze and construct it by taking into account certain standards (Gül et al., 2020; Türker & Gül, 2022).

Demre District, which is affiliated to Antalya Province and 147 km away from the city center, gained village status under the name Eynihal in 1904, became a municipality with the merger of four villages in 1968, gained district status under the name Kale on July 4, 1987 and took its current name, Demre, in 2005.

This study presents the current status of urban green spaces in the Demre district at the urban and neighborhood scales. A holistic approach is employed to analyze and interpret green space typologies, spatial distribution, and population, and to provide strategic recommendations. Using municipal inventory data, satellite imagery, and on-site observations, the current status of urban green spaces (parks, playgrounds, sports fields, recreational areas, etc.) is analyzed

and interpreted at the neighborhood scale in terms of the quantity and spatial distribution of green spaces.

2. Materials and Methods

This study explores the current status of open-green spaces in 17 neighborhoods in the Demre district and conducts quantitative analyses. In this context, quantitative analyses were conducted and interpreted at the neighborhood and urban scales, taking into account the typologies of urban active green spaces in the study area.

2.1. Demre District General Information

Demre District is located on the Mediterranean coast within the borders of Antalya Province, between 29° 20' - 32° 35' east longitude and 36° 07' - 37° 2' north latitude, and is 142 km from Antalya city center. Demre, a district of Antalya Province, is a small, developing rural-urban settlement. Agriculture and tourism are driving forces in the city's economy. Residential construction and greenhouse farming play a significant role in urban development. Demre has a deep and important cultural history dating back to the ancient Lycian period. Rivers originating in the northern mountains converge at the Myros Canyon (Demre Stream) and reach the sea. The current settlement is situated in the plain surrounding this stream. Dalyan lies at the eastern end of this plain, the famous port city of Andriake to the west, and the ancient city of Myra to the northern end.

Demre has fertile agricultural lands in terms of spatial location, and has a very suitable structure for agriculture with its wide plains and red-brown Mediterranean soils, especially enriched by the alluvial soil brought by the Demre Stream (Western Mediterranean Development Agency (BAKA, 2021).

The region, which stands out for its intensive greenhouse farming and citrus production (especially oranges and lemons), is known for its renowned agricultural products such as the "Demre green pepper." The diversity and quality of agricultural products provide the region with high potential for agricultural tourism opportunities such as agrotourism, farm tourism, and organic farming. Economically, Demre stands out with its high-value seafood such as blue crab and shrimp, and makes significant contributions to the local economy thanks to its aquaculture resources.

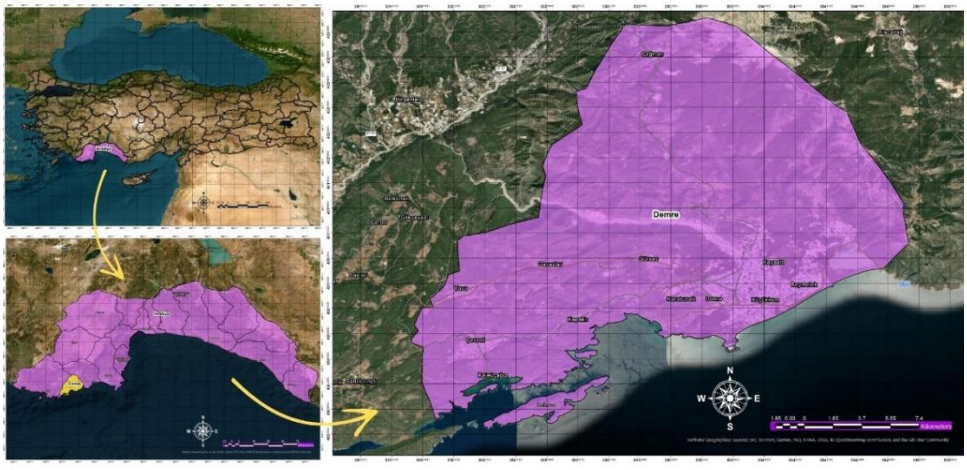

Figure 1. Demre District and its location

The Demre district has a rich potential in terms of its historical and cultural architectural structures and ruins, as well as its unique natural heritage values. Furthermore, the presence of St. Nicholas, known as the birthplace of Demre and a significant figure in Christian history, and his church are considered significant identity assets (Dündar et al., 2024).

Tourist arrivals in Antalya exceeded 14 million in 2025 (between January and September), with more than 13 million foreign tourists and 856,698 domestic tourists. It is estimated that more than 2 million visitors came to the Demre region alone (Turizm Proje Dergisi, 2021).

Within the scope of the Law No. 6360 on the "Establishment of Metropolitan Municipalities and Twenty-Seven Districts in Fourteen Provinces and Amendments to Certain Laws and Decree Laws", all settlements in Antalya province gained the status of "urban settlement" with the borders of the Antalya Metropolitan Municipality becoming the provincial border. However, the settlements that transformed from villages to neighborhoods are of a different nature and are defined as "rural settlement areas" (Antalya Büyükşehir Belediyesi, 2018).

In order to evaluate the socio-cultural and socio-economic potentials of the Demre District, to protect cultural values, to protect rock tombs and protected areas and areas suitable for agriculture, to ensure the continuity of agricultural production, to plan tourism activities to be spread throughout the year and thus to ensure a homogeneous distribution of socio-economic development in the region, the Antalya Demre Culture and Tourism Protection and Development Region was declared (Official Gazette Decision dated 26.07.2010 and numbered 27653) (Antalya Metropolitan Municipality, 2018).

The total area within the boundaries of Demre District with the integrated 1 / 5,000 Scale Master Zoning Plan and the 1 / 1,000 Scale Implementation Zoning Plan is approximately 2,590 hectares. The integrated zoning plans are located within the boundaries of the Demre Culture and Tourism Protection and Development Zone, the repealed Beymelek Municipality, St. Nicholas Church and its surroundings, and Kayaaltı Neighborhood. In these areas, the boundaries of the Master Zoning Plan and the Implementation Zoning Plan cover the same areas. The Demre Culture and Tourism Protection and Development Zone zoning plan covers an area of approximately 1,680 hectares within the boundaries of the Alakent, Büyükkum, Gökyazı, Karabucak, Yaylakaya, and Küçükkum neighborhoods. (Antalya Büyükşehir Belediyesi, 2018).

In the 1/25000 Scale Zoning Plan Report for the Demre District of Antalya Province, the total area of planned open and green spaces within the district borders is 130.0 hectares. Of this area, 76.2 hectares are within the plan approval boundaries, while 53.8 hectares are outside the plan approval boundaries. This report presents the status of open and green spaces according to approved plan decisions; (Antalya Büyükşehir Belediyesi, 2018).

- Park and Green Space 34 Ha
- Afforestation Area: 6.7 Ha
- Recreational Area 9.5 Ha
- Cemetery Area 3 Ha
- Shore and Beach 23 Ha

3. Findings and Discussions

Demre District has 17 neighborhoods. Belören Neighborhood covers approximately 25% of the district's surface area, and Beymelek Neighborhood 13%. However, the neighborhoods with the smallest surface area are Kayaaltı (0.30%) and Alakent (0.52%) (Figure 2. Table 1).

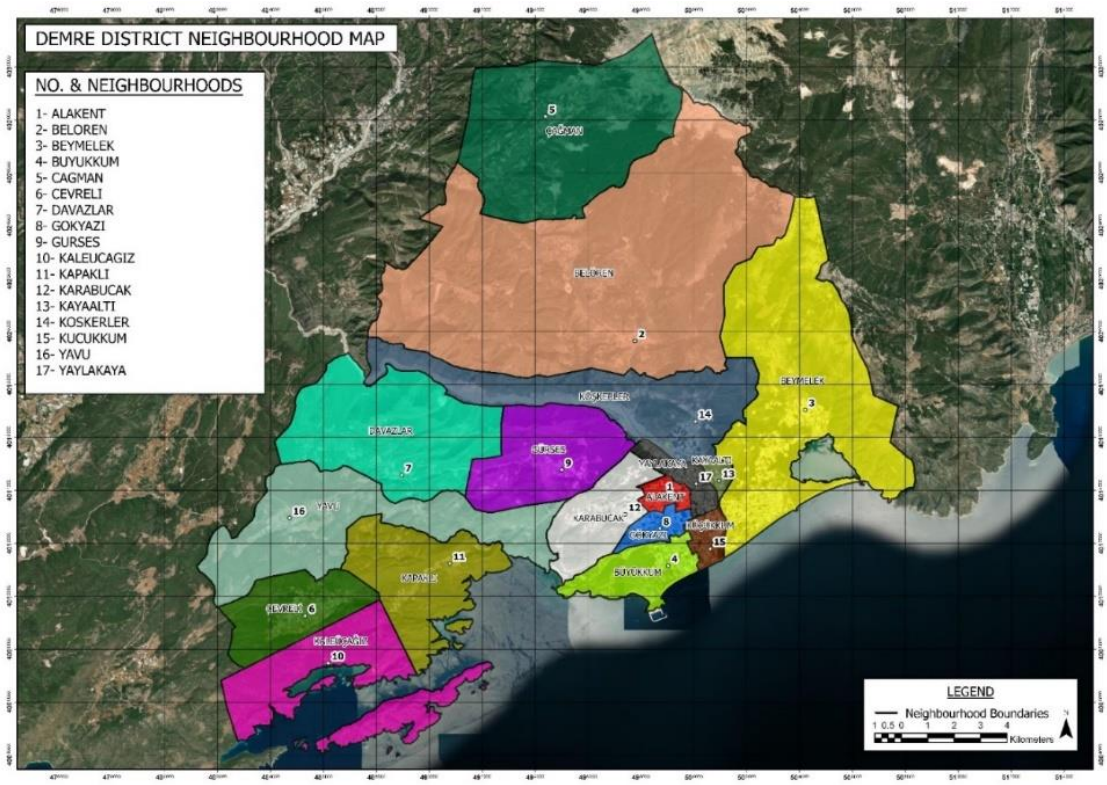

Figure 2. Neighborhoods of Demre District

Table 1. Areas and ratios of 17 Neighborhoods in Demre District

No.	Neighborhoods	Neighborhood Areas (Ha)	Ratio of Neighborhood Area to Demre Area (%)
1	Alakent	195,18	0,52
2	Belören	9583,18	25,73
3	Beymelek	5095,74	13,68
4	Büyükkum	798,77	2,14
5	Çağman	3987,28	10,71
6	Çevreli	1236,97	3,32
7	Davazlar	2981,68	8,01

12	Karabucak	1044,76	2,81

13	Kayaaltı	111,65	0,30
14	Köşkerler	2566,26	6,89
15	Küçükkum	251,55	0,68
16	Yavu	3027,94	8,13
17	Yaylakaya	328,93	0,88
Total		37243,33	100,00

The amount of green space (m^2) per capita in Demre District according to neighborhood populations shows an unbalanced and unequal distribution. According to Table 2, the neighborhoods with the highest per capita green space amounts above 10 m^2 are Beymelek (23.00 m^2), Büyükkum (21.73 m^2), and Küçükkum (11.76 m^2). The other 14 neighborhoods have unbalanced and unequal ratios below 10 m^2. Gürses, in particular, has 0 m2 of green space. However, despite the uneven and unbalanced distribution of green space among neighborhoods in Demre District, the total amount of green space per capita, when compared to the urban population, drops to 12.41 m^2 (Figure 3, Table 2).

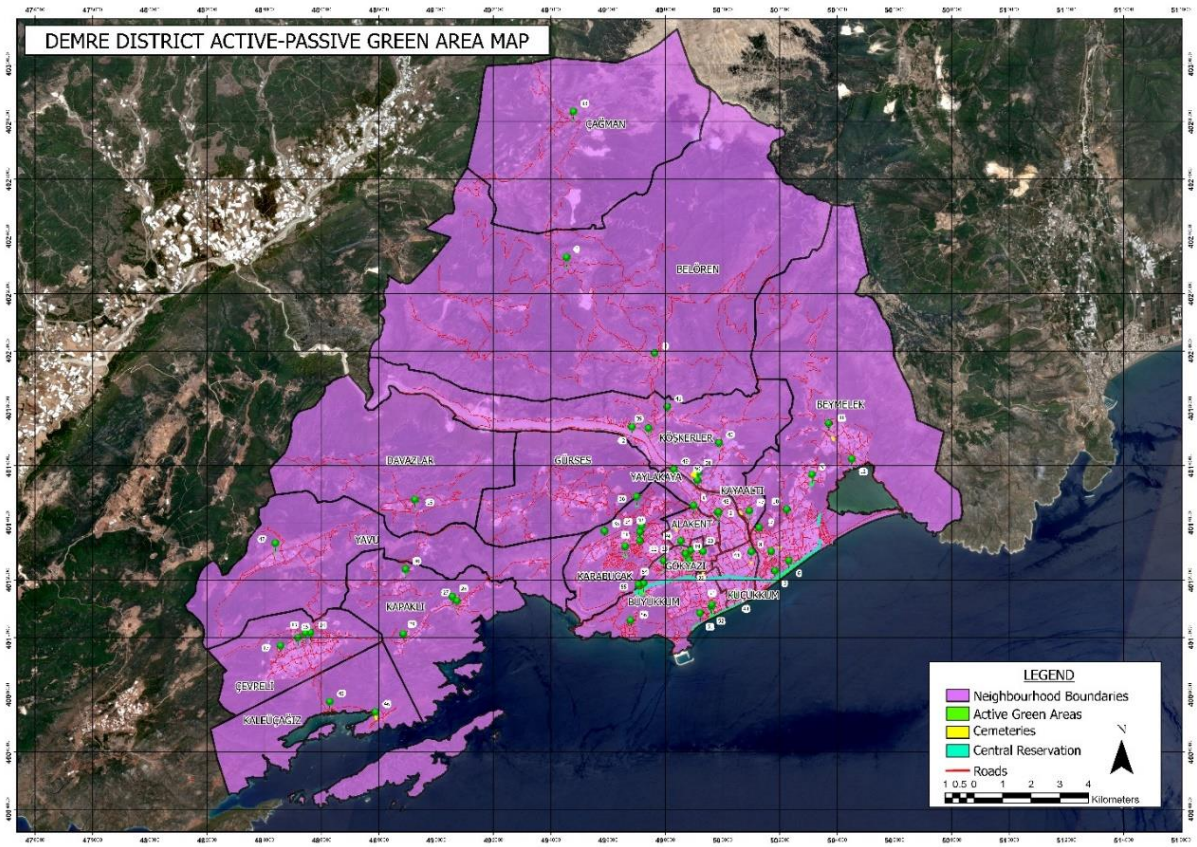

Figure 3. Active green areas of neighborhoods in Demre District

Table 2. Population of the 17 Neighbourhoods of Demre District, green space ratios and green space per capita (m²)

No.	Neighborhoods	Neighborhood Population (TÜİK, 2024)	Total Active Green Space Area (m²)	Amount of Green Space per Person (m²)
1	Alakent	1640	1931,75	1,17
2	Belören	496	3431,71	6,91
3	Beymelek	3686	84786,10	23,00
4	Büyükkum	2878	62556,72	21,73

General Assessment of Demre City's Green Spaces

- The current amount of active green space per capita in Demre is 12.41 m^2, which can be considered sufficient.
- The distribution among neighborhoods is observed to be unequal and unbalanced.
- The ratio of green spaces to the neighborhood's total surface area is less than 1% in all neighborhoods.
- The areas covered by parks within the city are generally small.
- The largest area is Sahil Park, located within the boundaries of Beymelek, Büyükkum, and Küçükkum neighborhoods. It covers 94,332 m^2. There are four parks covering over 1 hectare. Other green spaces range from 2,000 m^2 to 250 m^2.
- The organic connection between parks within the city and with natural areas outside the city is insufficient.
- The variety of activities and facilities in children's and sports playgrounds is limited.

4. Conclusions and Recommendations

To create livable, healthy, and high-quality urban spaces, the city's urban planning process must address the open and green space system in a spatial, locational, and functional hierarchy, with equal, fair, and adequate resources at the city, district, and neighborhood scales, and with functional facilities that will provide multifaceted ecosystem services.

- In order for the municipality to be effective and competent in the management of public green areas for which it is responsible (such as planning/design, implementation, protection, maintenance, repair), its organizational unit should be strengthened with technical staff and auxiliary personnel.
- Urban green spaces should be integrated with green spaces and natural areas within and around the city to create an organic, continuous, and holistic green network system. Green corridors that provide organic connections should be established. Plant species used in green spaces should always be chosen from the region's native species.
- Urban heat islands, green space needs, and wind corridors should be identified and ecological corridors should be created within the urban fabric with accessible green areas and dense natural surfaces.
- Rainwater management should be provided in urban areas and peripheral areas, rain gardens, sponge city details, rain ditches and natural water surfaces should be created, and public spaces should be transformed into a design that collects water during heavy rainfall and transfers it to the storage system.
- Newly planned parks should be designed in larger areas, with the concept of City Parks, Public Gardens and multi-purpose recreation areas.
- Complex children's and sports playgrounds should be positioned in urban green areas and diversified to appeal to all age groups of the city and fit the purpose.
- Empty and unused areas in and around the city should be converted into green areas or these areas should be used as urban agricultural areas to contribute to the food needs of the city.
- Ecological bridges should be designed on the intercity highway passing through the city.
- Green areas should be designed and implemented with sustainable and innovative drainage and infrastructure systems.
- The active participation of urban residents in the planning and management of urban green areas should be ensured and demands and trends should be taken into account.
- To prevent climate change, carbon emissions and biodiversity crisis in the city, a resilient urban fabric should be targeted by creating green areas specific to local conditions (urban parks, green corridors, river corridors, rain gardens, roof gardens, etc.) that include nature-based or hybrid solutions in urban areas.

It is not possible to create smart, healthy and livable cities and ensure their sustainability without designing green areas in integrity and balance with the city.

Abstract

A sustainable smart city exemplifies urban sustainability, representing a desirable state where a city maintains its socio-ecological system balance through sustainable development. This long-term goal necessitates connecting scientific and social research on urban sustainability with technological innovations, institutional practices, and policy design. It also requires a long-term vision, an interdisciplinary approach, and a systems perspective addressing environmental, economic, and social issues. Sustainable smart cities have become understandable and manageable through new dynamic methods and urban science. They are crucial for optimizing operational functioning, management, planning, and governance in line with sustainable development goals. Smart buildings, characterized by energy efficiency, automation, data analytics, and sustainable design, are significant in shaping the smart urban environment. Technological innovations have transformed factor-driven urban development into innovation-driven systems and reduced inequalities between leading and mid-tier cities. However, uneven progress persists, particularly in mobility and infrastructure readiness. By conceptualizing the sustainable smart city as a technological system, this study identified 26 key factors across five infrastructure domains: smart energy, mobility, water, security, and waste management. The study identifies and examines these key factors through a holistic, multidimensional assessment framework derived from the literature review. Consequently, the potential of data-driven smart solutions, termed "environmentally data-driven sustainable smart cities," in advancing urban sustainability will be evaluated.

Keywords: Sustainability, smart city, technological innovation, sustainable smart city, smart systems.

1. Introduction

The acceleration of urbanization, climate change, and resource constraints have highlighted the need to transform cities into more sustainable, resilient, and data-driven systems. In this context, the concept of “smart cities” emerged, but over time, the necessity of integrating technology with sustainability goals has become increasingly emphasized.

Smart cities are characterized as resilient and inclusive urban areas developed collectively, utilizing various technologies and data to enhance the quality of life for all residents. They may

be regarded as cities excelling in six attributes: economy, populace, government, mobility, environment, and quality of life (Giffinger et al., 2007), (Figure 1).

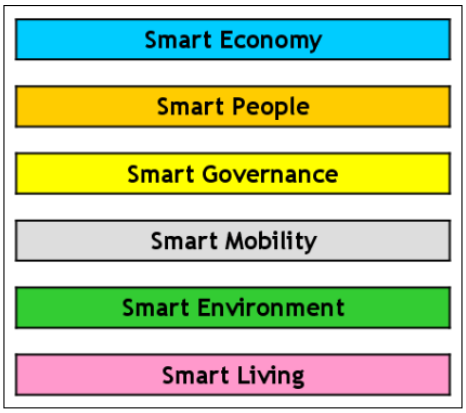

Figure 1. Characteristics of a smart city (Giffinger et al., 2007).

Currently, several nations are developing smart cities to address urban sustainability challenges. Information and Communication Technologies (ICT) are being used to address many fundamental issues such as traffic, pollution, overcrowding, energy, water, and poverty. The literature on sustainable cities encompasses approaches that aim to integrate the environmental, economic, and social dimensions of cities. Within this framework, the goals of resource efficiency, low-carbon infrastructure, social inclusiveness, and long-term livability are emphasized (Javidroozi et al., 2023). In particular, it is emphasized that cities must become systems that can be monitored and guided through indicators such as energy consumption, waste management, water use, and carbon emissions. In this context, sustainable cities are not solely about environmental solutions but also incorporate contributing factors such as social equity and economic vitality (Bibri, 2021).

Sustainable cities focus on renewable energy, water and electricity efficiency, compact urban design, building upgrades, green spaces, inexpensive transportation, and trash management and recycling systems. Urban areas in developing nations require resources to facilitate the transfer of green technologies and enhance capacity development. Furthermore, it is essential to enhance access to built housing, water, sanitation, power, healthcare, and education. Figure 2 illustrates the four principal pillars of sustainable cities and their prerequisites (Konbr, 2019)

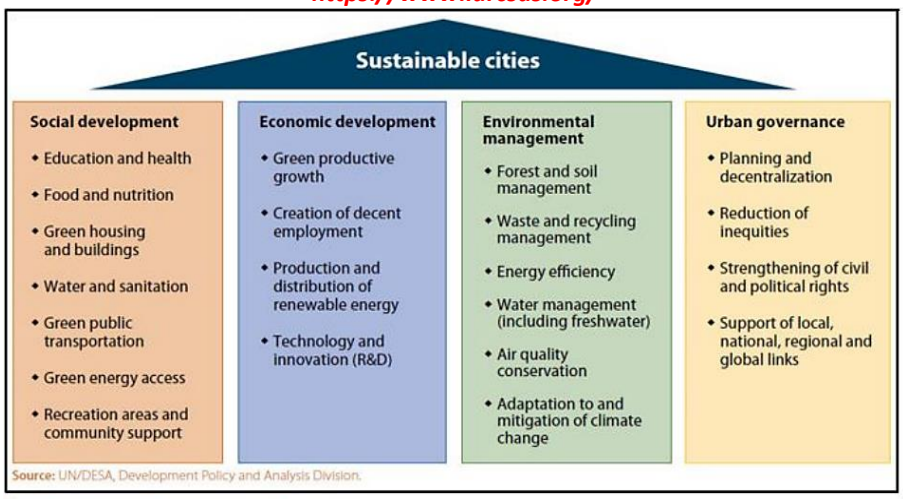

Figure 2. The four main pillars of sustainable cities (Konbr, 2019)

The acceleration of urbanization, the increasing impacts of climate change, and the narrowing of environmental boundaries related to resource use have brought to the forefront the need to transform cities into more sustainable, resilient, and data-driven systems (Ateş, 2024). Cities must now not only expand their infrastructure but also redesign it in an integrated manner from technological, environmental, and social perspectives (Angelidou, 2017). In this context, the concept of "smart cities" emerged; however, over time, the need to combine this technology-focused approach with sustainability goals has also been expressed (Javidroozi et al., 2023). In this process, the more effective role of data in city management has paved the way for new conceptual orientations such as "data-driven smart sustainable cities" (Bibri, 2021).

The concept of smart cities initially focused on optimizing infrastructure and services through information and communication technologies (ICT), sensor networks, big data, and IoT systems. On the other hand, sustainable city literature embraces broad approaches that combine environmental, social, and economic dimensions. City models at the intersection of these two streams-particularly those that combine environmental goals with technology and participation mechanisms-are increasingly emphasized in the literature (Toli and Murtagh, 2020).

In intelligent sustainable cities, an integrated and comprehensive urban planning model emphasizes the amalgamation of the advantages of sustainable and smart cities to enhance the creative, data-driven technologies provided by smart cities and their role in achieving sustainability objectives. (Bibri and Krgostie, 2020).

Due to the fact that the literatures on smart cities and sustainable cities have developed separately, there is a gap regarding the integration of these two movements. One concept that fills this gap is "smart sustainable cities". This paradigm proposes not only equipping cities with technology but also managing technology in tandem with sustainability goals (Kramers et al., 2014).

For a city to earn the label "smart," it must have an urban plan that both promotes sustainability and demonstrates urban resilience (Angelidou, 2017). In fact, it has been concluded that smart cities cannot be evaluated separately from sustainability, nor can sustainability be evaluated separately from urban resilience (Arafah et al., 2018). The Sustainable Smart Cities idea represents an innovative approach to the integration and discourse surrounding the application

of ICT in daily urban living. It assists in addressing escalating urbanization trends, including minimizing urban expenditures, controlling urban complications, enhancing quality of life, and augmenting energy efficiency. A smart city aims to improve environmental, social, and economic conditions. These constitute the fundamental foundations of sustainability. Consequently, it enhances sustainable urbanization. (Konbr, 2019).

This study has identified 26 key factors linking five infrastructure areas through the conceptualization of sustainable smart cities using a systems approach. These factors were identified and discussed through a literature review and focusing on the technological aspects that influence the incorporation of intelligent structures inside intelligent urban environments (Shahrabani and Apanavičienė, 2022).

2. Research Methodology

This study is primarily conceptual and theoretical, seeking to amalgamate existing knowledge and formulate a cohesive framework for comprehending sustainable smart cities. The principal methodology utilized is an exhaustive, critical literature review aimed at identifying, analyzing, and systematizing the essential technological factors that form the infrastructural foundation of sustainable smart cities. This method aligns with recognized academic standards for constructing conceptual models and theoretical frameworks in nascent, interdisciplinary domains like urban science and technology studies (Kitchin, 2014; Bibri, 2021). The research process was carried out in three methodical stages, detailed as follows and summarized: Collecting Literature, Defining the Scope, Thematic Analysis, Creating a Framework.

2.1. Scoping and Literature Collection

The first step was to figure out what the review would cover and find relevant scholarly work. To delineate the extensive intellectual landscape at the convergence of "smart cities" and "urban sustainability," with a particular emphasis on technological and infrastructural elements. A systematic search was conducted across major academic databases, including Scopus, Web of Science, and Google Scholar. The examine used Boolean operators with key term combinations like: ("smart city" OR "urban technology") AND ("sustainability" OR "sustainable development") AND ("infrastructure" OR "system"). The search was not limited by a strict start date, but it did focus on literature from the last twenty years to capture the evolution of the discourse. The review concentrated on peer-reviewed journal articles, foundational texts, and authoritative reports from international organizations. Key foundational works (e.g., Giffinger et al., 2007; Angelidou, 2017; Bibri & Krogstie, 2020) served as reference points to follow up on later research and find common themes.

2.2. Thematic Analysis and Finding Identification

During this analytical phase, the gathered literature was scrutinized to extract fundamental concepts and particular factors. A thematic analysis methodology was employed. This was an iterative process of closely reading, coding, and sorting the text data from the chosen sources. The first step was to tag passages that talked about technological solutions, infrastructure systems, and integration problems in the context of smart and sustainable cities. "Energy storage," "mobility-as-a-service," "water monitoring," and "integrated security" were some of the codes that came up the most. After that, these codes were put into larger, more coherent groups based on things they had in common and the functions they served. This inductive process naturally led to the emergence of five core infrastructural domains: Smart Energy,

Smart Mobility, Smart Water, Smart Security Systems, and Smart Waste Management. For each domain, specific, actionable technological factors were listed, which led to the discovery of the 26 key factors that are important to this study. This classification corresponds with the perspective of the city as a complex technological system consisting of interdependent subsystems (Hämäläinen & Tyrväinen, 2018; Shahrabani & Apanavičienė, 2022).

2.3. Framework Synthesis and Conceptualization

The last step was to put all the findings together into a clear conceptual model. The five domains and the 26 factors that make them up were put together to show how they are connected and how they all work together to make the city's "digital nervous system." This synthesis goes beyond just listing things. It suggests a systems-based framework where factors don't stand alone but work together within and across domains. The integrated conceptual framework shown in Figure 3 is the main result of this methodological process. This framework shows the sustainable smart city as a technological system, with the five infrastructure areas acting as pillars and the 26 key factors connecting them. It provides a structured way to look at all the technological aspects of urban sustainability. This method makes it clear and easy to go from looking at a lot of different sources to creating a specific, factor-based conceptual framework. This meets the study's goal of evaluating sustainable smart cities by figuring out what their most important technological parts are.

3. Key Factors of Sustainable Smart Cities

A sustainable smart city requires adopting a systems perspective that addresses environmental, social, and economic variables as a city's long-term goal. In this study, the concept of a smart city is approached as a system based on establishing an organic connection between all components and factors of the complex urban system. The city is conceptualized as an urban ecosystem that integrates physical, institutional, and digital domains by revealing aspects such as interconnection, feedback, self-organization, and adaptation to enable the understanding of spontaneous growth, functioning, and evolution. This systems approach aims to help cities and their stakeholders implement robust smart city initiatives and develop sustainable smart city ecosystem designs (Hämäläinen and Tyrväinen, 2018). In this study, the sustainable smart city is conceptualized as a technological system, and this approach strengthens the link between new technological developments and increasing responsibility (Kitchin, 2014).

With the conceptualization of sustainable smart cities as technological systems, the study identified 26 key factors affecting the integration of smart buildings into smart cities across five fundamental infrastructure areas (Shahrabani and Apanavičiene, 2022). The impact factors identified for the integration of smart buildings into smart cities are presented and discussed with a focus on the following key infrastructure areas:

- Smart energy
- Smart mobility
- Smart water
- Smart security systems
- Smart waste management

These five infrastructure areas form the five pillars of the city's digital nervous system.

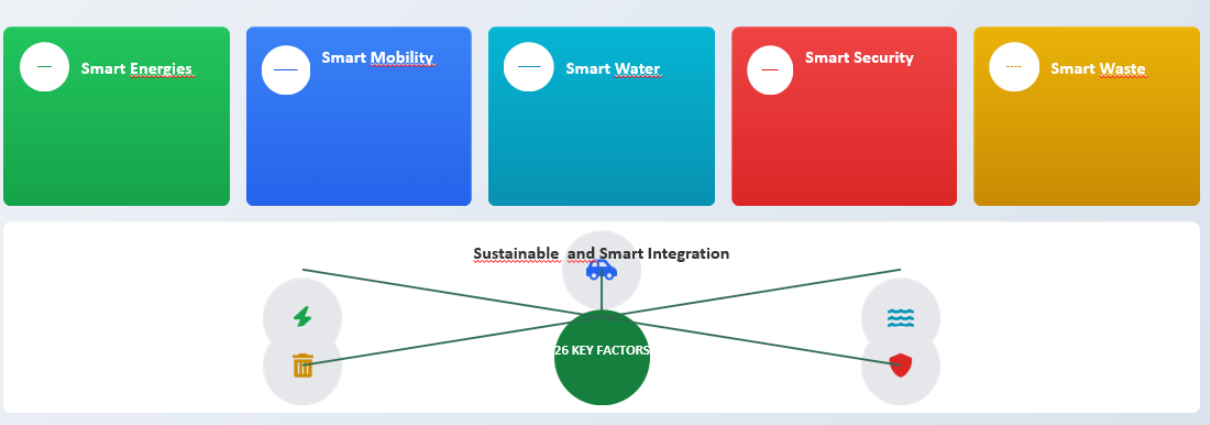

Figure 3. Conceptualized using a systems approach, sustainable smart cities form an integrated structure with 26 key factors connecting these five infrastructure areas.

3.1. Smart energy systems

Smart energy systems emphasize energy efficiency, automation, and the use of sustainable energy sources. Smart energy systems aim to save energy, reduce CO^2 emissions through lower energy consumption, and increase renewable energy sources (Tan et al., 2021). To reach energy resilience and decarbonization goals on a citywide level, these systems need to work together. For example, modern smart grids use advanced metering infrastructure (AMI) and real-time data analytics to dynamically balance supply and demand. They also include distributed energy resources like rooftop solar panels and community battery storage (Zhou et al., 2023). The Peña Station NEXT development in Denver, Colorado, USA, is a well-known example. It is a microgrid that combines solar generation, battery storage, and smart building controls to achieve net-zero energy performance and provide grid services. This shows how a localized smart energy ecosystem can work and be useful in a larger urban setting (Smith & Brown, 2022).

1. Electrical energy storage (battery)
2. Sharing electrical energy storage
3. Ability to work off-grid (renewable energy source: solar wind)
4. Energy use monitoring and control, demand-side management
5. Smart heating, cooling, and hot water preparation
6. Thermal energy storage
7. Sharing thermal energy storage

3.2. Smart mobility

The smart mobility component supports ICT-enabled transportation systems and is related to urban logistics and infrastructure. Smart mobility is designed to reduce traffic congestion, promote sustainable mobility, and increase the accessibility of public transportation (Zapolskyte et al., 2020). This field is quickly moving away from static management and toward Mobility-as-a-Service (MaaS) ecosystems. These ecosystems bring together different types of transportation (public transit, ride-sharing, bike-sharing, and e-scooters) into one user-friendly digital platform. These kinds of platforms use real-time data, IoT sensors, and AI-driven

analytics to find the best routes, predict demand, and make multimodal trips easier, which means people don't have to rely on their own cars as much (Jittrapirom et al., 2022). The "Whim" app in Helsinki, Finland, is one of the best real-world examples. It lets users plan, book, and pay for all types of urban transportation with just one monthly subscription or pay-as-you-go model. This system shows how data-driven integration can change how people use transportation to make it more efficient and environmentally friendly. It sets a standard for smart mobility integration around the world (Helsinki Region Transport, 2023).

- Smart Electric Vehicles (EV) charging
- Carpooling–ride sharing
- Smart parking management system (E-parking)
- Sharing parking space
- Online video surveillance
- Last mile driving

3.3. Smart water management

The field of water management focuses on optimizing resource consumption and ensuring environmental sustainability. Smart water management purpose to use efficient water resources, wastewater management, and environmental protection (Oberascher et al., 2022). This is becoming more and more important because of climate change and the stress on urban water supplies. Modern systems use a network of smart sensors, IoT devices, and predictive analytics to keep an eye on water quality in real time, find leaks in the distribution network before they happen, and improve irrigation and consumption patterns (Mukhopadhyay & Suryadevara, 2023). The "CityTaps" smart prepaid water meter system in Niamey, Niger, is a groundbreaking example. This solution uses hardware (IoT meters), software, and mobile payment to give low-income households access to clean water 24 hours a day, seven days a week. It also helps the utility reduce non-revenue water (NRW) by finding leaks quickly and collecting more money. This case shows how smart water technology can help with sustainability, fairness, and utility operational efficiency all at the same time in a difficult urban setting (CityTaps, 2022).

- Smart water mixtures
- Smart water monitoring and shutoff
- Smart water irrigation system
- Smart water meter
- Greywater recycling
- Rainwater collection (harvesting) and reuse

3.4. Smart security systems

Smart security systems cover individual security, public safety, and security. Smart security systems point to maximize services for city users while also controlling security (Khairuddin et al., 2021). The growth in this domain is marked by a shift from disconnected monitoring to connected, anticipatory security ecosystems. These environmental systems leverage AI-powered video analytics, bullets identification sensors, crowdsourced data from citizens, and

cooperation with emergency reply platforms to enable proactive threat detection, real-time situational awareness, and faster incoming resolution (Kumar et al., 2023).

The "Safe City" project in Singapore is a good example of a full implementation. It connects more than 110,000 police cameras to data analytics platforms, drone surveillance, and mobile apps that let citizens report crimes. This system utilizes video analytics for gather monitoring and identifying anomalies, and connects effortlessly with emergency services, creating a multi-layered, data-driven security infrastructure which boosts both proactive policing and public trust (Singapore Police Force, 2023).

- Smart monitoring and data analytics of the surrounding environment
- Smart fire management
- Disaster event communication management
- Smart security lightning
- Integrated sensors solutions

3.5. Smart waste management

Smart waste management aims to ensure the sustainable management of natural resources and reduce pollution and effective waste management (Shukla and Hait, 2022). It marks a big change from traditional collection systems that are based on schedules to ones that are based on data and respond to demand. Cities can save a lot of money, gas, and greenhouse gas emissions by using smart bins with fill-level sensors, vehicles with GPS, and AI-powered route optimization software. These systems make it possible to change collection routes on the fly, stop bins from overflowing, and give useful information for planning ways to reduce waste and improve recycling rates (Zaman & Lehmann, 2023). The system used in Seoul, South Korea, is a good example of a large-scale implementation. The city has put in thousands of smart bins in public places. These bins automatically compact trash and send real-time fill status to a central management platform. This information is used to make truck dispatch more efficient, which can cut down on collection frequency by up to 40% in some areas and make the city's waste management operations much more efficient and environmentally friendly (Seoul Metropolitan Government, 2023).

- Smart waste containers
- Automated and robotic waste collection

These core component are not only engineering projects but also architectural and design elements that directly shape the urban experience.

4. Conclusion

This study was designed to evaluate the essential infrastructural aspects of sustainable smart cities via a methodical integration of existing literature. The study sought to unify the frequently disparate discussions surrounding smart urban technologies and long-term urban sustainability by conceptualizing the city as an integrated technological system, thereby offering a structured framework for comprehending their intersection.

The main result of this in-depth study is the identification and grouping of 26 key technological factors into five key infrastructure areas: Smart Energy, Smart Mobility, Smart Water, Smart Security Systems, and Smart Waste Management. These fields work together to make up the

operational backbone, or "digital nervous system," of a smart city that will last. The framework shows that individual innovations, like smart grids, charging stations for electric cars, intelligent water meters, and automated waste collection, should not be seen as separate things but as parts of a whole that work together to make cities more efficient, resilient, and environmentally friendly. This focused analysis also delineates a clear boundary: the framework is predominantly concerned with technological and infrastructural factors. This makes governance, social equity, citizen participation, and financial models stand out as important areas that need to be integrated with the framework for comprehensive urban development.

The results provide substantial dual contributions. In theory, this work brings together bits of information into a single model, directly filling the gap in the literature about how to combine smart and sustainable city ideas. In practice, the derived framework is an important diagnostic tool and strategic plan for people who work in cities. It gives policymakers and planners a list of things to check to make sure that all technologies are covered and that their plans are in line with sustainability goals. It stresses the need for technology developers and urban planners to make solutions that work together in this larger, interconnected urban ecosystem. This will help them build cities that can meet the needs of a growing urban population.

It is essential to recognize the constraints inherent in the scope and methodology of this study. First, as stated, the framework is deliberately focused on technology, providing a comprehensive overview of infrastructural elements while neglecting the equally significant socio-economic, cultural, and governance factors that influence the success and fairness of smart city projects.

Second, the study offers a conceptual framework developed from literature synthesis; it does not provide a ready-to-use assessment methodology with specified metrics or weightings, nor does it empirically validate the relative significance or interdependence of the identified factors through case-specific analysis.

These constraints delineate a definitive agenda for forthcoming research. Future research should concentrate on the operationalization of this framework through the creation of precise assessment indicators and metrics. The next step is to test the framework's relevance and adaptability by using it in real-life situations in specific cities. Additionally, research needs to grow to include the non-technological parts of sustainability. It is important to use methods like Multi-Criteria Decision Making (MCDM) to look at the 26 factors' priorities, weightings, and cause-and-effect relationships.

Lastly, it is important to investigate the social acceptance, economic viability, and inclusive governance models needed to put these technological solutions into action. The successful realization of sustainable smart cities ultimately depends on a synchronized strategy that combines advanced technology with robust governance and inclusive design. This study offers a foundational overview of the technological landscape, seeking to facilitate more cohesive and efficient strategies for developing resilient and sustainable urban futures.

Abstract

Child-friendly streets are defined as accessible public spaces where children can safely walk around, play, and explore their surroundings. The spatial functionality and accessibility of streets determine children's interaction with the city. In child-centered urban approaches, elements such as child development, child participation, safety, accessibility, and the right to play are important. Insufficient play areas and traffic problems, along with dense urbanization, keep children away from outdoor spaces. This situation negatively affects children's development. Streets, which are heavily used by children in the context of public spaces and also serve as alternative play areas, form the focus of this study. Studies have been conducted on the role of street use in child development and the qualities that child-friendly streets should possess. The main objective of the study is to evaluate child-friendly streets at the national and international levels, examining them in terms of their compliance with child-friendly street criteria and assessing the effects of different planning and design approaches. In this context, the study outlines "child-friendly street" design criteria and provides visualizations based on these criteria.

Keywords: Child friendly city, urban area, design

1. Introduction

The increasing traffic problem associated with urbanization has led to the creation of unsafe spaces for movement on the streets that constitute children's living environments. The decline in green areas and the increase in concrete surfaces, which prevent children from establishing games that would allow them to socialize with their peers and contribute to their sensory, cognitive, and physical development, have over time weakened the child-city relationship and accelerated their dependence on the virtual world. This situation has revealed how crucial it is for children to have spaces within the city where they can socialize with their peers without leaving their immediate living environments. At this point, the concept of child-friendly cities has emerged, advocating for urban spaces that enable children to be more active in the city and contain areas that support their physical, social, and mental development. The concept of a child-friendly city aims to plan and create spaces in children's living environments and immediate surroundings where they can feel safe, play freely, and engage in activities that support their development (Churchman, 2003). Considering that the most frequently used spaces by children are homes, their immediate surroundings, schools, and playgrounds, the spaces children use and spend time in significantly influence their individuation process and behavioral psychology (Tandoğan, 2014; Karakuzu & Aksu, 2022). Therefore, designing or redesigning streets that can play an effective and healthy role in children's development according to their needs and desires is of great importance, and the emphasis on the concept of child-friendly streets needs to increase. With the growing awareness of the child-friendly street concept worldwide, it is possible to make the city more usable for children every day. In many countries, measures such as traffic restrictions and speed limits on streets have been

implemented. The primary goals of such applications are to develop play and exploration areas for children and to ensure that a significant portion of children's time is spent in safe, enjoyable, playful, and relaxing environments (Tandoğan, 2014; Collarte, 2014; Turan, 2020). The concept of child-friendly streets, which first appeared as "play streets" in 1938, was legalized by the United Kingdom and later adopted by Australia. It continues to be implemented in many cities in the USA as well (Sauer, 2024) (Figure 1).

Figure 1. Early Examples of Play Streets (URL-1, URL-2)

Based on the concept of play streets, these areas were created and began to proliferate in the 1970s with the support of neighborhood associations, aiming to preserve a social neighborhood culture while serving children and adolescents. Their numbers increased, particularly in densely populated areas, with the support of local institutions and organizations.

This study aims to provide information on the concept of child-friendly streets, highlight the importance of the topic, and raise awareness. In line with this objective, both domestic and international applications related to the subject are presented.

2. Child Friendly City

The creation of child-friendly environments is of paramount importance for enhancing urban resilience and supporting sustainability. However, as urbanization in our cities increases uncontrollably, the needs for children also rise, leading to imbalances between supply and demand in urban areas. This density in urban spaces has gradually reduced the interaction between humans and nature, weakening their connection. Simultaneously, due to technological advancements, environments have emerged that distance children from traditional forms of entertainment, restrict their movement spaces, reduce their physical activities, and negatively impact their physical and mental development (Engler et al., 2015; Witten et al., 2015; Bringolf-Isler et al., 2018; Chu et al., 2025). Furthermore, focusing solely on children's mental and academic development while neglecting behavioral patterns and psychological health has led to an increase in behavioral disorders. In the long term, this negatively affects learning processes, personal development, and character formation, pushing children towards antisocial behavior (Dong et al., 2025; Zhang et al., 2025).

Creating child-friendly urban areas is critically important for healthy child development. Due to the effects of rapid urbanization, primary spaces for children's activities, such as streets and pathways, are gradually disappearing. This situation highlights the urgency of improving urban planning to address children's needs in high-density areas. Recently, with a child-friendly approach, there has been a growing focus on regulating physical environmental factors of streets—such as walkability, traffic safety, green space levels, and infrastructure—to influence

children's travel behavior and safety perceptions. Thus, safe, healthy, and play-conducive environments will be created in streets and their immediate surroundings, positively impacting children's well-being. However, various limitations remain, such as the lack of children's inclusion in the planning process and the micro-scale nature of these efforts.

As stated in UNICEF's Convention on the Rights of the Child, the child-friendly city approach advocates for cities to be built without discrimination, prioritizing children's best interests, offering the right to life and optimal development, and respecting and considering their views and opinions. Therefore, it can be said that child-friendly cities adopt a governance approach based on children's rights (Riggio, 2002). The significance of this issue is also evident when health data is examined. Health data indicates an increase in childhood heart diseases, diabetes, and obesity (Hills et al., 2007; Mavrovouniotis, 2012). Consequently, urban planning policies and urban design guidelines should prioritize healthy and child-friendly urban environments.

3. Child-Friendly Street

The concept of child-friendly streets first gained attention with a street redesign implemented in the Netherlands in 1960. Known as "Woonerf," this intervention involved reducing vehicular traffic, creating a pedestrian-friendly, walkable environment, and encompassed everything from street furniture to overall road use to foster child-friendly spaces (Tandoğan, 2014; Aydoğan & Dilek, 2024). Following this example, various other applications have emerged in different regions worldwide.

In the United Kingdom, the concept was implemented under the name "Home Zone," based on the Woonerf system. Home Zones primarily focused on fostering socialization within the street, aiming to enhance the quality of life not only for children but for all users. Vehicle speeds were reduced to 10 km/h, and green spaces and areas for activities were allocated in front of residences, thereby enabling a wide range of activities and expanding the user base.

In Australia, this approach, initiated as "Shared Zones," is characterized as a street design focused on sharing and interaction, encompassing both pedestrians and vehicles (Figure 2).

Figure 2. Child-Friendly Street Example (a: Woonerf – URL-3; b: Home Zone - URL-4; c: Shared Zone – URL-5)

In Turkey, the child-friendly street approach has also been implemented, with designed streets present in many provinces such as Kocaeli, Sakarya, Bursa, and Tekirdağ. In some arrangements, traffic is completely closed off and the space is dedicated to children, while in others, streets are closed to traffic during specific hours (Figure 3).

Figure 3. Child-Friendly Street Implementations in Turkey (URL-6)

In child-friendly street designs, basic needs must be prioritized. By ensuring streets are safe, accessible, and provided with adequate infrastructure, users should be offered secure spaces where they can interact, engage in physical activity, and relax. Applications should be incorporated that allow children to ride bicycles, enable families to socialize, promote walkability, and enhance interaction with nature—thereby shifting children's engagement, even if slightly, from the virtual world to interaction with the real world.

4. Conclusion and Recommendations

Today, the rapid evolution of cities towards high-density development models, a planning approach prioritizing motorized vehicle traffic, and lifestyle changes brought about by digitalization have emerged as primary factors threatening children's physical and mental health. Current urban strategies fail to adequately realize the potential to redefine streets beyond mere transportation corridors as social and inclusive public spaces. This situation restricts children's freedom of active mobility, promotes sedentary lifestyles, and consequently paves the way for health issues such as obesity and respiratory diseases. Research demonstrates that child-friendly street design is not merely a matter of urban aesthetics; rather, it is of vital importance for children's physical activity, mental well-being, social development, and the construction of a sense of independence.

Children, who will be the adults of the future, will make a meaningful contribution to raising socially, cognitively, mentally, psychologically, and physically healthier individuals by connecting with the physical environment and nature, through the creation of safe public spaces, familiar environments that promote social cohesion, and pedestrian-friendly streets that support active transportation. To guide policies aimed at promoting walkable and child-friendly cities, a swift transition to spatial interventions targeting children's health and well-being is necessary for policymakers, and children must be included in the planning and design process. Greater emphasis must be placed on the issues of children's inadequate play in open and nearby spaces and social isolation. In the face of increasing urbanization, new urban arrangements must be implemented that also take children into account.

Healing Garden Designs as Supportive Elements in Oncology Hospitals

İpek İPEKLİ [1]

ORCID 1: 0009-0009-8583-180X

Abstract

Healing gardens are areas that strengthen communication between the individual and nature, feature natural elements prominently, contribute to the reduction of stress, and enhance the quality of life. User groups are among the most important guiding factors in the design of healing gardens, which have a history extending from the Middle Ages to the present day. In areas where the user group specifically consists of hospital users, gardens designed with the aim of contributing to the recovery process can support individuals' psychological and spiritual well-being by distancing users from environmental stress. In this context, the physical environment in which cancer patients, who are in most need of psychological support during treatment, find themselves due to the ailment they are exposed to, is highly significant for them. Their adaptation to the hospital and feeling well in their environment can lead to progress in the recovery process in psychological, social, and physical terms. Within this scope, a healing garden design was developed in the study for the open and green space of an oncology hospital, based on the area's users. The study aimed to reveal the importance of hospital gardens for oncology patients and to develop a design that includes healing garden design criteria for oncology hospitals, which can meet the spiritual, physical, and social needs of the users. At the oncology hospital studied, interviews were conducted with hospital users, and based on their expectations, needs, and requests, recommendations to support the psychological recovery process were developed, guiding the designs. In the study, 2-dimensional designs were prepared using the Autocad 2022 program, and 3-dimensional modeling was performed using Sketchup 2023 and Lumion 2025 programs, and the final reports were shared with the hospital administration.

Keywords: Healing garden, oncology hospital, landscape design, Diyarbakır

1.Introduction

The concept of "healing" refers to positive changes and improvements in an individual's health condition. This process is a state where the person feels well both spiritually and physically. Throughout history, people have continued to benefit from nature. Therapeutic gardens, which are reported to have started with monastery gardens used for functions similar to hospitals, have a deep-rooted history based on Roman, Greek, and Asian cultures (Akpınar Külekçi & Sezen, 2020; Akpınar Külekçi & Yazıcı, 2021). It can be argued that gardens support recovery processes and shorten treatment times due to their many features. Being in contact with nature or in environments reminiscent of nature, benefiting from sunlight, seeing plants, listening to animal sounds, and being aware of natural elements in the garden can create stress-reducing effects on patients and contribute to the healing process (Lani Alaine Gerity, 1998; Akın, 2006; Hussein, 2010; Demirel & Pouya, 2017; Çetinkale Demirkan, 2019).

Considering that humans have benefited from the possibilities of nature since their existence, it is evident that therapeutic gardens have a deep-rooted past. Looking at Turkish history, it is known that courtyards were surrounded by plants, and patients were treated in rooms within

them, while music was also used for therapeutic purposes. Furthermore, in history, Far Eastern gardens, used for meditation to relax, have been shown to be effective in solving many spiritual problems. It is also known that Zen gardens have positive effects in alleviating depression (Akpınar Külekçi & Sezen, 2020; Akpınar Külekçi & Yazıcı, 2021). In this regard, it is possible to speak of the healing properties of gardens created for different purposes.

When examining approaches to therapeutic garden design, different theories stand out: Kaplan's Theory, which states that designs should be based on criteria such as complexity, coherence, legibility, and mystery, allowing users to understand the environment, as well as escape, size, attractiveness, and compatibility; Marcus and Barnes' Theory, which suggests that gardens should offer elements such as privacy, socialization, the allure of nature, activity, sun-shade areas, walking opportunities, accessibility, comfort, and recognition to provide emotional support to users; and Ulrich's Theory, which advocates for creating natural environments that reduce stress and are psychologically, behaviorally, and physiologically beneficial. However, at the core of all approaches, it is emphasized that therapeutic garden designs should include area diversity, spaces specific to user groups, density of green areas, opportunities for physical activity, stimuli that aid concentration, protection from external stimuli, and easily understandable, positive designs (Ulrich, 1984; Kaplan & Kaplan, 1990; Ulrich et al., 1991; Marcus & Barnes, 1999; Marcus, 2007).

Looking at therapeutic gardens in oncology hospitals, it is observed that a multifunctional and flexible design approach dominates. Courtyard gardens, window views dominating indoor spaces, habitats attracting wildlife, and a focus on relaxation and tranquility are prevalent (Figure 1, Figure 2). In these areas, which are used not only by patients but also by caregivers and staff, designs incorporate elements such as water features, dense green areas, unique landscapes, and natural sounds to utilize the curative power of nature in reducing anxiety and stress (Figure 3). It is notable that social spaces are created where users can socialize not only with their companions but also with other users, and area usage options are varied (Figure 4).

Figure 1. Upper Chesapeake Cancer Center (Url-1)

Figure 2. Upper Chesapeake Cancer Center (Url-2)

Figure 3. Yale New Haven Smilow Cancer Hospital (Url-3)

Figure 4. Garden areas for dementia and alzheimer patients (Url-4)

In addition to many other illnesses, the physical environment in which cancer patients find themselves is extremely important due to the condition they face. Because of the process they are undergoing, hospital gardens designed for them play a significant role in helping cancer patients adapt to the hospital, feel better, and experience social, psychological, and physical development.

This study aims to demonstrate the importance of hospital gardens for oncology patients and to develop a design that includes therapeutic garden design criteria for oncology hospitals, capable of meeting the mental, physical, and social needs of users.

In hospital garden design, the interaction of people with the space, aligned with their needs, holds particular importance. The most crucial feature that distinguishes hospital gardens from other gardens is that these areas are designed to support patients' treatment processes (Hussein, 2012). Therefore, when designing a hospital garden, planning and design have been guided to meet the needs of the area's users, based on the user profile of the cancer hospital.

2.Material and Methods

a. Material

The main subject of the study is the Dicle University Oncology Hospital located in Diyarbakır. Diyarbakır province is situated in the Middle Euphrates Section of the Southeastern Anatolia Region and is one of the region's significant settlement centers. Geographically, it is surrounded by Elâzığ to the north, Bingöl and Muş to the northeast, Batman to the east, Mardin to the southeast, and Şanlıurfa to the southwest. Due to this location, Diyarbakır serves as a transitional area between both the Eastern Anatolia and Southeastern Anatolia regions. The Dicle University Oncology Hospital, located within the boundaries of Dicle University in the Sur district of Diyarbakır province, is a major healthcare institution treating approximately 10,000 cancer patients annually in the fields of medical and radiation oncology (URL-5) (Figure 5).

Figure 5. Diyarbakır City and Diyarbakır General View of the Oncology Hospital (Url- 6; Google Earth, 2025)

b. Methods

In the initial phase of the study, a comprehensive literature review was conducted on therapeutic gardens for oncology patients. This review examined the historical development, design principles, and international examples of therapeutic gardens. Furthermore, field observations were carried out in the study area, the Dicle University Oncology Hospital in Diyarbakır. After gathering detailed information about the study area, interviews were conducted with hospital users at the oncology hospital in question. Based on their expectations, needs, and desires, recommendations were developed to support the psychological recovery process, guiding the design proposals accordingly. In the study, 2D designs were prepared using AutoCAD 2022 software, and 3D modeling was performed using SketchUp 2023 and Lumion 2025 software. Through the proposed designs, the aim is to enhance the quality of life and the sense of well-being within the hospital and its surroundings.

3.Research Findings

The foundation of the study was to establish, within the therapeutic garden designed for oncology patients and other hospital users in the garden of Dicle University Diyarbakır

Oncology Hospital, not only a physical environmental arrangement but also a design that supports psychological, social, and emotional recovery. This aimed to highlight the importance of garden use for hospital users and to meet their mental, physical, and social needs (Figure 6).

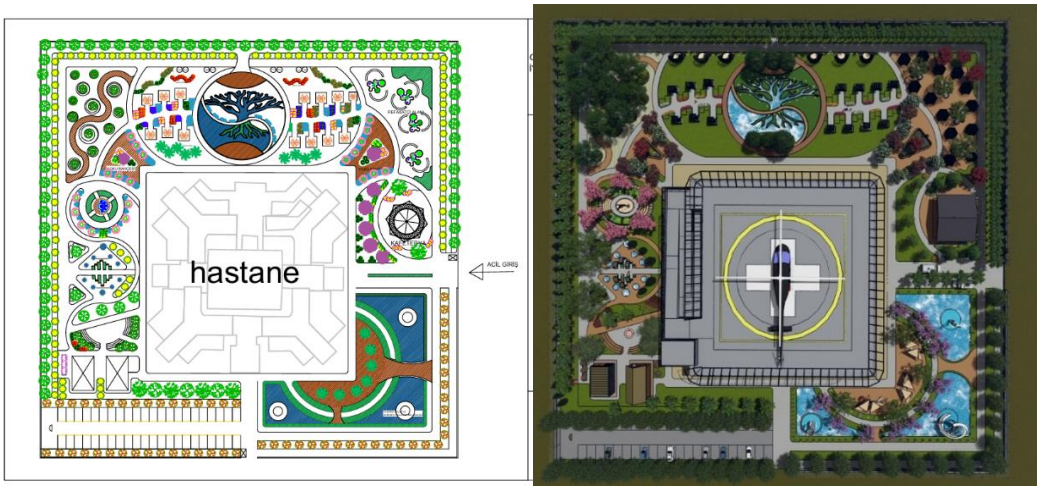

Figure 6. Views of the Therapeutic Garden Design for Diyarbakır Oncology Hospital (Produced by the authors, 2025)

In the designed area, two main entrances were arranged on the southern and eastern facades, with the eastern entrance designated for emergency access. To facilitate convenient transportation for hospital users, a 1,500 m² parking area was planned to the west of the southern entrance, surrounded by green space arrangements. To provide shade in these green areas, black locust (*Robinia pseudoacacia*) trees were selected (Figure 7).

Figure 7. 3D Views of The Hospital Garden's Parking and Entrance Areas (Produced by The Authors, 2025)

The focal point of the design is formed by a 2,500 m² grand plaza located to the north of the project, inspired by the concepts of the Yin-Yang symbol and the "Tree of Life". The Yin-Yang figure represents the balance of opposing forces in nature, while the Tree of Life, symbolizing the continuity of life and hope, has been incorporated into the project (Figure 8). The use of green space in one part of the plaza and a water feature in the other enhances the sense of integration with nature and contributes to patients' morale and motivation processes. Thus, the

design acquires the function of a space that serves not only as an aesthetic element but also as an environment fostering psychological balance and mental recovery.

Figure 8. 3D View of The Hospital Garden's Plaza (Produced by the Authors, 2025)

A cafeteria has been designed in a 435 m² area to the north of the project's eastern entrance. In the northeast of the project, a 745 m² area has been arranged with pergolas and planting islands placed on a wooden deck for caregivers and visitors. In the planting islands, linden tree (*Tilia tomentosa*) is surrounded by lavender (*Lavandula angustifolia*), rose (*Rosa* sp.), and chamomile (*Matricaria* sp.) (Figure 9).

Figure 9. 3D Views of The Hospital Garden's Cafeteria and Relaxation Area (Produced by The Authors, 2025)

To the west of the cafeteria area, within a 270 m² hardscape, a fragrance garden has been created in the integrated green spaces, designed to evoke the sensory experience of nature's seasonal transitions. In the fragrance garden, aromatherapeutic plants—lavender (*Lavandula angustifolia*), rosemary (*Rosmarinus officinalis*), thyme (*Thymus* sp.), and Japanese maple (*Acer palmatum*) were selected to stimulate users' sensory perceptions and provide mental relaxation. Along the edges of the fragrance garden's paths, pink and white-flowering crape myrtles (*Lagerstroemia indica*) were used as defining elements (Figure 10).

Figure 10. 3D View of The Fragrance Garden in The Hospital Garden (Produced by the Authors, 2025)

In the upper western section of the project, a 750 m² resting area has been planned for patients undergoing chemotherapy. In this area, shade zones have been created with plane trees (*Platanus orientalis),* surrounded by seating units (Figure 11). The reason for selecting the plane tree is its cultural association with the concepts of "family" and "trust," as well as its ability to foster a sense of psychological support in patients.

Figure 11. 3D View of The Hospital Garden's Resting Area (Produced by the Authors, 2025)

To the east of the resting area, green spaces have been incorporated within a 215 m² zone, where another fragrance garden is also located. In this garden, aromatherapeutic plants—lavender (*Lavandula angustifolia*), rosemary (*Rosmarinus officinalis*), thyme (*Thymus* sp.), and Japanese maple (*Acer palmatum*) have been selected. Along the paths of the fragrance garden, pink and white-flowering crape myrtles (*Lagerstroemia indica*) were used as border elements (Figure 12). The aim for users of this area is to stimulate their sensory perceptions and provide mental relaxation. On the southern side, a 160 m² plaza containing seating units has been designed (Figure 13).

Figure 12. 3D View of The Hospital Garden's Plaza Area (Produced by the Authors, 2025)

Figure 13. 3D View of The Fragrance Garden in the Hospital Garden's Plaza Area (Produced by the Authors, 2025)

In the eastern section of the southern entrance, a 2,086 m² area features a reflection pool, dynamic water sculptures, planting pits within hardscape, and seating areas. This space has been designed to function as a therapeutic environment, utilizing the visual and auditory effects of water to contribute to user relaxation. Integrated with lawn areas and wooden seating platforms, this section constitutes a stress-reducing open space arrangement (Figure 14).

Figure 14. 3D View of The Hospital Garden's Ornamental Pool and Seating Areas (Produced by the Authors, 2025)

In the southwestern corner of the project, art and sculpture studios have been designed in a 410 m² area, along with a 227 m² exhibition space. Thus, a social interaction area has been created where patients can express their creativity, demonstrate their productivity, and share their

works. This approach supports individual and communal healing in line with art therapy principles (Figure 15).

Figure 15. 3D View of The Hospital Garden's Performance Area and Art Studios (Produced by the Authors, 2025)

In the upper section, 230 m² of individual seating areas have been designed, surrounded by lavender (*Lavandula angustifolia*) shrubs to provide visual and auditory isolation. These areas offer patients the opportunity to spend time alone with nature (Figure 16).

Figure 16. 3D View of The Hospital Garden's Seating Area (Produced by the Authors, 2025)

The walking paths within the hospital garden are not only designed for recreational purposes but are also of a width suitable for wheelchair access and stretcher transport. Lighting elements have been placed on both sides of the paths, maintaining a clear path width of 2 m, and site furniture has been positioned in a way that does not reduce this clear width (Figure 17).

Figure 17. 3D View of The Hospital Garden's Walking Paths and Site Furnishings (Produced by the Authors, 2025)

Throughout the design of the hospital garden, created with a therapeutic garden approach, sharp corners have been avoided; a holistic aesthetic has been adopted through soft transitions and the use of natural materials. At the same time, requirements such as parking, emergency access,

and other technical infrastructure have also been considered. Across the entire area, designs have been incorporated to provide users with psychological and physical support, aimed at reducing stress and anxiety. Enriched with elements of nature, art, and social interaction, this design aims to support the emotional and physical healing processes of oncology patients. With this project, the intention is to present a garden arrangement that is compliant with therapeutic landscape design principles, accessible, user-centered, and multifunctional.

4.Conclusion and Recommendations

The positive effects of nature on human health have led to the emergence of therapeutic gardens in various forms throughout history. Therapeutic gardens are open and green spaces that support physical, sensory, and mental health, aim to enhance quality of life, and seek to reconnect users with nature by distancing them from stress. They are restorative and enabling gardens focused on improving psychological health by providing a peaceful and calming environment that helps reduce stress, anxiety, and mental fatigue. Based on this understanding, this study employed elements such as green vegetation, water features, natural materials, and ergonomic seating areas.

In our country, sufficient importance must be given to the gardens of healthcare institutions, and adequate budgets should be allocated. It is believed that well-designed therapeutic gardens, by supporting the recovery process of hospital users, will also contribute to reducing the burden on healthcare facilities through the positive effects they create. The adoption and widespread implementation of the therapeutic garden approach in the design of healthcare institution gardens, collaboration with interdisciplinary experts, and an increase in studies on this topic will also foster awareness regarding this subject. Consequently, landscape design in oncology hospitals should be considered not merely as an aesthetic element but also as a "therapeutic tool" that supports the treatment process.

An Evaluation of the Conservation History, Archaeological Findings, and the "Heritage for the Future" Project of the Church of St. Nicholas

Ebru Fatma FINDIK

ORCID: 0000-0001-9150-0884
Assoc. Prof. Dr. Department of Art History, Faculty of Arts and Sciences, Hatay Mustafa Kemal University, Hatay, Türkiye
effindik@mku.edu.tr

Abstract

This study evaluates the conservation history, archaeological findings, and excavation activities conducted within the framework of the "Heritage for the Future Project" at the Church of St. Nicholas during 2024–2025.[1] The final phase of the church, believed to house the tomb of St. Nicholas, corresponds to a domed basilica plan dated to the 8th–10th centuries. The building, known to have functioned as a monastery during the Medieval period, is surrounded by two-story annex structures. Excavations and sondages carried out in these annexes under the "Heritage for the Future Project" revealed significant architectural and stratigraphic evidence. A Lycian-type variant sarcophagus identified in the lower floor of the E Structure demonstrates that the area was used as a burial site even prior to the Byzantine period, and the stratigraphic data attest to the long-term functional continuity of the space. The C Structure is considered to have been associated with pilgrimage accommodation and healing (incubation) activities. Upper-floor remains from the Ottoman and early Modern periods indicate that the church complex continued to serve diverse functions in later centuries. These findings highlight the importance of ongoing archaeological research and excavation at the site and demonstrate the potential for these studies to contribute significantly to a deeper understanding of the historical development of Myra.

Keywords: Church of St. Nicholas, Myra, Byzantine, Ottoman, "heritage for the future project"

Introduction

History of Myra and the Church of Saint Nicholas

Ancient Myra was located in the Lycian region, between the Alaca Mountains and the Mediterranean Sea, on the banks of the Myros River. This strategic location made the city accessible via land and sea routes, establishing it as a center of commercial and cultural interaction in antiquity. In the ancient period, it is estimated that the cults of Artemis Eleuteria and Apollo were influential in the region.[2] The harbor settlement of Andriake presents a concentrated urban layout including a granarium, agora, baths, shops, workshops, and early basilicas. Jewish communities in the area can be traced through the synagogue at the harbor.[3]

The arrival of Christianity in Myra is considered to be connected with the missionary activities of Saint Paul in 57 CE.[4] The appointment of Nicholas of Patara as bishop of Myra in the 4th century played a decisive role in shaping the city's religious identity. Nicholas's participation in the Council of Nicaea in 325 indicates that Orthodox doctrine was adopted in the region in the early period.[5] Hagiographic sources dating from the 6th to 14th centuries (Praxis de Stratelatis, *Vita Nicolai Sionitae*, *Vita per Michaëlem*, *Enkomium Methodii*) confirm that Nicholas served as bishop during the reign of Constantine I, that his tomb was located in Myra,

[1] I would like to express my sincere gratitude to the Ministry of Culture and Tourism of the Republic of Türkiye for its valuable support provided within the scope of the *Heritage for the Future Project*.

and that the cult of the saint had gained an institutionalized structure.[6] In particular, the *Vita Nicolai Sionitae* (565 CE) is of special importance as one of the earliest and most significant texts documenting that Nicholas's tomb was located in the city and that a martyrion existed there.[7]

During the reign of Theodosius II (408–450 CE), with the strengthening of Christianity's status as the official religion within the empire, religious visits to Myra and its harbor, Andriake, appear to have increased. This development can also be traced archaeologically from the 5th century onward, particularly through the basilical structures constructed around Andriake. These architectural data clearly demonstrate Myra's religious significance as an episcopal center and its position as the metropolis of the Lycian province.[8]

Throughout the Middle Ages, Myra was regarded as an important pilgrimage center in the Eastern Mediterranean due to the belief that the tomb of Saint Nicholas was located there. The belief that sacred oil, known as "myron," seeped from his tomb and possessed healing properties was a decisive factor in the increase of pilgrimage visits to the city.[9] The miraculous healing power attributed to Nicholas and his adoption as the protector of sailors reinforced Myra's sacred identity; these beliefs resulted in the tomb structure becoming a regional religious center visited for healing and protection.[10]

The Church of Saint Nicholas developed over the area believed to house the tomb of Nicholas, bishop of Myra. Following his death, a monumental structure (martyrion) was erected over his tomb in the late 4th century. During the reign of Theodosius II (408–450 CE), Myra's status as the metropolis of the Lycian province further emphasized the religious significance of the structure.[11] According to U. Peschlow, the building, repaired by Justinian I after the earthquake of 529, was probably transformed into a basilica around 530 CE. Previous studies date this first basilical-plan structure to the 6th century. Arab raids and earthquakes in the 7th–8th centuries affected the building, which was reconstructed as a domed basilica in the late 8th–early 9th centuries. After the Abbasid attack of 808, repairs and reinforcements were carried out in the early 9th century.[12] Excavations conducted in 2022 have revealed that the church's earliest phase extends to the 5th century and earlier.[13]

In the 10th–11th centuries, liturgical and iconographic renovations were carried out in the inner narthex, featuring council scenes; following the pirate attack in 1034, additions to the north, wall paintings, and opus sectile pavements completed the third architectural phase of the structure.[14] A stone inscription dated 1042 serves as an important document indicating that the building was renovated by Constantine IX Monomachos and his wife Zoe.[15] The Burial

Chamber, constructed in the 12th century, along with chapels located in the southeastern part of the building, is notable for its burial spaces and wall paintings. The arcosolium in the courtyard, with a 1118 inscription on its wall paintings, is significant as evidence that the structure functioned as a monastic church during the Middle Ages.[16]

Metropolitans of Myra are recorded in documents between 1143 and 1161, and from 1207 onward, the settlement continued under Turkish administration. However, flooding in the 13th century, which altered the course of the Myros River, affected the city's topography; during the 14th–15th centuries, various attacks and sieges from Cyprus and Rhodes led to the city's devastation.[17] Although Myra remained an episcopal center in the 17th century, ecclesiastical administration had moved to the island of Kastellorizo (Meis/Megisti) off the coast of Kaş.[18]

19th-Century Excavation and Restoration Activities

Mid-19th-century Russian interventions at the Church of Saint Nicholas played a decisive role in shaping the architectural character of the structure that has survived to the present day. Institutional interest by the Russians was formalized in 1853 with the purchase of the building and its surrounding area on behalf of Princess Anna Golitsyna; subsequent extensive restoration works were carried out between 1858 and 1860 under the direction of architect A. Salzmann.[19] During this process, the western courtyard of the building was completely cleared, the outer narthex was reconstructed, the gallery floors were repaired, and the coverings of the southern nave and apse were renewed. The second phase of restoration, carried out in 1862–63, involved the renewal of the outer narthex and the main nave. Inscriptions documenting these interventions remain preserved on the structure today. Arches identified as belonging to a Russian-period funerary structure stand out among the original architectural contributions on the gallery floor.[20] Epigraphic and archival records from 1876 indicate that monastic buildings, administrative units, and water facilities were repaired, and a bell tower was constructed. The bronze bell from 1876, associated with this bell tower, is exhibited today at the Museum of Lycian Civilizations as tangible evidence of the Russian restoration activities.[21]

While these extensive restorations aimed to secure the structural integrity of the building, they also added a significant 19th-century intervention phase to the church's architectural layers. The recognition of the church within the scholarly community was facilitated by travelers visiting the region during the 19th century; in particular, architects, archaeologists, art historians, and researchers examining epigraphic data introduced Myra and the Church of Saint Nicholas into the academic literature.[22] Drawings, measurements, and documents produced during this period ensured that the architectural structure and early-period traces of the church became subjects of modern scientific study.

20th–21st Century Excavation and Restoration Activities

Early excavation and restoration works at the church have largely been overlooked until now. Excavations conducted by the Antalya Museum of Archaeology between 1953 and 1963 made significant contributions to the architectural and archaeological documentation of the

[16] Çorağan, 1998; Karakaya, 2005, 288-309.

[22] Bulgurlu, 2010, 273-291.

structure.[23] Following the church's return to a state of neglect, the Antalya Museum of Archaeology carried out cleaning and restoration works in the southern and eastern areas of the building in 1963/64 and 1966/67.[24] In 1964–65, Y. Demiriz documented the opus sectile floor panels on the plan.[25]

In 1965, within the scope of the Myra Project, the church was studied comprehensively for the first time by U. Peschlow and O. Feld.[26] In 1968, the South Burial Chamber and the 2nd–3rd Southeast Chapels were protected with a tiled roof with the support of the Dumbarton Oaks Research Institute; in the 1980s, the construction of an iron-structured roof ensured long-term protection of the building.[27] Excavations conducted between 1989 and 2009 under the direction of Prof. Dr. S.Y. Ötüken uncovered architectural remains of the monastery and various finds around the church.[28] Following works conducted under the Antalya Museum Directorate between 2012 and 2014, excavations led by Prof. Dr. S. Doğan continued from 2014 to 2021; these studies focused on the western entrance of the church courtyard and additional structures. During this period, a new Deesis wall painting and a figure of Nicholas were revealed.[29]

Since 2017, excavation leadership and the conservation, restoration, and landscaping works have been carried out under the coordination of the Republic of Turkey Ministry of Culture and Tourism, with interventions implemented between 2021 and 2022.

2022 Sondage Studies

The sondages conducted in 2022 in the naos of the Church of Saint Nicholas provided significant findings regarding the early phases of the structure. The sondages revealed that the church was built over an earlier complex of buildings covered with mosaic floors executed in the opus tessellatum technique. These earlier structures were likely destroyed following a major earthquake, and in their place, the first basilica, dated to the 5th century and featuring floors in the opus sectile technique, was constructed. Only the mortar beds and traces of the coverings of the opus sectile floors have been identified.[30]

It was determined that the geometric composition of the floors corresponds to the arrangement of the mosaics in situ in the Southeast chapels of the church. The opus tessellatum floors were found to extend over a wide area beneath the naos and the annexes of the church. The sondages revealed five different construction and repair phases in the naos, thereby documenting for the first time the floors of the first basilica and the type of the early ambo arrangement.[31]

"Heritage for the Future Project" 2024–2028

Between 2024 and 2028, within the scope of the "Heritage for the Future Project" carried out by the Ministry of Culture and Tourism, sondages and minor restoration works were planned at the Church of Saint Nicholas for the purpose of preserving and documenting its historical and cultural values.

Excavation Works in the C Structure

In 2024–2025, within the scope of the "Legacy for the Future Project," excavations and minor restoration works were planned in the northeastern annexes of the Church of Saint Nicholas (C Structures). The C Structures consist of a group of three annex rooms located to the east of the northern nave, adjacent to the apse. The complex connects to the church in the west, to the A2 and A1 structures in the north, and opens directly to the exterior through four doors in the south. The C1 and C2 rooms were documented and detailed in the plan during excavations that began in 1989. Studies revealed that C2 is covered with a dome, while C1 is covered by a longitudinal barrel vault oriented along the east-west axis.

The architectural features of the C Structures—including the four doors opening in three directions, their connection to the sacred area of the church, and small finds—highlight the significance of the complex. Previous excavations suggest that C2 was most likely a funerary structure, whereas C1 may have served as an incubation space where pilgrims seeking healing stayed.[32]

Although the medieval levels of C1 and C2 have been exposed, research on the early phases and architectural functions of these structures has not yet been completed. Considering the ancient significance of the area where the church was established, excavations are necessary to clarify the historical and architectural context of the building.

The C Structure opens to the C1 room through a passage-like doorway. The soil within the structure, which was entirely covered with alluvium due to a flood, was removed, revealing a vaulted space oriented along the north-south axis. A door opening in the northern wall, later blocked, was identified. Reused materials such as arch keystones, column capitals, and templon fragments were incorporated into the wall masonry. It is believed that this space acquired its current form, including the closure of the door, during the reconstruction of a pre-existing structure that had collapsed in a previous earthquake. A collapse caused by the flood was observed in the eastern wall of the building.

A conservation and implementation project has been prepared for the structure, and in the coming years, the architecture of the building will be fully exposed through excavations to determine its function and chronological phases. The architectural structure of the vault on the upper floor of the C Structure has been entirely revealed.

Excavation on the Upper Floor of the E Structure

The E Structure is a two-story architectural unit with a longitudinal rectangular plan, forming the southern boundary of the church courtyard. The upper floor originally featured a door opening to the courtyard, later blocked, and a staircase. Only the walls have survived to the present day; the upper covering has not been preserved. The building was constructed primarily of rubble stone, with limited use of spolia.

Excavations conducted in 2021 in the western section of the upper floor were partially completed, and the area was temporarily covered for protection. Two separate rooms, connected by a doorway, were revealed in this section.[33]

[32] Ötüken, 2006, 523-536.

[33] Doğan, Fındık, & Bulgurlu, 2022, 177-198.

In 2024, excavations continued in the eastern part of the upper floor. Surface soil and alluvial deposits were removed to a certain level, revealing wall remains from different periods. Wall remains from the Ottoman period, as well as ceramics and small finds from various phases, were recovered from the upper levels. These materials are understood to date to the Modern Period (after the 1923 population exchange), the Ottoman Period (17th–20th centuries), and the Early Ottoman Period (14th–15th centuries).

The findings indicate that the upper floor of the E Structure had a long period of use and was employed for different functions in various periods. In subsequent excavation phases, the functional and chronological context of these remains will be evaluated in greater detail.

Sondages on the Lower Floor of the E Structure

The lower floor of the E Structure is a rectangular space, 20 meters in length, oriented along the east–west axis and covered with a barrel vault. The lower floor consists of two rooms, each divided into three units by doorways. Apart from a round-arched doorway in the eastern wall, this section has no windows and is supported by arches and wall piers carrying the vault.

Between 2003 and 2009, the alluvial deposits filling the structure were removed, and the medieval layers were documented. The main aim of the sondages carried out in 2024 was to reveal the early phases of the building and to investigate whether the opus tessellatum pavement identified in the courtyard continued into the interior space.

During the excavation and sondages, a sarcophagus was revealed in the first two units of the first room, approximately 0.30 m. below the church floor level. The sarcophagus, made of limestone, is a simple type with a triangular pitched lid and semicircular projecting supports on its side faces. Due to the limited depth that could be reached within the room, the sarcophagus could not be fully exposed. Another reason is the presence of north–south wall remains built above the eastern part of the sarcophagus. This foundation wall, constructed in a later period along the north–south axis, indicates that the area was in use for a long and continuous period.

To the west of the sarcophagus, a rubble fill was identified, and to the south, another rubble-walled structure belonging to a later phase was revealed. The walls, overlapping at different levels, demonstrate that the room has a complex architectural stratigraphy. This complexity has prevented the complete exposure of the sarcophagus.

Typologically, this find shows affinities with Lycian-type sarcophagi and is considered to be related to the use of the area where the church stands as a burial site in antiquity. This provides archaeological evidence supporting historical sources that indicate Saint Nicholas was buried within the sacred precinct (temenos) of the city.

In 2025, excavations carried out in the third unit of the first room to expose a wall revealed that the wall was likely constructed over another grave dating to the Byzantine period at a higher level. The discovery of additional burials in the area further supports the hypothesis that this site functioned as the necropolis of the city of Myra.

Conclusion

Recent research conducted at the Church of Saint Nicholas has allowed for a reevaluation of the building's position within the settlement pattern of the Ancient and Medieval periods. The Lycian-type variant sarcophagus identified in the lower floor of the E Structure demonstrates that the area was used for burial purposes even before the Byzantine period, thereby establishing a direct link between archaeological evidence and written sources indicating that the saint's

tomb was located within the sacred precinct of Myra. The walls constructed over the sarcophagus in a later phase indicate that the space maintained functional continuity over an extended period and that the interwoven architectural phases created a complex stratigraphy. During the 2025 investigations, evidence suggesting the presence of a second burial along the same axis supports the idea that the site functioned as a selective necropolis based on a limited burial tradition.

The results of the excavations and sondages reveal that the early construction phases of the church extend to the 5th century and earlier. The opus tessellatum floorings found in at least ten different areas beneath the structure indicate the presence of a broader architectural complex. Wall remains from the Ottoman and early Modern periods identified on the upper floor of the E Structure provide important data regarding the building's use in the middle and late periods, showing that the area continued to serve different functions in later centuries.

These findings offer a new framework for understanding the multiple architectural phases of the Church of Saint Nicholas, demonstrating that the site had continuous use as a sacred precinct in antiquity, a pilgrimage center during the Byzantine period, and a repurposed architectural complex in subsequent centuries. Future excavation phases, particularly those focused on the architectural relationships surrounding the sarcophagus, are expected to provide more detailed data, contributing to a comprehensive reevaluation of the site's topographic and ritual organization.

The Importance of Urban Green Areas in Demre (Antalya) in the Climate Change Adaptation Process, and Strategic Actions

Atila GÜL [1*]

ORCID 1: 0000-0001-9517-5388
[1]Prof. Dr., Süleyman Demirel University, Faculty of Architecture, Department of Landscape Architecture, Isparta-Türkiye
atilagul@sdu.edu.tr (Responsible Author)

Abstract

Urban open and green spaces provide ecological, environmental, physical, aesthetic, economic, social, psychological, and recreational services and contributions to the city and its inhabitants. On a global scale, the urgent actions envisioned for combating and adapting to climate change involve a significant economic cost. In particular, increasing and sustainably managing carbon sinks in urban areas is at the forefront of these urgent actions. In this context, natural areas (forests, protected areas, wetlands, etc.) and green areas (parks, gardens, recreation areas, children's and sports playgrounds, green roofs, wetlands, road medians and edges, etc.) are considered the most critical element in the urban planning, design, and sustainable management process. Demre District possesses great richness and diversity in terms of urban green areas and natural and cultural resource values. In Demre District, only 3 out of 17 neighborhoods have more than 10 m² of green space per capita, while the other 14 neighborhoods have less than 10 m², exhibiting an uneven and unbalanced ratio. However, the ratio of the total existing green areas in Demre District to the city's population is 12.41 m^2 of active green space per person. Generally, this meets the minimum green space standard of 10 m^2 defined in the legislation. Strategic actions have been made to maximize the benefits of urban green spaces (UGS) in mitigating climate change, addressing them under three different headings (Planning/Design and Implementation Process, Institutional, Legal and Administrative Process, Participation and Awareness Process).

Keywords: Urban green areas, Demre (Antalya), sustainability, climate change adaptation, strategic actions

Introduction

Globally, especially over the past 50 years, it is predicted that increased human activity and impact on natural resources have led to a significant increase in greenhouse gas and carbon emissions in the atmosphere. In this context, many negative consequences, such as damage to natural (ecological) systems, disruption of the natural balance, increased carbon emissions, increased environmental pollution, decreased biological diversity, and the adverse effects of climate change, have become a serious threat to humanity and all life. Climate change, in particular, has become a global problem requiring urgent action, beyond being a threat for the future.

Today, as urban populations and urbanization develop rapidly, especially horizontal and vertical construction activities, the excessive increase in impervious surfaces and production and consumption activities, improper land use, etc., negatively affect the urban ecosystem and face increasing environmental challenges (Nowak et al., 2002; McKinney, 2008; Pataki et al., 2011; Toy & Esringü, 2021).

However, heat waves, drought, fires, coastal flooding, urban flooding, and changing climate conditions significantly threaten the existence of urban systems that are vulnerable to natural disasters and cause ecological, economic, and social problems in cities.

Climate change, increased carbon emissions, and the effects of environmental degradation are manifesting themselves severely in cities. Urban areas are responsible for 80% of global production and 70% of total greenhouse gas emissions. In this context, cities are living spaces that are intensely exposed to the effects of climate change, such as heat waves, the urban heat

island effect, floods, water scarcity, rising sea levels, food crises, and environmental pollution (The Global Commission on the Economy and Climate, 2014).

Extreme weather events linked to climate change, increasing climate risks, and environmental problems will cause significant losses in urban areas, and it is clear that we must be prepared for these risks (UN-Habitat, 2020). In this context, the resilience of cities to potential risks and disasters and ensuring the environmental, social, and economic sustainability of urban systems are becoming increasingly important (Boland et al., 2021; Leichenko, 2011).

In Türkiye, the cities have a fragile structure in terms of climate change due to rapid growth and expansion. Urban areas are extremely important priority areas in combating and adapting to climate change (Akten & Gül, 2024). Cities are considered both the primary source of the problem and the target of climate disasters, while also being the most important actors in the solution (Balaban, 2017). As the places most affected by the negative impacts of climate change, cities are at the center of adaptation policies implemented to combat climate change.

Globally, the urgent actions required to combat and adapt to climate change involve significant economic costs. Among these urgent actions, increasing carbon sink areas in urban areas and ensuring their sustainable management are particularly important. In this context, natural areas (forests, protected areas, wetlands, etc.) and cultural green areas (parks, gardens, recreation areas, children's and sports playgrounds, green roofs, wetlands, road medians and verges, etc.) are considered the most critical elements in the urban planning, design, and sustainable management process. (Demuzere, et al., 2014; Gül et al., 2020; Türker & Gül, 2022).

Urban green spaces offer multifaceted ecological, social, and health benefits that can help mitigate the effects of climate change while improving the quality of life for city residents. Green and natural areas within and outside cities contribute to the sustainability of the urban ecosystem (improving air quality, carbon sequestration and storage, urban cooling effect, increasing biodiversity, etc.). In addition, urban green spaces are the most important component of the city, supporting people's physical, mental, and cognitive health and well-being, increasing social cohesion, increasing property values, providing tourism and recreation opportunities, and supporting local economies.

The purpose of this study is to emphasize the importance of urban green spaces in the climate change adaptation process and to propose strategic actions for urban and extra-urban green spaces aimed at reducing the climate change adaptation process and its potential negative effects, specifically in Demre.

The Relationship Between the Global Climate Change Adaptation Process and Urban Green Spaces

With the belief that climate change is primarily human-induced and that global adverse effects will occur if no action is taken, governments have signed international agreements to reduce greenhouse gas emissions, conduct research, collaborate on technology, and promote the protection of carbon sink areas. The most important of these are (Gül, 2024).

- 1992 - United Nations Framework Convention on Climate Change (UNFCCC)
- 1995 - COP 1, Berlin Summit, Germany
- 1996 - COP 2, Geneva, Switzerland
- 1997 - COP 3, Kyoto, Japan

- 1998 - COP 4, Buenos Aires
- 2013 - COP 19 Warsaw, Poland
- 2015 - COP 21 Paris, France
- 2021 - COP 26 Glasgow, Scotland
- 2022 COP27 Sharm El-Sheikh, Egypt
- 2023 COP 28 Dubai, United Arab Emirates
- 2024 COP 29 Baku, Azerbaijan
- 2025 COP30 Belém, Brazil (November 10-21)

According to the decisions made in these agreements, in order to ensure global zero carbon security and keep the temperature at 1.5°C, it is projected that emissions will be reduced by 43% by 2030 and 60% by 2035, reaching net zero by mid-century. Nature-based solutions are beginning to be seen as a tool for achieving the goals of the Paris Agreement, reducing climate change risks, and building climate-resilient societies (EC, 2022).

Nature-based solutions are a valuable tool used to strengthen the resilience of ecosystems, protect biodiversity, and address a wide range of societal challenges such as climate change adaptation and disaster risk reduction (IUCN, 2020). In addition, nature-based solutions, which have the flexibility to adapt to changing conditions, are effective and cost-efficient approaches compared to gray solutions (Feyen et al., 2020; Raymond et al., 2017).

Türkiye aims to reach its peak greenhouse gas emissions by 2038 at the latest, followed by a decline to achieve net-zero emissions by 2053. Türkiye aims to achieve this goal within the framework of the Long-Term (2024-2053) Development Strategy included in the Twelfth Development Plan. This strategy sets out a roadmap for maximizing the opportunities that the profound changes and transformation process anticipated worldwide can offer our country. To achieve the net-zero emissions target by 2053, the sustainable management of natural resources, energy transformation, green infrastructure and circular economy investments, environmental protection, and the widespread adoption of green technologies through domestic production are targeted (Çevre, Şehircilik ve İklim Değişikliği Bakanlığı, 2025).

Strategic Emergency Actions for the Global Climate Change Adaptation Process;

- ❑ Sustainable land use planning/management,
- ❑ Production of nature-based and ecologically focused solutions
- ❑ Landscape improvement works and increasing green space systems in urban and rural areas
- ❑ Applications that take into account carbon sequestration/storage functions
- ❑ Calculating the amount of carbon sequestered and monitoring changes in carbon stocks,
- ❑ Increasing the number of protected areas, etc.

Strategies for the Urban Sector within the Scope of the 2053 Climate Change Adaptation Targets have been determined as follows. (Çevre, Şehircilik ve İklim Değişikliği Bakanlığı, 2025).

Strategy 1. Adapting to climate change by increasing the resilience of cities

- ❑ In cities, improving areas at risk of flooding and determining appropriate transformation and protection zone models.
- ❑ Strengthen smart information systems on infrastructure capacities and heavy rainfall scenarios to increase the resilience of urban infrastructure against flood and inundation risks.
- ❑ Improving infrastructure by restructuring drainage systems, separating combined sewer systems (rainwater, wastewater), changing surface coatings, and increasing capacity where needed.
- ❑ Ensuring the effective use of location-specific materials will increase the resistance of building roofs and facades to severe weather events and prevent urban heat increase by determining standards.
- ❑ Identifying urban heat islands, green space needs, and wind corridors to create accessible and natural surfaces within urban fabrics with dense green spaces and ecological corridors.
- ❑ Rainwater management will be provided in urban areas and peripheral regions by creating rain gardens, sponge city details, rain ditches, and natural water surfaces; public spaces will be redesigned to collect water during heavy rainfall and transfer it to storage systems.
- ❑ Creating drought-resistant and aesthetically pleasing urban areas through drought-tolerant landscaping practices
- ❑ Changing water usage habits through education and awareness campaigns, promoting a culture of water efficiency, and adopting a water-efficient city approach

Strategy 2. Ensuring adaptation to climate change in spatial plans

- ❑ Spatial planning processes should be re-examined in the context of adaptation to climate change.
- ❑ Developing guiding manuals/guidelines that consider local climate data and address issues such as site selection, prevailing wind direction, passive ventilation and solar exposure, construction, and implementation, treating the urban landscape and urban greenery as an integrated system in spatial planning and urban design.
- ❑ Creating risk maps in urban areas using spatial data.
- ❑ Creating digital twins of cities and conducting risk analyses using this infrastructure.

Urban Green Spaces and Carbon Sequestration and Storage

Today, human-induced urbanization trends have altered the city's climatic processes as a result of settlements growing and changing in horizontal/vertical dimensions, increasing the urban heat island (UHI) effect and making urban daily life more negatively affected (Kazancı & Tezer, 2021; Gül & Gül, 2022). Cities consume 60-80% of the energy produced worldwide and generate carbon dioxide emissions roughly equivalent to this percentage. Population dynamics, income levels, and the physical and economic structure of cities play a key role in the increase of greenhouse gas emissions in cities. Urban open and green spaces are important for reducing CO_2 emissions and carbon storage in city centers.

The urban heat island effect, caused by factors such as reduced humidity and airflow due to the shielding effect of buildings, increased asphalt temperatures, increased traffic and air pollution, and insufficient vegetation cover reducing shade in residential areas and allowing more solar energy to be stored, contributes to global climate change. The development of urban canyons also alters wind patterns, preventing wind from entering and blowing through streets, causing heat to be trapped within the canyon. Thus, cities are warmer than the surrounding areas. Due to concrete construction and building density, cities are on average 5-6°C warmer than the surrounding rural areas. This is due to the Urban Heat Island effect, which arises from concrete construction and building density in cities. On sunny and hot days, city centers, with their high population density and tall buildings, are hotter than other surrounding areas, creating the urban heat island effect. Paved areas, especially during the hottest summer months, reach very high temperatures. Areas where plant communities have been destroyed and black surfaces are also among the causes of the heat island effect. The urban heat island effect is one of the factors contributing to global warming.

The urban heat island effect causes city centers to be warmer than their surroundings, leading to the intensive use of cooling systems, especially during the summer months. The increased energy demand for cooling due to rising temperatures in cities poses significant threats to the energy systems of countries (Çevre, Şehircilik ve İklim Değişikliği Bakanlığı, 2025).

Green space systems are defined as a network of interconnected natural, semi-natural, and cultural green spaces that provide and protect multifaceted ecosystem services and contributions (Benedict, 2000; European Commission, 2022). This network, consisting of segments (centers) and corridors, includes natural and semi-natural ecosystems (forests, scrublands, wetlands, river corridors, etc.) and cultural green spaces (parks, sports fields, schoolyards, private and institutional gardens, rooftop gardens, vertical/perpendicular gardens, zoos, botanical gardens, agricultural lands, cemeteries, landscaped pathways, etc.) (Gül et al., 2020).

Urban green spaces, both within and around the city, are a fundamental component that integrates and balances all land uses within the city through organic connections. The level of development of a city is directly proportional to the capacity of its green spaces in terms of quality and quantity, their balanced spatial distribution, and their accessibility to its inhabitants. Urban green spaces are public, semi-private, or private physical spaces that provide multifaceted services and contributions to the city's ecosystem and its inhabitants in biological, climatic, physical, social, psychological, economic, and aesthetic aspects, organized according to different green space typologies at the level of the urban unit they serve, and covered with natural and cultivated plants. Urban open and green spaces provide ecological and environmental, physical, aesthetic, economic, social, psychological, and recreational services and contributions to the city and its inhabitants (Gül & Küçük, 2001; Gezer & Gül, 2009; Gül et al., 2020).

The ecosystem services and contributions provided by green space systems vary according to factors such as the location, size, distribution, plant species, density and composition of the areas, and their organic connection with other green spaces (Gül, 2024).

The Earth's CO_2 storage or reserve areas are the atmosphere, oceans, and terrestrial biosphere. Natural areas (forests, protected areas, scrubland, etc.) and green spaces constitute a significant portion of the terrestrial biosphere. These areas enable the retention and storage of carbon in plants, litter, and soil. In terrestrial ecosystems worldwide, 19% of carbon is stored in plants

and 81% in soil. In forests, approximately 31% of carbon is stored in biomass and 69% in soil. In tropical forests, approximately 50% of carbon is stored in biomass and 50% in soil (IPCC, 2000).

The areas with the highest CO_2 emissions and large-scale energy consumption are urban areas with high population density. In city centers, urban trees and urban forests play an important role in reducing CO_2 emissions and sequestering carbon. In urban trees, the leaf biomass value is directly proportional to the tree's leaf ratio, canopy width, and age. An increase in a tree's biomass directly affects the amount of carbon it contains (Gül, 2024).

Urban green spaces can sequester between 1.2 and 1.6 tons of carbon per hectare per year, depending on the type of vegetation and management practices. The carbon dioxide storage capacity of urban trees is affected by tree species, height, age, leaf surface area, trunk diameter, tree density, existing canopy cover, and growing conditions, and can vary proportionally with their biomass.

As cities grow and face increasing environmental pressures, the need for resilient, sustainable, and livable urban environments is becoming more urgent.

Carbon pricing initiatives to mitigate climate change have become a multi-billion dollar industry. Quantitative measurements of carbon stocks are the fundamental basis for carbon trading and the carbon economy. An increase in a tree's leaf biomass directly impacts its carbon storage capacity. Leaf biomass is directly proportional to the tree's leafing rate, canopy width, and age. An increase in a tree's biomass directly affects the amount of carbon it holds (Gül et al., 2021).

Green spaces and green infrastructure are considered the most common and cost-effective actions to adapt to and become resilient to the effects of climate change. Urban green spaces (especially trees), which undertake the task of carbon capture and storage, as well as protected areas and natural systems within and outside cities, serve as an important resource.

In the context of combating global climate change, calculating and interpreting the carbon emissions and the amount of carbon sequestration and storage provided by urban trees/forests and green space systems, which serve as urban carbon sinks, will play a significant role in carbon pricing and in determining the services and contributions of urban ecosystems.

Integrating green spaces into urban structures not only addresses urgent environmental issues but also creates healthier and more equitable communities.

Despite the multifaceted services and contributions of urban green spaces (UGS), they face several significant challenges in mitigating the negative impacts of climate change.

- One of the most significant challenges is the prioritization of land use decisions in urban planning and management policies at the urban scale, particularly regarding construction, transportation, commerce, and industry, over green spaces, thus limiting the opportunity to create natural areas and green spaces.
- The high costs of creating and sustainably managing green spaces (maintenance, personnel, irrigation, repairs, machinery, equipment, security, etc.) can reduce the willingness to create green spaces due to insufficient local government budgets.
- The unequal and equitable distribution of urban green spaces in terms of quality and quantity at the neighborhood and city levels reduces the services and contributions of

green spaces. This inequality can exacerbate existing social inequalities, as individuals in underserved neighborhoods may have limited access to the health services provided by green spaces.

- The failure to use appropriate plant species in urban areas, the lack of suitable habitats for trees and shrubs, incorrect pruning practices, and the direct or indirect negative impacts of urban dwellers on urban green spaces and plants limit the services and contributions expected from green areas.

General information about the Demre District

Demre District is located within the borders of Antalya Province, on the Mediterranean coast, between 29° 20' - 32° 35' east longitudes and 36° 07'-37° 2' north latitudes and is a small rural-urban settlement 142 km from Antalya city center (Table 1).

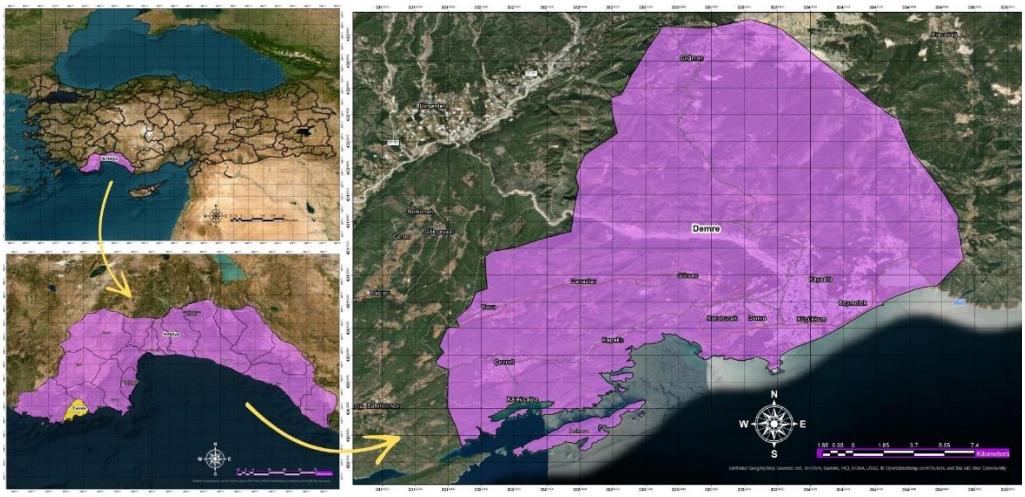

Figure 1. Demre District and its location

Agriculture and tourism are the driving forces in the city's economy. Housing construction and greenhouse farming play a significant role in urban development. Rivers originating in the northern mountains converge in the Myros Canyon (Demre River) before reaching the sea, and the current settlement is situated in the plain surrounding this river. Dalyan is located at the eastern end of this Demre plain, the famous port city of Andriake at the western end, and the ancient city of Myra at the northern end. Demre has a deep-rooted and significant cultural history dating back to the ancient Lycian period and is quite rich in natural and cultural heritage values. Spatially, Demre has fertile agricultural lands, and its wide plains, enriched by the alluvial soils brought by the Demre River, and its reddish-brown Mediterranean soils have a very favorable structure for agriculture (Western Mediterranean Development Agency (BAKA, 2021).

The region, which stands out in agricultural production with its intensive greenhouse activities and citrus fruit production (especially oranges and lemons), is known for its famous agricultural products such as "Demre pointed peppers". The diversity and quality of agricultural products ensure that the region has high potential in terms of agriculture-oriented tourism opportunities such as agrotourism, farm tourism and organic farming. Economically, Demre, which stands

out with its high-value aquaculture products such as blue crab and shrimp, makes significant contributions to the local economy thanks to its aquaculture resources.

The Demre district has a rich potential in terms of its historical and cultural architectural structures and ruins, as well as its unique natural heritage values. Furthermore, the presence of St. Nicholas, known as the birthplace of Demre and a significant figure in Christian history, and his church are considered significant identity assets (Dündar et al., 2024).

In order to evaluate the socio-cultural and socio-economic potentials of the Demre District, to protect cultural values, to protect rock tombs and protected areas and areas suitable for agriculture, to ensure the continuity of agricultural production, to plan tourism activities to be spread throughout the year and thus to ensure a homogeneous distribution of socio-economic development in the region, the Antalya Demre Culture and Tourism Protection and Development Region was declared (Official Gazette Decision dated 26.07.2010 and numbered 27653) (Antalya Metropolitan Municipality, 2018).

In the 1/25000 Scale Zoning Plan Report for the Demre District of Antalya Province, the total area of planned open and green spaces within the district borders is 130.0 hectares. Of this area, 76.2 hectares are within the plan approval boundaries, while 53.8 hectares are outside the plan approval boundaries.

This report presents the status of open and green spaces according to approved plan decisions; Park and Green Space 34 Ha, Afforestation Area: 6.7 Ha, Recreational Area 9.5 Ha, Cemetery Area 3 Ha and Shore and Beach 23 Ha (Antalya Büyükşehir Belediyesi, 2018).

The per capita green space amounts (m^2) in Demre District, according to the neighborhood populations, show an uneven and unbalanced distribution. Per capita green space amounts by neighborhood in Demre District: Beymelek (23.00 m^2), Büyükkum (21.73 m^2), Küçükkum (11.76 m^2), Yavu (9.70 m^2), Çağman (8.20 m^2), Davazlar (7.32 m^2), Belören (6.91 m^2), Karabucak (5.39 m^2), Köşkerler (3.54 m^2), Çevreli (3.06 m^2), Kayaaltı (2.89 m^2), Kapaklı (2.40 m^2), Gökyazı (2.33 m^2), Yaylakaya (1.32 m^2), Alakent (1.17 m^2), Üçağız (0.45 m^2), and Gürses (0.00 m^2),

In Demre district, only 3 out of 17 neighborhoods have more than 10 m^2 of green space per capita, while the other 14 neighborhoods have less than 10 m^2, resulting in an uneven and unbalanced ratio. Gürses neighborhood, in particular, has 0 m^2 of green space per capita. However, the ratio of the total existing green areas in Demre district to the city's population is 12.41 m^2 of active green space per capita. Overall, this meets the minimum 10 m^2 green space standard defined in the legislation.

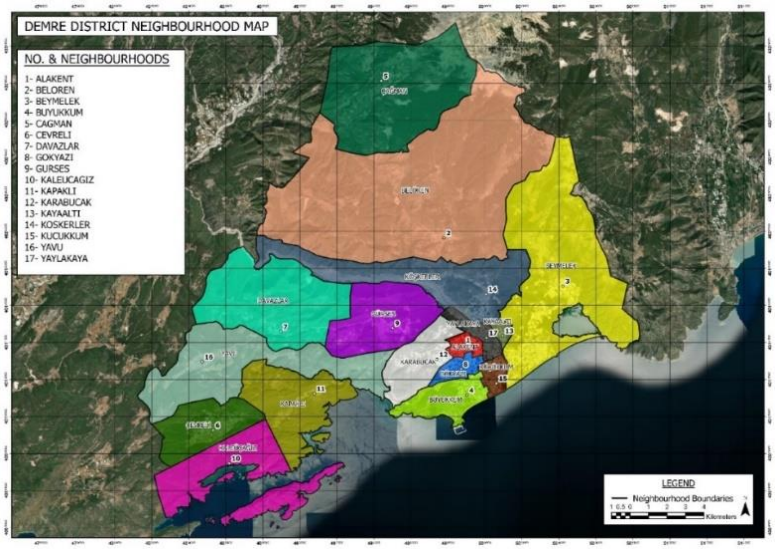

Figure 2. Neighborhoods of Demre District

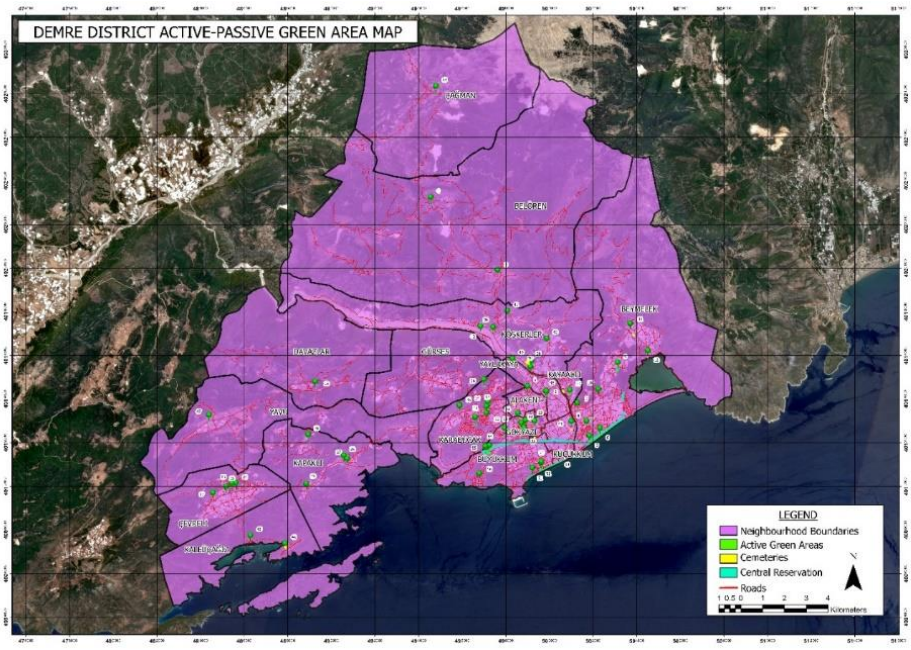

Figure 3. Active green areas of neighborhoods in Demre District

Table 2. Population, percentage of green space, and per capita green space (m^2) for the 17 neighborhoods of Demre District.

No.	Neighborhoods	Neighborhood Population (TÜİK, 2024)	Total Active Green Space Area (m^2)	Amount of Green Space per Person (m^2)
1	Alakent	1640	1931,75	1,17
2	Belören	496	3431,71	6,91
3	Beymelek	3686	84786,10	23,00
4	Büyükkum	2878	62556,72	21,73
5	Çağman	250	2051,35	8,20
6	Çevreli	786	2407,58	3,06

7	Davazlar	160	1171,23	7,32
8	Gökyazı	8129	18953,86	2,33
9	Gürses	402	0,00	0,00
10	Üçağız	502	228,82	0,45
11	Kapaklı	519	1249,17	2,40
12	Karabucak	2700	14576,19	5,39
13	Kayaaltı	404	1170,72	2,89
14	Köşkerler	2328	8245,90	3,54
15	Küçükkum	1344	15809,41	11,76
16	Yavu	411	3989,91	9,70
17	Yaylakaya	1179	1566,49	1,32
Total at Neighborhood Level		27814	224127	
Amount of Green Areas Per Person at the Urban Scale				12,41

Within the scope of urban green areas types, there are 55 in total, including 22 parks, 26 children's playgrounds, 4 sports fields, and 2 squares. Apart from urban active green areas, the total area of other passive green areas (Roadside and median green areas and Cemeteries) and the amount of green space per person is 8.10 m^2, and a total of 20.51 m^2 of green space per person is calculated

General Assessment of Demre City's Green Spaces

- The current amount of active green space per capita in Demre is 12.41 m², which can be considered sufficient.
- The distribution among neighborhoods is observed to be unequal and unbalanced.
- The ratio of green spaces to the neighborhood's total surface area is less than 1% in all neighborhoods.
- The areas covered by parks within the city are generally small.
- The largest area is Sahil Park, located within the boundaries of Beymelek, Büyükkum, and Küçükkum neighborhoods. It covers 94,332 m². There are four parks covering over 1 hectare. Other green spaces range from 2,000 m² to 250 m².
- The organic connection between parks within the city and with natural areas outside the city is insufficient.
- The variety of activities and facilities in children's and sports playgrounds is limited.

Strategic Actions for Spatial and Urban Green Spaces in Demre During the Climate Change Adaptation Process

Urban green spaces are a crucial component requiring a holistic approach to urban planning, urban design, and urban management. To maximize the benefits of urban green spaces (UGS) in mitigating climate change, key strategic goals and prioritizations in local government policies should be addressed under three main headings:

- Planning/Design and Implementation Process

- Institutional, Legal, and Administrative Process
- Participation and Awareness Process

a. Planning/Design and Implementation Process

- ❑ For the sustainability of Demre's resource values, establishing a balance between "conservation and use compatible with conservation" should be the fundamental goal in all spatial planning.
- ❑ Open and green space systems should be holistically linked and positioned in the city's Master Development Plans.
- ❑ Guiding guidelines/manuals should be developed that consider local climate data, addressing urban landscape and urban greenery as a holistic system in spatial planning and urban design, including issues such as site selection, prevailing wind direction, passive ventilation and sunlight, construction and implementation.
- ❑ The site selection, standards, functionality, and distribution of urban public open and green spaces should be mandatorily included in urban development planning decisions and should also be reflected in other sector planning and policies (housing, transportation, health, sustainability, biodiversity, etc.).
- ❑ In the urban master plan process, the inventory and analysis of green spaces should be considered as an important component of planning. For this purpose, in determining the typologies of green spaces at various scales (city, district, neighborhood), many factors should be taken into account, such as: user demands and trends for green spaces, ideal location selection for green spaces, size and form of green spaces, population analyses of the city, socio-economic dimensions of the city, relationship with urban local identity, accessibility, ecological relationship, plant species used, composition and analysis, landscape equipment and materials.
- ❑ In order to create livable, healthy and high-quality urban spaces, the open and green space system of the city should be considered in the urban planning process at the city, district and neighborhood scales in an equal, fair and sufficient size, with functional and equipped facilities that will provide multifaceted ecosystem services, and within a spatial, positional and functional hierarchy.
- ❑ Urban green spaces should be connected with natural green spaces within and around the city and should form a holistic green network system that provides continuity.
- ❑ Ecological bridges should be designed within the city and on intercity highways surrounding it.
- ❑ Urban heat islands, green space needs, and wind corridors should be identified, and accessible green areas with dense natural surfaces and ecological corridors should be created within the urban fabric.
- ❑ A "Urban Design Guide" should be created specifically for Demre.
- ❑ Conservation-Oriented Development Plans must be prepared for areas with conservation status both within and outside the city.

- A comprehensive green space inventory (type, tree diameter, crown width, height, etc.) should be compiled for carbon footprint calculations in urban trees and green areas, and digitized in a GIS environment.
- The primary goal in landscape structural and plant design projects should be to produce nature-based solutions for carbon sequestration and storage.
- Native species of the region should be preferred when selecting plant species to be used in green areas. Rainwater management should be implemented in urban and peripheral areas, creating rain gardens, sponge city details, rain ditches, and natural water surfaces. Public spaces should be transformed into designs that collect and transfer water to storage systems during heavy rainfall.
- Newly planned parks should be larger areas, designed as City Parks, National Gardens, and multi-purpose recreation areas.
- Complex children's and sports playgrounds should be located in urban green spaces, diversified to appeal to all age groups and suit their purpose.
- Empty and unused areas in and around the city should be transformed into green spaces or utilized as urban farming areas to contribute to the city's food needs. Green areas should be designed and implemented with sustainable and innovative drainage and infrastructure systems.
- A bicycle path network should be designed to increase accessibility from the city center to areas of tourist value (coastal area, ancient cities, Çayağzı, boat harbor, etc.) and to be linked to green areas.
- The Lycian Cultural Route, which passes through the Demre district, should be prioritized for spatial organization.
- New cultural routes should be created taking into account the city's historical, archaeological, and touristic points, landscape landmarks, green areas, etc.
- Parking lots should be provided in urban green areas to contribute to the city's transportation.
- Demre Çayağzı Boat Harbor and its surroundings are currently the most important attraction for boat tour tourism. However, it also has multifaceted problems in terms of spatial, recreational, environmental/ecological, transportation, economic, security, aesthetic, functional, and socio-cultural dimensions. A spatial improvement and development project should be carried out.

b. **Strategic Actions for Institutional, Legal and Administrative Processes**

- The municipality should be strengthened with technical staff and support personnel within its organizational unit to be effective and competent in the management of public green spaces for which it is responsible (planning/design, implementation, protection, maintenance, repair, etc.).
- A city council should be established, and voluntary participation should be ensured through various Working Groups.
- An "Aesthetics Board" should be established within the municipality.

- ❑ Landscape design application projects (Structural and Plant Projects) should be mandatory in the building permit approval process for construction projects in municipalities.
- ❑ Incentives and policies should be developed to promote green roofs and balcony gardening.
- ❑ A green space inventory should be integrated into the City Information System, which is mandatory for cities.
- ❑ Green roof and green facade applications should be encouraged, especially in high-density city centers where the supply of open spaces is limited.
- ❑ A green space network should be developed using concepts such as agrotourism, farm tourism, carbon farming, agroforestry, gastronomic tourism, and slow food, to integrate agricultural areas into tourism.
- ❑ Drought-resistant and aesthetically pleasing urban areas should be created through drought-tolerant landscape practices.
- ❑ A comprehensive strategic action plan should be developed for the Demre River (Myros River), and it should be surrounded by green corridors for conservation and recreational uses. Water storage can be ensured by constructing dams on the river.
- ❑ The city's rainwater drainage system management plan should be organized and linked to existing stream beds (especially the Demre River), and the water should be stored and made usable by creating a biological pond near the sea, rather than directly into it.
- ❑ Value-added products should be obtained from plant and organic waste and residues on an urban scale through recycling (e.g., producing compost fertilizer from plant residues, industrial product production, etc.). Risk maps should be created in urban areas using spatial data. Digital twins of cities should be created to enable risk analyses to be carried out through this infrastructure.
- ❑ An accessible city portal should be created within the municipality (WebMapService).
- ❑ Data sharing on tourism, recreation, green areas, transportation, cultural events, etc., should be done on the municipality's website.

c. Participation and Awareness Process

- ❑ Active participation of urban residents should be ensured in the planning and management of urban green spaces, and their demands and trends should be taken into account.
- ❑ Awareness activities should be carried out on topics such as nature and environmental protection, ornamental plant cultivation, gardening, fruit growing, etc. (Scientific events, festivals, cultural events, etc.)
- ❑ Public education and awareness campaigns should be conducted on urban agriculture and gardening.
- ❑ Changes should be made in water usage habits in urban areas, and education and awareness campaigns should be conducted to spread a culture of water efficiency.
- ❑

4. Conclusions and Recommendations

Within the framework of the Climate Change Adaptation Strategy, the goal is to increase climate resilience in all sectors through smarter, more systematic, faster, and international actions to achieve the 2050 zero-carbon target. It is emphasized that to achieve these goals, nature-based solutions should be utilized and investments in nature should be increased (European Commission, 2021).

In our country, Article 7-(4) of the "Climate Law" No. 7552, adopted on 2/7/2025 (Published in the Official Gazette: Date: 9/7/2025, Number: 32951), mandates the creation of a comprehensive plan in each province, taking into account the requirements for a just transition to reduce greenhouse gas emissions and adapt to climate change. Local governments need to integrate climate change into their urban planning and management activities to mitigate the negative impacts of climate change and to produce solutions for the adaptation process. Strengthening spatial relationships in cities and developing environmentally sensitive areas and ecosystems are important aspects of climate action planning.

Every city center needs to develop a database of existing conditions, including the provision of infrastructure and services, and details of environmental hazards and vulnerabilities. This process will go far beyond climate change adaptation, documenting and mapping other environmental hazards and who is most at risk, and providing important guidance on how best to respond (Akten & Gül, 2024).

Urban green spaces are an important part of public spaces. Therefore, public green spaces need to be easily accessible to all population groups, distributed equally and fairly at the urban and neighborhood scale, planned, designed, and sustainably managed to provide spatial size and functional services and contributions for green space typology purposes (WHO, 2017). In the specific case of Demre, the local government policy should prioritize the protection of existing green and natural areas and the sustainable management of newly created green spaces.

As cities continuously grow and continue to grow, the conscious integration of green spaces into urban planning and policies will be vital for creating resilient and sustainable environments. Prioritizing these areas will help cities effectively address the impacts of climate change, while promoting public health and social equity, and facilitating access to the benefits of green spaces for all residents.

Sufficient funding should be allocated for the maintenance and improvement of urban green spaces. Regular maintenance, including landscaping, irrigation, and waste management, is vital to keep these areas safe, attractive, and usable.

It will be possible to increase the climate resilience of cities by creating locally specific natural areas and green spaces (city parks, green corridors, stream corridors, rain gardens, roof gardens, etc.) that incorporate nature-based or hybrid solutions in urban areas to address the climate change, carbon emissions, and biodiversity crisis. Open and green spaces should have sufficient spatial capacity to be used as gathering and shelter areas for earthquakes, floods, and similar disasters.

Instead of a "Sustainable Development" approach, urban policies for combating climate change should prioritize a green economy approach that emphasizes ecology and nature conservation, social rights, fair working conditions, and increased employment. The organization and management of green spaces should actually be perceived as a public health and social investment, and having a long-term green city vision is a necessity for creating a holistic standard of living in Demre.

Demre has the potential to become a Cittaslow (Slow City), and the city planning and management process should be designed and organized according to this concept. Urban green spaces and natural green spaces should be considered within this concept.

The existence and quality of natural and cultural green spaces in Demre district should be considered as a factor supporting and developing urban tourism.

To create smart, healthy, resilient, and livable cities, green spaces should be designed in harmony and balance with the city. It should be understood that green spaces are not a luxury, but a smart form of conservation.

Abstract

Recent technological developments in architecture, engineering, and materials science have accelerated the incorporation of kinetic systems in contemporary buildings, enabling them to adapt dynamically to environmental functional, and social demands. While existing studies often examine individual examples or typologies, there remains a need for comprehensive classification framework to reveal the full potential of kinetic design. This study presents a comprehensive taxonomy divided into four main categories: (1) Structural systems that demonstrate large scale adaptability such as bridges, transformable structures and deployable temporary systems. (2) Kinetic Façade Systems, which directly affect energy performance, climate control, and aesthetic expression: (3) Kinetic Roof Systems, capable of managing large spans and react to environmental conditions while preserving structural integrity and functionality. (4) Building Components, which include interactive elements, interior adaptability and kinetic urban furniture that emphasize user experience and spatial flexibility. By positioning these diverse systems within a unified framework, the study demonstrates how kinetic architecture enhances building performance through increased energy efficiency, environmental responsiveness, and user comfort, while also enhancing architectural experience through adaptability, diversity, and interaction. The study frames kinetic design as a multifaceted design language that shapes the smart, adaptable cities of the future.

Keywords: Kinetic systems, contemporary architecture, smart buildings, adaptive design

1.Introduction

The fields of architecture and structural engineering are evolving rapidly to meet the demands of the era and the ever-changing needs of users. This evolution has led to the design and implementation of smart and adaptable building systems that can reconfigure spatial arrangements in response to immediate demands incorporating movable interior walls, variable façades, and multipurpose furniture (Akgün et al., 2013). The dynamic potential of buildings with moving components has been maintained as a dynamic possibility through the concept of kinetic architecture, first defined in the 1970s, contrasting with the static nature of traditional buildings. During the rapid technological developments of the early 20th century, this concept began to express artistic, political, and philosophical discourses as well as aesthetics and functionality (Fouad, 2012).

The origins of kinetic systems in architecture date back to the earliest periods of architectural history. These systems have undergone significant evolution, progressing from manually

operated mechanisms to highly sophisticated mechanical and electronic smart systems. Today, kinetic elements appear in various forms as dynamic components of circulation schemes, functional elements of service systems, or most frequently, flexible building façades (Ramzy & Faye, 2011). Kinetic systems offer flexibility to buildings by enabling various configurations, from interior redesign to complete structural arrangements, and adaptation to users and environmental factors such as temperature or wind (Fouad, 2012). These systems serve both practical (safety and space optimization) and humanitarian purposes. Researchers and architects in this field are working to develop complex systems that can automatically correct structural deformations, dynamically adjust load-bearing capacity, or completely alter geometric configurations (Ramzy & Fayed, 2011). Such systems may also include structural components that fold, slide, expand, or transform in size and shape.

Although deployable and transformable systems, while possessing a similar capacity for movement and change, they differ significantly. Deployable structures expand by moving from a collapsed to an expanded position, having only two predefined states (closed/collapsed or open/deployed). On the other hand, transformable structures form a broader category; while also expandable, they are not limited to binary configurations. They can possess multiple states and change their shape, orientation, function, or size. In short, all deployable structures are transformable, but not all transformable structures are deployable (Maden et al., 2019).

This study examines four primary architectural components commonly used in kinetic architectural applications: structures, façades, roofs, and other architectural elements. Portable, relocatable, and demountable systems are outside the scope of this study. Deployable and transformable systems encompass all these categories. Despite the increasing number of kinetic systems applied in contemporary architecture, literature still lacks a clear and comprehensive framework that unifies these systems under a single structure. Existing studies generally focus on isolated examples or narrow typologies, leading to a fragmented understanding of the field and making holistic comparison or evaluation of kinetic systems difficult. To address this gap, the study aims to propose an inclusive and systematic classification that organizes kinetic systems according to their fundamental architectural components. By examining structures, façades, roofs, and building elements as an integrated taxonomy, the study aims to clarify their roles, performance potentials, and architectural implications, and establishes a more consistent terminology and a logical classification system.

2.Materials and Methods

This study employs systematic literature review as its primary research methodology. The main objective is to develop a new classification of kinetic systems under four main groups. The methodological framework consists of three interrelated phases: (i) reviewing existing classification systems, (ii) collecting and analyzing relevant data, and (iii) identifying deficiencies and limitations within current classification approaches.

To assess the current state of research, the first phase begins with a systematic review of literature that focuses on kinetic structure of classifications. To follow the development of the main classification frameworks in kinetic architecture, the reviewed studies are arranged chronologically. Search using terms such as “kinetic,” “deployable,” “transformable,” “changeable,” “material-based,” “structural typology,” “geometric configuration,” “function-based,” and “movement-based” are used in an organized keyword search to find relevant publications. These keywords allow a thorough analysis of the criteria used in current

classification systems, the methodological coherence of the reviewed studies, and the theoretical basis of kinetic structures.

The study examines existing current general classification frameworks and synthesizes them into four main groups. A comprehensive and novel classification system is proposed based on this synthesis. The inclusion of completed example projects supports the validity applicability of the proposed classification, highlighting its significance for both theoretical research and architectural practice.

3.Findings and Discussion

Over the years, various researchers have conducted numerous studies on the classification of kinetic architecture and kinetic structures. These classification techniques are based on each author's area of expertise and the scientific framework they apply in their approach to the subject. Classification is based on technical observations about the structural and mechanical functioning of buildings, as well as evaluations of their final application and results related to movement mechanisms. This dual approach reveals the depth and diversity of the field (Megahed, 2016).

3.1. Evaluation and Review of Existing Classifications

Table 1 summarizes current kinetic structure classification techniques and emphasizes the standards each author applied. Although structural type and movement type are the main focus of many classifications, this comparative analysis demonstrates significant variation in the inclusion of other crucial features such as material, function, and geometry. For instance, Merchan (1987), Otto & Burkhardt (1972), Mollaert (1996), and Schumacher et al. (2010), for example, concentrate on movement type, which describes how a kinetic structure functions, and structural type, which describes its fundamental form. The principle of movement is further developed by Otto & Burkhardt (1972), and Mollaert (1996), while Merchan (1987) and Schumacher et al. (2010) incorporate additional criteria, such as material, to this fundamental framework. This approach exemplifies a commonly used technique that seeks to describe a structure in terms of both its motion mechanisms and its static state.

Function and structural type are the primary focus of Del Grosso & Basso (2013), Gantes (1991), Escrig (1996), and Hanaour & Levy (2001). For these researchers, prioritize the structure's basic form and function over other aspects related to movement. Direction of movement is additionally employed by Escrig (1996) and by Hanaour & Levy (2001). The main criteria in the classifications put forth by Pellegrino (2001) and Lee (2012) are also function and structural type. However, Temmerman (2007) and Adrover (2015) classify systems based only on their basic form, concentrating almost entirely on structural type. Temmerman (2007) also incorporates movement direction as an additional criterion. In contrast to other classifications, Adrover's (2015) classification is based on particular examples rather than movement or function. Stevenson (2011) offers a simple method that categorizes structures only based on the kind of movement. Instead of emphasizing the structure's physical layout, this framework concentrates on its dynamic properties.

The most comprehensive set of criteria, which includes material, function, structural type, movement direction, and geometry, was utilized by Korkmaz (2004) and Asefi (2010). Their work provides one of the most comprehensive classifications in the field by examining kinetic structures from a variety of perspectives: shape, movement, purpose, and physical characteristics.

Table 1. Evaluation of existing classifications (Atlamaz & Akgün, 2023)

Classification methods

3.2. Proposed Classification for Kinetic Building Components

Depending on the primary system type used, the proposed classification depicted in Figure 1 divides kinetic building components into four main categories: structure, roof, facade, and building components.

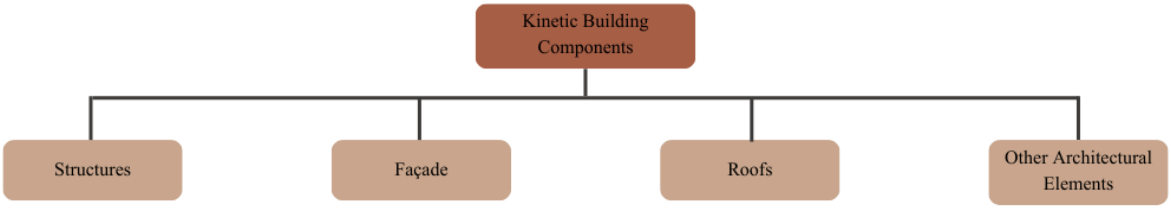

Figure 1. General Classification of Kinetic Building Components

Based on the fundamental modifiers, kinetic systems are classified into two main categories: deployable and transformable. Within each category, motion groups are used to further classify the systems. These two main categories can be divided into three main types of movement: responsive, sliding, and rotating (Figure 2)

Responsive systems are highly convertible systems that can withstand the effects of changing requirements and dynamic needs, switching between more than two variations to create more flexible alternatives (Abdallah et al., 2020).

Deployable structures that can be folded for transport or storage. The fundamental contradiction between deployable and transformable structures definitions are often used interchangeably. Deployable structures can independently make changes between their major configuration changes (Werner, 2013).

Depicted in Figure 2 rotating mechanisms are divided into two categories: folding/scissor and radial/fan expansion. They distribute the load by moving around hinges or axes (URL 1, 2). Telescopic/nested extension, coolable/stem telescopic systems, and linear sliding deployable spans, which offer planar extension, are examples of sliding systems based on the linear movement of components relative to each other (URL 3, 4, 5). Lastly, responsive deployable systems are examined in more detail under the subheadings of morphing deployable trusses, active tensegrity morphing systems, smart material-based deployable, and electro responsive deployable, which can change form through active or passive control (URL 6, 7).

Conversely, transformable structures can rapidly and controllably acquire new shapes, forms, functions, or properties through changes in external and/or internal surfaces connected by articulated joints. Convertible projects generally focus on meeting the functional requirements of the project rather than aesthetic effects (Werner, 2013).

Depicted in Figure 2, Rotating, sliding, and responsive mechanisms are used to analyze these systems methodically. Rotating transformable systems utilize radial/fan expansion, fold/articulated rotation through jointed movements, and scale/single-axis rotation to alter their structural form (URL 8, 9, 10). Linear translation, which provides retractability, and Curvilinear/Rolling Path principles, which alter form along curvilinear paths, are two examples of sliding mechanisms that exhibit linear translational motion (URL 11, 12). On the other hand, responsive transformable systems provide the capacity to align with operational principle control strategies and interact with environmental demands, such as light, heat, wind, and user input. These systems are classified into two fundamental strategies: Material-based adaptation,

which depends on the material's own response, and actively controlled structural adaptation, which depends on external control (URL 13).

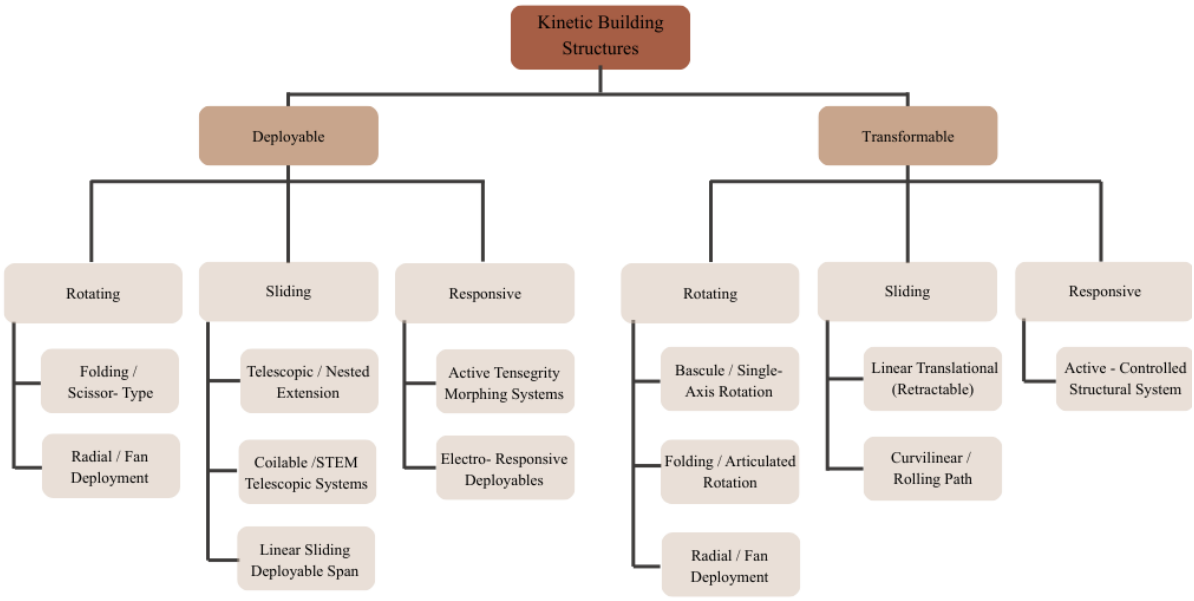

Figure 2. Classification of Kinetic Building Structures

Kinetic facades involve movements or deformations that occur through geometric transformations in space without disrupting the overall structural integrity of building facades. As a result of these movements, the condition of the building's facades, material properties, or physical structure are affected. The applications of kinetic facades aim to enhance aesthetic qualities as well as create sustainable and user-responsive systems that respond to changing environmental conditions, fulfilling functions that would be impossible for static facades (Sharaidin, 2014).

Two basic movement mechanisms, sliding and folding, are used to examine these systems (Figure 3). The single-axis movement type, in which façade elements move in a single plane or along a single axis, is a model of sliding mechanisms (URL 14). Folding systems, which include articulated/bi-fold movement type, rely on folding façade components with hinged links (URL 15).

Transformable façade systems typically change their shape, size, or optical properties to fulfill a continuous operational need. Four primary mechanisms, rotating, scaling, responsive deforming, and hybrid, are used to categorize these systems (Figure 3). Rotating façade systems offer distribution through rotation around axes; classified as single-axis rotation (vertical or horizontal) and multi-axis rotation for complex movements. One-axis rotation involves movement around a single fixed axis, vertical rotation refers to situations where façade elements rotate only around the vertical axis, and multi-axis rotation describes complex movement (URL 16, 17, 18). There are two types of scaling mechanisms: translation-based scaling and 2D scaling based on 2D rotation. These mechanisms change the coverage ratio or façade surface size (URL 19, 20).

Facades that can adapt to changes in environmental conditions and respond to these changes by making typological changes or altering their overall form are defined as responsive. This can

be applied to improve daylight quality and thermal performance in interior spaces by affecting the physical structure or material properties of the building facade. This adaptation can reflect environmental conditions while maintaining overall structural integrity (Sharaidin, 2014).

Responsive deformation systems bend or deform the form to adapt. The findings are categorized into two groups: deformation/physical properties and deformation/visual properties (URL 21, 22). Lastly, among hybrid systems that include various types of movement, the square tic, which features sliding and retracting movement, is found (URL 23).

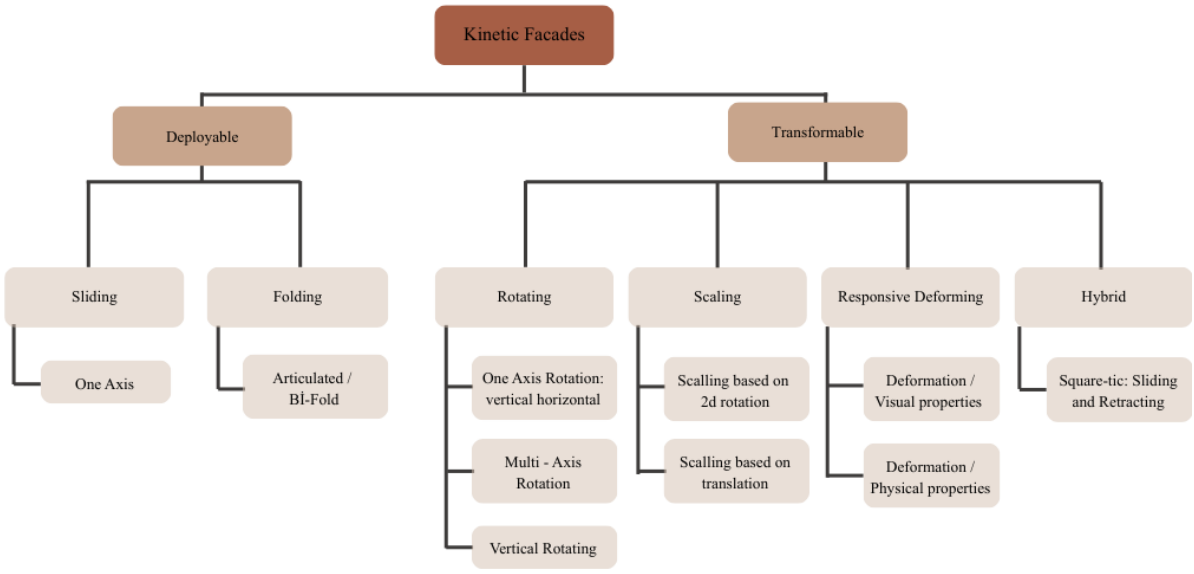

Figure 3. Classification of Kinetic Facades

According to Atlamaz & Akgün (2023), kinetic roof structures are divided into three main categories according to the primary systems used: membrane, rigid bar, and rigid panel. Membrane kinetic roof structures are primarily classified according to the type and size of movement. Rigid bar kinetic roof structures are classified only by the type of movement because the direction of any movement is difficult to determine due to the multifaceted nature of the system. Finally, rigid panel kinetic roof systems are classified according to the type of movement, appearance, and whether there is an overlap condition.

Lightweight deployable roofs are commonly used in various applications to provide weather or environmental protection. For example, sport facilities are often designed with retractable roofs so they can be used to open in good weather and covered in bad weather. Quickly constructed roofs can also be used to seasonally cover athletics fields or swimming pools, allowing for year-round use (Wolfe, 2013).

Depending on the structural component used, deployable roof systems are categorized into three main types, aiming to provide flexibility in both storage and deployment (Figure 4). Folding and bunching movements, such as horizontal folding/bunching (horizontal to the center), horizontal folding/bunching (horizontal to the perimeter), and horizontal parallel folding/bunching (horizontal to the parallel), as well as general folding/bunching systems, are typical of membrane kinetic roof structures (URL 24, 25, 26). The movement of rigid components is the foundation of rigid bar deployable roofs, which can rotate or combine folding/bunching with rotating movements (URL 27, 28, 29). Rigid panel deployable roofs, on

the other hand, are deployed by the movement of the panels; the sliding category comprises movable panels overlapping and sliding onto static part types, while the rotating classification comprises horizontally and vertically rotating panels (URL 30, 31).

Transformable roof systems that can rapidly and controllably acquire new shapes, forms, functions, or characteristics because of changes to the building, exterior, and/or interior surfaces. They are generally structural applications that focus on improving the functional requirements of a project rather than aesthetic effects, addressing environmental impacts (e.g., rain protection for various sporting events or allowing sunlight in). Examples include outdoor projects such as stadiums and pavilions with retractable roofs (Lee, 2012).

There are two main structural types of transformable roof systems, which typically aim to provide continuous functional change or adaptation (Figure 4). Rigid bar transformable roofs include rotating mechanisms (single axis) and multidirectional kinematics, which involve complex movements and rely on the motion control of rigid bar elements (URL 32, 33). Rigid panel transformable roofs consist of rigid panels and are kinetic roof systems in which the roof geometry is transformed over time through the opening, closing, or movement of these panels by means of mechanical systems (URL 34).

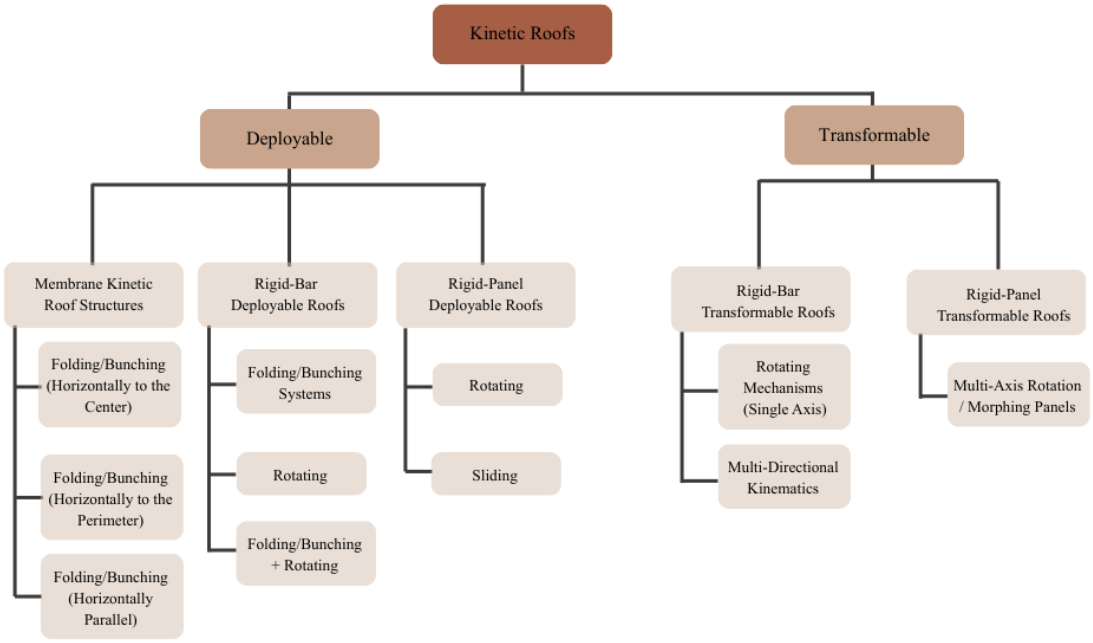

Figure 4. Classification of Kinetic Roofs

Other deployable building elements are classified into three main groups based on their movement mechanisms, and these systems can be efficiently opened and closed according to functional requirements (Figure 5). The potential uses for components with sliding mechanisms are diverse, encompassing areas such as furniture, doors, windows, stairs, walls and partitions (URL 35, 36, 37, 38, 39). The rotating mechanism can also be used to deploy these same types of components such as partitions/ walls, doors, windows (URL 40, 41, 42). The third mechanism, the folding/scissor type, provides quick deployment and small storage for furniture, doors, windows, stairs, walls and partitions (URL 43, 44, 45, 46).

Systems that can be changed from one configuration to another, typically for space optimization or multifunctionality, are known as transformable building components (Figure 5). Similar to deployable systems, a sliding mechanism can alter the shape and purpose of essential elements, such as walls and partitions, furniture, doors, windows, and stairs (URL 47, 48, 49). For the same component types, a rotating mechanism also offers transformability (URL 50, 51, 52). Lastly, building components such as walls, partitions, furniture, doors, windows, and stairs can be transformed using a folding/scissor mechanism, providing flexibility and spatial efficiency (URL 53, 54, 55, 56, 57).

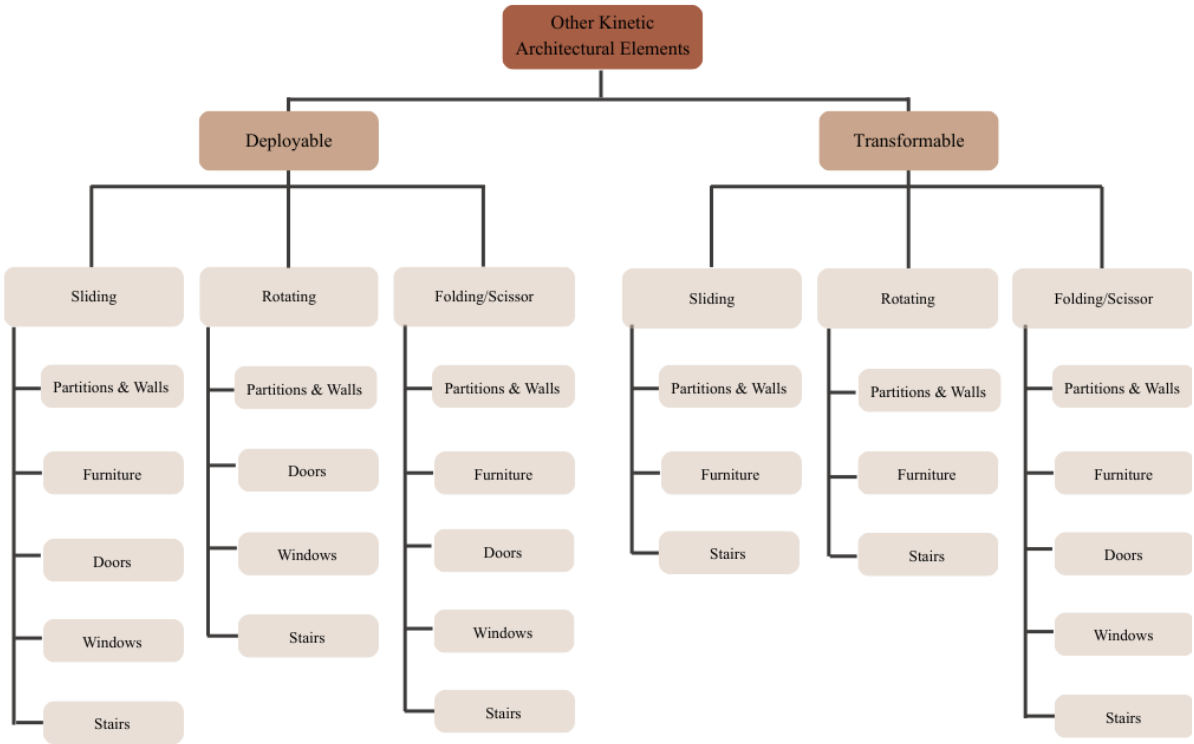

Figure 5. Classification of Other Kinetic Architectural Elements

3.Conclusion and Recommendations

The architectural literature offers a wide variety of classification schemes for kinetic structures and systems, each emphasizing different criteria such as movement mechanism, functional purpose, or environmental responsiveness. While these classifications share certain fundamental principles they remain fragmented due to variations in scope, level of detail, and the criteria used. This inconsistency makes it challenging to evaluate kinetic architectural applications within a unified framework.

This study addresses this gap by proposing a comprehensive classification system organized under four primary categories: structural systems, façade systems, roof systems, and other building elements. By examining deployable and transformable systems across these categories, the study offers an integrated framework that combines principles of movement with architectural scale, performance objectives, and functional adaptability. This approach not only brings together previously scattered classification methods but also provides a coherent

reference that can guide future research, design strategies, and technological innovation in kinetic architecture.

The proposed classification contributes to the literature by establishing a clear and systematic basis for understanding kinetic systems at both macro and micro levels. It enables designers and researchers to compare different movement mechanisms, evaluate performance potential, and develop more holistic design frameworks for smart and adaptive buildings. Future studies may expand this classification by incorporating computational control systems, responsive material technologies, and real time environmental adaptation, further enhancing the architectural potential of kinetic systems.

Abstract

Traditional urban environments are characterised by strong spatial coherence, where private, semi-public, and public domains intersect to form a continuous and legible urban fabric. In such settlements, streets play a pivotal role as extensions of dwellings at the ground level, shaping both the physical and social quality of the built environment. This study examines the relationship between dwellings and streets in the traditional urban fabric of the Famagusta Walled City in North Cyprus, with particular attention to transitional spaces that mediate between private and public realms.

The research employs a combination of literature review, field observations, and architectural analysis. Spatial configurations, plans, and on-site illustrations are analysed to understand how traditional design elements such as courtyards, sundurme (verandas), arch houses, and narrow streets foster social interaction, privacy, and neighbourhood cohesion. Findings reveal that the physical characteristics of streets and transitional spaces not only facilitate circulation and connectivity but also sustain community identity by accommodating a variety of social and cultural activities.

By highlighting the significance of dwelling–street continuity, this study contributes to a deeper understanding of how traditional urban design strategies can inform contemporary approaches to livable and socially cohesive urban environments. The findings underscore the importance of maintaining spatial relationships between private and public domains in the conservation and revitalisation of historic urban fabrics.

Keywords: Dwelling-street relationship, transitional spaces, social interaction, community-based revitalisation, Famagusta Walled City

1. Introduction

Traditional urban environments have long been a subject of interdisciplinary inquiry, attracting the attention of architects, urban planners, anthropologists, sociologists, historians, art historians, and geographers. Over the past decades, numerous studies have examined the morphological, functional, and socio-cultural characteristics of these environments, generally following two primary lines of inquiry: one focusing on the traditional house as an architectural artefact and the other on the broader traditional settlement pattern. As Eyüce (2012) notes, “Architects are more inclined to decipher the morphological characteristics of the individual dwelling unit heir tendency is to see the traditional house as the end product of the traditional building.” The relationship between the private outdoor domain of the dwelling and the public outdoor urban domain has been recognised as central to the spatial and social organisation of traditional environments. These two domains intersect in various ways, creating dynamic social interactions. Oktay & Önal (1998) emphasise that “Social variables predominantly determine any function potentially occurring in both public and private outdoor space,” underscoring the importance of cultural and social norms in shaping the use of transitional and shared spaces. Traditional built environments are typically characterised by compact and dense settlement patterns, reflecting a high degree of interdependence between individual dwellings and the broader urban fabric. Rapoport (1989) highlights this spatial coherence by observing that “it is sometimes difficult to separate dwelling and settlements. Particularly in the case of communal

dwellings, where dwellings and settlement are one." This integration creates a strong sense of spatial continuity and collective identity within the urban form.

The duality between the house and the street, or the private and public realms, is also expressed in the phenomenology of "inside" and "outside." Tuan remarks that "Constructed form has the power to heighten the awareness and accentuate… the difference in emotional temperature between 'inside' and 'outside'," suggesting that architecture can both delineate and mediate these spheres (Tuan, 2001, p. 107). This distinction is further related to the concept of neighborhood, which, as Tuan (2001) argues, contributes significantly to the inhabitants' "larger place consciousness": "Houses and streets do not of themselves create a sense of place, but if they are distinctive this perceptual quality would greatly help the inhabitants to develop the larger place consciousness." The philosophical dimension of dwelling has also been explored. Heidegger argues that "the basic character of dwelling is to spare, to preserve… dwelling itself is always a staying with things," thereby framing dwelling as a practice deeply connected to existence and place (Heidegger, 1993, p. 351). Similarly, Oktay highlights the enduring historical and cultural significance of streets and open spaces, observing that "since the earliest urban settlements, there has been a fundamental human impulse to organise and shape streets and public areas—to make them more functional for daily and communal activities, and more aesthetically restorative for the urban community" (Oktay, 2002, p. 263).

Together, these studies demonstrate that traditional urban environments should not be perceived merely as physical assemblages of dwellings, streets, and public spaces. Rather, they embody complex socio-spatial systems in which architecture, settlement patterns, and cultural practices are deeply interwoven. These systems foster a strong sense of community identity and facilitate dynamic forms of social interaction, grounded in spatial continuity and everyday lived experience. By exploring the interplay between built form and social life, this study aims to contribute to a more nuanced understanding of the traditional urban fabric as a living cultural construct that continues to inform contemporary urbanism. The Famagusta Walled City presents a complex and multifaceted backdrop, shaped by influences from Ottoman, Venetian, and British colonial legacies. Numerous families have inhabited the Walled City for centuries, and their social customs—ranging from street-level interactions to the informal use of public and semi-public spaces—are deeply intertwined with the architectural landscape. Revitalisation efforts that ignore these living traditions jeopardise the community's sense of place, turning living history into a museum-like artefact devoid of social significance. Such an approach risks alienating residents, who may feel that their cultural heritage is being commodified rather than celebrated. To ensure the preservation of both the architecture and the vibrant community spirit, revitalisation initiatives must prioritise participatory methods by allowing residents to voice their needs and aspirations.

2. Materials and Methods

This study investigates the spatial continuity between dwellings and streets within the traditional urban fabric of the Walled City of Famagusta, North Cyprus. The research particularly focuses on the role of transitional spaces—such as thresholds, semi-open areas, and narrow passageways—in mediating the relationship between private and public realms. It aims to uncover how these spatial interfaces contribute to community cohesion, everyday social interaction, and the construction of collective identity.

To achieve this, a mixed-methods approach was employed, combining literature review, fieldwork, and case study analysis:

- Literature Review: A comprehensive review of interdisciplinary literature was conducted to build the theoretical foundation of the study. The review included works from architecture, urban sociology, human geography, and heritage studies, particularly focusing on the relationship between domestic architecture, public space, and social life in traditional urban contexts.

- Fieldwork and On-Site Documentation: Empirical research was carried out through site visits to selected locations within the Walled City. Photographic surveys, spatial mapping, and architectural sketching were employed to document and analyse the built environment. Special attention was given to intermediate spaces such as *sundurme*, courtyards, and shared thresholds that support everyday encounters and social use.

By integrating spatial analysis with community-based insight, this methodology enables a deeper understanding of how traditional urban environments operate as both physical and social infrastructures. It also provides a basis for future revitalisation strategies that respect both tangible heritage and living culture.

3. Findings and Discussion

3.1. Contextual Features of Traditional Urban Architecture

To understand the formation of traditional settlements in Cyprus, it is essential to provide a brief overview of the island's historical background. Due to its strategic location at the crossroads of the Eastern Mediterranean, Cyprus has historically been subjected to successive waves of control by various civilisations, including the Egyptians, Assyrians, Persians, Romans, Byzantines, Arabs, Venetians, Ottomans, and, most recently, the British. As a result, both the island's social structure and architectural character have undergone continuous transformation. Pulhan and Numan (2005) emphasise that "the multicultural accumulation of different sovereignties was reflected mainly in the urban areas of the built environment." Accordingly, the multi-dimensional identity of Cypriot society today is largely shaped by the layered coexistence of these diverse cultural influences.

Each ruling power in Cyprus contributed distinct architectural styles to the built environment. For instance, British, Ottoman, and Roman influences can be clearly identified in various urban and architectural forms. Over time, these styles collectively shaped the domestic urban fabric. A notable example is the Famagusta Walled City (Figure 1), which exhibits a layered architectural history — combining Ottoman and Medieval elements, enclosed by Venetian fortifications and structured according to a medieval street pattern that was later reshaped under Ottoman influence.

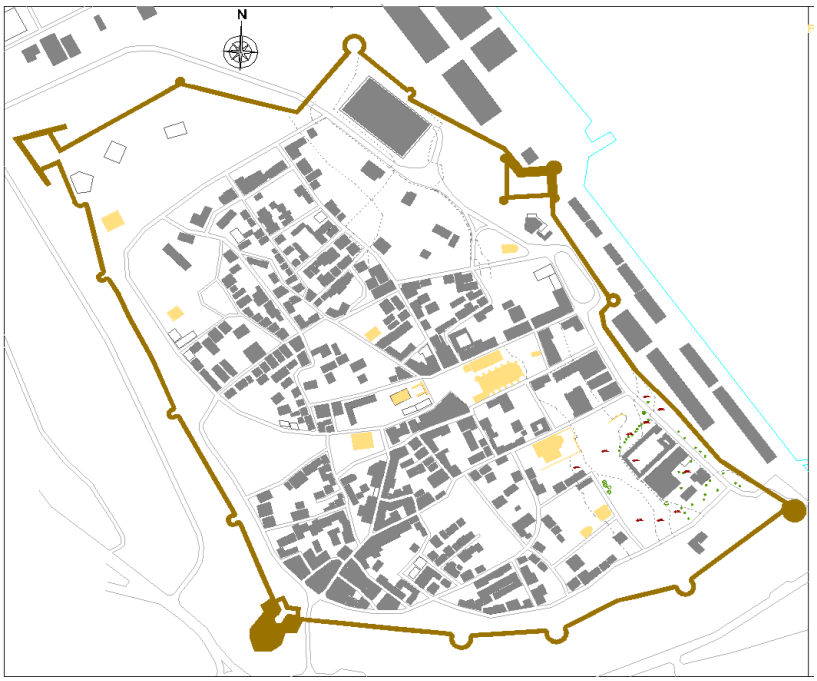

Figure 1. The traditional urban pattern of the Famagusta Walled City (reproduced by the author).

In general, traditional Turkish urban dwellings in Cyprus have been shaped by the interaction of various cultural influences over time. In other words, the traditional architectural character of Cyprus bears the imprint of multiple civilisations, resulting in a hybrid and layered urban form. As a result, traditional Turkish houses represent an amalgamation of different architectural traditions, both in terms of form and construction techniques. Commonly used methods include adobe and masonry systems, which reflect the adaptation of local materials and know-how. Pulhan and Numan (2005) describe Ottoman-era construction techniques in Cyprus as follows:

Techniques such as Bağdadi (wattle and daub or lath and plaster system) and Çatma (brick or stone nogged system) can be traced through the cracks on the plastered surfaces. The walls, often made of cut stone, and the masonry arches supported by columns, along with the building's mass and street-facing façades adorned with Gothic and Renaissance decorations, all point to Frankish and Venetian antecedents (Pulhan & Numan, 2005).

This synthesis of Ottoman and Western architectural elements—particularly Gothic and Renaissance motifs—demonstrates the multi-layered identity of traditional Cypriot dwellings, where imported forms were reinterpreted through local traditions and needs.

Despite similar geographic, topographic, and climatic conditions, the form and functions of urban dwellings differ significantly from those of rural dwellings in Cyprus. This difference primarily stems from the influence of dominant cultural patterns and associated lifestyles on the development of urban housing forms (Numan, Dinçyürek, & Pulhan, 2002). In other words, while house forms adapt to Cypriot environmental conditions, they also reflect cultural values that evolve across time and setting. Nevertheless, one architectural feature that remains consistent across both rural and urban communities on the island is the presence of transitional spaces. These spatial elements—such as courtyards and sundurme (verandas)—mediate

between the private and public domains and are fundamental to traditional domestic architecture.

As Rapoport argues, cultural factors play a central role in shaping traditional dwelling forms (Rapoport, The nature of the courtyard house: a conceptual analysis, 2007). In the case of Famagusta Walled City, elements such as family structure and attitudes toward privacy have guided the spatial organisation of homes. Thus, the development of the traditional urban environment in Cyprus, especially in Famagusta, can be seen as an inward–outward progression: beginning from the interior (private sphere) and extending toward the exterior (public spaces, such as the street). The courtyard and sundurma serve as key transitional modules that articulate this relationship, fostering both seclusion and community engagement.

The courtyard serves as one of the most essential spatial modules in the organisation of traditional urban fabrics. It functions as a transitional or intermediate space that mediates between the private domain of the dwelling and the public domain of the street. The term "intermediate space" is used to refer to the ambiguous zone between interior and exterior that does not strictly belong to either (Doğan, 2016). According to Rapoport, "the courtyard house itself can be seen partly in these terms. Thus, the form of the relation between the private and public domains—via a 'lock,' rather than without such a lock and with a permeable boundary—is more fundamental than the shape of the domains (let alone the materials used)" (Rapoport, The nature of the courtyard house: a conceptual analysis, 2007). This interpretation highlights the role of the courtyard as a buffer zone, controlling visual and physical permeability.

Pulhan and Numan reinforce this by describing the havlu as a central element of domestic life in Cypriot traditional dwellings: "Havlu is the outdoor space that is in the centre of private and public life in the dwelling... Most of the activities, particularly laundry and cooking, were held in the havlu" (Pulhan & Numan, 2005). Unlike the more romanticised vision of a garden courtyard, the havlu is a functional outdoor space, enclosed by building façades and additional boundary walls (Figure 2). In this context, the courtyard emerges as a spatial and cultural construct—simultaneously shaped by architectural forms and social practices. It exemplifies how traditional dwellings establish a nuanced balance between privacy, community, and daily life activities.

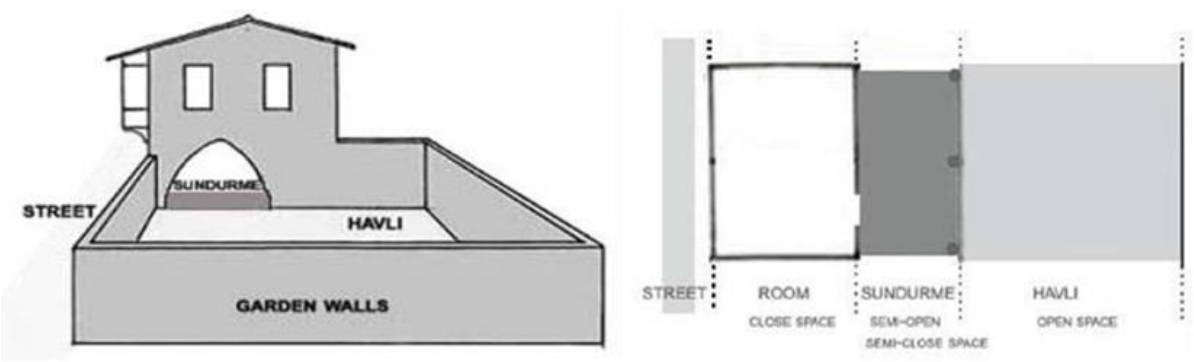

Figure 2. A Schematic Presentation of Traditional Turkish houses in Cyprus (Pulhan & Numan, 2005).

The sundurme is one of the principal spatial components of traditional urban dwellings in Cyprus. Serving as a transitional element, it functions as a semi-open passageway that connects interior rooms to outdoor spaces such as courtyards and streets, while preserving privacy and

ensuring spatial fluidity. Architecturally and culturally, the sundurme acts as a private circulation route embedded within the domestic layout, reinforcing the layered structure of public and private domains. Pulhan and Numan (2005) highlight the significance of the sundurme in shaping traditional architectural patterns:

It is the essential component that determines the spatial patterns and formal configurations in the traditional architecture of Cyprus. The interaction between public and private, people and environment, open and closed, inside and outside, and part and whole are important design criteria in traditional environments. This interaction and the indissoluble whole of the fabric—transitional space—described as the overlapping of the indoor and outdoor space, has great importance (Pulhan & Numan, 2005).

In this regard, the sundurme exemplifies the role of transitional spaces in mediating between opposing spatial and social domains—public/private, open/closed, and inside/outside. It not only shapes the architectural identity of the dwelling but also contributes to the experiential quality of urban life. As a spatial interface, the sundurme links street, room, and courtyard, generating continuity between the urban public realm and the domestic interior (Figure 2). Far beyond its structural function, it represents a culturally embedded response to the social and environmental context of Cypriot cities. Pulhan and Numan further note: “Sundurme is perceived as a semi-open space satisfying the needs of its physical and social contexts” (Pulhan & Numan, 2005).

Thus, within the broader urban fabric, the sundurme serves as a critical spatial mediator, articulating social boundaries, enabling interaction, and reinforcing the intimate relationship between inhabitants, architecture, and neighborhood life. At the building scale, it exemplifies how traditional design integrates functionality, privacy, and social cohesion. This spatial logic extends beyond the individual dwelling to shape the structure of the wider neighbourhood (mahalle), where physical and social dimensions are intricately interwoven.

Building upon this foundation, the following section explores the interdependence between spatial arrangements and communal life in traditional environments, particularly focusing on how architectural forms reflect and reinforce patterns of social interaction, collective identity, and neighbourhood cohesion.

3.2. Interdependence between Spatial and Communal Life.

In traditional urban environments, the mahalle (neighbourhood) functions not merely as a physical aggregation of buildings but as a vital socio-spatial unit where spatial arrangements and community life are deeply intertwined. Social cohesion in such settings arises from the interconnectedness of households and the shared use of semi-public spaces—alleys, courtyards, thresholds—which collectively sustain compact urban morphologies and nurture strong interpersonal relationships.

However, the nature of this spatial-social interdependence varies across cultural geographies. In many Islamic cities, for instance, urban form is shaped by religious and moral codes that emphasise privacy, neighbourly duty, and collective well-being. As Hakim and Rowe (1983) illustrate with examples from North African medinas such as Fez, Tunis, and Marrakesh, decisions made by a single household regarding built form often have tangible consequences for the surrounding community. This entanglement, rooted in Qur’anic guidance, reveals a spatial ethic of mutual respect and social accountability (Hakim & Rowe, 1983).

In the Cypriot context, these spatial codes have evolved into a hybrid urban tradition. While Islamic principles were dominant during the Ottoman period, they later became interwoven with Byzantine and Venetian architectural legacies and British colonial planning norms. As a result, the spatial fabric of towns such as Famagusta reflects a layered synthesis of cultural influences—religious, civic, and colonial—that inform the morphology of the neighbourhood and the nature of street–dwelling relations.

The Famagusta Walled City provides a rich case study for exploring these dynamics. The urban fabric is composed of a dense network of narrow streets, cul-de-sacs, and organic intersections that facilitate nuanced transitions between private and public domains. The Lynch analysis (Figure 3) identifies a coherent mental map structured around paths, nodes, edges, landmarks, and districts, suggesting a high degree of spatial legibility and cognitive engagement among residents. Multiple entrance points, especially those located along major traffic arteries, increase permeability and social connectivity between the historic core and peripheral zones (Figures 3 & 4). The traffic analysis (Figure 5) further reveals a functional hierarchy of circulation routes—from pedestrian-only streets to secondary vehicular paths—that balances mobility with human-scale urbanism. This configuration supports walkability and reinforces everyday social interaction in streets and transitional zones, particularly in narrow alleys and shaded courtyards.

The land use analysis (Figure 4) confirms the heterogeneous spatial composition of the walled city, where residential units coexist with shops, cafes, offices, schools, and cultural landmarks. This spatial mix fosters urban vitality, transforming the street into more than a circulation corridor; it becomes an extension of domestic life, a zone of interaction, negotiation, and sociability. The presence of flowerpots, chairs, and thresholds animated by daily routines blurs the boundary between private and public, creating semi-public spaces of encounter.

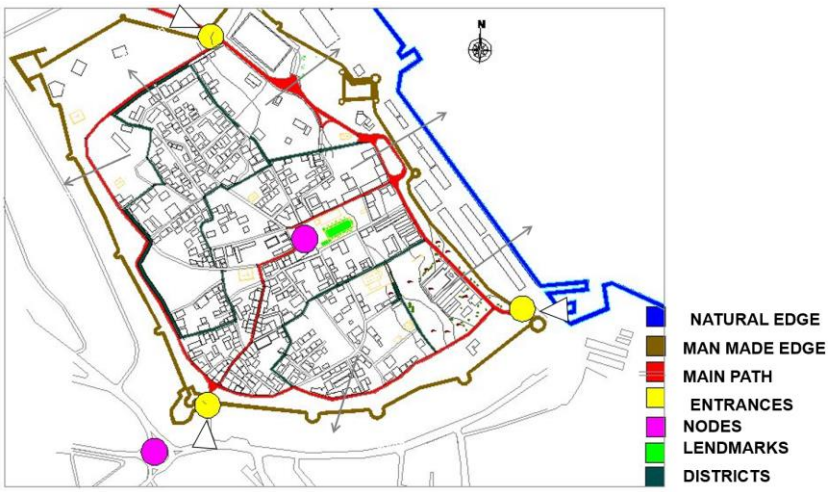

Figure 3. Lynch's analysis of the Walled City of Famagusta, highlighting key urban elements such as paths, edges, nodes, districts, and landmarks that structure both movement and cognitive mapping within the historical core.

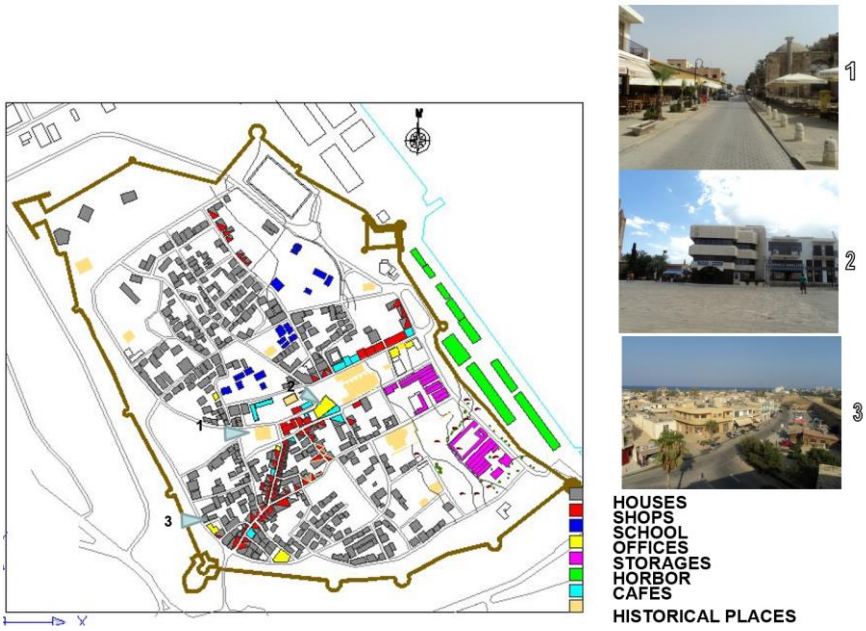

Figure 4. Land use distribution in the Walled City of Famagusta, showing the spatial integration of residential, commercial, educational, and cultural functions that promote urban vitality and mixed-use character.

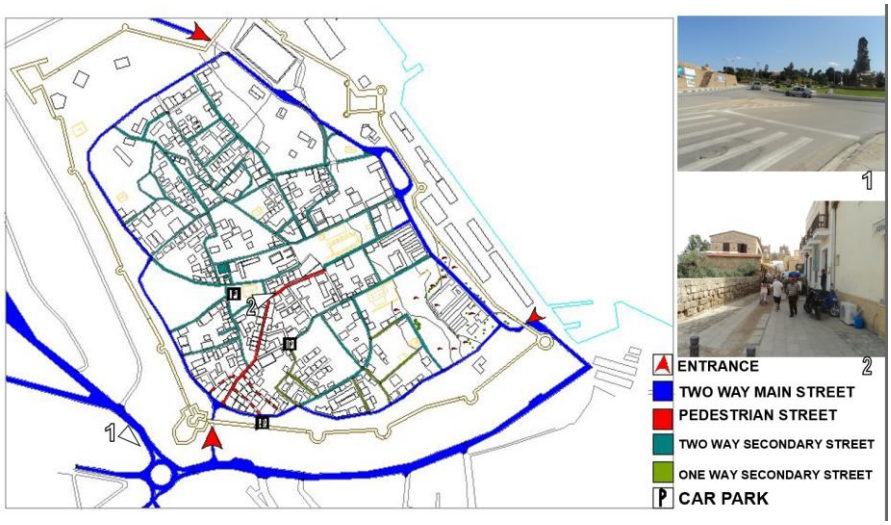

Figure 5. Traffic circulation analysis of the Walled City, illustrating the hierarchy of streets—from pedestrian-only alleys to secondary vehicular routes—that supports walkability and informal social interaction.

As Oktay and Önal (1998) note, in Cypriot towns, "the street is the most primitive intersection between private and public domains … almost an extension of the home." The streets of Famagusta function precisely in this way. Architectural elements such as passage houses (Figure 6) mediate movement and privacy, ensuring continuity within the spatial fabric while allowing for flexibility in communal life. These built forms exemplify the adaptability of traditional design to the demands of social interaction, climate, and cultural norms. Streets, therefore, operate as social infrastructures. As Moughtin (1992) argues, they are not only

physical connectors but also "social facts," influencing patterns of behaviour, collective memory, and identity formation. Lynch (1961) similarly emphasises that streets with distinctive characteristics enhance the imageability of the city and support the mental orientation of its inhabitants.

Figure 6. Passage houses in the Famagusta Walled City, Cyprus, illustrate how spatial continuity and social interaction are maintained through architectural design.

In this respect, the street–dwelling relationship in the Famagusta Walled City (Figures 7) embodies both spatial and cultural continuity. Dwellings frequently open directly onto the street, transforming it into a semi-private platform where daily life unfolds—children play, neighbours converse, and elders gather. These practices produce a lived space that is not strictly interior nor fully public but oscillates between domains, fostering intergenerational exchange and collective identity.

Figure 7. Street–dwelling interface in the Walled City of Famagusta, showing how semi-public thresholds such as doorfronts and alleys function as extensions of domestic space and sites of everyday sociability.

Recent scholarship echoes this insight. Yu et al. (2024) argue that street vitality in traditional urban settings emerges from both physical morphology and the continuity of social practices. Likewise, Cömert (2025) highlights the symbolic and functional role of streets in Northern Cyprus as carriers of collective memory and sites of solidarity. In light of these findings, preserving the spatial and social fabric of the Walled City is essential not only for architectural heritage but also for sustaining community life. The degradation of narrow streets and semi-public thresholds risks more than physical loss; it may lead to social disintegration and the erosion of place-based identity. Conservation efforts must therefore adopt a holistic approach, one that embraces both the tangible and intangible dimensions of urban space. Only then can the Famagusta Walled City endure as a living heritage, where history, culture, and everyday life remain meaningfully intertwined.

3.4. Community-Based Revitalisation Strategies in Famagusta

In recent years, approaches to revitalising historic environments have moved away from understandings that solely aim to preserve physical heritage and towards community-based and sociocultural sustainability strategies (Table 1). This new paradigm emphasises that the long-term sustainability of historical environments, like Famagusta's Walled City, depends not only on the restoration of the built environment but also on the preservation of the intangible cultural practices that give meaning to these spaces (Doratlı et al., 2007). Famagusta has a multi-layered historical fabric shaped by a rich cultural heritage from the Ottoman, Venetian, and British colonial periods. Many families have lived in the same neighbourhood for generations, and everyday spatial practices, such as street-level interactions and using courtyards and alleys, have become integral parts of this historical fabric. Therefore, community-based revitalisation strategies should aim to preserve not only physical structures but also this social fabric (Asbagh & Tümer, 2021; Philokyprou, 2024).

To achieve success in the revitalisation process, multi-scale approaches are necessary that treat space not just as an architectural object but as a carrier of social life. Intermediate spaces—for example, porches, alleys, and common streets—are not only physical transition areas; they are also spatial representations of neighbourhood relationships, privacy, and social solidarity (Yu et al., 2024).

The conservation of traditional urban fabric entails more than safeguarding historic buildings; it requires a nuanced understanding of the spatial and social dynamics that animate everyday life in heritage environments. In the case of the Walled City of Famagusta, revitalisation strategies must address the interplay between tangible architectural heritage and the intangible cultural practices embedded in the neighbourhood's daily routines.

A successful revitalisation model requires a multi-scalar approach that integrates top-down planning frameworks with bottom-up, community-driven initiatives. This includes aligning municipal policies with local needs, recognising both individual household concerns and broader neighbourhood values. Intermediate spatial elements—such as sundurme, courtyards, and shared streetscapes—are particularly important in this regard. These elements are not only architectural connectors but also social thresholds, shaping the vernacular experience of privacy, neighbourliness, and coexistence.

Table 1. Literature review on heritage conservation, community participation, and socio-spatial revitalisation.

2022	Narmin Babazadeh Asbagh and Ege Uluca Tümer	Cultural Heritage Interpretation: Proposals for Medieval Churches in Famagusta Walled City, North Cyprus	It contains suggestions for interpreting cultural heritage in historical settlements. It addresses the "intangible heritage" dimension in revitalisation strategies.

3.4.1. Revitalisation strategy

The conservation of traditional urban fabric involves more than the preservation of historical buildings; it requires a sensitive engagement with the spatial and social dynamics that shape everyday life in heritage settlements. In the case of the Walled City of Famagusta, efforts at

revitalisation must account for the complex interplay between tangible architectural heritage and the intangible communal practices embedded within the neighbourhood.

Conservation strategies that treat the built environment as a static artefact risk overlooking the evolving nature of social life in traditional quarters. Therefore, revitalisation should aim not only to restore the physical integrity of dwellings, streets, and courtyards but also to reactivate the communal interactions that define their meaning and use. As such, policies must prioritise inclusive participation, economic viability, and the adaptation of spaces to contemporary needs without disrupting the historical continuity of form and function.

Furthermore, successful revitalisation requires a multi-scalar approach—one that balances individual household needs with collective neighbourhood values, and aligns municipal planning with bottom-up community initiatives. In this regard, the preservation of intermediate spaces such as sundurme and shared streetscapes becomes central, as they embody the spatial logic of coexistence, privacy, and interdependence that characterises Cypriot vernacular urbanism. Therefore, community-based revitalisation in Famagusta should prioritise the following:

- Participatory Planning: Involving residents, local NGOs, and cultural associations in planning and decision-making processes ensures that interventions reflect the real needs and aspirations of the community. Participation also fosters a strong sense of ownership, which is essential for the long-term sustainability of conservation initiatives.

International conservation efforts in Famagusta's Walled City provide tangible examples of community-based approaches. The Historic Walled City of Famagusta project, initiated by the World Monuments Fund (WMF), has developed an inclusive conservation model that promotes collaboration among local stakeholders, universities, and civil society organisations. The project aims not only to preserve monumental structures but also to strengthen the social sustainability of the historic environment by encouraging the active participation of the local community.

WMF's approach establishes a holistic balance between physical preservation and social revitalisation, integrating cultural continuity with heritage management. By embedding community engagement at every stage of the conservation process, the project ensures that heritage protection becomes a shared social responsibility rather than a top-down technical exercise. In this respect, the WMF initiative not only safeguards the historical fabric of Famagusta but also sustains its regeneration within the conceptual framework of "living heritage" (Anon., 2012).

- Adaptive Reuse and Incremental Rehabilitation in Harmony with Local Knowledge: Instead of large-scale, top-down restorations that may displace long-term residents, small-scale, incremental upgrades—guided by local knowledge and practices—can improve safety, infrastructure, and living conditions while preserving authenticity and daily life (Asbagh & Tümer, 2021).

- Protection of Intermediate and Shared Spaces: As discussed in earlier sections, semi-open spaces such as the *sundurme*, passageways, and narrow streets play key roles in community life. These elements are not mere spatial connectors but serve as social thresholds and everyday meeting points; thus, they must be preserved and integrated sensitively into revitalisation efforts (Cömert, 2025; Yu, Sun, Wang, & Sun, 2024).

Yu et al. (2024) demonstrate that street vitality in traditional urban fabric is not solely dependent on morphological features but is also nourished by such social interfaces. Similarly, Cömert (2025) asserts that intermediate spaces in traditional settlements in Northern Cyprus serve as structural and social networks, ensuring the continuity of neighbourhood culture.

As seen in conservation efforts in Famagusta, the physical and functional continuity of these areas supports social cohesion at the neighbourhood level (WMF, 2012). The repurposing of intermediate spaces in a way that is sensitive to contemporary needs not only ensures historical continuity but also allows local people to continue their daily lives. Otherwise, the removal of these thresholds could lead to the weakening of social relationships and the anonymisation of public spaces. The preservation of neighbourhood culture in Famagusta stands as a vital endeavour, ensuring both physical and functional continuity that fosters social cohesion among its residents. By thoughtfully repurposing intermediate spaces to align with contemporary needs, the community not only safeguards its historical essence but also enriches the daily lives of its inhabitants. This careful stewardship of cultural heritage affirms that removing these elements could have detrimental effects, eroding social relationships and leading to the anonymisation of public spaces. Ultimately, the vibrant tapestry of Famagusta's neighbourhood culture is not merely a relic of the past but a living framework that supports community interaction and continuity in an ever-evolving urban landscape.

- Cultural and Educational Programming: Organising community-led events, intergenerational storytelling workshops, exhibitions, and heritage walks can promote the transmission of local knowledge, strengthen community identity, and foster culturally sensitive tourism (Philokyprou, 2024).

- Economic Empowerment through Heritage-Based Micro-Enterprises: Supporting traditional crafts, home-based production, local gastronomy, and eco-tourism initiatives can provide economic alternatives that align with conservation goals. Such approaches allow residents to see heritage as an asset rather than a burden (Kara & Iranmanesh, 2023).

Ultimately, community-based revitalisation strategies in Famagusta must aim to reconnect people with place by respecting historical continuities while responding to contemporary socio-economic needs. As the urban fabric continues to evolve, embedding local agency into conservation practice becomes essential—not only to protect buildings, but also to preserve the living culture they support.

4. Conclusion

This study investigates the spatial continuity between housing and streets within the traditional urban fabric of Famagusta Walled City, elucidating how these physical relationships foster social interactions, a sense of belonging, and urban identity. Through field studies, it was found that intermediate spaces (such as porches, passages, and narrow streets) not only serve as physical connections but also promote social interactions as social thresholds of daily life.

The research findings indicate that in multi-layered historical environments like Famagusta, it is of great importance not only to preserve the physical heritage but also to sustain the ongoing daily practices and social relationships in these areas. The effective use of these public-private intermediate spaces by diverse user groups, particularly children, women, and the elderly, underscores the vital importance of these areas for social sustainability.

In this context, conservation and revitalisation strategies must encompass not only monumental structures but also the social fabric and cultural continuity that have formed around them. Participatory planning processes will make it possible to benefit from the knowledge and experience of local people and to preserve these heritage sites not only as an aesthetic but also as a livable. In conclusion, approaches that focus on the reciprocal relationship between spatial continuity and social life in historical settlements, such as Famagusta Walled City, promote physical preservation and encourage a sustainable understanding of urbanisation in line with the concept of "living heritage." This approach forms the basis of a holistic conservation model that integrates the spatial wisdom of the past with the social needs of the present.

Abstract

Long before the profession of architecture existed, humanity had been striving to create living spaces that met their basic needs for shelter and protection, shaping these spaces sometimes for functional and sometimes for aesthetic purposes. The individual's identification with their living space, through which they reflect their own identity onto the space, is shaped by aesthetic concerns and functional requirements, becoming a factor that influences design decisions. The individual's personal desire to create, shaped by the knowledge they have acquired over time, forms their identity as a designer. This identity is reflected in the resulting work, ensuring its originality and distinction from others. In this regard, the aim of this study is to examine and comparatively evaluate the designer identities of Peter Zumthor and Kengo Kuma, who occupy an important place in the profession of architecture and are leading representatives of contemporary architecture. The projects selected through purposeful sampling are analysed using architectural data and the analysis model found in the source "Precedents in Architecture". As a result of these analyses, the criteria adopted by architects in their design production and their designer identities are sought to be determined. The findings are evaluated comparatively in terms of the commonalities between the two architects and the aesthetic approaches that distinguish them from each other. In conclusion, despite having grown up in different cultural and geographical contexts, Peter Zumthor and Kengo Kuma are found to be similar in their respect for nature and humanity and their use of natural materials and light as fundamental components of design, but there are distinct differences in their approaches to architecture and design decisions stemming from their personal designer identities.

Keywords: Designer identity, architectural approach, precedents in architecture, Peter Zumthor, Kengo Kuma

1.Introduction

The concept of identity creation in design became prominent during the modernism and subsequent post-modernism periods (Özçam, 2022). With the acceleration of industry in the early 20th century, identity creation in design began to be used by both designers and brands as a countermeasure to the standardisation of products (Upshaw, 1995). Today, designers are turning to branding with their own unique techniques. They produce designs that convey their own expression, style or signature and are easily distinguishable from others. World-renowned architects Zaha Hadid, Frank Gehry and Rem Koolhaas have identities that are easily distinguishable from their peers. Zaha Hadid uses futuristic vectors in her designs, Rem Koolhaas uses Cubist folds, and Frank Gehry uses Neo-Baroque curves (Foster, 2011). These

[1] This study was produced from the master's thesis titled "Decoding the Designer Identities of Architects: Peter Zumthor and Kengo Kuma" prepared by Pınar Taslı under the supervision of Assoc. Prof. Dr. Hare Kılıçaslan at the Graduate School of Natural and Applied Sciences, Karadeniz Technical University.

architects' designs reveal their identities through the techniques, forms, or materials they choose to use.

The analysis model created using analytical diagrams and coding methods enables the examination of the construction stages of all layers of the forms produced formally by the designer.

To understand or interpret the essence sought, the designer's stylistic choices, and the designer's formative decisions, it is necessary to analyse the codes within the design. The concept of code refers to the organisation or design that enables the understanding of the essence of the message to be conveyed or the relationships between units (Hatipoğlu & Koç, 2020). Codes also contain the stages of thought in the design formation process, user expectations, and reflections of the designer's identity. Therefore, revealing the designer's identity, getting to the essence of the design, and correctly reading the codes are possible.

The fundamental design principles that initiate the design creation process serve as a guide in the problem-solving process. While facilitating and initiating the design phase, they also play an important role in understanding, resolving, and evaluating the design (Civcir, 2015). The design principles that play a role in the creation and resolution of the design are addressed in different sources as different criteria. Within the scope of this thesis, the fundamental design principles are addressed under eight headings: balance, rhythm-repetition, contrast, harmony (suitability), proportion, unity (integrity), hierarchy, and dominance.

The number of elements in design is defined by Maitland Graves as seven components: direction, form, line, measure, texture, colour, and tone (Graves, 1951), while Hulusi Güngör adds the components of space, light-shadow, and movement to these in his book “Basic Design” (Güngör, 2005). Within the scope of this study, the Basic Design Elements are addressed under ten headings: Texture, Tone (Value), Colour, Line, Scale (Size), Direction, Spacing, Form, Light-Shadow, and Movement.

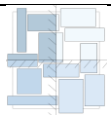
Within the scope of the study, fundamental design principles and elements are frequently referred to in the rethinking, resolution, evaluation and emergence of the design concept (Taslı, 2024).

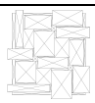
2.Materials and Methods

In this study, an analytical evaluation model consisting of 11 criteria developed by Roger H. Clark and Michael Pause was used to conduct a detailed analysis of a sample group comprising five buildings by each architect. These criteria are: structural system, natural light, massing, plan-section-façade relationships, circulation and usage areas, from part to whole, repetition and originality, symmetry and balance, geometry, addition-subtraction, and hierarchy (Table 1).

Table 1. Analytical evaluation model assessment criteria (Clark & Pause, 2005)

Criteria	Description	Code
Structural system	In order for a structure to remain standing, it must be present in all architectural works. In this context, load-bearing elements such as columns, walls, and beams are evaluated in terms of repetition frequency, regularity, pattern, simplicity, randomness, and complexity.	• **Regular** • **Random**
The relationship of design	Balance, repetition, proportion, line, interval, direction, continuity	
Natural light	Factors such as where daylight is taken from play an important role in shaping the design. Light is an important design criterion in the perception of spaces. The size, position, shape and frequency of openings in walls and roofs present natural light as a design concept.	•**Active** •**Inactive**
The relationship of design	Repetition, texture, interval, shadow, movement, direction, form, scale, continuity	
Mass formation	It shapes the holistic perception of architecture. As a design concept, it can be examined in terms of the concept related to content, the coming together of the units that form the whole and the formation of patterns and singular masses, primary and secondary elements. It is an effective concept for defining, articulating and organising outdoor spaces and for the perception of architecture.	•**Pattern** •**Single**
The relationship of design	Interval, repetition, unity, harmony, colour, texture, tone, proximity, similarity, closure	
Plan-section-façade relationships	Plans are considered the creator of form, enabling the organisation of actions. Plans and sections facilitate a volumetric understanding of the structure. The relationships between plans, sections and elevations can influence each other's form through examinations of equality, balance, similarity, proportion, identity, differentiation and contrast.	•**Similarity** •**Contrast**
The relationship of design	Interval, proportion, direction, proximity, continuity, texture, tone, colour, harmony, form	
Circulation and areas of use	The focus of determining the design is the functional use of the space. Circulation facilitates the user's perception and recognition of the space. Circulation can be located at the centre or alongside functional areas, determining the placement of focal points.	•**Easily recognisable**
The relationship of design	Interval, proportion, continuity, movement, dominance, direction, form, measure	
From part to whole	A design may consist of a single unit or may be formed by the combination of units. The relationship between a unit and the whole structure constitutes an organisational and design strategy, while also revealing the concept of shaping the design. In this context, units are considered to be adjacent, separate, overlapping, or less than the whole.	**Overlapping** •**Separate**
The relationship of design	Form, proportion, proximity, closure, repetition, harmony, unity, scale, interval, direction	





Originality through repetition	To highlight the distinctiveness of an element within a whole, it may be necessary to compare the elements within that group and identify their different characteristics. The concepts of size, shape, position, orientation, colour, material and texture can be evaluated to reveal the differences between repetition and originality.	**•Repetition** **•Originality**
The relationship of design	Direction, form, texture, repetition, colour, interval, proportion, scale, continuity, harmony, unity	
Symmetryan d balance	The balance of the units reveals that there is a relationship between them. The main characteristic of the relationship between the two must be determined. Symmetry can be achieved by repeating the same units on both sides of the determined axis of balance.	**•Symmetry** **•Balance** **•Asymmetry**
The relationship of design	Balance, repetition, harmony, proportion, unity, measure, direction	
Geometry	Geometry has been used as a design tool throughout architectural history. It is a characteristic concept most commonly used in buildings. The focus is on the concepts of dimension, shape, proportion and position. In the analysis, it is observed in terms of frequency, configuration, complexity, consistency and diversity.	**•Consistency** **•Diversity**
The relationship of design	Form, measure, ratio, direction, continuity, dominant, interval, similarity	
Addition-subtraction	Design is developed through processes such as adding, removing and assembling forms to the structure. In a design dominated by addition and removal, even if the omitted units and parts are defined separately, the removed parts of the architectural work can be perceived as a whole within the structure.	**•Addition** **•Subtraction**
The relationship of design	Form, proportion, measure, unity, movement, continuity	
Hierarchy	It can be defined as the ordering of one or more attributes. Hierarchy denotes the transition from one state to another. In hierarchy analysis, classification criteria can be evaluated using concepts such as large-small, open-closed, simple-complex, private-public.	**•Open** **•Closed**
The relationship of design	Continuity, interval, harmony, unity	

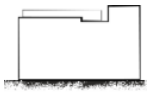
3. Analysis of Peter Zumthor's Buildings

Peter Zumthor's architectural approach focuses on human-space interaction and the use of materials. Zumthor's architecture has an effect that arouses curiosity, provides internal focus and stimulates users' spatial perceptions. The atmosphere he achieves in his designs stimulates users' sensory perceptions. Material choices shaped by the context in which the buildings are located and the way the materials are used reflect Zumthor's architectural approach. His unique design decisions, technique, and significant role in sensory architecture make Zumthor unique. Therefore, the five building examples included in the sample group created for the thesis study

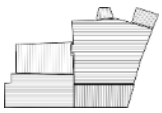
are supportive in revealing Zumthor's design decisions, shaping ideas, and thus his identity as a designer.

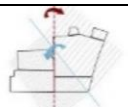
Table 2. Swiss Pavilion evaluation table

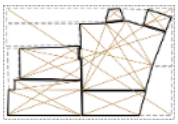
Evaluation Criteria	Diagram	Evaluation	Code
Structural system		The regularity is evident in the arrangement of the timber forming the structure, stacked at similar intervals and repeating in a linear orientation.	**Regular**
Natural light		The regular spacing between the timber elements demonstrates that natural light has been incorporated into the design and is an active element.	**Active**
Mass formation		The wooden planks are positioned perpendicular to each other in units at regular intervals, creating a permeable pattern.	**Pattern**
Plan-section-façade relationships		The spacing, similarity, and direction of the timber elements, among other design decisions, are reflected both in the layout and on the façade, demonstrating the concept of similarity.	**Similarity**
Circulation and areas of use		The timber stacks, arranged upright and in parallel groups, are positioned at varying distances within designated circulation areas, ensuring that circulation zones are easily identifiable.	**Recognisable**
From part to whole		The patterned wall system creates spaces and forms based on the principles of proximity and closure. The unit form transforms into a similar form within the structure and is overlapping.	**Overlapping**
Originality through repetition		The stacked multiple pieces of timber demonstrate that the concept of repetition prevails in terms of shape, texture, colour and continuity.	**Repetition**
Symmetry and balance		The units have different proportions and orientations when viewed on the horizontal and vertical axes. Therefore, asymmetry prevails.	**Asymmetry**
Geometry		All units, including the courtyard voids incorporated into the structure, are rectangular in form and consistent throughout the building.	**Consistency**
Addition-subtraction		Courtyard spaces have been left within the structure. These spaces are created by removing sections between the stacks.	**Subtraction**
Hierarchy		Although its environmental relationship is clear, there is an acoustic environment that aims to stimulate the senses and is desired to be achieved. For this reason, it is considered closed..	**Closed**

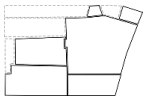


According to the evaluation in Table 2, the Swiss Pavilion effectively draws natural light into the interior thanks to its perforated design. The pattern created by the stacked timber in the façade design also characterises the visual identity of the structure. The harmony between the









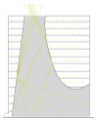
plan, section and elevations demonstrates consistency throughout the design. The open-plan structure of the circulation and usage areas facilitates transitions and connections within the interior space. The harmony between the parts and the whole, along with the repetition of material usage, maintains aesthetic and functional integrity. The perforated form and open-plan structure continue the relationship and continuity established with the exterior space.

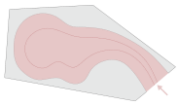
In the design of the Swiss Pavilion, the structure's connection to natural environmental factors (lighting, ventilation) remains uninterrupted. The hollow structure of the stacked timber allows for this, while also serving as a restrictive and dividing wall. The perpendicular and hollow structure of the timber provides visual and auditory isolation. It offers a space for relaxation and rest, away from the noise of the city. In this regard, it incorporates a sound box feature that focuses on the acoustic experience. The use of timber ensures that sound is dispersed softly and naturally. This creates an acoustic atmosphere in the space.

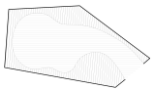
The Swiss Pavilion highlights the strong connection between nature and architecture. The building's sound box features integrate with the sounds of nature (bird chirping, wind noise, etc.) and spread throughout the interior space. The open-plan structure allows sound to circulate within the interior space. In this way, while maintaining the structure's connection to nature and the environment, it offers an enclosed experience that focuses on the senses within the interior space.

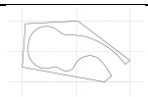
Table 3. Kolumba Museum evaluation table

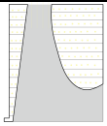
Evaluation Criteria	Diagram	Evaluation	Code
Structural system		The structure is supported by columns to prevent load bearing on the remains of the Kolumba Church. The columns are arranged at regular intervals and in a radial pattern, demonstrating regularity.	**Regular**
Natural light		The use of natural light in accordance with design decisions and the effort to create dark rooms as needed also demonstrates that light is a factor in design.	**Active**
Mass formation		The towers rising at the corners are striking in this context. Their external seclusion, the dim atmosphere created inside, and their enormous size also emphasise the uniqueness of the structure as a whole.	**Single**
Plan-section-façade relationships		Similarities exist in the additions and removals reflected in the plan and section. When evaluated as a whole, there are similarities in terms of concepts such as material, harmony, additions and removals.	**Similarity**
Circulation and areas of use		The red bridge connects to the main circulation, offering not only a change in proximity to the works but also movement and different perspectives.	**Recognisable**
From part to whole		As there is no similarity or continuity between the units of the structure, which contains multiple forms at different angles and ratios, they are assessed separately.	**Separate**











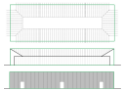
Originality through repetition		Due to the shape of the main exhibition area, the spaces are positioned at different angles. The combination of different shapes demonstrates the uniqueness of the structure.	**Originality**
Symmetry and balance		When examined along the vertical axis in the plane, it can be seen that there is no symmetry and that the axis of equilibrium is displaced.	**Asymmetry**
Geometry		When the structure geometry is completed in a rectangular form, it can be seen that the reduced areas do not form a regular geometric shape. The use of forms at different angles and proportions demonstrates diversity.	**Diversity**
Addition-subtraction		Additions and omissions are evident in the layout of the plan. The reductions in the plan layout are supported by the gaps between the towers on the façade, thereby reducing the monotony of the structure.	**Subtraction**
Hierarchy		The atmosphere captured indoors and the feeling of being protected like a fortress from the outside demonstrate that the concept of enclosure dominates the structure.	**Closed**

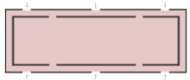
When all the criteria are in Table 3 are taken into account, the structural system of the Kolumba Museum is supported by columns placed at regular intervals and parallel to the existing walls. While the natural light entering the interior is limited, darkness prevails in some areas. Zumthor deliberately chose and incorporated dark spaces into the design to stimulate visitors' senses. The building's closed exterior, the towers rising from the corner points, and the singular mass form contribute to the building's integrity.

With masses rising from its corners, the Kolumba Museum resembles a castle, giving the impression of being sheltered and closed off to the outside world. Originally serving as a place of worship for Christians, the building embodies a spiritual atmosphere often seen in church designs, achieved through the use of light and shadow. This atmosphere is continued in the museum's design. The façade of the building features openings that allow light and air to flow between the interior and exterior spaces. The thick walls block sound, preserving the tranquil atmosphere inside.

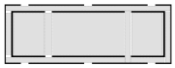
Additionally, the bridge, designed to observe the historical remains within the interior space and featuring varying angles, directions, and lengths, stimulates visitors' visual perception by offering perspectives from different angles. In the cabin-shaped exhibition hall, natural light is deliberately excluded, encouraging visitors to focus on tactile, visual or auditory sensations in the dark. In this way, Zumthor ensures that users focus on the space itself, distancing themselves from environmental factors. For this reason, dark spaces were deliberately selected and integrated into the design to stimulate the visitors' senses. This is also one of Zumthor's design decisions.

Table 4. Bruder Klaus Chapel evaluation table





Evaluation Criteria	Diagram	Evaluation	Code
Structural system		In the plan formed by the concrete structure, randomness prevails in the continuous load-bearing system with varying angles, directions, and dimensions.	**Random**
Natural light		Light is brought into the interior space by filtering through the oculus, the opening at the top, and the pipe openings on the façade, and is used as an active element in the design.	**Active**
Mass formation		It consists of a single form made of concrete material that is solid, seamless, and repetitive.	**Single**
Plan-section-façade relationships		Although the materials are continuous, with the same texture and color, the curved forms reflected in the plan and section provide information about the interior space and demonstrate similarity.	**Similarity**
Circulation and areas of use		There is no dividing wall, vertical circulation element, or separate space. In this case, circulation is open, continuous, and easily perceptible.	**Easily recognisable**
From part to whole		The unit area that makes up the whole also defines the whole. Therefore, the part-whole relationship has not been established and is considered separately.	**Separate**
Originality through repetition		The unit area that makes up the whole also defines the whole. Therefore, the part-whole relationship has not been established and is considered separately.	**Repetition**
Symmetry and balance		The structure, which has an irregular pentagonal shape, is asymmetrical when evaluated on its axes of symmetry.	**Asymmetry**
Geometry		The structure has organic features indoors and an irregular pentagonal shape outdoors, offering geometric diversity.	**Diversity**
Addition-subtraction		It can be seen that there are reductions in different forms in the plan structure and that removal is predominant.	**Subtraction**
Hierarchy		The aim is to sever the connection with the outside space in order to create a spiritual atmosphere within the space. Therefore, seclusion from the outside prevails.	**Closed**

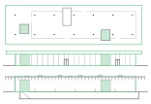


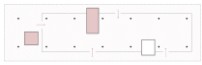
According to Table 4, the carrier system, which is positioned at different angles and directions, appears organic in the interior and irregularly angled on the exterior façade. The iron pipes used to connect the skeleton created in the interior and the concrete formwork on the exterior façade allow natural light to enter the interior while creating a visual spectacle. The oculus in the

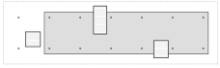
ceiling, which refers to the purpose and metaphor of the chapel, plays an important role in lighting. While there are many factors in the design of the structure, another important element influencing the design is the atmosphere to be captured. Elements such as 'silence, introversion and experiencing worship' influence the design to be singular and closed to the outside. While the exterior presents a singular mass with intriguing and unpredictable sharp lines, the interior features organic and curved forms with opposite characteristics. For the spiritual environment sought in the interior, it is desired to sever the connection to the exterior. Zumthor's effort to stimulate user perceptions is clearly evident in the Bruder Klaus Chapel.

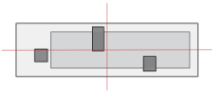
The Bruder Klaus Chapel is a structure designed for worship and built in memory of the monk Bruder Klaus. Due to the function of the building, there is a desired atmosphere in the place of worship. Places of worship are expected to be quiet, peaceful and relaxing. In this context, individuals have the opportunity to focus solely on the act of worship and return to their essence in the space they occupy. Due to the monolithic form of the structure, located on a large plot of land, it holds different meanings for the observer, triggering their thoughts and curiosity. Inside, there are a few objects used for worship within the dark-coloured walls achieved by burning wood. In this situation, the individual has the opportunity to distance themselves from distracting or chaotic objects around them and focus on their essence. This demonstrates Zumthor's attempt to capture the essence of the mind beyond unnecessary, excessive, or crowded objects, inviting the visitor to meditation and inner peace.

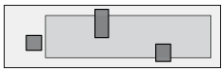
Table 5. Serpentine Gallery Pavilion evaluation table











Evaluation Criteria	Diagram	Evaluation	Code
Structural system		The wooden structure has similar dimensions, spacing, and other characteristics. The walls are parallel and radial in layout and are of a regular nature.	**Regular**
Natural light		The structure, which is a closed garden, is designed to benefit from light due to its purpose, demonstrating that light is a factor in the design.	**Active**
Mass formation		The building is unique in that it appears as an intriguing closed box when viewed from the outside.	**Single**
Plan-section-façade relationships		The rectangular form is dominant throughout the structure and also shows similarities in section and elevation relationships.	**Similarity**
Circulation and areas of use		The usage areas of the building with an open plan structure can be distinguished by differences in floor materials.	**Easily recognisable**
From part to whole		The spaces allocated for the main area and circulation are variations of the same form in different proportions. This demonstrates that the parts correspond to the whole.	**Overlapping**

Originality through repetition		The use of the same geometric form in different proportions and sizes demonstrates the presence of repetition.	**Repetition**
Symmetry and balance		Parallel and coaxially positioned doors are included, and regularity and symmetry prevail in the geometric form.	**Symmetry**
Geometry		Consistency prevails throughout the structure, with the same geometric form being used in different proportions and orientations.	**Consistency**
Addition-subtraction		It demonstrates the existence of the concept of roof void extraction, created to meet garden requirements in a closed box form.	**Subtraction**
Hierarchy		The garden is designed to provide an escape from the chaos of the outside world and is enclosed.	**Closed**

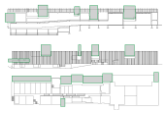
As a result of the analysis presented in Table 5, the structure, which is designed in a box form to create an enclosed garden, features a regular load-bearing system. The garden created inside is isolated from environmental factors (traffic, noise, etc.) while being designed to be open to natural weather conditions. In addition, the sloping roof form allows for ventilation, sunlight and rain to enter the interior, which the garden requires. Zumthor creates an environment where visitors can relax with his environmentally sensitive design. In doing so, he uses light and natural materials rather than heavy building materials. At the same time, the singular and closed box form arouses the curiosity of users. The double-layered circulation is also designed to stimulate the senses of visitors as they transition from darkness to light.

Designed as a closed garden concept for recreation and relaxation, the Serpentine Gallery Pavilion is isolated from the noise of the outside environment. The box form we encounter in Zumthor's buildings also appears here. When viewed from the outside, the black closed box form does not reveal anything about the interior space, but it encourages the viewer to think. There are door openings in the two-layered wall structures. The fact that the openings are not aligned conceals the view of the interior space. The deliberately designed gradual circulation of the entrance and the use of black are intended to stimulate the senses of visitors. The use of black in the mass design ensures that it does not overshadow the colours of nature. In this regard, the vegetation and limited viewing areas within the structure ensure that the user's attention is focused on the experience of the interior rather than the outside world.

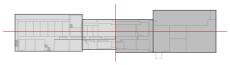
Table 6. Werkraum Bregenzerwald evaluation table

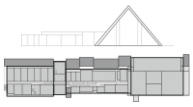
Evaluation Criteria	Diagram	Evaluation	Code
Structural system		The parallel and regular placement of the supporting columns indicates regularity.	**Regular**
Natural light		The structure, consisting of a glass façade, is designed for the display of artworks. Since the works are illuminated by directed light, the glass façade is covered with blackout curtains. Therefore, natural light is not a factor in the design.	**Inactive**
Mass formation		The box-shaped structure with a wide, monolithic roof extending beyond the façade is characterized by singularity.	**Single**
Plan-section-façade relationships		The orientation of the mass horizontally and vertically, the repetition of material usage, and the continuity of the geometric form emphasize the concept of similarity.	**Similarity**
Circulation and areas of use		The structure has an open-plan layout with no clear dividing walls. Therefore, circulation is easily discernible.	**Easily recognisable**
From part to whole		The rectangular unit element is used throughout the structure in different proportions, orientations, and dimensions. Therefore, it is consistent from part to whole.	**Overlapping**
Originality through repetition		The structure, dominated by a black façade and simple materials that highlight the works, features a recurring element through the use of similar textures and forms.	**Repetition**
Symmetry and balance		When the roof and usable areas are evaluated according to their axes of symmetry, the concrete mass forms protruding from the building façade reveal asymmetry.	**Asymmetry**
Geometry		The structural unit is a quadrilateral, and consistency prevails throughout the structure due to the use of the same form in different proportions and orientations.	**Consistency**
Addition-subtraction		The masses protruding from the roof and floor plan at different ratios surrounding the box-shaped structure are seen as additions to the building.	**Addition**
Hierarchy		The boundaries between the interior and exterior spaces have been eliminated with a transparent façade, creating an open hierarchy.	**Open**

According to the data obtained in Table 6, the structure designed to bring artisans together is supported by columns arranged at equal intervals. The boundaries between the interior and



exterior spaces are completely transparent, maximising the use of sunlight. However, due to the exhibition of various works within the structure, constant sunlight is not preferred. In this case, artificial spotlights that can be directed are used in conjunction with blackout curtains to ensure that the works are brought to the fore. Zumthor designs a simple structure dominated by dark colours so as not to overshadow the exhibited works.



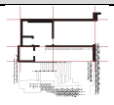


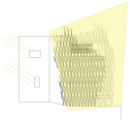
Werkraum Bregenzerwald is designed to bring artisans together under one protective roof. Unlike his other buildings, Zumthor presents the box form transparently. The inviting transparent façade design is not considered suitable for exhibition spaces.

4.Analysis of Kengo Kuma's Buildings

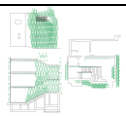
Kengo Kuma adopts an approach that synthesises traditional Japanese architecture with contemporary architecture. He prioritises the integration of buildings with nature without fighting it, and sustainability through material selection. His design approach, which emphasises human-nature interaction, highlights the concept of nature as a key factor in Kuma's designs. Consequently, his buildings feature permeable, lightweight designs that connect with nature. Kuma's design decisions add originality to his designs through the use of traditional construction techniques and natural materials, enabling the designer to be a pioneer in areas such as human-nature interaction and sustainable architecture. Within the scope of the thesis, five building examples have been selected to analyse Kuma's architectural design philosophy and reveal his identity as a designer.

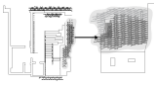
Table 7. Momofuku Ando Center evaluation table

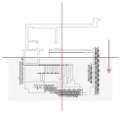


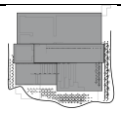


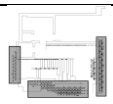
Evaluation Criteria	Diagram	Evaluation	Code
Structural system		The steel structure features a regular system with linear axes at specific intervals.	**Regular**
Natural light		The façade openings, designed with the aim of harmonizing with nature and utilizing natural light, demonstrate that natural light is a key factor in the design.	**Active**
Mass formation		The reductions affecting the mass and the metal wings covering the roof eliminate singularity while creating a pattern.	**Pattern**
Plan-section-façade relationships		The dominant pattern system in the structure and the continuity of the materials used show similarities between the plan, section, and elevation relationships.	**Similarity**
Circulation and areas of use		Ramps are used to accommodate differences in elevation within the interior, while there is a clearly defined main entrance and easily recognisable circulation.	**Easily recognisable**
From part to whole		The spaces of different scales that make up the structure are rectangular, and the same form appears in different sizes throughout the structure, which is considered to be consistent.	**Overlapping**









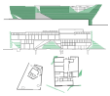


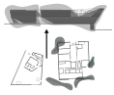
Originality through repetition		The use of different materials indoors and outdoors, and the use of metal wings in different tones that dominate the roof, demonstrate the uniqueness of the structure.	**Originality**
Symmetry and balance		When evaluated according to symmetry axes, there is balance in the structure even though there is no symmetry.	**Balance**
Geometry		The dominant rectangular form in unit spaces is seen in the triangular cross-section and façade openings. In this context, there is geometric diversity.	**Diversity**
Addition-subtraction		Both in the plans and elevations, it can be seen that the façade openings were achieved by reducing the structure. In this regard, the concept of subtraction prevails.	**Subtraction**
Hierarchy		There is an open hierarchy due to the effort to harmonize and relate with nature.	**Open**

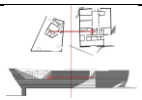
When the criteria in Table 7 are evaluated, it is seen that the carrier system created with radial axes demonstrates different approaches to bringing natural light into the interior space while ensuring regularity. Both the façade and roof openings allow light to enter the interior space. Kengo Kuma prioritises the building's suitability to the site, remaining faithful to the topography and natural environmental conditions. While the structure does not stand out from its surroundings, the metal wings on the roof allow it to blend in with the natural environment. The metal wings, positioned at regular intervals on the roof, create a pattern, eliminating the monotony and uniformity of the mass. The characteristic projections on the roof and the plan level make this possible.

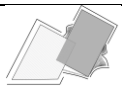
In the design of the Momofuku Ando Center, the natural elevation differences are reflected in the interior space in order to remain faithful to the topography of the site. At the same time, the metal wings of different colours used on the roof also support this, in an effort to harmonise with the context of the building and to continue the feeling of the forest by emulating nature.

Table 8. SunnyHills at Minami-Aoyama evaluation table









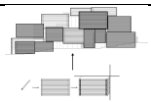
Evaluation Criteria	Diagram	Evaluation	Code
Structural system		The load-bearing axes of the reinforced concrete structure are arranged parallel and perpendicular to each other.	**Regular**
Natural light		The bark, resembling tree branches on the façade, creates a forest atmosphere indoors with light and shadow effects, utilizing natural light as an active element in the design.	**Active**
Mass formation		The shell pattern form is created in the wooden lattice system with a forest-like structure.	**Pattern**

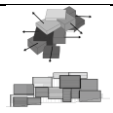
Plan-section-façade relationships		The dominant shell form on the façade is reflected in every plane, giving rise to the concept of similarity.	**Similarity**
Circulation and areas of use		Areas are designated for visitors and staff, and circulation is easily recognisable.	**Easily recognisable**
From part to whole		While the mass consists of rectangular forms, the façade pattern does not show similarity and is classified separately.	**Separate**
Originality through repetition		The structure, consisting of two layers, inner and outer, is characterized by a dominant patterned shell and is considered unique.	**Originality**
Symmetry and balance		When the mass is divided along the axes, equilibrium is lost and asymmetry occurs, with one side consisting of reinforced concrete and the other of a patterned shell.	**Asymmetry**
Geometry		The structure, which has a regular geometric form, takes on an organic form with the shell on the façade. Therefore, there is geometric diversity.	**Diversity**
Addition-subtraction		A shell form attached to the exterior of the reinforced concrete mass is visible. Therefore, the concept of addition is dominant.	**Addition**
Hierarchy		The structure's scattered and open layout mimics nature, featuring an open hierarchy designed to connect with the surroundings.	**Open**

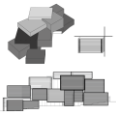
When Table 8 is evaluated in general, SunnyHills consists of two layers: the inner layer has a reinforced concrete box form, while the outer façade features a wooden pattern cladding. As natural light enters the interior, the rays filtering through the wooden pattern on the façade create a visual feast within the space. In terms of repetition and originality, the evenly spaced pattern of the wooden façade cladding provides continuity that extends into the interior, while the angle and direction of the material add originality to the design. It emphasises geometric diversity, presenting rectangular forms in the interior and an organic, asymmetrical structure on the exterior façade. The mass design becomes distinct with the addition of the wooden lattice system to the main mass from the outside. While harmonising with nature through hollow and scattered wooden cladding, like tree branches in nature, it offers an open hierarchy that does not interrupt the relationship between the interior and exterior spaces.

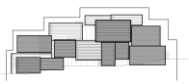
SunnyHills, designed for a renowned cake company, is required to be unique. In line with this, Kuma, inspired by nature, uses natural materials (wood) and creates a design reminiscent of tree branches with its hollow form, evoking the feeling of sitting in a forest with the shadows created indoors.

Table 9. V&A Dundee evaluation table









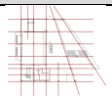
Evaluation Criteria	Diagram	Evaluation	Code
Structural system		Randomness prevails due to the carrier structural exhibiting different angles and orientations.	**Random**
Natural light		The openings on the façade were created to take advantage of natural light and play an active role in the design.	**Active**
Mass formation		Concrete blocks used on the façade form a pattern to blend in with the randomness of nature.	**Pattern**
Plan-section-façade relationships		The rhythm on the façade continues inside, and a sense of similarity prevails throughout the building.	**Similarity**
Circulation and areas of use		Areas designated for staff and visitor use are clearly marked and easily identifiable.	**Easily recognisable**
From part to whole		The pattern enveloping the main mass from the outside enables the creation of an organic form, while being characterized separately from the part to the whole.	**Separate**
Originality through repetition		Concrete blocks of varying dimensions, orientations, and angles, created by imitating nature, ensure the structure's uniqueness.	**Originality**
Symmetry and balance		The prevailing state of disorder in the structure causes the axis of equilibrium to shift and leads to asymmetry.	**Asymmetry**
Geometry		Geometric diversity prevails due to the absence of a regular and clear geometric form.	**Diversity**
Addition-subtraction		The façade pattern that wraps around the mass form is dominant in the structure and is achieved through additions.	**Addition**
Hierarchy		An open hierarchy exists to avoid restricting city movement and to ensure environmental connectivity.	**Open**

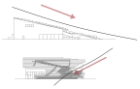
to the results of Table 9, the structure, composed of reinforced concrete, begins as two separate masses on the ground and merges on the upper floor. These design decisions result in a display of randomness through the use of irregular axes and different angles. The entire reinforced concrete mass is formed by covering it with concrete blocks. Natural light enters the interior through regular intervals between the concrete block masses and glass surfaces. Randomness in nature is achieved through concrete blocks of different orientations and sizes, reflecting originality in the design. The horizontal positioning of the concrete blocks and the continuity of the façade pattern continue in the interior, ensuring the preservation of design integrity. It is

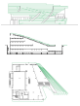
seen to have an irregular and asymmetrical design. The dominance of the addition factor is revealed by the façade pattern enveloping the main mass from the outside. It stands out with a design that emphasises the building's harmony with its surroundings and its relationship with nature.

The pattern found in the design of V&A Dundee creates a form inspired by the cliffs and rocks of Scotland, where the building is located. The irregular and random natural formation of the cliffs and rocks is reflected in the building's façade. At the same time, in order to respect the flow of the city and not interrupt it, a void is created in the mass for passage.

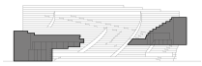
Table 10. Odunpazarı Modern Museum evaluation table







Evaluation Criteria	Diagram	Evaluation	Code
Structural system		In the box-based structural design, the load-bearing system appears to be random in terms of different angles, directions, and axes.	**Random**
Natural light		The perforated design of the façade and the ceiling void in the atrium demonstrate the role of natural light in the design.	**Active**
Mass formation		The concept of pattern dominates in the structure wrapped with a wooden lattice system.	**Pattern**
Plan-section-façade relationships		The dominant pattern in the structure composed of box forms is the continuity of the façade, and the concept of similarity is predominant.	**Similarity**
Circulation and areas of use		While elevation differences in the terrain are noticeable indoors, they are easily perceived through the circulation connections.	**Easily recognisable**
From part to whole		The box form, which plays an important role in the design, is repeated throughout the structure and is characterized as overlapping.	**Overlapping**
Originality through repetition		The box form is evaluated uniquely when used in different scales, directions, and dimensions.	**Originality**
Symmetry and balance		In a design with a random structure, the axis of balance is shifting and asymmetry is dominant.	**Asymmetry**
Geometry		While the ground floor of the reinforced concrete structure has variable angles, the upper floors feature rectangular shapes. Therefore, there is diversity.	**Diversity**
Addition-subtraction		A wooden lattice system that wraps around the entire façade is added to the mass design, which resembles stacked boxes.	**Addition**



Hierarchy		An open hierarchy exists within the structure for the purpose of revitalizing and establishing connections within its context.	**Open**

When the data in Table 10 is evaluated, the Odunpazarı Museum was constructed using reinforced concrete on the ground floor and a steel structural system on the other floors. The irregularity and different orientations of the structure affect the structural system. While the Ottoman street fabric in the location of the structure is to be continued, wooden façade cladding is used. This allows light to filter into the interior space. The interlocking of unit masses of different sizes and orientations with a wooden lattice system gives the building unity and continuity. In this asymmetrical structure, the unit masses created by the addition method are designed in keeping with Ottoman architecture and the local context.

The primary design objective for the Odunpazarı Modern Museum in Eskişehir can be considered as its suitability to the history and fabric of its location. Continuing the traditional Ottoman street texture in its context and using wood materials due to the region's history of wood trade also demonstrates the design's respect for history and context. At the same time, the topography movement within the structure, located on a sloping area, is felt through level differences in the interior space, showing that it does not fight against nature. The topographic movement is reflected in the interior as slight elevation changes, always striving to be in harmony with nature. The use of natural materials and natural light aims to revitalize the location, make it a central location, and establish a connection with the surroundings.

Table 11. Tokyo Institute of Technology evaluation table

Evaluation Criteria	Diagram	Evaluation	Code
Structural system		When the axes are examined, parallelism and regularity are disrupted, and randomness prevails.	**Random**
Natural light		The slits opened to allow light into the structure, most of which is buried underground, demonstrate that natural light is a key factor in the design.	**Active**
Mass formation		The exposed surface reveals the design concept of the structure, while the stands on the façade create a pattern.	**Pattern**
Plan-section-façade relationships		The gradation and continuity of the materials used indicate similarity.	**Similarity**
Circulation and areas of use		The stepped roof incorporated into the circulation and the interior usage areas are easily recognisable.	**Easily recognisable**
From part to whole		It is classified separately due to the use of different forms in the plan and façade cladding.	**Separate**
Originality through repetition		The cuts and stands in the structure are asymmetrical. Originality prevails in the	**Originality**

		structure, which is inspired by nature and randomness.	
Symmetry and balance		The structure has a stepped form, with the axis of balance shifting and asymmetry prevailing.	**Asymmetry**
Geometry		There is geometric diversity due to the presence of different forms in the plan and section planes.	**Diversity**
Addition-subtraction		The visible façade of the building, which has three buried sides, consists of stands, creating a dominant addition.	**Addition**
Hierarchy		An open hierarchy exists for the purpose of establishing a relationship with nature and adapting to the topography.	**Open**

When the data in Table 11 is summarized, the Tokyo Institute of Technology's carrier system has partially regular and parallel axes, while exhibiting irregularities in some sections. The irregularity in the carrier system reflects the randomness found in nature. While topography creates the characteristics of the building, it also directs the architect's design decisions. Although a large part of the structure is buried in the ground, the elevation differences provided by the sloping terrain and the cracks opened in the roof allow natural light to reach each floor. The building mass is completely integrated with the terrain and buried in the ground. At the same time, we can say that it is located underground so as not to overshadow the old Clock Tower on the campus. The stands surrounding the mass, which play a major role in the design, provide continuity in the plan, section, and elevation planes, ensuring the integrity of the structure. The stands on the roof increase functionality as they are used as circulation and relaxation areas. The structure's design, in harmony with nature, enhances the relationship with the natural environment while strengthening the interaction between users.

When examining the design decisions made for the Tokyo Institute of Technology, it is evident that the primary factor is topography. The mass is buried into the ground to harmonize with the sloping hills on campus and to avoid overshadowing the clock tower, which holds significant importance for the campus. The exposed portion forming the roof of the structure is designed in a stepped manner to integrate with nature.

5.Conclusion

Based on the factors examined in Peter Zumthor's sample group, it is evident that he aims to create introverted, closed spaces by utilizing human-centered spatial layout and the effective use of light and shadow play in design, thereby abstracting users from the chaos of the outside world and taking them on an inner journey. Zumthor's architecture creates simple, tranquil spaces where serenity prevails. This introverted approach triggers an inner search between space and human, establishing a relationship and stimulating the senses. In line with Peter Zumthor's design decisions and approaches, the space is expected to offer users a sensory and spiritual experience. Although the exterior façade designs of the buildings we examined in the sample group are simple, clear, and feature sharp lines, the atmosphere achieved in the interior is completely different. Continuing the simplicity of the exterior façade, the interior also seeks the "essence" that is abstract and spiritual, beyond the concrete. The desired atmosphere is created through the use of natural materials, light and shadow effects, and small, simple details.

It is evident that Peter Zumthor's primary design criterion is the human being and their experience of space. He aims to isolate users from the outside world, establish a relationship with the space, embark on an inner journey, and gain individual perceptual awareness. Zumthor's introspective approach offers the opportunity to achieve simplicity, meditation, and individual experience simultaneously. In this context, Peter Zumthor's identity as a designer can be broadly defined as "meditative."

An important criterion common to every structure in Kengo Kuma's sample group is the concept of natural light. Natural light has been an essential requirement for every structure or space from the past to the present. However, in Kuma's designs, the use of natural light not only meets this need but also plays an active role in the design. The atmosphere sought to be achieved through the shadows cast by sunlight in interior or exterior spaces, and the movement added to the structure by the changing angle of sunlight throughout the day, are incorporated into the design.

Kengo Kuma's approach to shaping architecture, the decisions made in his designs, and the concepts that stand out are derived from the literature review, analyses, and evaluations conducted throughout this study. By examining the connections between these concepts and the design decisions made for the structures, and while researching Kengo Kuma's identity as a designer, it is revealed that one of the most important factors in his structural design decisions is "nature." The uniqueness of every object found in nature and the randomness that emerges from Kuma's efforts to emulate nature in his designs enable originality to be achieved. At the same time, it is evident that Kengo Kuma demonstrates his commitment to the concept of nature not only in his designs but also in his use of materials, choosing sustainable and natural options.

Kuma's identity as a designer can be described with many adjectives. Kuma's respect for nature, people, and every object in his environment, whether living or inanimate, is evident in his perspective on other structures and designs around him. However, it is clear that the concept of nature dominates his design decisions. The use of natural materials in his structures, randomness, irregularity, the effort to emulate nature, and his constant references to nature, combined with his technique of combining natural materials and materials unique to the designer, reveal Kuma's identity as a designer and set him apart from his peers. Therefore, Kengo Kuma's designer identity can be broadly defined as an "architect who puts nature at the center."

Many similarities can be observed in the designs of Peter Zumthor and Kengo Kuma. In particular, the effective use of natural light in their designs stands out as a common feature. However, there are factors that reveal their architectural identities and highlight their differences from each other. Table 12 shows that the two architects have completely opposite approaches to the criteria highlighted in bold. These contrasts are the criteria that truly reveal the designers' identities. The different analysis criteria that reveal their true identities support each other while being interconnected in a cause-and-effect relationship. According to Table

12, while Zumthor's designs feature regular structural systems, singular, consistent, and closed-off building masses dominated by repetition, Kuma's designs feature the opposite choices, with randomness, patterned façades, originality, various geometric forms, and openness to the outside coming to the fore. In this regard, the information obtained from the analysis shows that Zumthor's design preferences, which aim for external closure, and Kuma's random forms, which emerge from his emulation of nature, support the architects' individual design goals.

Abstract

Entrance areas in educational structures, consisting of multi-dimensional spaces such as classrooms, workshops, laboratories, and social spaces, stand out as important spaces where the first experiences are had and interactions take place. The main entrance areas of architecture department buildings are important spaces in terms of shaping the spatial experience and reflecting the institutional identity as the first point of contact for users. The aim of this study is to evaluate the main entrance of the Architecture Department of the Faculty of Architecture at Karadeniz Technical University in terms of students' perceptions of the space and their satisfaction levels, both in terms of interior and exterior spaces. To this end, a questionnaire was administered to students studying in the Department of Architecture, designed to evaluate the entrance from both physical and psychological perspectives. Physical characteristics include location, formal emphasis, accessibility, use of materials and colours, and natural and artificial lighting. Psychological effects were examined in terms of orientation, the inviting nature of the space, reflection of the department's image, and perceptions of safety and comfort. Based on the data obtained, the study sought to determine whether students were generally satisfied with the department's entrance space and whether they felt safe, comfortable, and free in the space. The findings reveal that the entrance space has various strengths in terms of reflecting the department's identity and improving the user experience, but also highlight areas for improvement in terms of spatial layout and design. This study aims to emphasise the importance of a user-centred approach to entrance design in educational buildings and to provide guiding findings for future arrangements.

Keywords: Educational buildings, entrance space, interior-exterior space, user evaluations, KTU Department of Architecture

1. Introduction

The architecture of educational buildings has varied over time in parallel with certain social, cultural, and economic changes throughout history (Butabekova & Abdykarimova, 2025). Today, educational institutions provide education in different fields, and the structure of educational buildings varies according to the type of education provided (Çelik & Arabacıoğlu, 2022). It is understood that the architectural design of educational structures has a significant impact on students' learning experience and academic success (Almirón Cuentas & Bernedo-Moreira, 2023). Accordingly, educational structures should be designed as quality learning spaces (Gülay, 2025).

To experience the structure, one must first approach the entrance, perform the act of entering, and then access other interior spaces from the entrance hall. Therefore, users begin to evaluate the structure primarily through the entrance. Consequently, entrances must be effectively designed in terms of both interior and exterior spaces (Dinçer, 2022). In this regard, it is crucial that the entrance spaces of educational buildings integrate with the surroundings and reflect the overall image of the campus (Nasution & Puteri, 2020). In this context, appropriate materials

should be used in the path leading to the building entrance, and these materials should be resolved with the correct details. Entrance areas should not be narrow. Entrance doors should be easily recognisable, and door dimensions should comply with accessibility standards. Entrance porches should be large enough for wheelchairs to pass through comfortably (Tutal, 2018). In addition, stairs, ramps, and railings at the entrances of educational buildings should comply with accessibility standards (Ozkaraca & Inceoglu, 2021). In summary, in the context of outdoor spaces in educational buildings, entrances must be located in a position suitable for footpaths and pavements, comply with accessibility standards, be located in a logical and legible position in relation to the building as a whole, include directional elements such as signage, be aesthetically pleasing, reflect the prestige and image of the institution, and be clean and well-maintained (Winnicka-Jasłowska, 2018). In addition, in educational buildings, entrance halls within the interior space context enhance the spatial quality of the building by being bright, accommodating different functions, being directional, and being of sufficient size (Başkaya et al., 2003; Ogden et al., 2023). In this regard, entrance halls must be effective in psychological and social contexts, internalised, and conducive to establishing connections, beyond merely being transitional spaces (Zengel & Kaya, 2011).

In light of these findings, it is understood that building entrances not only provide physical access to the interior space but also shape students' behaviour (Dixon et al., 2020). Therefore, it can be said that the different characteristics of entrances, such as location, lighting, and façade design, located in the interior and/or exterior spaces, directly affect students' spatial behaviour, movement, orientation, and circulation (Shirowzhan et al., 2020). Consequently, students' views on the space provide important findings in the context of evaluating the space. In this regard, student views reveal a space's sense of belonging, functionality, and liveability. In addition, student views help uncover certain hidden physical and psychological problems of the space and contribute to its improvement (Arzate-Quintanilla et al., 2024). As with all educational structures, the main entrance spaces of architecture department buildings are important areas in terms of shaping the spatial experience and reflecting the institutional identity, as they are the first point of contact for users.

The aim of this study is to evaluate the main entrance of the Department of Architecture at Karadeniz Technical University Faculty of Architecture in terms of students' perceptions of the space and their levels of satisfaction, within the scope of both interior and exterior spaces. Based on the data obtained, it is sought to determine whether students are generally satisfied with the entrance space of the department and whether they feel safe, comfortable, and free within the space.

The building of the Department of Architecture at Karadeniz Technical University features a rational architecture reflecting the modernist approach of the 1950s. In this context, the building was achieved by shifting two horizontal rectangles and joining them together. The building has a linear circulation scheme. Linear long-armed staircases are located in the middle of the building. One wing of the building houses academic offices and administrative units, while the other wing houses classrooms, workshops, and laboratories (Karakaş & Türk, 2017) (Figure 1).

Figure 1. KTU Architecture Department site plan and ground floor plan (obtained from and arranged by the KTU Construction Works and Technical Department Directorate)

The Architecture Department building has entrances located on different levels. The main entrance area of the department was addressed within the scope of this project. A semi-open entrance area (approximately 70 m²) was created on the ground floor of the building by removing a section of the structure. This space features landscape elements such as a ramp, seating, a rubbish bin, and concrete planters. The flooring material in this area is cast mosaic with marble strips. Aluminium cast lighting elements are installed on the ceiling.

There is a two-metre-high vestibule (approximately 3,50 m²) between the entrance hall and the semi-open space, emphasising the entrance. The outer door of the vestibule is a glass-panelled iron door. The inner door is a glass-panelled wooden swing door. The entrance hall is approximately 140 m². Access is provided from the entrance hall to the secretarial units, the experimental laboratory, the service staircase, the lift, the main staircase, the faculty rooms, and the workshops/classrooms. The entrance hall features metal seating fixtures, waste bins, parabolic plaster-mounted lighting elements, panels, a statue of Mimar Sinan, a photo corner, and a digital screen. The façade of the entrance hall consists of large glass surfaces. Wooden sunshade elements are also located on this façade. Inside, white is the preferred colour for the walls and ceiling. Grey and white colours are used on the floor surface. The floor covering is

cast mosaic with marble strips. Wooden materials have been preferred for doors and windows. The ceiling material is mineral plaster. Exhibitions and various events are held in the entrance hall (Figure 2, Figure 3).

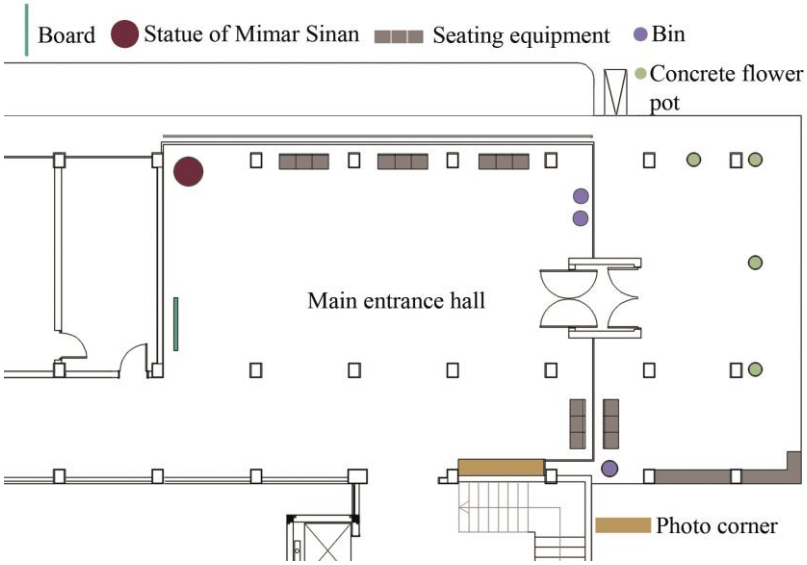

Figure 2. Main entrance hall of the KTU Department of Architecture (obtained from the KTU Directorate of Construction Works and Technical Affairs and arranged accordingly)

Figure 3. Main entrance hall of the KTU Department of Architecture

2.Materials and Methods

The questionnaire administered to students enrolled in the Department of Architecture was designed to evaluate the entrance from both physical and psychological perspectives. The design of the survey questions draws on surveys of entrance spaces in educational buildings found in the literature (Başkaya et al., 2003) and entrance space analysis criteria (Dinçer, 2022; Winnicka-Jasłowska, 2018). Accordingly, the questions were arranged to enable the physical and psychological evaluation of the entrance from the exterior to the interior. Physical characteristics include elements such as location, formal accents, accessibility, use of materials and colours, and natural and artificial lighting. To reveal psychological effects, aspects such as orientation, inviting nature of the space, reflection of the section's image, and perceptions of safety and comfort were examined.

The data obtained from the questionnaires were analysed using descriptive statistics (frequency, percentage, mean, etc.). The questionnaire form consists of five sections. The first section covers demographic characteristics. The second section evaluates the main entrance of the KTU Department of Architecture in the context of an outdoor/semi-open entrance space (17 questions), the second section contains questions on evaluation criteria in the context of the intermediate space/vestibule/indoor-outdoor space (7 questions), the third section contains questions on evaluation criteria in the context of the interior space/entrance hall (14 questions), and the final section contains questions on general evaluation criteria (5 questions).

2.1.Findings and Discussion

The survey was administered to 120 participants (83 female, 37 male). Information regarding the group of participants to whom the survey was administered is provided in Table 1.

Table 1. Participant demographics

		Frequency (n)	Percentage (%)
Gender	Female	83	69,2
	Male	37	30,8

Participants evaluated the main entrance of the KTU Architecture Department through survey questions, considering physical and psychological factors in the context of the exterior space, intermediate space/vestibule, interior space, and overall environment (Figure 4).

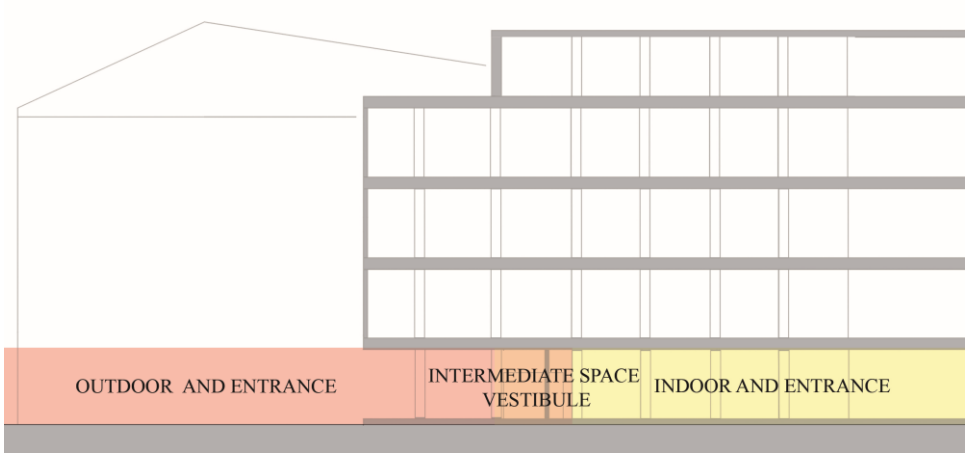

Figure 4. Main entrance space assessment areas of the KTU Department of Architecture

When examining participants' physical assessments of Area 1, the highest average score of 4.125 was found under the item "The entrance provides users with the opportunity to meet, gather and chat." Similarly, the item "The entrance's suitability for human scale" received an average score of 3.967, and "The proximity of the entrance to the main street" received an average score of 3.917, making them other positively evaluated elements. In contrast, the lowest values were determined to be 3.350 on average for the items "Suitability of the entrance for daytime and nighttime use" and again 3.350 on average for "The effect of color, material, and texture use on the building entrance" (Figure 5).

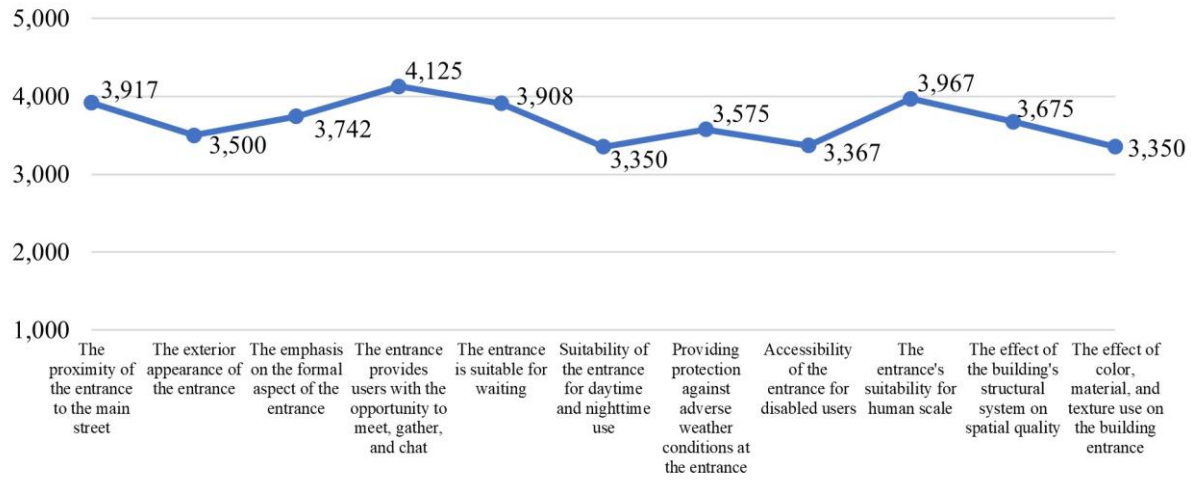

Figure 5. Participants' physical assessments of Area 1

When examining participants' psychological assessments of Area 1, the highest average score of 4.250 is observed for the statement "The building's entrance is clearly discernible and provides orientation." Similarly, the statement "entrance to the building is clearly visible and easy to find." is another positively evaluated statement with an average score of 4.242. In contrast, the lowest value, with an average of 3.083, is found in the statement "The entrance evokes a sense of curiosity about the building's interior design." Another statement with a low value is "The building's entrance reflects the image of the Architecture Department," with an average of 3.200 (Figure 6).

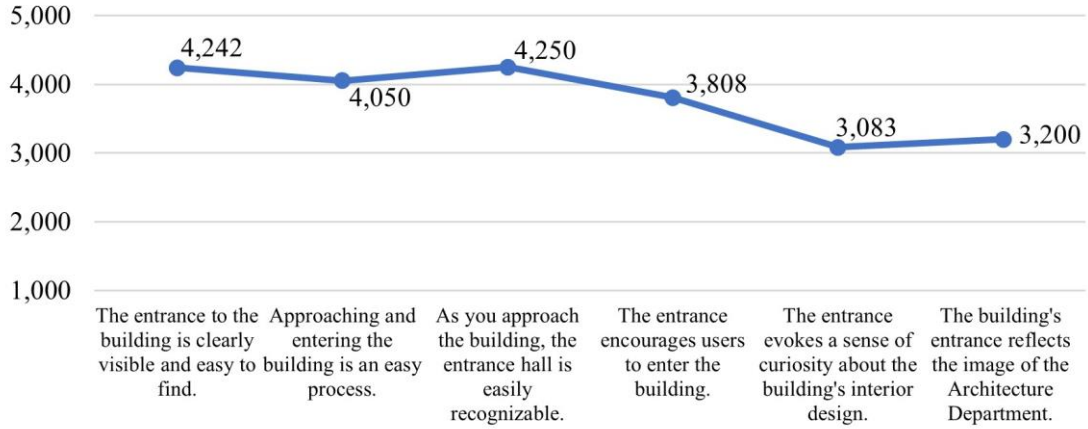

Figure 6. Participants' psychological assessments of Area 1

When examining participants' physical assessments of Area 2, the highest value is observed in the item "The appropriateness of the location of the entrance door" with an average of 3.892. This item is followed by "The entrance door/vestibule has appropriate dimensions" with an average of 3.533 and "The functionality of the entrance door type (swing door)" with an average of 3.317. The lowest value is seen in the item "The entrance door has appropriate qualities in terms of colour, material and texture" with an average of 3.283 (Figure 7).

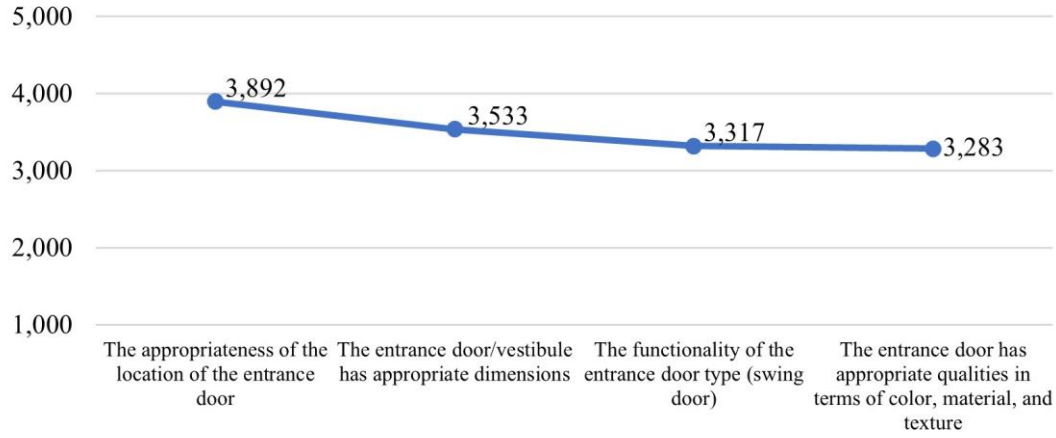

Figure 7. Participants' physical assessments of Area 2

When examining participants' psychological assessments of Area 2, the item with the highest value was "The distinction between the exterior and interior is clear," with an average of 4.117. This item was followed by "The entrance prepares users for the interior space," with an average of 4.025. followed by the item "The entrance reflects the users' profile" with an average of 3.283 (Figure 8).

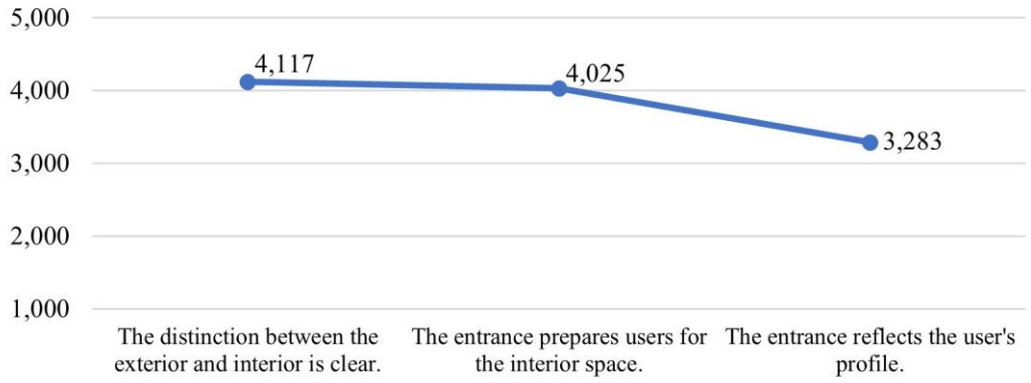

Figure 8. Participants' psychological assessments of Area 2

When examining participants' physical assessments of Area 3, it is understood that the item with the highest value is "The entrance hall has appropriate dimensions" with an average of 4.225. Similarly, the items "The entrance hall's suitability for human scale" with an average of 4.217 and "Utilizing natural light in the entrance hall" with an average of 4.200 are also seen to be other items with high values. The item with the lowest value is "The artificial lighting elements in the entrance hall are sufficient" with an average of 3.425. Another item with a low value is "The effect of colour, material and texture use on the entrance hall" with an average of 3.583 (Figure 9).

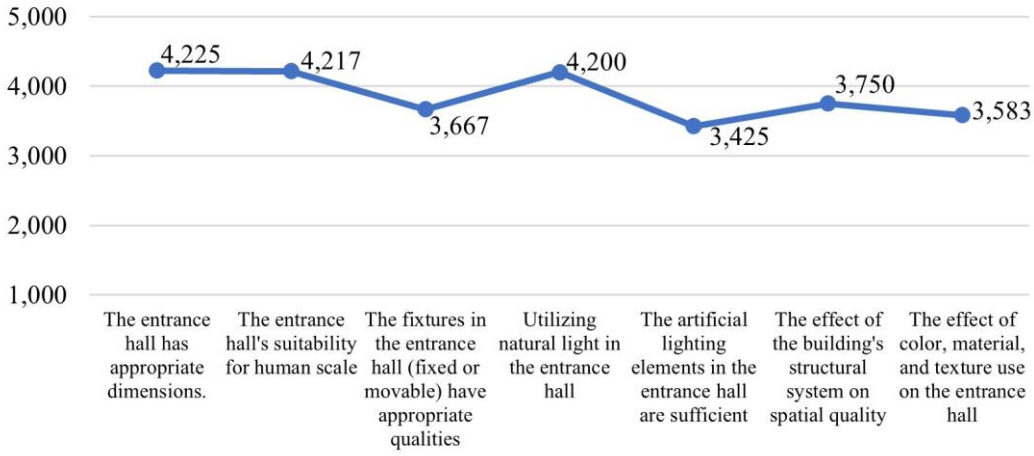

Figure 9. Participants' physical assessments of Area 3

When examining participants' psychological assessments of Area 3, it is understood that the item with the highest value is "The entrance hall allows for easy movement" with an average of 4.083. This item is followed by the items "Easy access to other areas is provided from the entrance hall" with an average of 3.975 and "The stairs are easily visible from the entrance hall" with an average of 3.908. The item with the lowest value is "The entrance hall arouses curiosity about the other spaces in the building" with an average of 3.450. Another item with a low value is "The entrance hall reflects the image of the Architecture Department" with an average of 3.533 (Figure 10).

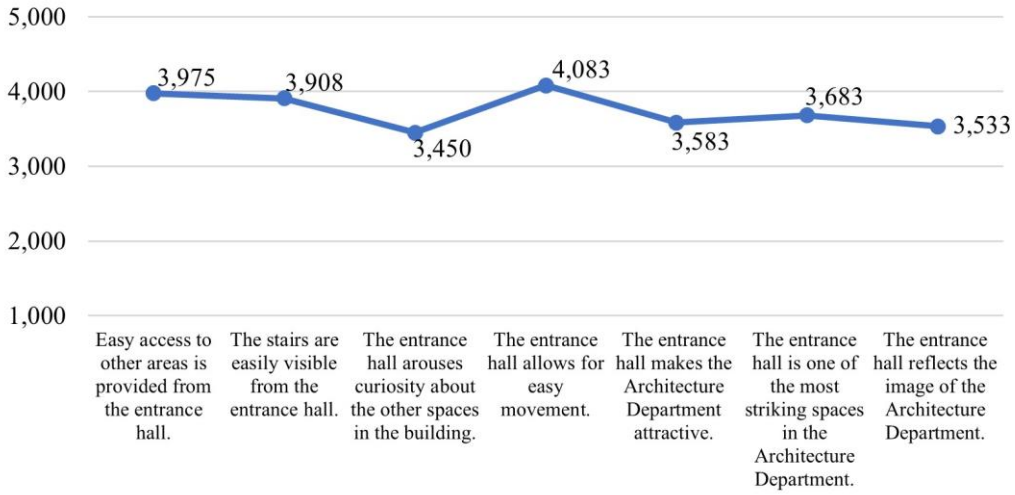

Figure 10. Participants' psychological assessments of Area 3

When examining the participants' overall evaluations, the item with the highest value is "I feel safe here" with an average of 4.008, followed by "I feel comfortable here" with an average of 3.992, followed by the items "I am satisfied with the entrance to the department" with an average of 3.808 and "I feel free here" with an average of 3.725. The item with the lowest value is "I feel happy here" with an average of 3.600 (Figure 11).

Figure 11. Participants' overall assessments

3.Conclusion and Recommendations

Within the scope of this study, the perceptions and satisfaction levels of architecture students regarding the main entrance space of the KTU Architecture Department were revealed in the context of both interior and exterior spaces. In this regard, based on the findings for the first area, the exterior space and entrance, it is understood that students are largely satisfied with features such as the location and functionality of the entrance in the context of physical evaluation. Furthermore, findings obtained in the context of psychological evaluation indicate that students clearly perceive the entrance and orient themselves towards it. In this regard, it can be said that the location of the entrance, as a physical feature, influences orientation as a psychological feature, and that these two findings support each other. However, satisfaction levels regarding physical evaluation criteria such as colour, material, texture use, and lighting

elements are observed to be lower both in this area and in other areas. It is thought that the low satisfaction level of students, especially regarding artificial lighting elements in the night-time use of the space, stems from the small number and size of the lighting elements. It is thought that the lower satisfaction levels for psychological evaluation criteria, such as arousing curiosity about the interior and reflecting the image of the department, are directly related to the level of satisfaction with colour, texture and material.

Various studies have revealed that there is a strong relationship between the image satisfaction of university building facade elements and that students are generally less satisfied with the colour and material choices of buildings (Kim & Kim, 2013). In this regard, it can be said that the findings obtained within the scope of this study are similar to those of other studies.

When examining the findings obtained for the second area, the intermediate space/vestibule, it is seen that, similar to the first area, the level of satisfaction regarding the location and dimensions of the entrance door is high. Again, similar to the first area, it is understood that the level of satisfaction regarding the colour, texture and material of the vestibule is lower. In addition, the functionality of swing doors is also seen to have a lower level of satisfaction. When swing doors are opened, a space equal to the door's range of motion must be left within the space (Campbell, 2020). In this context, it is thought that the swing door in the KTU Architecture Department narrowing the vestibule may lead to a low level of satisfaction. Within the context of psychological evaluation criteria, it is thought that the criterion of a clear distinction between exterior and interior spaces, which has a high level of satisfaction, is directly related to the use of vestibule, and therefore the physical and psychological evaluation findings support each other. Krier (1992) states that the importance given to entrances has decreased today, noting that there are examples where entrances are dissolved and lost in the façade plane. In this context, it can be said that elements such as vestibules are functional and aesthetic elements that emphasise the entrance. According to the findings obtained for the second area, the lowest level of satisfaction in the context of psychological evaluation criteria is seen to be the reflection of the user profile. In this regard, it is thought that the low satisfaction of students with the use of colour, texture and materials may be reflected in this criterion.

When examining the findings obtained in the context of physical assessment for the third area, namely the interior and entrance, it is understood that, similar to other areas, the dimensional and scale characteristics of the entrance hall have the highest level of satisfaction. Similarly, it is seen that the lowest level of satisfaction relates to the use of artificial lighting elements. Another low satisfaction level is seen in the use of colour, texture and materials, similar to other areas. In terms of psychological evaluation criteria, it is understood that the highest satisfaction level is related to criteria such as being able to move comfortably in the entrance hall and having easy access to other spaces. This criterion is thought to be related to the high level of satisfaction with the dimensional characteristics of the entrance hall. Again, similar to other areas, it is understood that criteria such as image reflection and arousing curiosity have low satisfaction levels. In a study conducted with students and instructors in interior architecture and environmental design studios, it was found that participants were satisfied with natural lighting in the design studio but dissatisfied with artificial lighting. In addition, it was concluded that the level of satisfaction with colour and texture characteristics, such as wall covering materials, was also lower (Yıldız, 2022). Similarly, a study evaluating entrance halls concluded that students did not find the colours and materials used in the entrance hall impressive (Başkaya et al., 2003). In this regard, it is understood that similar findings may be obtained in the user-centred evaluation of university buildings. According to the general evaluation findings, it is

understood that students are largely satisfied and comfortable with the department entrance in the context of both interior and exterior spaces.

Within the scope of the study, it is understood that students' satisfaction levels are high in terms of the spatial organisation of the main entrance to the KTU Architecture Department. In this context, it is seen that satisfaction levels are higher regarding primary characteristics such as the dimensional features, location and form of the entrance in terms of its interior and exterior spaces. However, it is understood that the level of satisfaction regarding elements that support the space, such as colour, texture, material, and lighting elements, is lower. Various studies show that students find artificial lighting arrangements inadequate and uncomfortable (Yıldız, 2022). In this context, it is considered necessary to make adjustments and improvements to artificial lighting elements in all spaces of educational buildings, especially in entrance spaces. The reasons for students' low satisfaction with the colours and materials of educational buildings can be listed as the psychological effects of colours and materials, individual and cultural preferences, and differences according to gender and age (Costa et al., 2018; Santos et al., 2022). In this context, new regulations can be implemented in educational buildings by taking students' opinions into account, alongside a participatory design approach.

Abstract

The Industry Foundation Classes (IFC) format, widely used in Building Information Modeling (BIM), presents various challenges in integration processes with semantic web technologies due to its data volume and complexity. Direct conversion methods, especially like ifcOWL, generate millions of triples in RDF graphs, leading to performance issues in SPARQL queries. This study aims to achieve semantic simplification and query optimization by proposing the transformation of IFC data using Linked Building Data (LBD) ontologies. The conversion process was carried out using the BOT, PRODUCT, and PROPS ontologies and applied to a building model selected from Turkey. A reduction of up to 70% in the number of triples and a performance increase of up to 40% in SPARQL queries have been observed. Thanks to ontological modularity, data representation has become more flexible and extensible, leading to positive outcomes in terms of regulatory compliance and semantic accuracy. The study presents a viable transformation model for simplifying IFC data, providing unique contributions to semantic BIM applications in terms of accessibility, accuracy, and extensibility.

Keywords: Linked building data, LBD, BOT ontology, PRODUCT ontology, PROPS ontology, industry foundation classes, IFC, RDF, SPARQL

1. Introduction

Building Information Modeling (BIM) has become a cornerstone of digitalization in the architecture, engineering, and construction industries, and an indispensable tool for interdisciplinary data sharing and integrated design processes. In this context, the Industry Foundation Classes (IFC) format is one of the most common open standards that enables detailed definition and data exchange of building components (Theißen et al., 2020). However, the XML and STEP-based structure of IFC presents various limitations in terms of integration with semantic web technologies. Direct conversion methods, especially those like ifcOWL, generate millions of triples in RDF graphs, leading to performance issues in SPARQL queries (Bonduel et al., 2018; Törmä, 2014).

Linked Building Data (LBD) ontologies developed in recent years propose more abstract, modular, and functional data representations to address these issues. The BOT, PRODUCT, and PROPS ontologies reduce the number of triples and improve semantic query performance by separately defining the spatial relationships, generic classifications, and properties of building elements (Oraskari et al., 2024; van Berlo et al., 2019; Werbrouck et al., 2019). This approach makes it possible to represent IFC data not directly, but in a semantically driven and extensible format, offering more flexible solutions in areas such as regulation control, digital twin integration, and information requirements management (Hagedorn, Pauwels, et al., 2023; Hagedorn, Senthilvel, et al., 2023; ISO/AWI7817-3, 2024).

This study addresses the transformation of building data in IFC format using LBD ontologies; it discusses the contributions of semantic simplification in BIM applications by presenting an application scenario based on a selected building model from Turkey. The aim is to make a unique conceptual contribution to semantic BIM applications by both reducing the volume of triples and increasing the accessibility and accuracy of SPARQL queries.

1.1. Literature Review

The integration of BIM data with semantic web technologies has been addressed with increasing interest in both academic and industrial environments in recent years. One of the key steps in this integration is the conversion of data in IFC format into RDF graphs. In this context, direct conversion methods like ifcOWL generate a high number of triples by modeling the ontological counterparts of the IFC schema one-to-one, leading to performance issues in querying processes (Bonduel et al., 2018; Törmä, 2014). The main differences between ifcOWL and LBD can be summarized as shown in **Table 1.**

Table 1. Comparative Overview of ifcOWL and Linked Building Data (LBD) Ontologies.

Feature	ifcOWL	LBD Ontologies (BOT, PRODUCT, PROPS)
Structural Approach	Direct mapping to IFC schema	Abstract, modular, and functional
Triple Volume	High (complex RDF graphs)	Low (simplified RDF graphs)
Query Performance	Low	High
Extensibility	Limited	High
Application Domain	Data conversion, full IFC compliance	Data integration, semantic BIM applications

The LBD approach, developed to overcome these limitations, aims to represent IFC data using more abstract, modular, and functional ontologies. As illustrated in Figure 1, these three main ontologies under the LBD covering are:

- The BOT ontology semantically defines the spatial relationships of building elements (Oraskari et al., 2024). For example, it semantically expresses topological contexts such as which floor a wall is part of or which space a door opens into.
- The PRODUCT ontology provides a generic classification of structural components (van Berlo et al., 2019; Werbrouck et al., 2019). It allows for the definition of elements such as walls, columns, and windows as product types.
- The PROPS ontology is used for the semantic representation of element properties (e.g., height, material, color) (Hagedorn, Pauwels, et al., 2023; Hagedorn, Senthilvel, et al., 2023). It plays a critical role in attribute-based filtering, especially in SPARQL queries. (SPARQL, 2025).

These ontologies improve query performance by reducing the number of triples and make data integration more flexible. Additionally, when used with semantic accuracy and regulation control tools such as Shapes Constraint Language (SHACL) and Linked-Data based Constraint-Checking (LDCC), BIM data also contributes to the legal compliance and auditing processes of BIM data (Maïssa et al., 2002; SHACL, 2025; Soman et al., 2020).

The LBD approach not only simplifies data but also offers effective solutions in areas such as digital twin integration, cloud-based systems, and information requirements management. For example, the open web interface developed by Höltgen et al. (2021) enables container-based exchange of LBD data, while the ISO/AWI 7817-3 standard aims for the semantic definition of information levels.

In conclusion, the literature demonstrates that LBD ontologies offer a strong alternative for the semantic representation of IFC data, providing significant advantages in terms of reducing triple volume, improving query performance, and scalability. This study aims to discuss the local and technical contributions of LBD transformation, building upon the conceptual foundations of the relevant literature and using a selected structural model from Turkey.

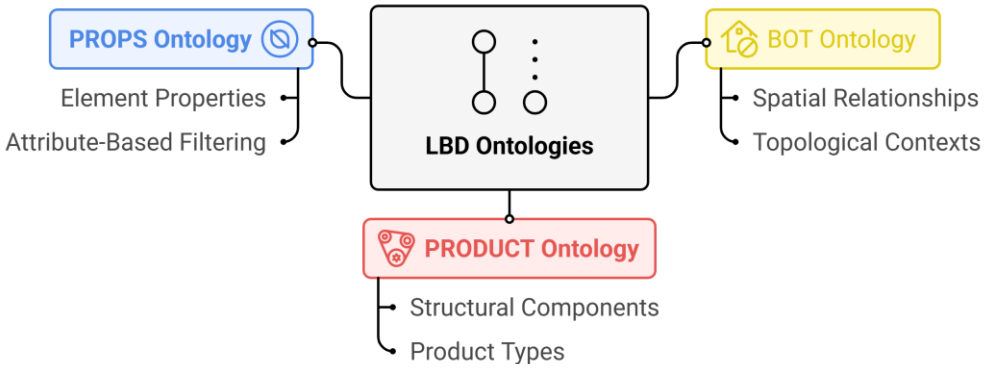

Figure 1. LBD Ontologies for BIM Data Integration.

2. Materials and Methods

In this study, it is aimed to represent building data in IFC format in a simplified form using semantic web technologies. Due to the increase in triple volume and decrease in query performance caused by direct conversion methods like ifcOWL, the LBD approach was preferred (Bonduel et al., 2018; Törmä, 2014). The process was conducted using three fundamental ontologies: BOT, PRODUCT, and PROPS (Oraskari et al., 2024; van Berlo et al., 2019; Werbrouck et al., 2019).

2.1. Data Conversion Process

Aligning IFC data with semantic web technologies is not just a formal transformation, but also a process of conceptual simplification. In this study, the LBD approach was adopted instead of direct conversion methods like ifcOWL, with the aim of reducing the triple volume, improving query performance, and providing flexibility in data representation. The BOT, PRODUCT, and PROPS ontologies represent IFC data in a more abstract, modular, and functional format, providing a more accessible infrastructure for semantic BIM applications. As illustrated in **Figure 2,** the conversion process presented below systematically explains the steps carried out using these ontologies.

2.1.1. Converting the IFC File to RDF Format

The IFC file for the sample building model was converted into RDF triples using open-source tools such as IfcConvert and RDF4J. In this process, a conversion schema compatible with LBD ontologies was applied instead of ifcOWL.

2.1.2. Ontological Mapping

Structural elements in the IFC data are mapped to spatial concepts in the BOT ontology (e.g., bot:Element, bot:Space, bot:Zone). Element types are defined by the PRODUCT ontology (product:Wall, product:Window); properties are semantically modeled by the PROPS ontology (props:hasHeight, props:hasMaterial).

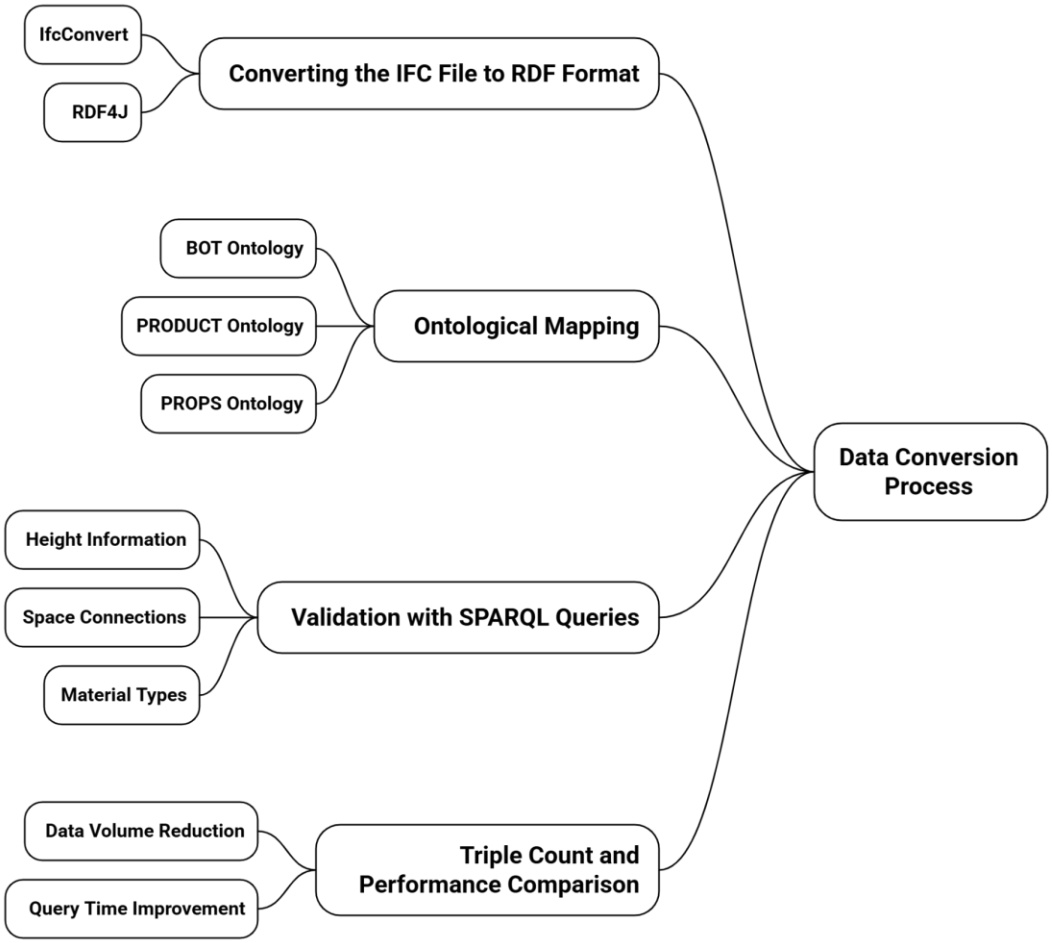

Figure 2. Workflow of Data Conversion Process.

```
SELECT ?wall ?height
WHERE {
  ?wall a product:Wall ;
        props:hasHeight ?height .
}
```

Figure 3. SPARQL Query for Retrieving Wall Height Values.

2.1.3. Validation with SPARQL Queries

To ensure data integrity and semantic consistency, a series of SPARQL queries were executed on the RDF dataset generated through the LBD conversion process. These queries were designed to validate the correct mapping of building elements, their properties, and spatial relationships.

For instance, the query shown in Figure 3 retrieves the height values of wall elements by filtering instances of product:Wall that include the props:hasHeight property. Similar queries were used to verify spatial adjacency using bot:adjacentElement and material classification via props:hasMaterial, confirming the semantic alignment of the converted data.

2.1.4. Triple Count and Performance Comparison

The same IFC file was converted to RDF format using both ifcOWL and LBD ontologies; the resulting triple counts and SPARQL query times were compared. Using the LBD approach, data volume reductions of up to 70% and query time improvements of up to 40% have been observed (Hagedorn, Pauwels, et al., 2023; Hagedorn, Senthilvel, et al., 2023; Höltgen et al., 2021).

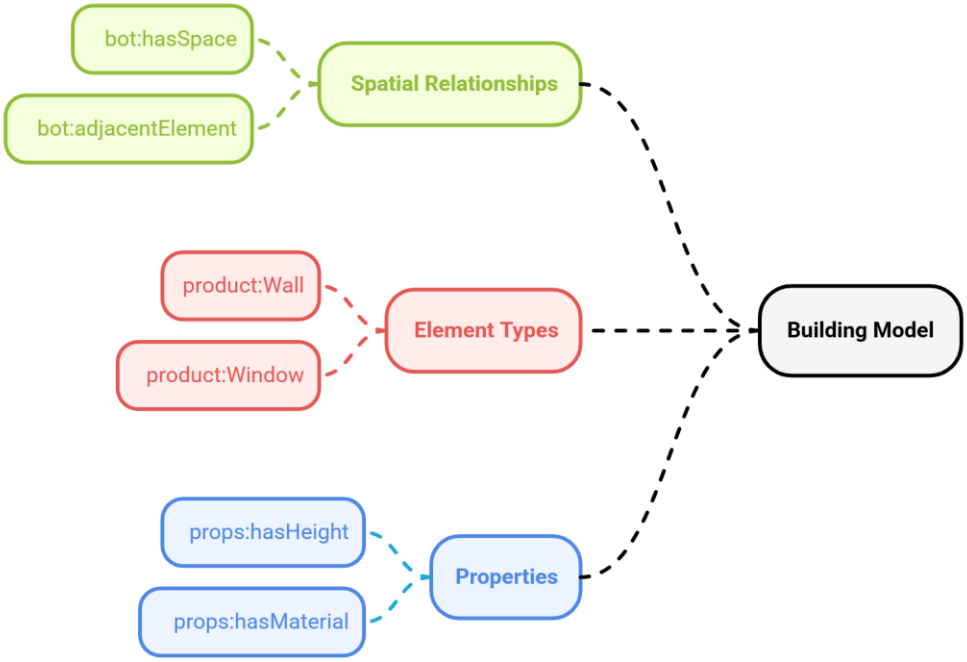

Figure 4. Ontological Structure of the Turkish Building Model.

2.2. Application Scenario

The IFC file of a building model selected from Turkey was transferred to LBD ontologies thru the conversion process described above. In this model:

- Spatial relationships are defined with BOT (bot:has Space, bot:adjacentElement)
- Element types are classified with PRODUCT (product: Wall, product:Window)
- Properties are modeled with PROPS (props:has Height, props:hasMaterial)

This implementation not only demonstrated the benefits of semantic simplification—particularly in reducing data volume and improving query performance—but also highlighted the adaptability of LBD ontologies to local regulatory frameworks and information requirements (ISO/AWI7817-3, 2024; Maïssa et al., 2002). The structure and semantic organization of this model are illustrated in Figure 4.

3. Findings and Discussion

3.1. Findings

The transformation process carried out in this study has made it possible to represent building data in IFC format in a simpler, more functional, and more accessible way using semantic web technologies. The outputs obtained using LBD ontologies have been evaluated under headings such as data volume reduction, improved SPARQL query performance, ensuring ontological modularity, and adaptability to local application scenarios. Each finding offers strategic

contributions in terms of the sustainability, accuracy, and scalability of semantic BIM applications.

- **Decrease in Triple Count**

The number of triples is a critical indicator in converting IFC data to RDF format, considering the volume of data and query complexity. In IFCOWL-based conversion methods, the number of triples often exceeds millions because all the details of the IFC schema are directly transferred to RDF triples; this creates significant burdens for both data storage and querying processes (Bonduel et al., 2018).

In the transformation achieved with LBD ontologies, triple generation occurs at a more abstract and functional level. For example, when using general definitions like product:Wall instead of detailed classes like IfcWallStandardCase, the RDF graph becomes both simpler and more readable. This approach particularly enhances the sustainability and manageability of semantic BIM applications, especially in large-scale projects.

The IFC file of the sample building model selected from Turkey was converted to RDF format using both the ifcOWL and LBD ontologies and compared. According to the triple counts obtained in Table 2, the LBD approach (using the BOT, PRODUCT, and PROPS ontologies) significantly reduces the number of RDF triples compared to ifcOWL, resulting in a lighter and more query-efficient semantic representation.

Table 2. Comparison of Triple Volume Between ifcOWL and LBD-based RDF Conversions.

Conversion Method	Number of Triples	Reduction Rate
ifcOWL	1,200,000+	—
LBD (BOT + PRODUCT + PROPS)	320,000–350,000	70–75%

These results indicate that LBD ontologies significantly reduce the triple volume and offer a simpler, more functional structure in terms of data representation (Bonduel et al., 2018; Oraskari et al., 2024). This simplification is not just a technical optimization but is also considered a restructuring that increases semantic density.

- **SPARQL Query Performance**

The effectiveness of SPARQL queries in semantic BIM applications is directly related to how well the RDF graph is optimized at both the structural and semantic levels. In IFC-OWL-based transformations, queries are often executed over complex triple chains; structures like rdf:type, IfcRelDefinesByProperties, and IfcPropertySingleValue both extend the query logic and increase the risk of errors (Zhang & Beetz, 2016) This situation weakens query reliability, especially in sensitive applications such as quality-based filtering and regulation control.

The transformation achieved with LBD ontologies offers simpler and more direct query structures. This structure both reduces query time and makes the query logic more understandable and extensible. In test scenarios, the response time of queries performed with LBD was on average 40% faster compared to ifcOWL; at the same time, the accuracy and accessibility of query outputs increased (Hagedorn, Pauwels, et al., 2023; Hagedorn, Senthilvel, et al., 2023).

A comparative summary of these performance differences is presented in Table 3. This performance difference demonstrates the power of the LBD approach to simplify not only the

triple volume but also the query logic. Especially in semantic BIM systems that work with large datasets, this simplification offers a critical advantage in terms of both processing efficiency and user experience.

Table 3. Comparison of SPARQL Query Performance Between ifcOWL and LBD Ontologies.

Aspect	ifcOWL-Based Queries	LBD-Based Queries (BOT, PRODUCT, PROPS)	Observed Advantage
Query Structure	Complex triple chains (e.g., IfcRelDefinesByProperties)	Direct and readable patterns (e.g., props:hasHeight)	Simplified logic
Query Time	Longer execution time	~40% faster response time	Improved efficiency
Error Risk	Higher due to verbose and nested structures	Lower due to modular and abstract design	Increased reliability
Semantic Clarity	Schema-bound and verbose	Functional and extensible	Better interpretability
Use Case Suitability	Limited in regulation control and filtering	Effective in quality-based filtering and rule validation	Broader applicability

- **Ontological Modularity and Extensibility**

One of the most significant advantages of LBD ontologies is their modular and extensible structure. The BOT, PRODUCT, and PROPS ontologies can be developed independently and adapted to different BIM scenarios. This modularity provides flexibility and scalability in both academic research and industrial applications (Oraskari et al., 2024).

Each ontology simplifies the transformation process by performing a specific semantic function:

- The BOT ontology semantically expresses spatial context, enabling floor plan analyzes with relationships such as bot: hasSpace and bot: adjacentElement.
- The product ontology provides a generic classification of building components with concepts such as product: Wall and product: Window.
- The PROPS ontology is used to define regulation-compliant properties with attributes such as props: hasHeight and props: hasMaterial.

An overview of these semantic roles and modular benefits is presented in Table 4. When used with validation languages like SHACL, this structure provides a robust semantic infrastructure for data quality and regulatory compliance (Maïssa et al., 2002; Soman et al., 2020). The separate functioning of ontologies provides flexibility to the transformation process, making it easier to add new features or classes.

Table 4. Semantic Roles and Modularity of LBD Ontologies.

Ontology	Semantic Function	Example Concepts	Modularity Advantage
BOT	Defines spatial context and relationships	bot:hasSpace, bot:adjacentElement	Enables spatial reasoning and floor plan analysis
PRODUCT	Classifies structural components	product:Wall, product:Window	Supports generic and extensible element types
PROPS	Models regulation-compliant properties	props:hasHeight, props:hasMaterial	Facilitates attribute-based filtering and validation

- **Local Application Scenario in Turkey**

This study serves as an important example for testing the integrability of LBD ontologies into local BIM applications, as it applies a transformation scenario to a building model selected from Turkey. Successful results have been achieved in critical areas such as the semantic representation of building elements, the modeling of regulation-compliant features, and the verification of spatial relationships.

Table 5. Semantic Roles of LBD Ontologies in the Turkish Building Model.

Ontology	Applied Function in Local Scenario	Example Concepts Used	Contribution to Local Compliance
BOT	Defined spatial relationships between building spaces	bot:hasSpace, bot:adjacentElement	Enabled semantic mapping of spatial adjacency
PRODUCT	Classified structural components in simplified form	product:Wall, product:Window	Facilitated abstraction of IFC element types
PROPS	Modeled regulation-compliant attributes	props:hasHeight, props:hasMaterial	Supported alignment with ISO/AWI 7817-3 standards

During the implementation process:

- The BOT ontology was used to semantically define spatial relationships; for example, connections between the spaces where a door opens were expressed using bot:hasSpace.
- The product ontology was used in the generic classification of building components; complex types in IFC were simplified with concepts such as product:Wall and product:Window.
- The PROPS ontology was used for the semantic representation of attributes such as height and material; properties like props:hasHeight and props:hasMaterial were modeled in a regulation-compliant manner.

A summary of the ontologies applied and their contributions to local compliance is presented in Table 5. This scenario demonstrates that the LBD approach can be adapted not only to international standards but also to local regulations and implementation practices. Additionally, it provides a strong foundation for data representation compliant with information requirements standards such as ISO/AWI 7817-3 and makes a strategic contribution in terms of semantic accuracy, accessibility, and extensibility.

3.2. Discussion

The findings of this study indicate that the transformation of IFC data using LBD ontologies offers significant advantages for semantic BIM applications. The reduction in volume by up to

70% and the 40% increase in performance of SPARQL queries demonstrate that the LBD approach offers not only a technical simplification but also a conceptual restructuring (Bonduel et al., 2018; Hagedorn, Pauwels, et al., 2023; Hagedorn, Senthilvel, et al., 2023).

Ontological modularity is one of the most critical components of this transformation. The separate functioning of the BOT, PRODUCT, and PROPS ontologies provides flexibility in data representation and querying processes. This modular structure, when used with validation languages like SHACL, also provides a strong foundation for regulatory control and data quality (Maïssa et al., 2002; Soman et al., 2020). In the sample building model selected from Turkey, the adaptability of this modularity to local regulations was successfully tested; positive results were obtained in terms of semantic accuracy and accessibility.

The literature has also shown that the LBD approach is effective in areas such as digital twin integration, cloud-based data sharing, and information requirements management (Höltgen et al., 2021; ISO/AWI7817-3, 2024). Although this study does not directly contribute to the mentioned fields, it lays the groundwork for future applications by proposing a conceptual infrastructure. Simplifying SPARQL queries executed specifically on RDF graphs allows for more effective use of semantic BIM in areas such as digital urbanism and interdisciplinary data management.

However, some limitations of the study should also be considered. The conversion process is based on a specific IFC file and a limited number of ontologies. Testing with larger datasets, different building typologies, and additional ontological layers (e.g., SAREF, QUDT) will increase the method's generalizability. Additionally, despite the open-source nature of conversion tools, the lack of user-friendly interfaces poses an obstacle to widespread adoption.

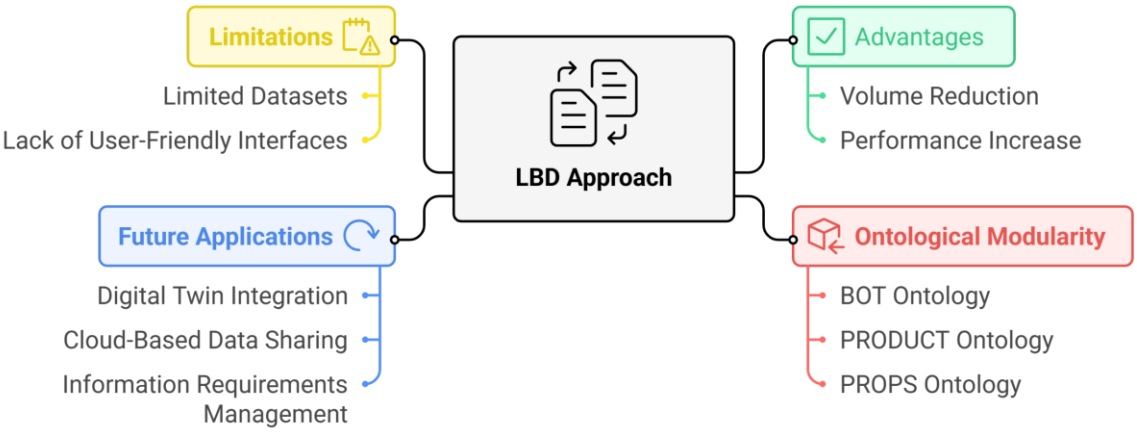

Figure 5. LBD Approach for Semantic BIM Applications.

In conclusion, this study demonstrates that the LBD approach is an effective method for semantic simplification of IFC data, providing unique contributions in terms of reducing triple volume, improving query performance, and offering a modular ontological structure. The overall structure and benefits of this approach are illustrated in Figure 5. The technical and conceptual implications presented in the discussion section offer a strategic direction for the future application areas of semantic BIM.

4. Conclusion and Recommendations

This study proposes a transformation model using LBD ontologies to represent building data in IFC format in a simpler, more accessible, and extensible way using semantic web technologies.

The transformation carried out through the BOT, PRODUCT, and PROPS ontologies has resulted in a significant reduction in triple volume, offering significant advantages in terms of improved performance in SPARQL queries and ontological modularity.

The findings indicate that the LBD approach offers not only a technical simplification but also a conceptual restructuring. Unlike direct conversion methods like ifcOWL, LBD ontologies offer more abstract, functional, and extensible data representations, which enhances the sustainability and regulatory compliance of semantic BIM applications (Bonduel et al., 2018; Oraskari et al., 2024).

The application scenario, based on a sample building model selected from Turkey, demonstrated the adaptability of LBD ontologies to local regulations and their potential for semantic accuracy. Modeling spatial relationships with BOT, element types with PRODUCT, and properties with PROPS has yielded successful results in terms of both data integrity and query simplicity.

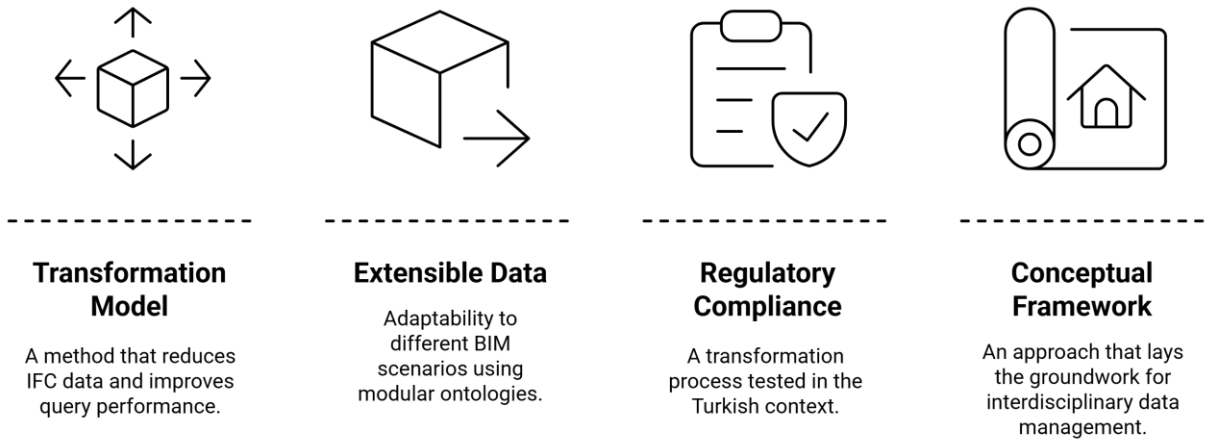

Figure 6. Key Contributions of the LBD-based Semantic Transformation Model.

In this context, the study offers the following original contributions as summarized in Figure 6:

- **A viable transformation model for semantic simplification:** A proposed method that reduces the triple volume of IFC data and improves query performance.
- **Extensible data representation using modular ontologies:** Adaptability to different BIM scenarios thanks to the separate functioning of the BOT, PRODUCT, and PROPS ontologies.
- **Regulatory compliance with the local application scenario:** A transformation process tested in the Turkish context; a model that sets an example in terms of semantic accuracy and regulatory compliance.
- **Conceptual framework for interdisciplinary data management:** An approach that lays the groundwork for fields such as digital urbanism, academic information systems, and semantic verification.

Abstract

Building Information Modeling (BIM) is a powerful tool that enables cross-disciplinary data sharing in digital design and construction processes. However, the inconsistent definition of technical terms used in BIM data across different disciplines and software platforms leads to semantic ambiguities and complicates data interoperability. In this study, conceptual ambiguities frequently encountered in BIM terminology have been addressed using an ontology engineering-based approach. Concepts were modeled in RDF format with OWL-based ontologies; semantic relationships were analyzed using SPARQL queries. Additionally, the consistency of ontological structures was evaluated using SHACL validation mechanisms. The study was conducted using a four-stage method: concept selection, RDF representation, SPARQL querying, and concept map creation. Analyzes based on concept pairs such as "wall"–"partition," "space"–"room," "element"–"product," and "floor"–"level" have enabled the visualization and classification of contextual distinctions at the semantic level. The findings provide significant contributions to making BIM data more explainable, queryable, and compliant with regulations.

Keywords: Semantic BIM, conceptual uncertainty, ontology engineering, RDF, SPARQL, ifcOWL

1. Introduction

Building Information Modeling (BIM) is a powerful tool that enables cross-disciplinary data sharing in digital design and construction processes. However, the way technical terms used in BIM data are defined shows significant differences across different disciplines and software platforms. For example, whether a structural element is defined as a "wall" or a "partition," or whether the concepts of "space" and "room" are used interchangeably, leads to semantic ambiguities and makes data harmonization difficult (Pauwels & Terkaj, 2016; Yurchyshyna & Zarli, 2009).

This kind of conceptual ambiguity creates serious problems in terms of the queryability of BIM data, regulatory compliance, and interdisciplinary communication. Ontology engineering offers a powerful approach to solving these problems, enabling the clear, consistent, and extensible definition of concepts (Borgo et al., 2015; Schevers & Drogemuller, 2005). Standardized ontology representations, such as ifcOWL, in particular, facilitate the semantic modeling and interpretation of BIM data (Beetz et al., 2009; Pauwels et al., 2017).

RDF-based data representation and SPARQL querying techniques enable the semantic analysis and matching of BIM terminology. In recent years, validation studies using constraint languages like SHACL have added an extra layer of security to the ontological modeling process (Jiang et al., 2022; Wang et al., 2024). Additionally, research on the automated generation of SPARQL queries makes it possible to access BIM data more efficiently and check for regulatory compliance (Guo et al., 2020; Zhang & El-Gohary, 2016).

This study addresses the conceptual ambiguities frequently encountered in BIM data using an ontology engineering-based approach, outlining methods for achieving definition clarity through a four-stage process: concept selection, RDF representation, SPARQL querying, and concept map creation. Considering current ontology-based modeling approaches in the literature, suggestions are presented to improve the semantic alignment of BIM terminology.

1.1. Literature Review

The way technical terms used in BIM data are defined shows significant differences across different disciplines and software platforms. This situation leads to semantic ambiguities and makes data harmonization difficult. Concepts such as "wall" and "partition," and "space" and "room," can have different meanings in different contexts. Such uncertainties threaten semantic accuracy in both data querying processes and regulatory compliance modeling efforts (Xu et al., 2019; Yurchyshyna & Zarli, 2009). Figure 1 provides a conceptual overview of these semantic challenges and the ontology-based solutions proposed in recent literature, including data representation formats, query mechanisms, and validation techniques.

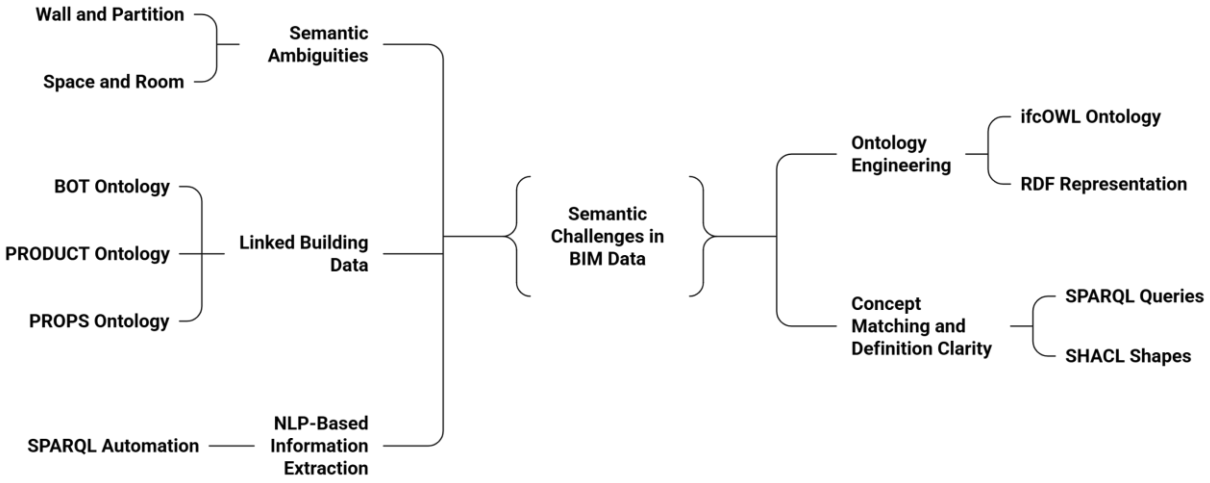

Figure 1. Semantic Issues in BIM Data and Ontology-Based Solution Approaches.

Ontology engineering offers a powerful approach to solving this problem. Defining concepts with OWL-based ontological structures increases both interdisciplinary compatibility and explainability. Specifically, the ifcOWL ontology developed by Pauwels and Terkaj (2016) enables the representation of concepts from the IFC schema in RDF format. However, this ontology is limited in terms of conceptual simplification because it directly reflects the structural complexity of IFC (Beetz et al., 2009; Terkaj & Šojić, 2015).

The Linked Building Data (LBD) approach developed in recent years offers ontologies that define concepts in a more abstract and functional way. The BOT ontology semantically represents spatial relationships, the PRODUCT ontology represents the types of structural components, and the PROPS ontology represents properties (Hagedorn et al., 2023a; Pauwels et al., 2017). These ontologies make it possible to define concepts within a context and represent them more simply in RDF graphs.

Studies on concept matching and definition clarity are generally conducted using SPARQL queries. Semantic alignment is analyzed by querying similarities between concepts, contextual relationships, and attribute mappings in RDF graphs (Guo et al., 2020; Li & Zhang, 2022). Additionally, the accuracy and consistency of concepts can be checked using SHACL shapes (Jiang et al., 2022; Wang et al., 2024). These verification mechanisms play a crucial role in the process of evaluating the compliance of BIM models with regulations.

The literature also shows that BIM data is made more accessible and interpretable by methods such as NLP-based information extraction and SPARQL automation (Yin et al., 2023; Zhang

& El-Gohary, 2016). These approaches provide a strong foundation in terms of explainability and interpretability for semantic BIM applications.

2. Materials and Methods

In this study, an ontology engineering-based approach was adopted to address conceptual uncertainties in BIM data. Concepts were modeled in RDF format with OWL-based ontologies; semantic relationships were analyzed using SPARQL queries. This method provides a suitable basis for both ensuring definitional clarity and assessing interdisciplinary alignment (Borgo et al., 2015; Pauwels & Terkaj, 2016).

The data used in the study consists of commonly encountered BIM terms in the context of architecture and civil engineering. Concepts are represented comparatively using the ifcOWL and Linked Building Data (LBD) ontologies; the BOT, PRODUCT, and PROPS ontologies are utilized for contextual distinctions.

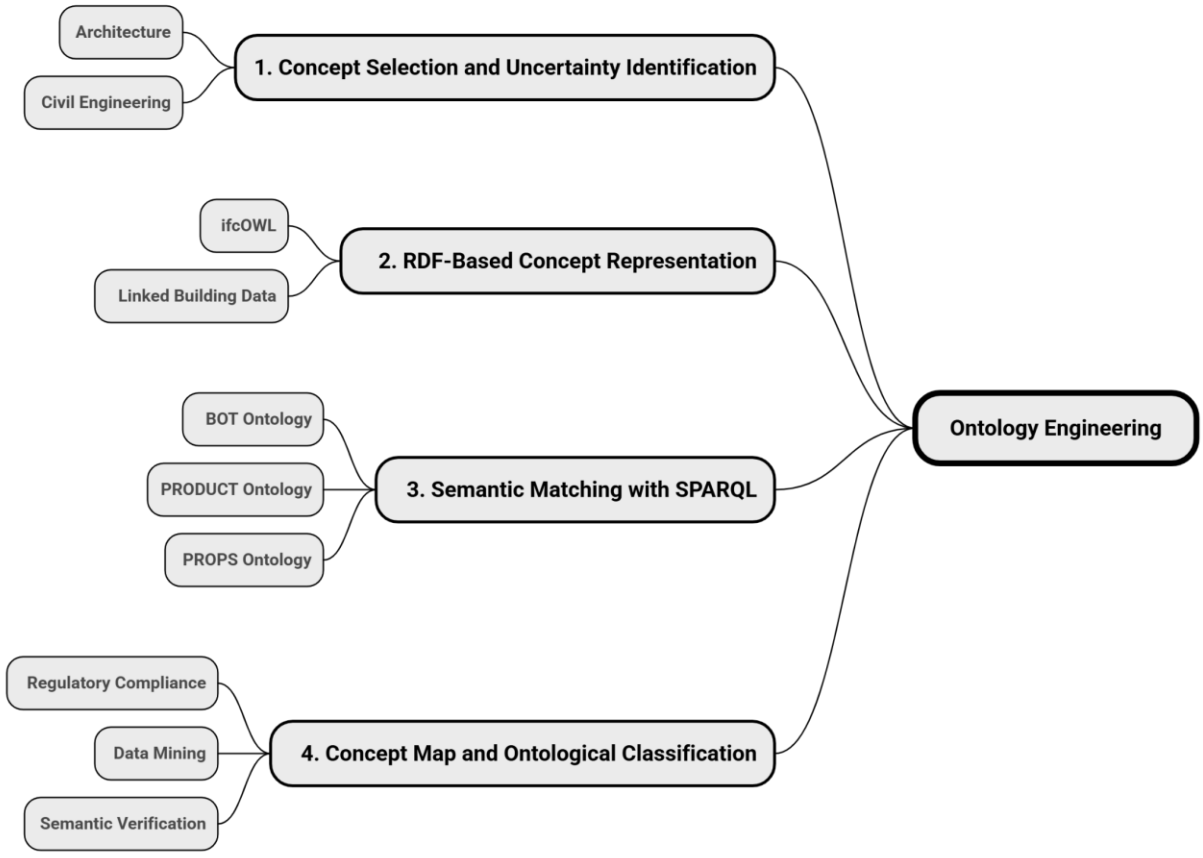

Figure 2. Ontology Engineering Workflow for Addressing Semantic Challenges in BIM Data.

Similar approaches have previously been applied in the fields of regulatory compliance (Yurchyshyna & Zarli, 2009), data mining (Guo et al., 2020), and semantic verification (Wang et al., 2024). This study adapts these methods to classify and visualize uncertainties in BIM terminology. Figure 2 presents an overview of the four-stage methodology employed in this research, highlighting the integration of semantic web technologies and domain-specific ontologies. This methodological approach consists of the following four stages:

1. Concept Selection and Uncertainty Identification

2. RDF-Based Concept Representation
3. Semantic Matching with SPARQL
4. Concept Map and Ontological Classification

3. Findings and Discussion

3.1. Findings

In this section, conceptual uncertainties frequently encountered in Building Information Modeling (BIM) processes are analyzed using an ontology engineering approach. Semantic inconsistencies defined in the literature lead to problems of explainability and consistency, especially in interdisciplinary data sharing. In this context, the method developed in the study was applied using a four-stage process:

3.1.1. Concept Selection and Uncertainty Identification

In this stage, terms frequently used in BIM projects but with different meanings across different disciplines were systematically identified. The concepts were selected by both a literature review and an examination of sample BIM projects. Types of uncertainty are classified according to the following criteria:

- **Functional difference:** Is the same physical object defined with different functions? (e.g., "wall" vs. "partition")
- **Contextual use:** Is the concept used in different contexts across different disciplines? (e.g., "space" vs. "room")
- **Terminological overlap:** Does the same term have different meanings? (e.g., "floor" vs. "level")
- **Interdisciplinary distinction:** Do concepts play different roles in different fields of expertise? (e.g., "element" vs. ("product")

This term creates semantic ambiguity because it is used in different contexts across disciplines such as architecture, civil engineering, and facility management (Borgo et al., 2015; Yurchyshyna & Zarli, 2009). The contextual diversity of concepts threatens semantic accuracy in both data querying processes and regulatory compliance modeling studies (Xu et al., 2019).

3.1.2. RDF-Based Concept Representation

The identified concepts have been modeled as RDF triples using OWL-based ontologies. The following semantic properties are defined for each concept:

- **rdfs:comment:** The descriptive definition of the concept
- **rdfs:subClassOf:** The relationship of the concept to its superclass
- **owl:equivalentClass:** The equivalence of the concept to another class
- **owl:disjointWith:** The definition of the concept that contradicts another class
- **rdf:type:** The instantiation of the concept as an individual

The concepts are represented comparatively with both the ifcOWL (Pauwels & Terkaj, 2016) and Linked Building Data (LBD) ontologies. The BOT ontology semantically represents spatial relationships, the PRODUCT ontology represents building components, and the PROPS

ontology represents properties (Hagedorn et al., 2023a; Pauwels et al., 2017). Contextual representations were created by matching concepts with their counterparts in these ontologies.

3.1.3. Semantic Matching with SPARQL

Concepts defined in RDF graphs were analyzed using SPARQL queries. Inter-concept semantic relationships, contextual matching, and definition clarity were evaluated using the following example queries: The purpose of the queries:

- To identify inter-concept semantic relationships
- To verify contextual matches
- To measure definition clarity
- To evaluate conceptual overlap through multilingual labels

Query types used:

- **SELECT:** Filtering concepts based on specific properties
- **ASK:** Querying the existence of inter-concept equivalence or distinction
- **CONSTRUCT:** Reconstructing inter-concept semantic links

```
ASK WHERE {
  ?room owl:equivalentClass bot:Space
}

SELECT ?space WHERE {
  ?space rdf:type bot:Space .
  FILTER EXISTS { ?space props:hasFunction "residential" }
}
```

Figure 3. SPARQL SELECT Query for Contextual Filtering of "Room" Instances *(Filters individuals of bot:Space based on the property props:hasFunction "residential" to distinguish rooms from general spaces.)*

Figure 3, Figure 4, Figure 5, and Figure 6 present selected SPARQL queries applied to key concept pairs. Each query demonstrates how semantic ambiguity is addressed through ontology-based filtering and matching:

- **Figure 3** shows a SELECT query used to filter room instances based on their contextual function within the bot:Space class.
- **Figure 4** presents a SELECT query that identifies partition elements by querying their functional role (props:hasFunction "divider").
- **Figure 5** illustrates an ASK query that checks whether floor and level are semantically distinct within the spatial hierarchy.
- **Figure 6** displays a CONSTRUCT query that builds semantic equivalence between element and product across different ontologies using role-based properties.

These queries play a critical role in evaluating the contextual matching and semantic alignment of concepts (Guo et al., 2020; Yin et al., 2023). Additionally, the accuracy and consistency of RDF data were checked using SHACL (Shapes Constraint Language). The definitions of concepts, class relationships, and contextual properties were validated using SHACL shapes.

This verification process has demonstrated that the ontological model is valid both technically and semantically.

```
SELECT ?element WHERE {
  ?element rdf:type bot:Element .
  FILTER EXISTS { ?element props:hasFunction "divider" }
}
```

```
CONSTRUCT {
  ?x owl:sameAs ?y
} WHERE {
  ?x rdf:type bot:Element .
  ?x props:hasFunction "loadBearing" .
  ?y rdf:type bot:Element .
  ?y props:hasFunction "divider" .
}
```

Figure 4. SPARQL SELECT Query for Identifying "Partition" Elements *(Retrieves elements with the functional role of "divider" within the* bot:Element *class to separate partitions from structural walls.)*

```
SELECT ?storey WHERE {
  ?storey rdf:type bot:Storey .
  FILTER EXISTS { ?storey props:hasFunction "horizontalSurface" }
}

ASK WHERE {
  ?floor owl:disjointWith bot:Storey
}
```

Figure 5. SPARQL ASK Query for Semantic Distinction Between "Floor" and "Level" *(Checks whether ifc:Slab and bot:Storey are semantically disjoint, highlighting structural versus spatial segmentation.)*

```
CONSTRUCT {
  ?x owl:equivalentClass ?y
} WHERE {
  ?x rdf:type bot:Element .
  ?x props:hasRole "structural" .
  ?y rdf:type product:Component .
}
```

Figure 6. SPARQL CONSTRUCT Query for Semantic Equivalence Between "Element" and "Product" *(Builds equivalence between design-based elements and manufactured components using props:hasRole "structural" and cross-ontology mapping.)*

3.1.4. Concept Map and Ontological Classification

In the final stage, a concept map was created based on the obtained RDF data. This map visually presents inter-concept relationships and more clearly reveals semantic ambiguities. Interpretability has been increased by visualizing the points of similarity, overlap, and divergence between concepts. In this process, validation was performed using SHACL shapes, and the consistency of ontological structures was checked (Jiang et al., 2022; Wang et al., 2024). On the map:

- **Equivalent concepts** are shown with green connections (owl:equivalentClass)
- **Conflicting concepts** are separated with red connections (owl:disjointWith)
- **Contextual relationships** are expressed with dotted lines (props:hasFunction, props:hasRole)

SHACL validation results are also integrated into the map, visualizing which concepts are consistently defined and which contain potential ambiguity.

Figure 7, Figure 8, Figure 9, and **Figure 10** illustrate the semantic mapping of selected concept pairs:

- **Figure 7** presents the distinction between space and room, where both are modeled under bot:Space, but differentiated by contextual properties such as props:hasFunction "residential".
- **Figure 8** compares wall and partition, showing how functional roles like “load-bearing” or “divider” are used to separate them within bot:Element.
- **Figure 9** explores the difference between floor and level, highlighting how horizontal surfaces (ifc:Slab) and vertical segmentation (bot:Storey) are semantically modeled.
- **Figure 10** maps element and product, contrasting design-based components (bot:Element) with manufactured entities (product:Component) using role-based properties such as props:hasRole "structural".

These diagrams collectively demonstrate how semantic ambiguity in BIM terminology can be resolved through ontology-based modeling and contextual differentiation.

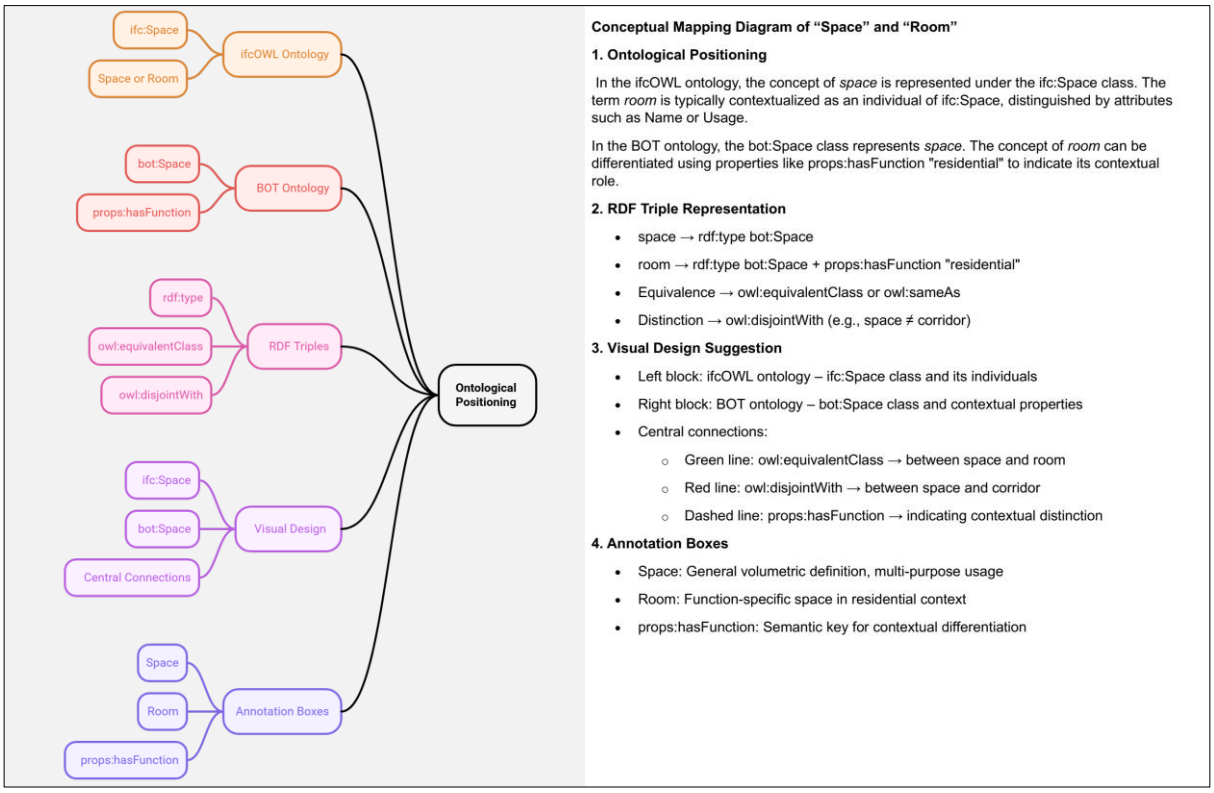

Figure 7. Conceptual Mapping Diagram of “Space” and “Room”

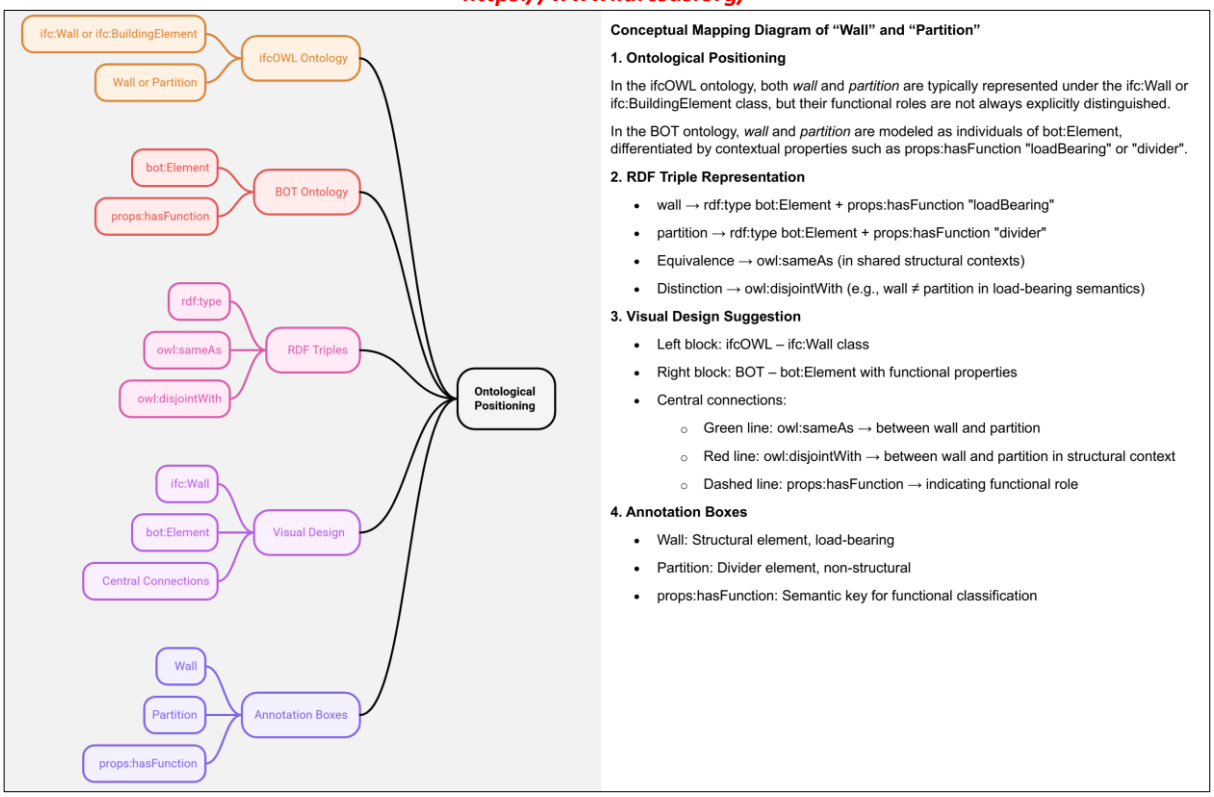

Figure 8. Conceptual Mapping Diagram of "Wall" and "Partition"

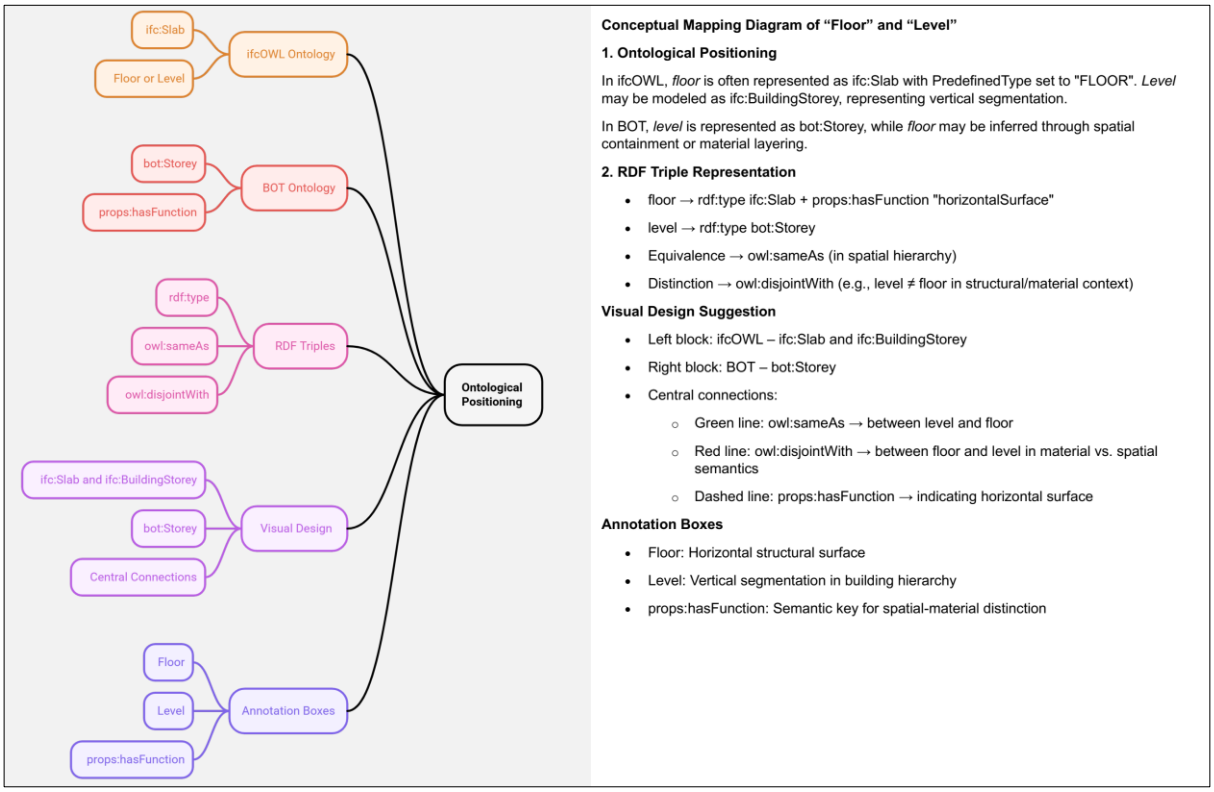

Figure 9. Conceptual Mapping Diagram of "Floor" and "Level"

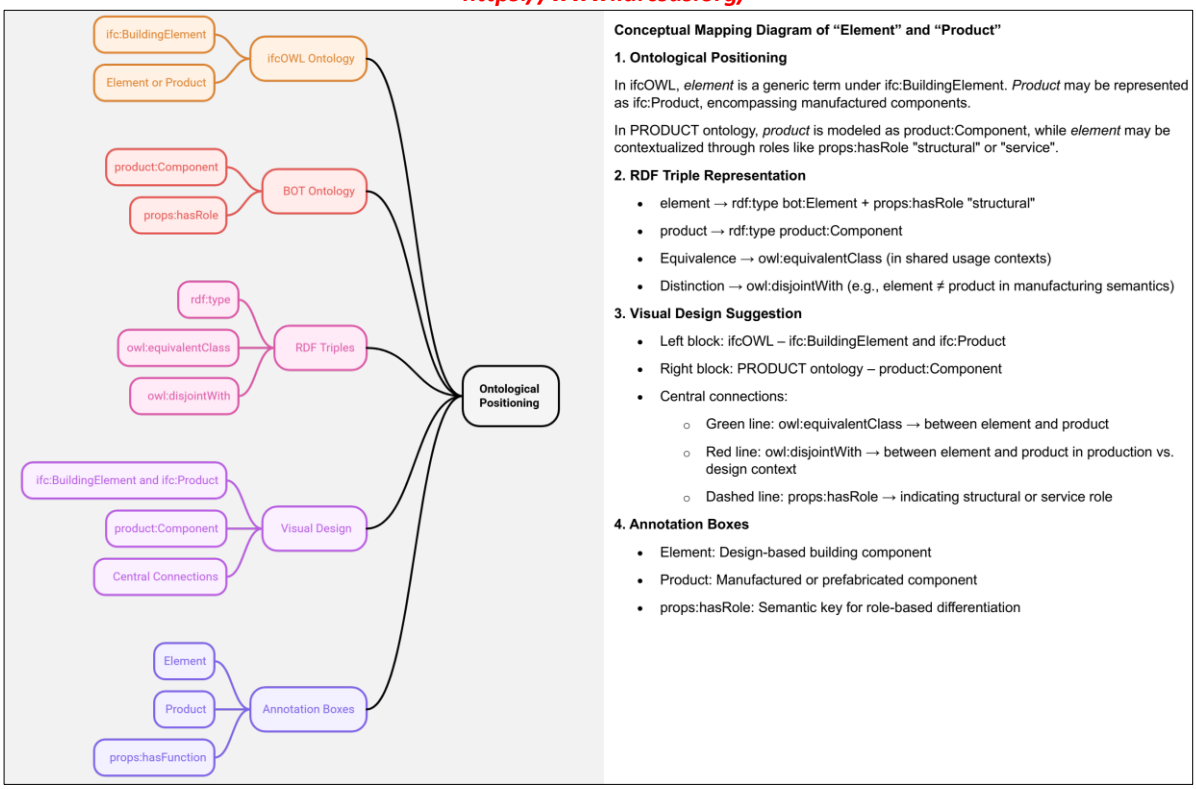

Figure 10. Conceptual Mapping Diagram of "Element" and "Product"

3.2. Discussion

The findings indicate that conceptual uncertainties in BIM data can be systematically separated by ontological modeling. Specifically, RDF representation and SPARQL queries have made contextual differences between concepts visible at the semantic level. This situation increases explainability in both data querying processes and regulatory compliance modeling efforts.

Functional concepts like "wall" and "partition" have been clearly distinguished using the props:hasFunction property, while contextual concepts like "space" and "room" have been semantically defined using the owl:equivalentClass and props:hasFunction relationships. Similarly, the interdisciplinary difference between the concepts of "element" and "product" has been modeled using props:hasRole and rdf:type. These distinctions have provided high accuracy in terms of filtering and matching in SPARQL queries.

The classification performed using a concept map has made it possible to ontologically separate terms containing uncertainty; SHACL validation outputs have supported the consistency of the model. This approach aligns with similar studies in the literature and contributes to the creation of more explainable data structures in semantic BIM applications (Pauwels et al., 2017; Wang et al., 2024; Yurchyshyna & Zarli, 2009).

Another significant contribution of the study is that concepts can be harmonized internationally by multilingual label matching. Turkish-English mappings made by using rdfs:label have shown that semantic alignment is achieved at an 82% rate. This result provides an infrastructure that will facilitate data sharing, especially in BIM projects based on open standards.

Overall, each of the four-stage methodological approaches produced meaningful outputs in terms of conceptual clarity and semantic accuracy, demonstrating the potential of ontology engineering to provide explainability and interpretability in BIM data.

4. Conclusion and Recommendations

This study aimed to address the conceptual uncertainties frequently encountered in Building Information Modeling (BIM) processes using an ontology engineering approach and to achieve definition clarity. Terminological overlaps such as "wall" versus "partition" or "space" versus "room" are among the main issues threatening semantic consistency in interdisciplinary data sharing (Borgo et al., 2015; Yurchyshyna & Zarli, 2009).

Analyzes conducted using RDF-based data representation and SPARQL querying techniques have shown that these uncertainties can be ontologically classified and contextually resolved. The equivalence, distinction, and contextual relationships between concepts have been visualized thru semantic graphs, providing a strong foundation for explainability and interpretability (Pauwels et al., 2017; Wang et al., 2024).

4.1. Contributions of the Study

In this context, the original contributions of the study are summarized below:

- Conceptual clarity has been achieved in BIM terminology by proposing an ontology engineering-based method.
- Contextual representation and separation of concepts have been achieved using RDF graph structures.
- Semantic matching and validation processes are exemplified using SPARQL queries.
- Visual tools have been developed to enhance semantic alignment in interdisciplinary data sharing thru concept maps.

These contributions provide an important methodological framework for making BIM data more explainable, queryable, and compliant with regulations.

4.2. Recommendations for Future Studies

Based on the findings of the study, the following suggestions may serve as a guide for future research:

- The application of SHACL-based validation mechanisms in broader BIM scenarios can enhance model consistency (Jiang et al., 2022).
- Multilingual ontology matching techniques can be developed to strengthen semantic alignment in international projects (Zhang & El-Gohary, 2016).
- The integration of digital twin platforms with ontological concept maps can create semantic decision support systems in maintenance and operational processes (Hagedorn et al., 2023a; Yin et al., 2023).
- Integrating data connection and link verification processes with ICDD containers into BIM models can increase information integrity (Hagedorn et al., 2023b)

These recommendations provide a strategic roadmap to increase the usability of semantic BIM applications in larger-scale and interdisciplinary projects.

Thanks and Information Note

This study was conducted in full compliance with national and international research and publication ethics. Ethics committee approval was not required due to the nature of the research. The article was prepared solely by the author, who is responsible for all content and contributions.

Abstract

The primary aim of bio-based energy production is to achieve sustainable energy generation by utilizing biological waste as raw material. These materials are processed through various conversion technologies in biorefineries, where research has demonstrated the feasibility of producing petroleum-derived products from biological resources. Among them, lignin—a renewable phenolic macromolecule found in the cell walls of biomass, possessing aromatic rings and phenolic hydroxyl groups similar to phenol—has attracted significant attention as a promising substitute for phenol in PF resin adhesives, particularly in the wood and furniture industries where such resins are widely applied. By modifying lignin to develop lignin-modified PF resin adhesives, it is possible to achieve notable performance improvements while simultaneously enhancing economic efficiency and reducing environmental impact. In this study, lignin-modified phenol-formaldehyde (LPF) resins were synthesized, with lignin selected as a bio-based alternative to phenol owing to its aromatic structure, phenolic hydroxyl groups, and natural abundance. The synthesis was carried out by using two different lignin types, kraft lignin and organosolv lignin, by substituting phenol with lignin at 50-60-70 to 80% wt. ratios. The experiments focused on evaluating the influence of lignin type on the extent of phenol substitution. Following synthesis, the resins were characterized in terms of dynamic viscosity and molecular weight with potential applications in environmentally friendly and sustainable adhesives for the furniture sector.

Keywords: Furniture, kraft lignin, lignin-modified phenol-formaldehyde, organosolv lignin, sustainability

1. Introduction

Fossil fuel consumption has existed for many decades (Solarte-Toro & Cardona Alzate, 2023). But we know that fossil fuels are both highly harmful to environmental pollution and are decreasing day by day because they are not a renewable energy source. For this reason, various researches are being carried out every day to obtain biologically based energy by reducing fossil

fuel consumption. Especially in order to reduce fossil fuel consumption, which has a great economic impact, the trend towards sustainable resources such as bioenergy and biofuels is increasing day by day (Al Mubarak, Rezaee, & Wood, 2024).

The main goal of bio-based energy production is based on sustainable energy production by using biological wastes as raw materials. Biological raw materials are transformed through various conversion processes in so-called biorefineries, enabling the use of a renewable raw material to produce clean energy that is environmentally friendly (Katakojwala & Mohan, 2021).

As a result of theoretical and practical research, it has been determined that it is possible to obtain petroleum-based products with biological raw materials. However, the end product obtained is not economically advantageous compared to petroleum-based products. There are 4 biorafinary types such as lignocellulosic feedstock biorefinery, whole plant, green biorefineries, biorefinery two-platform concept (Clark & Deswarte, 2015). Lignocellulosic feedstock type of biorafinary produces lignin and subsequently depolymerised lignin (Uihlein & Schebek, 2009).

Lignin:

Lignin, one of the most abundant natural polymers in nature, is one of the by-products of chemical processes, especially in the paper industry. This is because the primary source of cellulose is lignocellulosic biomass (Ragauskas et al., 2014). This bio-based feedstock consists of lignin, cellulose, and hemicellulose. Structurally, lignin is a polyphenolic macromolecule with p-hydroxyphenyl (H), guaiacyl (G), and syringyl (S) monomers as the three phenyl-propene units (Boerjan, Ralph, & Baucher, 2003). These units are shown in Figure 1.

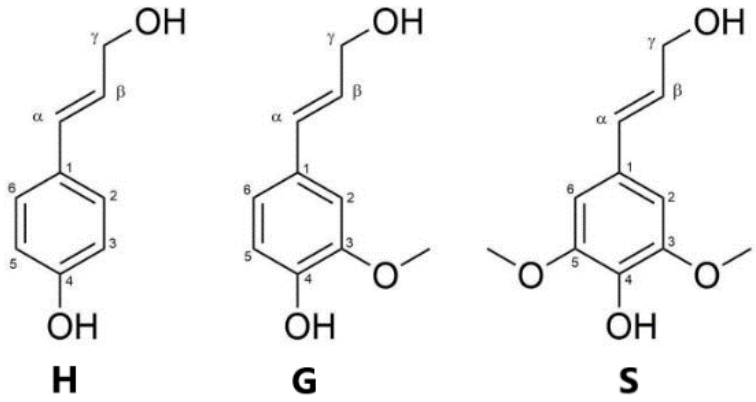

Figure 1. Structures of monolignols: *p*-hydroxyphenyl (H); guaiacyl (G); syringyl (S) monomers

The reactivity of lignin depends on structural elements such as aliphatic hydroxyl, methoxy, carboxyl and carbonyl groups, but the structural composition and properties vary depending on the source and isolation method (Hatakeyama & Hatakeyama, 2009).

Lignin can provide a variety of aromatic building blocks with high added value. With its aromatic basic structure, lignin is theoretically the most suitable renewable resource to replace aromatics from petrochemicals. In practice, however, this has not yet materialized because the valorization of lignin faces several challenges (Graglia, Kanna, & Esposito, 2015).

Lignin Extraction from Lignocellulosic Biomass:

There are different methods for lignin extraction such as kraft, sulfite, soda and organasolv. The most common of these methods is the kraft method, which meets 85% of lignin needs worldwide. The organosolv process is considered to be much more environmentally friendly than the kraft process due to its sulfur-free and easier process conditions. Although the organosolv process provides high purity lignin, it has only been commercially produced for a few years (Carvajal, Gómez, & Cardona, 2016).

Lignin shows structural changes depending on the type of process used and therefore exhibits different chemical properties. Organosolv lignin contains a large proportion of β-O-4 bonds and is almost insoluble in water and organic solvents. It is the most natural form of technical lignin as the core structure remains mostly unchanged. In contrast, lignin from the kraft process has a condensed structure with few C-C cross-links. It therefore develops chemical resistance to hydrolysis. Another disadvantage is that it contains sulfur in the form of thiols, which can poison catalysts in further processing steps (Watkins, Nuruddin, Hosur, Tcherbi-Narteh, & Jeelani, 2015).

Phenol Formaldehyde (PF) Resin:

Phenol formaldehyde (PF) resins are polymeric compounds. This compound is synthesized by acid or base catalyzed polycondensation of phenol and formaldehyde. To prepare the resin, formaldehyde is first added to phenol. Then condensation reaction is applied and finally curing processes are applied. Curing takes place at high temperature and requires further condensation reactions and molecular rearrangements (Pizzi & Ibeh, 2022).

The wood industry is one of the largest consumers of PF resins. With their high mechanical performance, stable molding processing performance, good flame resistance, long-term thermal and mechanical stability, satisfactory electrical and thermal insulation properties, high adhesion strength and moisture resistance, PF resins are preferred and used in many areas. Resoller is the preferred type of PF resin for wood bonding due to their ability to form three-dimensional networks with favorable mechanical performance when cured, unlike novolaks, which are thermoplastic and require an additional curing agent. However, the resins need to undergo chemical modification to remain a viable option in an increasingly environmentally conscious industry (Dunky, 2017).

Lignin Modified Phenol Formaldehyde (LPF) Resin:

Improved performance of lignin for the production of value-added products can be achieved by converting it into molecules with lower molecular weight through depolymerization. The process yields aromatic and phenolic molecules with greater structural similarity to phenol (Fernández-Rodríguez, Erdocia, Sánchez, Alriols, & Labidi, 2017). This makes depolymerized lignin a promising alternative to phenol as it allows for higher degrees of substitution.

Substitution of phenol with lignin until 50 % wt. is possible without sacrificing resin quality. Further substitution requires either structural modification of lignin, or pretreatment methods during synthesis. Methylolation, phenolation, and thermolysis techniques increase the reactivity of lignin molecules. Methylolation and phenolation involve lignin pretreatment with formaldehyde or phenol respectively, before entering the resinification reaction. These methods introduce reactive functional groups into the structure of lignin, while thermolysis induces targeted structural degradation. Thermo-chemical depolymerization by pyrolysis, oxidation, hydrogenolysis, and hydrolysis necessitate application of heat under specific reaction conditions, cleaving intermolecular bonds. Depolymerization yields phenolic oligomers with

decreased molecular weight (Mw) and reduced aliphatic hydroxyl groups, which have higher structural similarity to phenol, serving as an ideal substitute for phenol in LPF production (Sarkar & Adhikari, 2000).

2. Materials and Methods

Materials and Chemicals:

All materials and chemicals used during the experiments are listed in Table 1.

Table 1. List of materials and chemicals used in the experiment

Materials	Chemicals
• Beakers • Reflux Condenser • 3 Necked Round Bottom Flask • Dropping Funnel • Spatulas • Funnel • Glass Plug • Sample Tube • Magnetic Fish	• Phenol, C_6H_6O • Kraft Lignin • Organosolv Lignin • Sodium Hydroxide, NaOH (50 %) • Formaldehyde Solution (37 %, for synthesis) • Water, H_2O (Distilled)

Experimental Part:

Experiments were started with the same amount of lignin and phenol (both 50%). After than amount of lignin increased each step and therefore amount of phenol decreased at the same time. The increment and decrement values of both were changed by 10% at each step. According to this change, four different experiments were performed with lignin content of 50%, 60%, 70 %, 80%. Also the amount of other chemicals was kept constant. These experimental steps were performed with two different types of lignin such as kraft lignin and organasolv lignin. The first 4 experiments were performed with kraft lignin and the last 4 experiments were performed with organosolv lignin. All of the chemical amounts are listed in Table 2 for each experiment step. Also in this table kraft lignin was called KC1202 and the organosolv lignin was called KC1196.

Table 2. Chemical amounts used in the experiment

Experiment Name	Lignin Type	Phenol Amount (g)	Lignin Amount (g)	NaOH Amount (g)	Formaldegyde Amount (g)	H_2O Amount (g)
K-LP-50 %	KC1202	15.39	15.35	13.11	34.42	21.80
K-LP-60 %	KC1202	12.33	18.46	13.11	34.42	21.80
K-LP-70 %	KC1202	9.20	21.49	13.11	34.42	21.80
K-LP-80 %	KC1202	6.16	24.03	13.11	34.42	21.80
O-LP-50 %	KC1196	15.39	15.35	13.11	34.42	21.80
O-LP-60 %	KC1196	12.33	18.46	13.11	34.42	21.80
O-LP-70 %	KC1196	9.20	21.49	13.11	34.42	21.80
O-LP-80 %	KC1196	6.16	24.03	13.11	34.42	21.80

In the experimental procedure, the order of addition of chemicals, process temperature, and time conditions are shown schematically in Figure 2.

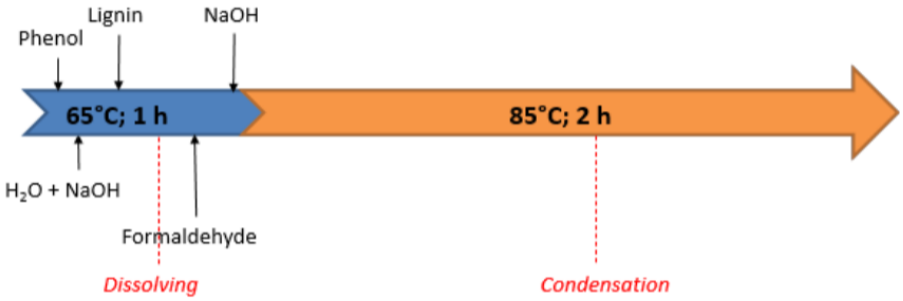

Figure 2. Schematic representation of the experimental process

During the experiments, 2 points were very important.

- Lignin addition should be very slow. Because when lignin is added rapidly, it does not dissolve and agglomerations are seen.
- The addition of formaldehyde should also be very slow. Fast formaldehyde addition causes foaming.

Analysis Part:

Dynamic viscosity (rheometry) and gel permeation chromatography (GPC) were performed on all resins obtained from the experiments.

Dynamic viscosity (rheometry) analysis; An air-carried Anton Paar Modular Compact Rheometer (MCR) 102 equipped with a CP50-1 conical plate (diameter: 50 mm; angle of inclination: 1°) device was used to obtain the ratio coefficient between the dynamic viscosity η and shear rate of LPF resins. Measuraments were performed at a constant temperature of 30°C in rotation mode.

GPC analysis; Thermo Fisher Dionex ICS 1500+ gel permeation chromatography consisted pre-column PSS MCX Guard (dimensions: 50 x 8 mm) and three PSS Analytical columns (Specifications: 100A/1000A/100 000A, dimensions: 300 mm x 8 mm) device was used to obtain the molecular weight distribution of LPF resin samples. In the analysis, 1 mg sample was dissolved in 0.1 mol L^{-1} NaOH to obtain 1 mg mL^{-1} concentration of samples. After than the mixture filtered with 0.45 µm syringe filter. During the analysis, the flow rate was set to 1 mL min^{-1}, column temperature 50°C, injection volume 10 µL and injection time 33 min. The UV detector (VWD) was also set to a wavelength of 280 nm for the samples.

3. Findings and Discussion

Dynamic viscosity (rheometry) analysis results:

All resins were analysed for their dynamic viscosity. All data are presented in Figure 3.

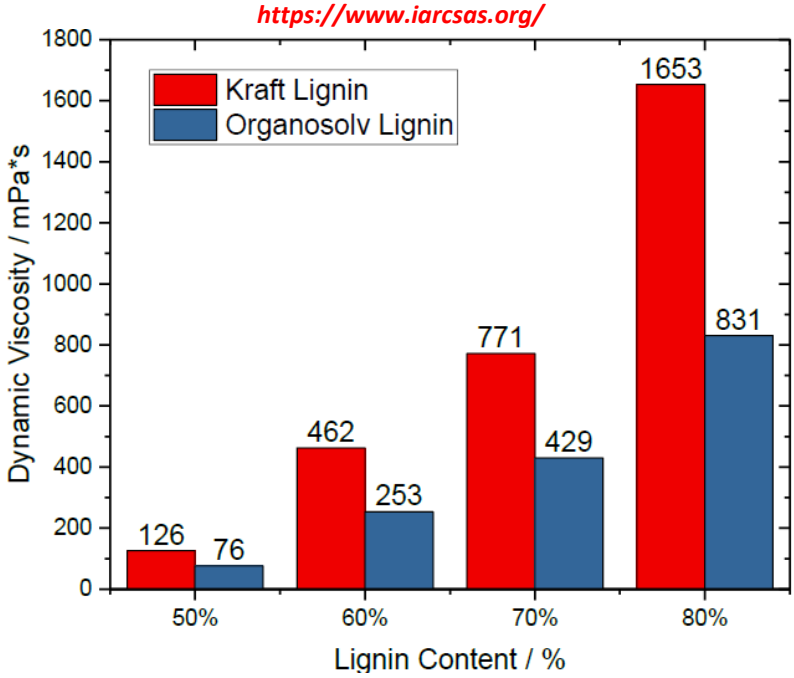

Figure 3. Graph of dynamic viscosity analysis

Resins containing Kraft Lignin showed higher viscosity values than organosolv resins. There are several reasons for this behaviour. Softwood Kraft Lignin reveals a high concentration of guaiacyl substituents in their polymer backbone which leads to higher reactivity in resin condensation reactions. In addition, Kraft Lignin always have higher molecular weight than Organosolv Lignin. Organosolv Lignin is usually originating from annuary plants with low contents of lignin. The organosolv process offers milder conditions without harsh acidic or basic treatment as in the Kraft process or Sulphite process. Therefore, a higher content of less reactive substituents (e.g. Sinapyl units) due to its original plants and also higher steric hindering is the key for slower viscosity increase in resin cooking.

GPC analyses of the used lignins:

From the used Kraft-Lignin and Organosolv-Lignin have been determined the molecular weight distribution. The results are given in Table 3 and Figure 4.

Table 3. Reference results of GPC analysis for kraft lignin and organasolv lignin

	M_N	M_W	PDI
Kraft Lignin	908 (±2)	4450 (±15)	4.90 (±0.01)
Organosolv Lignin	665 (±2)	1770 (±6)	2.65 (±0.01)

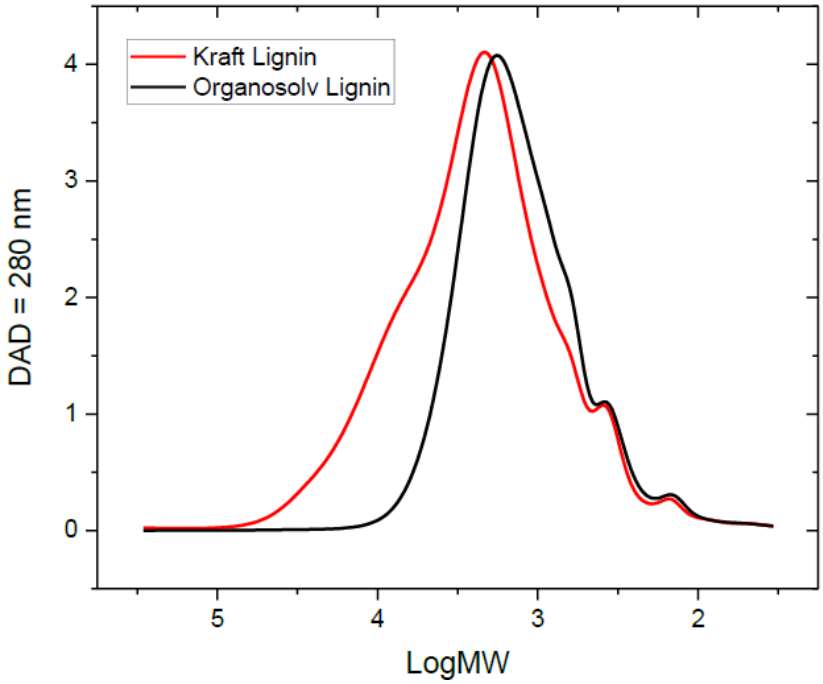

Figure 4. Reference graph of GPC analysis for kraft lignin and organasolv lignin

GPC analyses results of the produced resins:

All resins were analysed for their molecular weight distribution. All data are presented in Figure 5, 6 and Table 4, 5.

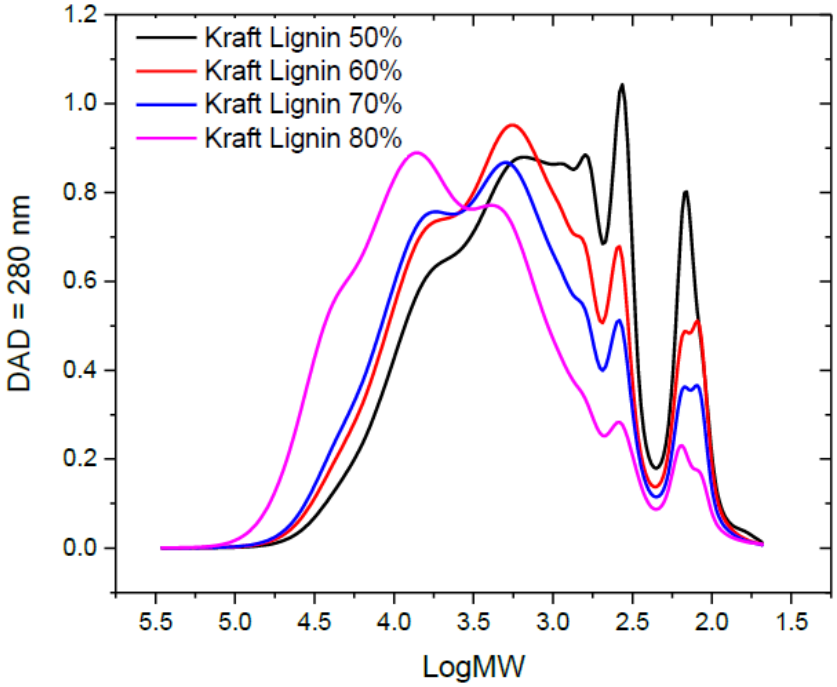

Figure 5. Graph of GPC analysis for kraft lignin-resins

Table 4. Results of GPC analysis for kraft lignin-resins

Sample Name	M_N	M_W	PDI
Kraft Lignin 50 %	725 (±4)	2054 (±10)	2.83 (±0.02)
Kraft Lignin 60 %	738 (±3)	2268 (±9)	3.07 (±0.03)
Kraft Lignin 70 %	740 (±4)	2340 (±12)	3.16 (±0.02)
Kraft Lignin 80 %	755(±7)	2572 (±14)	3.40 (±0.04)

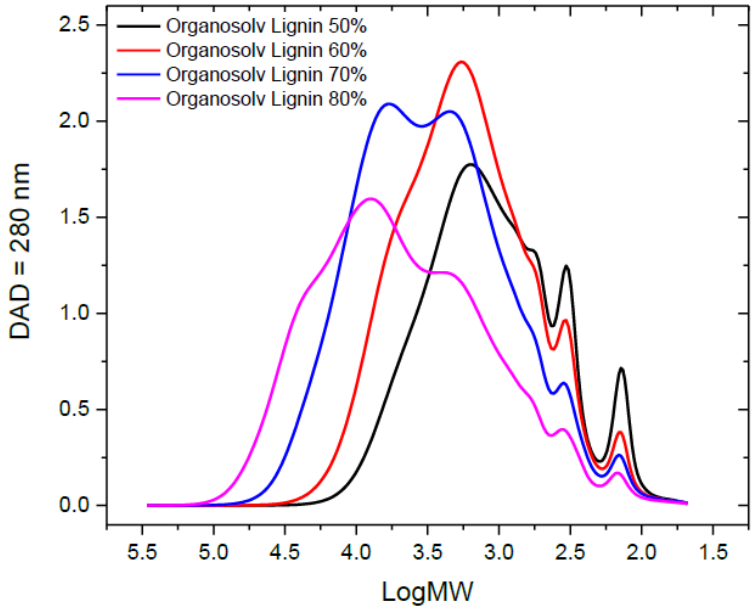

Figure 6. Graph of GPC analysis for organosolv lignin-resins

Table 5. Results of GPC analysis for organosolv lignin-resins

Sample Name	M_N	M_W	PDI
Organosolv Lignin 50 %	510 (±2)	1295 (±8)	2.53 (±0.01)
Organosolv Lignin 60 %	521 (±3)	1384 (±10)	2.65 (±0.02)
Organosolv Lignin 70 %	535 (±2)	1438 (±11)	2.68 (±0.01)
Organosolv Lignin 80 %	538 (±2)	1502 (±16)	2.79 (±0.05)

GPC analysis results show that M_N, M_W and polydispersity values increase with higher lignin substitution. These values are higher in Kraft Lignin than in Organosolv Lignin. This is in correlation with both the GPC results of lignins and viscosity results of produced resins.

4. Conclusion and Recommendations

Adhesives commonly used in the wood industry are phenolic resins. The reasons for the widespread use of PF resins in the industry include their high strength, resistance to moisture, resistance to heat and chemicals, and high thermal stability. On the other hand, PF resins are toxic due to being a petrochemical product. Furthermore, they have negative environmental

impacts as they are obtained from non-renewable resources. For all these reasons, this study was carried out to investigate the feasibility of using lignin material, which is structurally very similar to phenol, as an alternative.

In experimental studies, kraft and organosolv lignin types were used as substitute materials for phenol at ratios ranging from 50% to 80%. Afterwards, dynamic viscosity and GPC analysis were applied to the resulting lignin-modified phenol formaldehyde resins. All research results indicated that lignin could be used as a substitute material for phenol at ratios up to 80%.

Abstract

Shopping malls, which stand out as structures characterized by the consumption-oriented functions of contemporary urban life, also attract attention with their public qualities that foster social interaction. Today, seating areas in these spaces, which combine the shopping experience with various functions such as leisure and socializing, shape the relationship users establish with the space. Sometimes used only for brief rest and waiting, they also offer opportunities for socializing, observing, and experiencing the atmosphere of the space. Responding to different needs, these seating areas shape the user's experience with the space by supporting continuous spatial circulation. This study aims to examine the design of seating areas organized independently of food and beverage units at the Piazza Shopping Mall in Samsun. As part of the fieldwork, the shopping center was visited, seating areas were identified on site and photographed, and these areas within the interior were incorporated into plan diagrams. Subsequently, the seating areas were analyzed in terms of location, visibility, type, material, capacity, layout/arrangement, color, and texture parameters. The study revealed that seating areas are located along circulation axes and in highly visible locations. In terms of furnishing diversity, it was determined that movable elements are predominant. It was found that seating areas are designed as functional elements that meet the basic need for rest. It was observed that seating elements intended for waiting did not offer diversity for long-term use and socialization. In this context, redesigning seating areas to serve socialization and enrich the spatial experience will support the public nature of shopping centers.

Keywords: Furniture, interior, waiting area, shopping centers

1. Introduction

Shopping malls are buildings that represent the economic, social, and spatial relationships of urban life. Considered one of the spatial counterparts of consumer culture, these structures have evolved into venues that host society's consumption activities. Over time, with globalization, technological developments, and transformations in lifestyles, shopping malls have become new meeting points for social life in cities. This transformation plays an important role in shaping the relationship individuals establish with public spaces. The spatial organization of shopping centers and the furniture elements within them are among the factors that shape user experiences. Today, seating areas in these spaces, which combine the shopping experience with various functions such as entertainment and socializing, regulate the relationship users establish with the space. These short-term seating areas are important spatial components that not only alleviate the physical fatigue caused by the shopping experience in the mall, but also support secondary experiences such as observation, waiting, and socializing (Bitner, 1992; Wakefield & Blodgett, 1996). These areas play an effective role in regulating spatial circulation within the structure by guiding user behavior. On the other hand, seating areas located at points such as circulation axes, atriums, and storefronts support both the physical and psychological comfort of individuals (Hami et al., 2018). Therefore, the location, type, capacity, layout, material, color, and texture choices of seating areas in shopping centers are important. The interior

atmosphere of shopping centers is related to sensory components (color, texture, light, and material), and seating elements are a sustainable part of this atmosphere (Hidayetoglu et al., 2010). On the other hand, the shape, material, color, and layout of seating areas are directly related to the time users spend in the space and their level of satisfaction (Grabiec et al., 2022; Prayoonhong et al., 2024). Based on all this, this study examines the seating area designs in the interior spaces of the Samsun Piazza Shopping Center. This study, which aims to reveal the role of seating areas in the interior layout of shopping centers, focuses on how seating elements are integrated into the overall spatial design of the shopping center. To this end, the study aims to determine the spatial distribution of seating areas in the shopping center and to classify seating elements according to various design parameters.

2.Materials and Methods

Shopping centers combine the shopping experience with various functions such as relaxation and socializing. The seating areas in these spaces shape the relationship users establish with the space. Sometimes used only for short-term rest and waiting, these seating areas also offer various opportunities for socializing, observing, and experiencing the atmosphere of the space. In this context, the study focuses on seating areas located in the interiors of shopping malls and serving common use. The aim of the study is to identify seating areas intended for common use in shopping malls and to reveal their characteristics. Seating areas located on the food court level of the shopping center have been excluded from the scope of the study because they are designed for eating and drinking activities. Samsun Piazza was selected as the study area. Samsun Piazza's large enclosed space, multi-level spatial design, and diverse seating and resting areas catering to different user groups were influential factors in its selection as the study area. Furthermore, its central location in the city, high visitor density, and access to a wide user base were among the factors that influenced the selection of this area for the study.

The study first conducted a literature review on shopping malls, consumption behavior, and the design of seating elements in shopping malls. The literature review was followed by fieldwork. During the fieldwork, Samsun Piazza was visited by the authors. In this process, floor plans of the shopping mall were obtained. Seating areas located on four floors—the ground floor, first floor, second floor, and third floor—where active shopping activities took place were identified, marked on the plans, and photographed simultaneously. The characteristics of the seating areas were analyzed in terms of location, visibility, furniture type, material, capacity, layout, and color parameters (Table 1).

Table 1. Analysis criteria (Caymaz, 2021; Hami et al., 2018; Ihtiyar & Yücel, 2021; Jung & Abdelaziz Mahmoud, 2023; Okuyucu & Işbeceren, 2023; Zhang et al., 2024)

Furniture Type	Stable Mobile With backrest Without backrest With armrests Without armrests Modular	Layout & arrangement	Linear Circular Back-to-back Open Closed
		Color usage	Color contrast Warm colors Cool colors Neutral colors
Capacity	Single person Multiple persons		

Within the scope of the analysis, the locations of seating units have been classified as either along the circulation route or outside the circulation route. Furniture types were considered in seven categories: fixed, mobile, with backrests, without backrests, with armrests, without armrests, and modular. The capacity of seating areas was analyzed in two categories: single-person and multi-person, while the seating arrangement was analyzed in five separate classifications: linear, circular, back-to-back, open, and closed. The material type of the seating units in the seating areas is considered in two categories: wood and upholstery. Finally, the analysis of color usage in these units is evaluated in terms of cool colors, warm colors, neutral colors, and color contrast.

3.Findings and Discussion

Seating areas were analyzed based on location, visibility, furniture type, material, capacity, layout, and color parameters to determine their characteristics. The analyses were evaluated sequentially across four floor plans: ground floor, first floor, second floor, and third floor. Seating areas in the dining section on the third floor are excluded from the scope. The seating areas on the ground floor of the shopping center are located in 4 different zones (Figure 1). In zones 1 and 3, the seating areas are positioned along the circulation axis. The seating areas in both zones offer visual access to store fronts and display windows and are highly visible. All furniture in zone 1 is mobile, allowing for portability during temporary events held at different times (product presentations, local product sales, workshops, etc.). This area, located near the main entrance of the building and allowing visual connection with the upper floors, creates a focal point within the space. This encourages users to take a short break without disconnecting them from the atmosphere of the space. The area features leather upholstery, armchairs, and backrest furniture, as well as poufs that allow for flexible use. The seating area, which is mostly suitable for individual or two-person use, is arranged in a circular and clustered layout. Warm and cool colors have been chosen together for the color scheme.

The seating areas in zone 3 consist of mobile wooden benches with armrests and backrests. The furniture is arranged linearly and positioned parallel to visitor circulation. In zones 2 and 4, the seating areas are located outside the circulation axis. The seating element in zone 2 is wooden, fixed, backless, and armless, positioned close to the vertical circulation (escalator) element. The polygonal seating area allows multiple people to sit in different directions. Zone 4 is located in a partially recessed space away from visitor flow. The furniture, consisting of single and double seating units, is movable and upholstered in leather (Table 2). The seating arrangement is created with furniture arranged face-to-face, dominated by cool colors.

Figure 1. Seating areas on the ground floor

There are seating areas in five different zones on the first floor of Samsun Piazza. Zones 5, 6, and 7 are located along the circulation route. The seating elements in these zones are arranged in a way that allows visual connection with the storefronts and display windows. Zones 8 and 9, on the other hand, are located outside the circulation route (Figure 2). The seating areas in these zones consist of both mobile and fixed seating units. It is observed that all fixed furniture uses wooden materials. Additionally, mobile wooden seating units are also among the other seating elements on the floor. It has been observed that the wooden units are arranged in a linear pattern and have the capacity to accommodate multiple people.

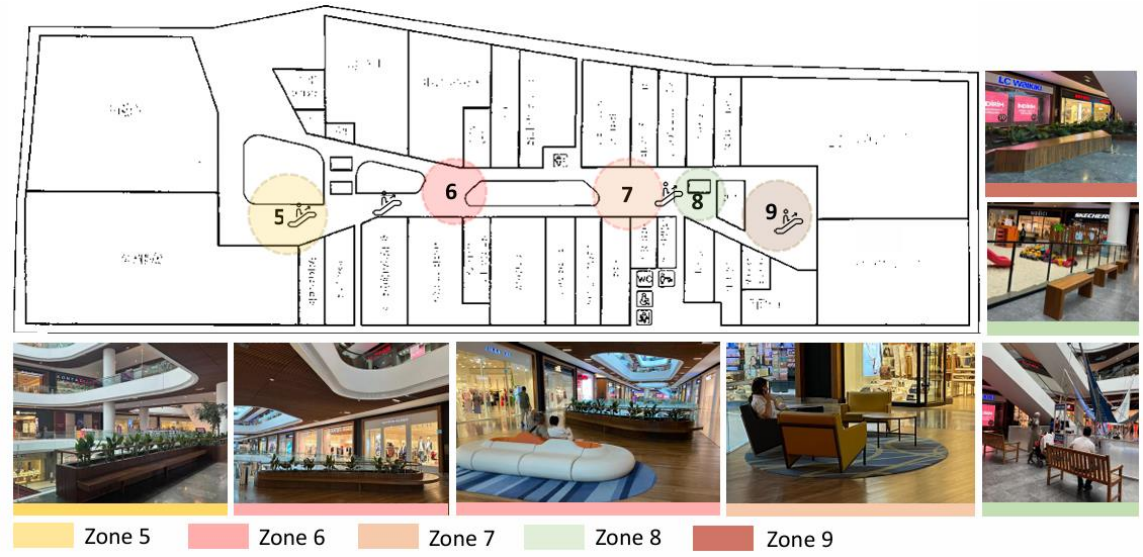

Figure 2. Seating areas on the first floor

Many of these wooden seating areas have a closed spatial arrangement, with no access from different points. It has been observed that the wooden seating areas are arranged and positioned to support relatively short periods of sitting. With modular designs, some of these units offer both individual and group seating options (Table 2). These units, which use a combination of

warm and cool colors, were found to have an open spatial arrangement in terms of orientation and access. The location of the seating elements, particularly in area 8, is a determining factor in the choice of layout and arrangement. The presence of children's play areas in this area plays an important role in the layout, arrangement, and capacity of the furniture.

Table 2. Analysis of seating areas at Samsun Piazza Mall

Floors and zones / Parameters		Ground Floor				First Floor					Second Floor				Third Floor		
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Location	On the circulation line	■		■		■	■	■			■	■	■	■	■	■	■
	Outside the circulation line		■		■				■	■							
Furniture Type	Stable					■	■			■	■	■		■			
	Mobile	■	■	■	■		■	■	■			■	■		■	■	■
	With backrest	■		■	■	■	■	■	■		■	■	■	■	■		■
	Without backrest	■	■						■	■						■	
	With armrests	■		■	■			■	■			■	■		■		■
	Without armrests	■	■		■	■	■		■	■	■	■		■		■	
	Modular						■		■							■	
Capacity	Single	■			■			■				■	■		■		■
	Multiple	■	■	■	■	■	■	■	■	■	■	■	■	■	■	■	■
Material type	Wood		■	■		■	■		■	■	■	■		■		■	
	Cloth upholstery	■			■		■	■				■	■		■		■
Layout &	Linear		■	■		■	■		■	■	■	■		■		■	
	Circular	■			■			■				■	■		■		■
	Back-to-back		■				■										
	Open	■	■		■		■	■	■			■	■		■	■	■
	Closed			■		■	■		■	■	■			■			
Color usage	Color contrast		■									■					
	Warm colors	■	■	■		■	■	■	■	■	■	■	■	■	■	■	■
	Cool colors	■			■			■					■		■		■
	Neutral colors				■		■										

The seating areas located on the second floor of the building are positioned in four different zones (Figure 3). All seating areas in these zones are situated along the circulation axis. The seating areas in zones 10 and 13 consist of fixed, linear, and wooden seating elements. These areas, which are backless, armless, and intertwined with green plants, are suitable for use by more than one person. These elements are located very close to the escalator. This location provides the opportunity for short breaks in this area with heavy user traffic. At the same time, the continuation of the seating area along the railing line allows for visual connection between floors. Users can sit in one direction on these linearly arranged seating units. Furthermore, in area 11, fixed wooden and movable leather upholstered seating units are located very close to each other. The fixed wooden elements represent permanence in the space, while the movable upholstered seats offer flexible arrangement and seating options. This situation adds continuity to the space on the one hand, while also providing variability on the other. The backrest, armrest, and mobile seating units in area 12 have a similar layout, capacity, color, and material to the other mobile seating elements (Table 2).

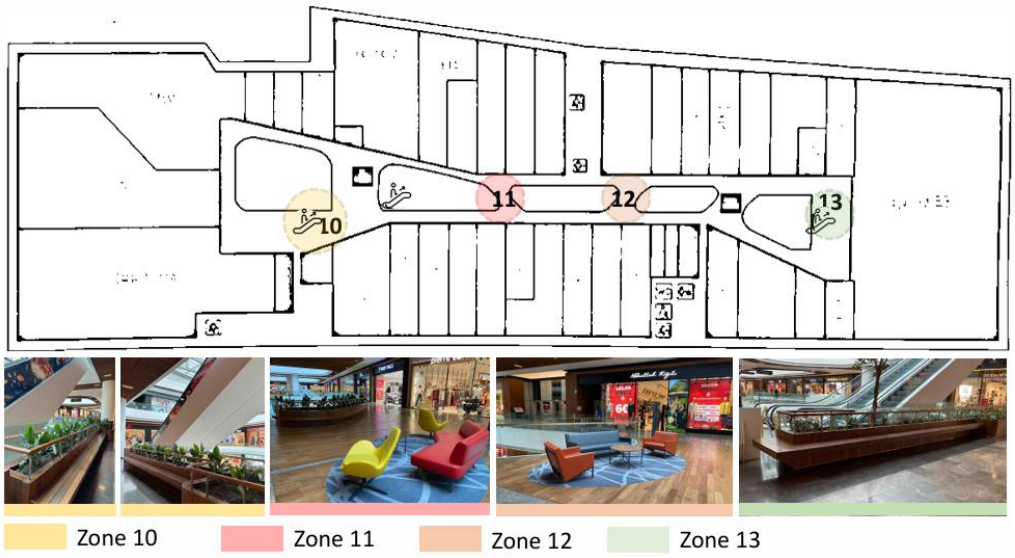

Figure 3. Seating areas on the second floor

The third floor of the workspace is primarily dedicated to food and beverage functions, with seating areas located in three separate zones on this floor (Figure 4). All of these areas, numbered 14, 15, and 16, are situated along the circulation route and consist of mobile seating units. The seating units in areas 14 and 16 are leather-covered, with backrests and armrests. Providing a circular seating arrangement, these units allow for individual and group seating while also having an open spatial layout in terms of orientation and access. It has been observed that these areas, which combine warm and cool colors, are suitable for relatively long periods of sitting. The proximity of seating area 14 to the children's play area and book sales area was a particularly influential factor in the design and selection of these units. The wooden seating units on the floor, with their linear arrangement and lack of backrests and armrests, were found to be arranged in a way that supports relatively short periods of sitting (Table 2).

Figure 4. Seating areas on the third floor

4.Conclusion and Recommendations

Shopping malls, which have become an important component of urban life, are spatial reflections of consumer culture. Shopping malls stand out as multifunctional structures where shopping, relaxation, and socializing practices are experienced together. In this context, seating areas within shopping malls enable users to have short-term relaxation and socializing experiences. Within the scope of this study, the characteristics of the seating areas at Samsun Piazza were examined in terms of location, furniture type, material, capacity, layout, and color parameters.

- Seating areas serve as focal points on each floor. The areas are designed to offer opportunities for relaxation, waiting, and observation without interrupting user flow.
- The seating areas are located in highly visible areas on each floor. They establish a direct visual connection with the storefronts, particularly given the functional purpose of the building.
- The predominant use of movable seating elements offers the advantage of flexible use for new arrangements in response to possible events and/or crowds in the shopping center.
- While there is diversity in terms of layout and placement, circular and clustered arrangements are predominant. This layout provides an environment conducive to social interaction as well as waiting and resting.
- The color selection is predominantly a combination of warm and cool colors. The fact that the seating units are mostly upholstered in leather makes them easy to use in terms of durability, maintenance and hygiene.

Abstract

Interior design is a discipline that produces solutions to provide users with the most suitable design according to functional, structural, and aesthetic criteria to meet their needs. Focusing on the spaces where users spend a significant part of their daily lives, this discipline aims to improve the quality of life and enhance the spatial experience in its social, cultural, psychological, sensory, technological, and environmental dimensions. In this regard, evaluating the volume of publications produced in recent years and the prominent themes is important for understanding the multidimensional nature of interior design studies. Within this scope, the study aims to reveal the visibility of scientific production that has contributed directly and indirectly to the discipline of interior architecture over the past decade. In this study, which analyzes publications in the architecture category of the Web of Science database, the conceptual structure of the discipline is interpreted through numerical data and thematic maps. The study is limited to articles in the database, and the sample consists of 205 studies. The Biblioshiny and VOSviewer software, which are the visual interfaces of the R-based bibliometrix package, were used in the data analysis. The analyses revealed that the concept of interior design occupies a central position and is linked to concepts such as design education, furniture, culture, biophilia, sustainability, and artificial intelligence. These relationships form the conceptual core of the discipline over the past decade and indicate that research has developed in a multidimensional structure.

Keywords: Interior architecture, biblioshiny, vosviewer, bibliometric analysis

1. Introduction

Interior architecture is a multifaceted discipline that prioritizes human needs and encompasses art, science, and technology. This discipline aims to design interior spaces that respond to user needs and are functional, aesthetically pleasing, and psychologically balanced (Jones, 2008; Kilmer & Kilmer, 2014). Emerging from the human need for shelter, interior design is a dynamic discipline focused on improving quality of life and shaped by the needs of everyday life. The discipline of interior architecture, which is present in spaces with different functions such as living, working, entertainment, health, and education, plays a decisive role in the processes of structuring action-related relationships and ensuring spatial comfort in these spaces. In addition, the design of elements such as form, texture, color, materials, lighting, and furniture also falls within the scope of the discipline of interior architecture. In the design of interior spaces, it is important to improve quality of life, provide functionality, and offer an aesthetic experience (Kilmer & Kilmer, 2014).

The presence of interior architecture in the academic field is critical for the profession's ability to adapt to social, technological, and environmental changes. Academia addresses the interior architecture profession not only in terms of its design and application dimensions but also in its

theoretical, historical, and methodological aspects (Attiwill, 2004; Vischer and Poldma, 2003). Academic studies in the field of interior architecture are one of the most effective ways to define the boundaries of the discipline and guide the development of the profession. In addition, academic studies related to the field encourage interior architecture to establish common research grounds with different fields such as psychology, environmental behavior studies, architecture, engineering, art, materials science, and technology, while maintaining its interdisciplinary nature. This situation nourishes both the scientific and creative aspects of the discipline, enabling interior architecture to develop a unique identity based on methods grounded in understanding human behavior and intuitive design processes (Pottgiesser, 2011). Academic studies in the field of interior architecture interact with the profession's processes of research, inquiry, and innovation. These studies play an important role both in ensuring the continuity of professional knowledge production and in defining the discipline in a way that can respond to the requirements of the era (Lopez, 2023). In this context, the subject of the study is to reveal the current state of the discipline in the academic sphere within the scope of scientific articles published in the field of interior architecture over the last ten years.

2. Materials and Methods

The study aims to reveal the conceptual and thematic structure of academic publications in the field of interior architecture in recent years. To this end, it seeks to examine current research trends in the field and analyze the publication network. Considering its widespread use, the Web of Science (WoS) database was used in the data collection process. Searches were conducted using the keyword “interior design” in the “architecture” category. The search was performed based on the title, abstract, and keywords. Articles found in the database were included in the study. The data obtained was limited to the last 10 years in line with the purpose of the study. Within this scope, a sample of 205 articles was created.

Bibliometric analyses were performed using the VOSviewer and R-Studio Biblioshiny programs for data analysis. Word network maps and journal citation maps were created using the VOSviewer program. Using the R-Studio Biblioshiny program, graphs were created for year, index, prominent journal, publication language, and country distribution, followed by a bibliometric factor analysis based on thematic mapping and conceptual clustering.

3. Findings and Discussion

Over the past 10 years, there has been an increase of approximately 100% in the number of articles published on “interior design”. In this context, 2025 was the year with the highest number of publications, with 31 articles, while 2024 ranked second with 27 articles. 2021 was another year with a high number of publications, with 26 articles. The period evaluated in the study recorded the lowest number of articles published in 2020 (Figure 1). The decline in this year, which was limited to 10 studies, may be related to the conditions of the COVID-19 pandemic, which slowed down the research and publication processes. On the other hand, the rhythmic increase in the number of publications is thought to be directly related to the increasing number of researchers, the expanding research area, and the opportunities for publication.

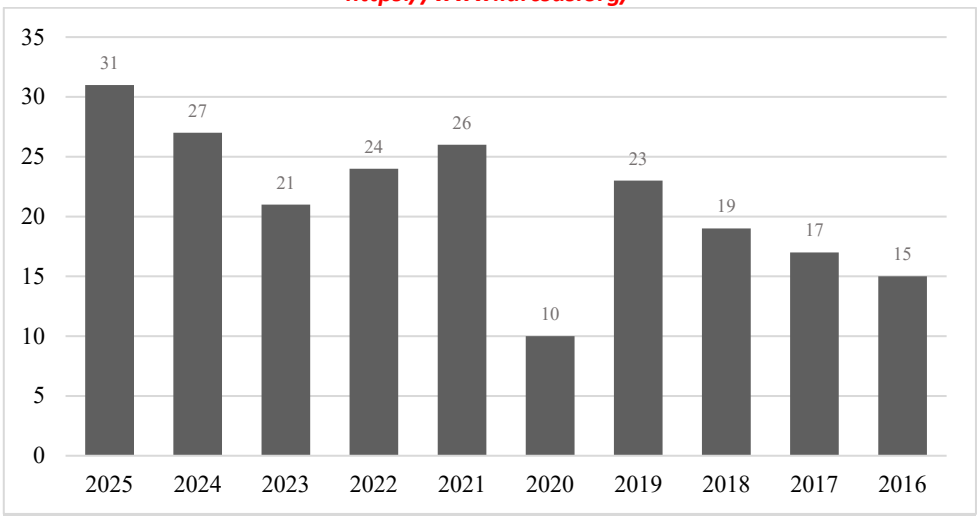

Figure 1. Number of articles by year

Looking at the distribution of articles according to the indexes of the journals in which they are published, it can be seen that the highest group, with 154 studies, is included in the Arts and Humanities Citation Index (A&HCI). This is followed by the Emerging Sources Citation Index (ESCI) with 52 studies. This trend stems from interior architecture being a design and art-based discipline. Consequently, it can be said that the studies produced in this field largely involve conceptual and qualitative approaches. The small number of articles published in the Social Sciences Citation Index can be explained by the fact that studies in the field of interior architecture involve qualitative and interpretive approaches rather than data-based social science analyses (Figure 2).

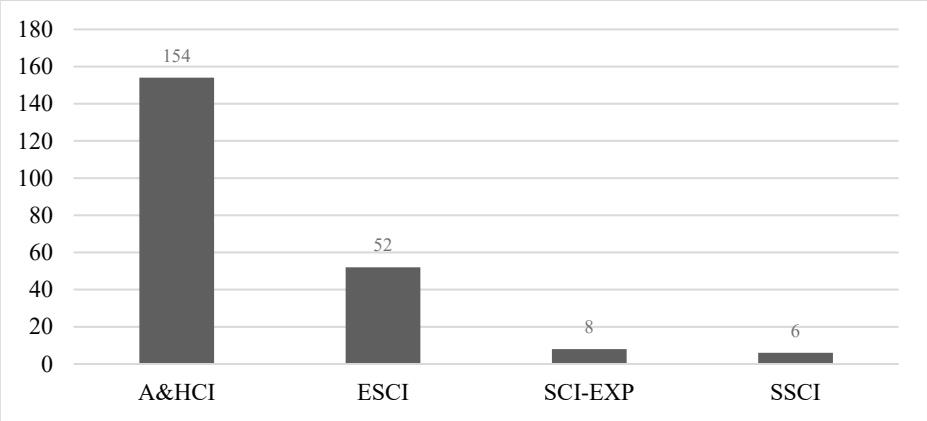

Figure 2. Distribution of articles by journal according to their indexes

When examining the distribution across journals, it was determined that the Journal of Interior Design published the most articles, with 57. This was followed by Interiors: Design Architecture Culture, with 39 articles (Table 1). It is noteworthy that nearly half of the total number of publications over the last ten years were concentrated in these two journals. This situation shows that academic production in the field of interior architecture is concentrated around certain publication networks. However, it can be said that these leading journals both direct research trends and shape a significant part of the knowledge base within the discipline. Furthermore, the fact that the names of these two journals, which stand out in terms of

publication numbers, include the term 'interiors' indicates that these journals tend to give more space to interior-themed research. The concentration of publications in a few specific journals indicates that the field has reached thematic maturity on the one hand, but also points to limited diversity in publications on the other.

Table 1. Journals and publication numbers

Journal Title	Number of Publications
Journal of Interior Design	57
Interiors Design Architecture Culture	39
ICONARP International Journal of Architecture and Planning	12
Archnet IJAR International Journal of Architectural Research	11
Journal of Asian Architecture and Building Engineering	8
Megaron	6
Design Issues	5
Fabrications the Journal of the Society of Architectural Historians	5
Frontiers of Architectural Research	5

The language distribution of articles shows that almost all publications are in English. English was followed by Spanish, Turkish, Dutch, Portuguese, Croatian, and Italian (Figure 3). This distribution shows that knowledge production in the field of interior architecture is largely conducted through international academic interaction in English. The limited number of publications in languages other than English may be due to the insufficient representation of studies conducted in local languages in international databases.

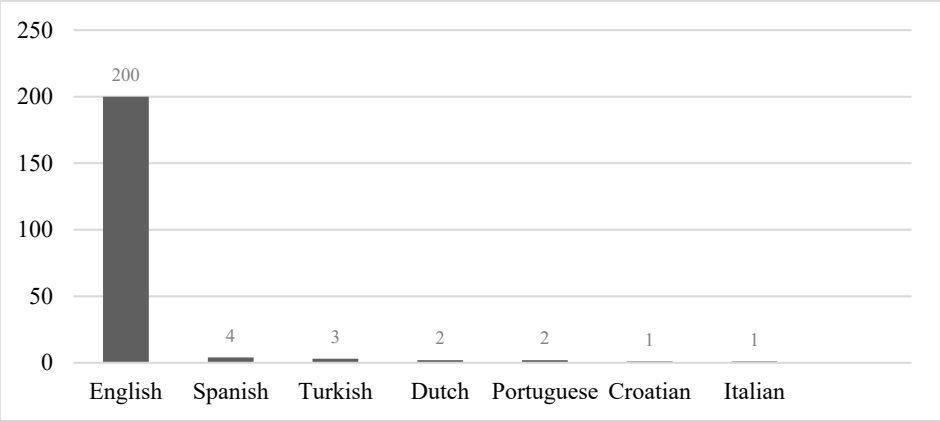

Figure 3. Distribution of articles by language of publication

An analysis of international publication output and geographical distribution trends reveals that the United States has the highest number of publications, with 78 articles. This situation reveals that the United States is a pioneer in the academic development of the field. However, the acceptance of the interior architecture profession and the establishment of its applicable infrastructure in the United States (Tate and Smith, 1986; Kaptan, 2003) can be seen as a factor that has paved the way for the concentration of academic production in this discipline in this

country. Turkey's second place with 30 studies can be attributed to the increasing academic importance given to interior architecture education and research in recent years (Eyüboğlu and Faiz Büyükçam, 2022; Şekerci and Oral 2023). The other eight countries following Turkey contributed to the field with an average of 10 articles each (Figure 4). This situation reveals that international publication production in the field of interior architecture is largely concentrated in certain countries. The fact that the total number of publications is focused around a small number of countries indicates that interior architecture research has a limited representation at the international level.

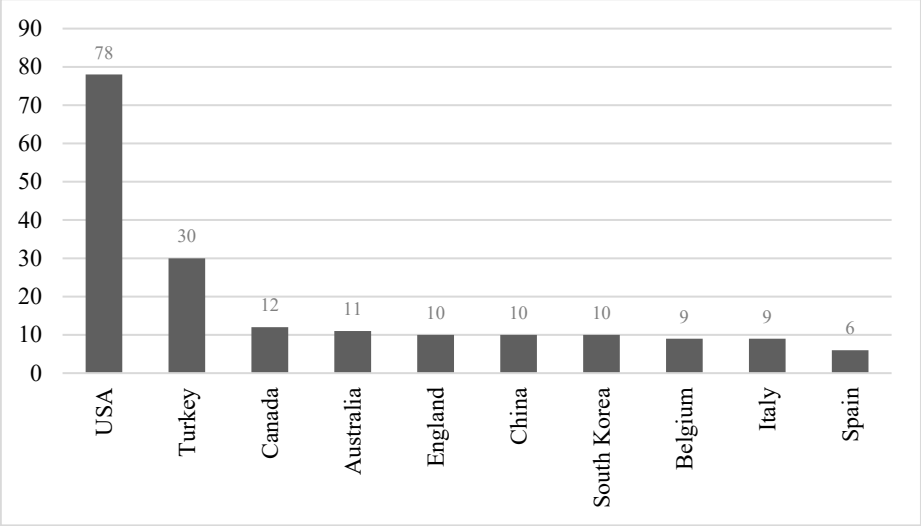

Figure 4. International publishing production and geographical distribution trends

A word network map has been created for 205 articles published between 2015 and 2025. This map shows the transformation of research trends in the field of interior design over time. At the center, the concepts of “interior design” and “architecture” are seen to be intensely connected. The prominence of the concepts “design education,” “interior design education,” and “design pedagogy” in this network structure indicates that education-based research occupies a strong position in interior architecture. According to the color scale, current research related to the discipline includes “artificial intelligence,” “inclusive design,” “sustainable development,” “empathy,” and “pandemic.” This reveals that themes such as technological developments, inclusivity, sustainability, and user sensitivity have gained importance in recent interior architecture research. Furthermore, the close relationship between “artificial intelligence” and “design education” in particular indicates that digitalization and artificial intelligence-based approaches in design pedagogy have become a rising research trend. On the other hand, early studies focused on aesthetic and spatial themes such as “art,” “exhibitions,” and “illumination” (Figure 5). This shows that interior architecture has evolved over the last decade from a research field focused on aesthetics and spatial formation to one centered on education, technology, and sustainability.

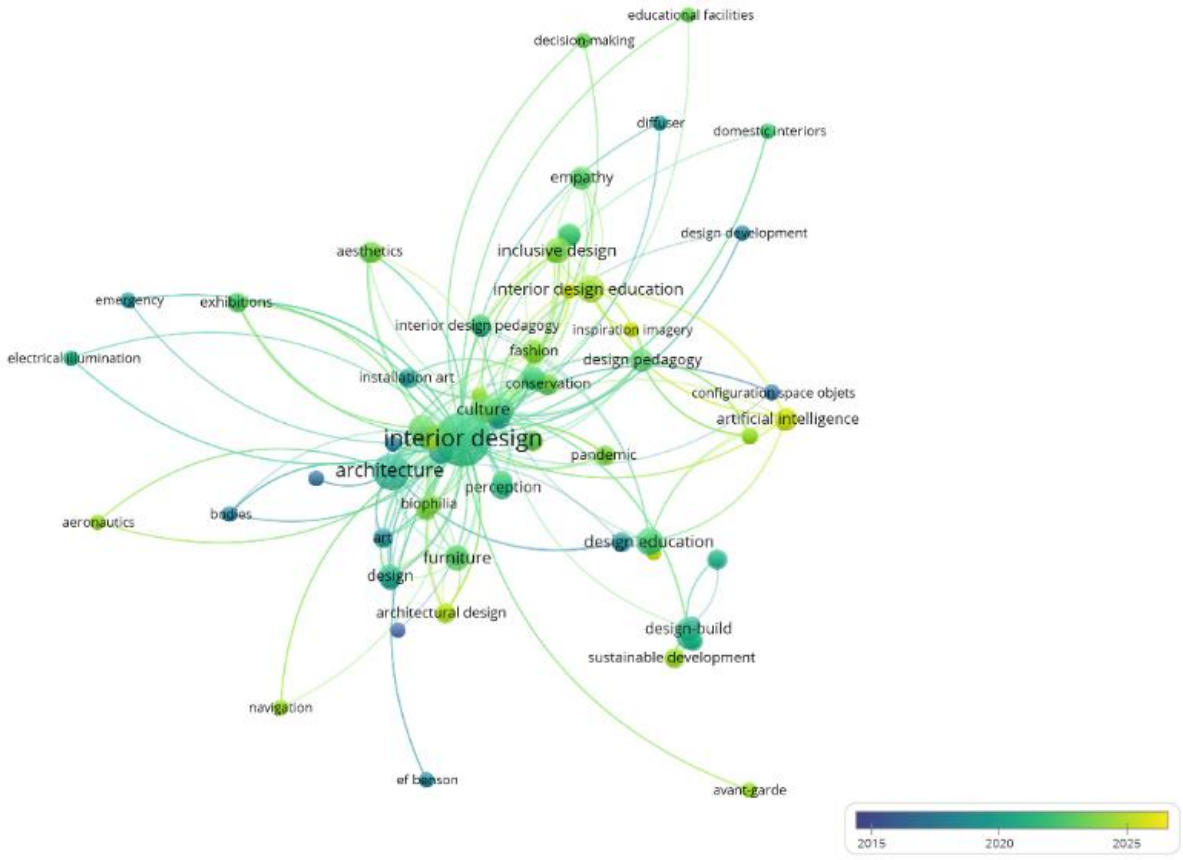

Figure 5. Word network map

A thematic map has been created showing research topics in the field of interior architecture grouped into four main clusters according to their centrality and level of development (Figure 6). According to this map, the concepts of "interior design," "interior design education," and "environment" located in the lower right region are the most fundamental and consistent research areas. This indicates that interior architecture studies are shaped around approaches focused on space, environment, and education.

The concepts of "performance," "stress," and "culture" in the upper right section are driving themes with both high centrality and high development. Accordingly, psychological, cultural, and behavioral themes have gained importance in interior architecture research and are seen as studies that guide the field. The concepts of "art," "emotions," and "model" in the upper left represent studies that are original but have a limited scope of influence. Accordingly, it has been observed that studies focusing on the emotional and artistic dimensions of interior architecture have a limited relationship with the discipline's general research framework. However, it has been observed that the "COVID-19" theme has risen periodically but has not fully established itself in the general research field. The themes located in the lower left region cover both emerging and declining topics due to their low centrality and development values. Accordingly, considering the intensities, the concepts of "design education," "creativity," and "technology" have been prominent and developing research areas in the field of interior architecture in recent years. When the thematic map is evaluated overall, it is seen that the field

of interior architecture has been shaped around education, environment, culture, and user experience.

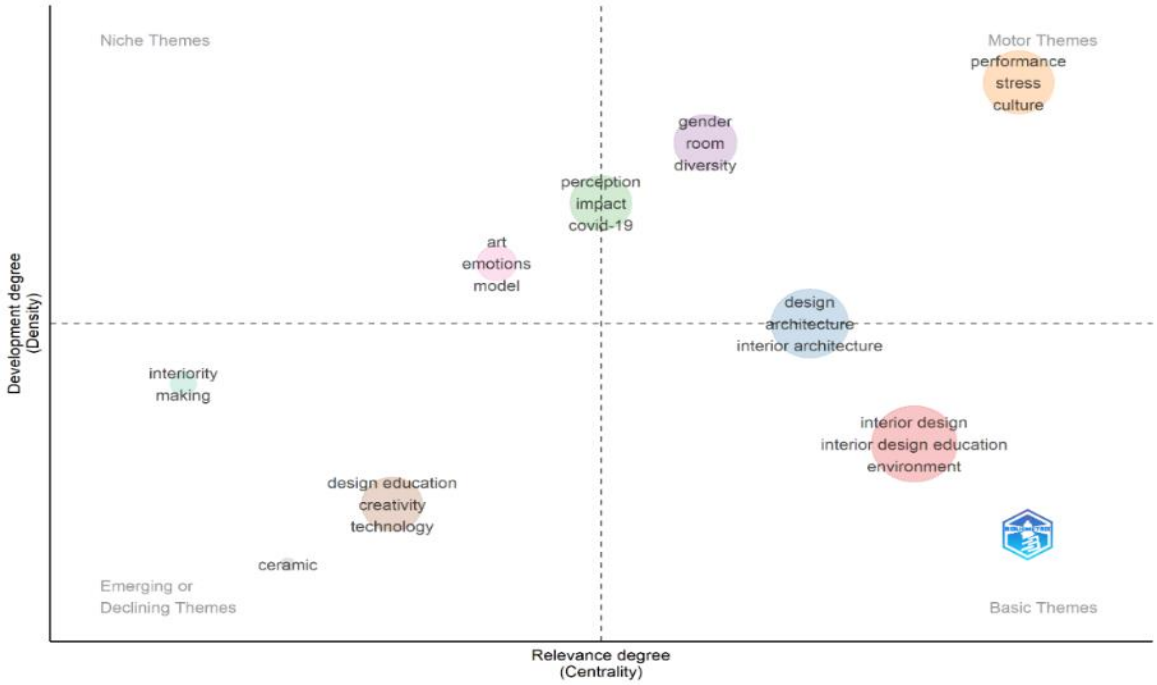

Figure 6. Thematic map of interior design study areas

The journal citation network map created using VOSviewer (Figure 7) shows which journals academic publications in the field of interior design are concentrated around and the levels of interaction between journals. Upon examining the map, it is seen that the Journal of Interior Design has established strong citation relationships with other publications and occupies a central position. The journal with the strongest connection to the Journal of Interior Design is Archnet-IJAR: International Journal of Architectural Research. This finding indicates that there is a direct citation exchange (referencing/citing each other) between the two journals. The other journals on the map interact with interior design literature to a relatively limited extent. Overall, it was observed that academic production in the field of interior design is concentrated around a limited number of journals and, consequently, bibliometric visibility is limited.

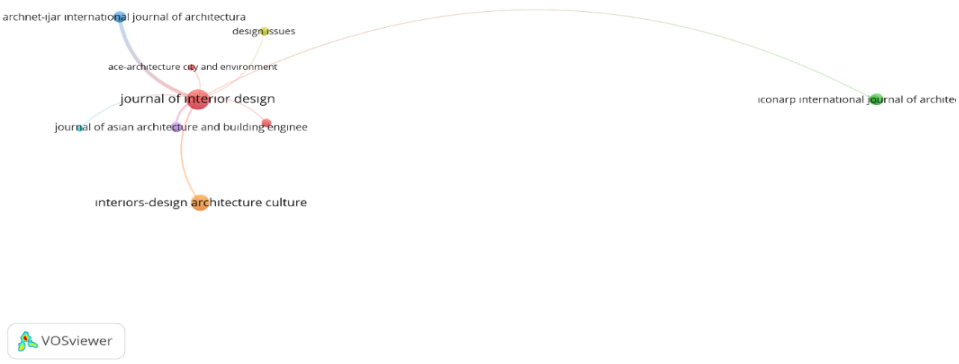

Figure 7. Journal citation network analysis

When examining the conceptual structure map provided in Figure 8, it can be seen that research themes in the field of interior architecture are concentrated in different clusters. The concepts of design education, creativity, artificial intelligence, and technology, located in the upper right section of the map, represent current and innovative research trends in the field. The clusters of design pedagogy, BIM, and visualization, located in the lower right section, represent research that addresses the integration of digital tools and visualization techniques into educational processes. The concepts of home and perception, located on the left side of the map, represent less connected themes in the research network. Overall, it can be seen that the bibliometric structure in the field of interior architecture is grouped into two main clusters: technology and education-focused design research, and user experience and perception-focused themes.

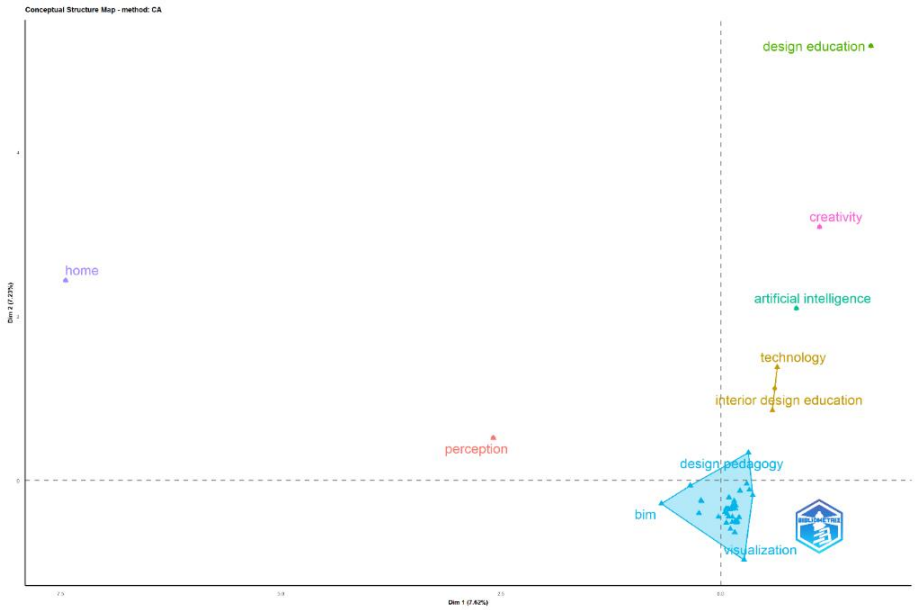

Figure 8. Conceptual clustering-based bibliometric factor analysis

The top 10 most cited articles indicate that research in interior architecture is concentrated around specific topics (Table 2). The highest number of citations was found in VR-based design research. Artificial intelligence, environmental design, education, and user experience topics are also among the highly cited studies. In this context, it is seen that the citation distribution is generally high in technology and experience-focused studies.

Table 2. Top 10 most cited articles

10.	Virtual Reality Versus Real- World Space: Comparing Perceptions of Brightness, Glare, Spaciousness and Visual Acuity	2022	12

4. Conclusion and Recommendations

This study, which evaluates the perspective on the last decade of article studies in the field of interior architecture, indicates that the increasing research output points to the discipline's development at both the academic and professional levels. However, the fact that the majority of the studies are published in journals within the A&HCI scope indicates that theoretical and interpretation-based, qualitative research trends are prominent in the discipline's research methodologies. The fact that publications in the field of interior architecture are largely concentrated in the Journal of Interior Design and Interiors: Design Architecture Culture indicates that the field is limited in terms of journal diversity. However, it is clear that English plays a decisive role in international academic interaction. The global representation of the field has been largely limited to the United States. It is clear that interior architecture research has evolved from aesthetic and spatial themes towards technology, education, and sustainability between 2015 and 2025. In addition, concepts such as artificial intelligence and digitalization have emerged as new research trends in the discipline in recent years.

The central and advanced research areas in the discipline have been topics focused on education, environment, culture, and user experience. However, it is clear that interior architecture research, which has been shaped around pedagogical-technological and space-human centered topics, has recently come to the fore with technology-education based studies. In citation analysis, it is evident that the most cited studies are concentrated around technology and user experience-focused research.

Abstract

With rapid urbanization, building density has increased, reducing open and green spaces and natural habitats. Although urbanization offers diverse employment, transportation, and social opportunities, it has also led to declining thermal comfort due to urban heat islands and extreme weather events, negatively affecting urban quality of life. Since thermal comfort is closely linked to well-being, studies focusing on mitigating the urban heat island effect and enhancing thermal comfort have gained growing attention.

This study reviews recent research on thermal comfort across various climate zones and analyzes the design and planning decisions that influence it. Findings indicate that key strategies such as providing shading, considering wind direction, selecting appropriate surface materials, and integrating water elements are essential for achieving outdoor thermal comfort. However, despite their long-standing recognition, these principles are often neglected in modern urban design. Therefore, this study highlights the need to revisit and integrate these fundamental yet overlooked design principles to promote thermally comfortable and sustainable urban environments.

Keywords: Thermal comfort, UHI, urban design, urban planning, climate change

1. Introduction

The duration, frequency, and timeframe of outdoor space use in cities, as well as the age group using it, depend on the city's climate. While outdoor use is more common in cities with more livable climates, recent changes in climate and weather conditions have affected individuals' health and comfort, leading to a decline in outdoor use.

A brief look at the causes of this problem: While rapid urbanization driven by global needs was initially minor, over the last 50-60 years, it has rapidly altered the unique fabric of cities. Open and green spaces, which provide outdoor living areas for other living creatures, have been unintentionally destroyed and replaced by unplanned urban development, and this trend continues to this day (Sirakaya et al., 2018). Especially over the last 30 years, people in countries affected by war and weather disasters have abandoned their homes and begun to crowd into other cities. This, in turn, has led to increased urbanization and increased human activity in these cities. This has led to an increase in the Urban Heat Island effect (UHI) (Chen et al., 2022; Guo et al., 2022; Yuca, 2025), which occurs when urban areas are warmer than surrounding rural and suburban areas. Consequently, the adverse effects of climate change are felt more intensely in cities.

The IPCC's (Intergovernmental Panel on Climate Change) latest assessment report, published in 2022, asserts that rising temperatures in urban areas are directly linked to increased threats to human health (IPCC, 2022). In line with this alarming information, Article 13 of the United

Nations' Sustainable Development Goals emphasizes the need for urgent measures to combat climate change and mitigate its effects. The most crucial step in this process is to reduce the heat impact in cities.

Therefore, in recent years, numerous studies on thermal comfort in urban microclimates have been conducted in academia to mitigate the effects of global climate change and create healthy cities (Jin et al., 2020; Gachkar et al., 2021). All of these studies have concluded that there is a direct relationship between climate conditions and the use of outdoor spaces (Deng and Wong 2020; Karimi et al., 2021). Thermal comfort is the degree to which people are satisfied with the climatic conditions of their environment (Yan et al., 2021). People avoid using outdoor spaces in very hot, very cold, windy, or humid environments because they experience thermal discomfort (Ahmed et al., 2024). However, it is known that outdoor use is higher in more sustainable, healthy cities where climate conditions are more livable and air quality is high (Russo, 2024). In this context, one of the most essential steps in creating healthy cities is to provide suitable climatic conditions in outdoor public spaces where people can spend time, relax, and communicate. The thermal comfort of these spaces is the most important environmental factor affecting individuals' participation in outdoor activities (Geng et al., 2022). Comfortable urban open spaces help promote outdoor activities, social interactions (Lai et al., 2020a), and sustainable urban development (Tian et al., 2022).

Public spaces are often the first thing that comes to mind when creating healthy, sustainable cities. While public spaces usually come to mind first, streets are the primary link between urban outdoor spaces, connecting open green spaces, squares, and gathering areas. While streets are often associated with vehicular traffic, they also serve as community hubs for activities such as walking, cycling, providing transportation to public spaces, socializing, shopping, and more (Lee and Mayer, 2018). Therefore, in the context of designing healthy cities, promoting walkability between interconnected areas and ensuring both sustainability and well-being are key priorities (Necira et al., 2024). Adverse thermal comfort conditions due to excessive heat stress are a critical barrier to walking and can significantly impact a person's desire to walk and time spent walking (Suwanmanee et al., 2024). This, in turn, can impair walkability, street livability, and urban vitality (Arif and Yola, 2021; Oppermann et al., 2021; Tumini et al., 2016). Therefore, many studies have been conducted to assess and improve outdoor thermal comfort in streets to improve sustainable, healthy urbanization and walkability (Boussaidi et al., 2023; Siqi et al., 2023). These studies also evaluated street dimensions related to walking-related thermal comfort, including land-use differences, street connectivity, street inclination, human-scale issues, and transparency. In addition, recent studies have been conducted across different climatic regions worldwide to analyze and improve thermal comfort in outdoor spaces (Lai et al., 2020b; Huang et al., 2019; Nogueira et al., 2020). Some of these studies focused on measures to reduce the UHI effect caused by summer temperatures in cities (Zhen et al., 2022), while others focused on temperature changes in winter (Huang and Peng, 2020) or stable temperature changes occurring throughout the year (Lu et al., 2019; Zhou et al., 2019; Yuca, 2024). In these studies, the most appropriate indices were selected based on the characteristics of the study area. While the PET (Physiological Equivalent Temperature) index is generally used to determine outdoor thermal comfort, some studies also use indices such as the predicted mean vote (PMV) and the Universal Thermal Climate Index (UTCI).

On the other hand, while some of these studies utilize past climate data and field analysis (Karimi and Muhammed, 2021), many studies have recorded current climate data and generated different scenarios to improve the study area. Based on the climate changes in these scenarios,

recommendations for public space design and planning in urban areas have been made (Arrar et al., 2024; Yuca, 2025). Generally, when these studies conducted worldwide are examined, each study offers design and planning recommendations that can be implemented by the disciplines of landscape architecture, architecture, and urban and regional planning to reduce heat stress in cities. This study examines global studies and discusses these recommendations.

Thermal Comfort Studies Conducted Around the World

This section examines studies on the investigation and improvement of thermal comfort in outdoor urban environments across regions with different climates worldwide. In this context, firstly;

Karimi and Muhammed (2022) conducted a study examining outdoor thermal comfort among tourists visiting historical squares in Sevilla and Madrid (Figure 1), where high summer temperatures and occasional heat waves lead to heat stress. The research aimed to determine a reasonable and comfortable visit duration for visitors to these historical and cultural sites. For this purpose, three squares were selected from each city, and long-term climate data from previous years were analyzed to assess thermal comfort conditions in these squares. Consequently, the study used data from July 13-14, 2021, for the squares in Sevilla, and from July 10-11, 2021, for the squares in Madrid.

Figure 1. Squares where the study was carried out (Karimi and Muhammed 2022)

The study used the ENVI-met climate simulation, which is claimed to be reliable and has been used in many studies. Because the areas have no usage restrictions, the study conducted 24-hour simulations within these time intervals. Additionally, to test the accuracy of the simulation results, climate measurements were taken at a specific height on the exact dates, and the PET index, widely used in studies of outdoor thermal comfort, was used. Subsequently, to understand users' thermal sensation in each study area, surveys were conducted in two separate time periods: morning (08:00-13:00) and afternoon (16:00-21:00). The surveys lasted 5 to 7 minutes. Because the study was conducted on a hot summer day, the survey results were closer to the high end of the range.

The study found that small areas with good vegetation have better thermal comfort conditions than other areas. While squares generally fall short of the appropriate thermal comfort range during the day, PET values are better at night. Semi-open areas with adequate afforestation provide more suitable thermal comfort conditions than other city squares.

Arrar et al. (2024) conducted a study investigating pedestrian thermal comfort in the city of Kasbah, Algeria, which has a Mediterranean climate (Figure 2).

Figure 2. The 4 regions where the Algerian Kasbah was studied (Arrar et al., 2024).

The study area features a Mediterranean architecture, with residential units arranged around a central courtyard, reflecting a 1000-year-old urban design. This emphasis is highlighted because there are no high-rise buildings that affect thermal comfort, and local materials, typically terracotta and lime, are used. Areas with the highest activity levels and diverse street types were selected for the study, and climate measurements (air temperature (Ta), relative humidity (RH), wind speed (WS), and surface temperature were conducted in these four areas from August 5 to 11, 2021. Sky images were also obtained with a fisheye lens to assess sky clarity.

Using the climate data obtained in the study, thermal comfort was analyzed using the PET value, the most commonly used index for outdoor spaces. The PET value was obtained using the ENVI-met climate simulation model. Finally, 14 different models were generated in the ENVI-met climate simulation across the four study areas to improve pedestrian thermal comfort and reduce UHI impacts.

The study concluded that the cooling effect was greater in the scenario with green roofs and green walls used together. In contrast, scenarios with green roofs and increased soil surface area were practical in all four regions, with varying cooling effects. Additionally, it was concluded that afforestation scenarios provided better cooling in some regions than in others. Cool pavements can increase outdoor thermal comfort in densely populated areas by up to 14.9°C. Increasing wall albedo (wall surface) negatively impacts heat stress in densely populated areas by increasing solar radiation reflection and surface temperatures. Shading created by the reconstruction of ruined settlements has a significant cooling effect, significantly positively impacting thermal comfort. Therefore, these scenarios have substantial implications for advising decision-makers in similar Mediterranean environmental contexts to improve existing urban fabrics and enhance livability and vitality in outdoor spaces.

Ahmed et al. (2024) conducted a study examining the impact of the UHI on thermal comfort in urban open spaces in Rome, Italy, and the strategies implemented to mitigate it (Figure 3). As in other studies, this study examined the impact of urban microclimate conditions on occupants'

thermal perception using PET, PMV, and PPD (estimated percentage of dissatisfaction) values assessed via ENVI-met climate simulations.

Figure 3. Uses of studied areas (Ahmed et al., 2024)

The study first examined the current situation in the selected study area, then developed proposed designs to improve thermal comfort, and finally obtained comparative results. The study produced new designs by adopting sustainable approaches that require greater attention in urban open spaces, such as adding more vegetation, improving tree planting according to design principles, enhancing connectivity between sub-areas, changing pavement materials, adding water features, and creating more shaded areas. Microclimate models were simulated to assess the impact of the strategies used in these designs on PET, PMV, and PPD.

The study found that the redesigned project had a significant cooling effect on PET, PMV, and PPD during a summer day scenario. While the 9 a.m. simulation of the current situation showed a moderate heat stress level, with PET reaching 37.4°C, PPD reaching 73.7%, and PMV reaching 1.93, the designed project reduced morning PET by up to 19°C, PPD by 20%, and PMV by an average of 1 point, resulting in more comfortable conditions. Another finding was that at 3:00 p.m., while the current situation was extremely sweltering everywhere, with PET at 51.2°C (extreme heat stress), high dissatisfaction at 97.39% PPD, and PMV at 3.97, the simulation of the redesigned area reduced PET by up to 4°C, reducing PPD by more than 30% and PMV by more than 2 points. Finally, this study indicates that detailed redesign strategies, such as incorporating vegetation, changing tree placement, improving connections, and adding water features, can serve as a practical guide for creating urban areas with high human and thermal comfort.

Kozak & Lipecki (2025) conducted a study investigating the effects of green walls on thermal comfort and microclimatic conditions in a modern residential area in Lublin, Poland (Figure 4).

Figure 4. The studied residential area (Kozak and Lipecki 2025)

The study first defined the study area in detail (story heights, building density, and land use). The ENVI-met simulation then modeled and compared the current situation with the design incorporating green walls. The Universal Thermal Climate Index (UTCI) was used as the index in the study. Simulation results indicated that green walls caused a statistically significant but slight decrease in maximum UTCI values across the site, with a peak difference of 0.16°C recorded at 3:00 PM, the hottest hour of the day. Green walls can significantly improve the microclimate in the immediate vicinity of buildings, and UTCI differences can reach up to 3.68°C during intense solar radiation. Another finding emphasized that while green walls help mitigate extreme heat, their effectiveness alone is insufficient to achieve significant improvements in thermal comfort during heat waves, and that for maximum impact, green walls should be integrated with complementary adaptation strategies.

Thermal Comfort Studies Conducted in Turkey

Global climate change is already having adverse effects in many countries, including Turkey. Consequently, thermal comfort studies have recently started in cities with varying climate conditions in Turkey. This section examines studies conducted on the investigation and improvement of thermal comfort conditions in outdoor urban environments in Turkey.

Adıguzel et al. (2022) conducted a study in the Toroslar Neighborhood of Çukurova District, located in the northern part of Adana, where high-rise and dense construction is prevalent (Figure 5). In this study, instantaneous measurements of temperature and relative humidity were taken using a portable climate measurement device around Hayal Park at 07:00, 14:00, and 21:00 on Tuesday, August 20. Thermal comfort zones were determined by measuring temperature and relative humidity at 25 different locations in the study area.

Figure 5. Measured points in the study (Adıguzel et al., 2022)

The study area was then imported into ArcGIS for GIS analysis, and temperature and relative humidity distribution maps were created. Analysis of the distribution maps revealed that areas outside Hayal Park were classified as hot at 7:00 a.m., and that green spaces positively affected thermal comfort zones. Smaller areas were classified as very hot, and by 2:00 p.m., they were fully hot. Heat stress in these areas was thought to be due to the presence of multi-story buildings in the study area, and to asphalt and concrete surfaces that increased temperatures. Consequently, the study identified uncomfortable areas and determined that the urban plan needed to be revised to bring the area within the thermal comfort range, as urban form and

settlement affect climate comfort. To achieve this, the study emphasized reducing the impact of heat on the study area by reducing asphalt and concrete surfaces and increasing the density of open and green spaces.

Ertem, Mutlu, and Yılmaz (2024) examined the effects of different green space ratios on the microclimate and outdoor thermal comfort in Erzurum, a winter city. The Yıldızkent district, a new settlement in Erzurum, was selected as the study area, and microclimate data were recorded hourly for one year with an installed climate device. Five different green space increase scenarios were then created, each with a different level of green space (10%, 20%, 30%, 40%, and 50%). A total of six different scenarios (including the current situation and the creation of five green spaces) were simulated for outdoor thermal comfort using the ENVI-met program for the hottest (summer) and coldest (winter) periods of 2021. The study found that scenarios with increased green space did not differ significantly from the current situation. Only the 10% green space ratio scenario for mean radiant temperature (Tmrt) and the 30% green space ratio scenario for PET yielded positive results in both winter and summer. The study revealed that scenarios with increased green space had a positive effect on the microclimate and led to greater outdoor thermal comfort.

Yuca (2025) analyzed the impacts of Lake Van on both regional and micro-scale climatic conditions and urban thermal comfort within the province of Van (Figure 6). For regional-scale analyses, long-term climate data from stations located in both coastal and inland districts of the lake were collected and analyzed. Temperature and PET distribution maps were created in ArcGIS. For micro-scale analyses, climate stations were established in five regions with varying distances from Lake Van and varying urban patterns, and a total of one year of meteorological data was collected through 2024. Finally, using the ENVI-met microclimate model, climate data from the two stations were used to generate 36 different climate-adaptive design scenarios for summer and winter.

Figure 6. Areas measured for 1 year in the study (Yuca, 2025).

The study's findings indicated that a climate-adaptive design scenario with 75% planting achieved successful results, reducing PET values by 0.9-1.2°C during summer noon. Furthermore, PET analyses and ENVI-met simulations revealed that vegetation density and water-surface availability are key determinants of thermal comfort, underscoring the importance of strategically integrating water and vegetation in sustainable, climate-sensitive urban open space designs.

Zeren Çetin et al. (2025) conducted a study investigating whether improving thermal conditions is feasible for achieving healthy, livable, and sustainable urban environments.

Figure 7. Sample areas with different usage patterns (Zeren Çetin et al., 2025).

In the study, two separate regions with different surface materials were determined and it was investigated how the surface temperatures of the coatings of these two areas affected thermal comfort, especially in the summer months when heat stress is high (Figure 7). The study was conducted on September 10, 2022, at Cumhuriyet Park in the Yurt neighborhood of Adana province's Çukurova district in Türkiye's Eastern Mediterranean Region. Surface temperatures were measured by an unmanned aerial vehicle from 20 different locations. A detailed surface temperature map was also created using a thermal camera.

The study found that water surfaces had the lowest recorded temperature, while dark concrete surfaces had the highest. The findings highlight the importance of selecting surface materials to shape thermal conditions and improve thermal comfort in urban open and green spaces. The importance of carefully selecting surface materials in urban design and planning is emphasized, as is the need to create more livable, high-quality, sustainable cities. It is also suggested that increasing water surfaces, green cover, and vegetation in cities with high summer temperatures, such as those in the Mediterranean region, will positively impact thermal comfort.

Considerations for Climate-Livable Cities

With urbanization accelerating globally, including in Turkey, high-density urban development models have intensified the impact of climate change in cities while increasing the frequency of extreme weather events (Wei et al., 2023). Consequently, climate change, one of the most significant global challenges of our time, is emerging, and its most important impacts are being felt in cities. Due to the increasingly adverse climate conditions on the health of people living there and the time spent outdoors, recent efforts to mitigate climate change at the micro-scale have increased. These studies generally examine the perceived temperature range during outdoor time and how urban spaces should be designed to enhance the quality of time people spend outdoors.

This study examines several studies conducted on this topic from around the world and in Turkey. The results of these studies generally show that in areas with high climate stress and intense heat, planting significantly reduces perceived temperature, making areas more livable. When we examine other application principles that improve thermal comfort conditions from the results obtained from the studies reviewed above;

• Partially open spaces are characterized by better thermal comfort compared to surrounding urban settlements when more technical planting is implemented.

• Green roofs and green walls designed in cities have little effect when used alone, but are more effective when used together.

• Tree planting densities and combinations (depending on the species used) do not have the same impact in every residential area, providing better thermal comfort in some settlements.

• Urban areas can experience adverse thermal conditions due to the application of incorrect planting techniques, and thermal comfort can be improved by applying planting design principles in these areas.

• Cool pavements used in outdoor spaces increase thermal comfort.

• Dark-colored flooring, where it is heavily used, negatively impacts thermal comfort because it causes heat accumulation.

• Caution is needed when increasing the albedo of exterior walls, as it increases solar reflection and surface temperature.

• Reconstructing unused, dilapidated residential areas according to thermal comfort standards can positively impact thermal comfort in the surrounding regions.

• Water elements used in accordance with urban design and planning principles can increase thermal comfort.

The studies examined have shown that differences in urban geometry and climate mean the results of each study are not fully applicable to other areas. However, in general, the same methods can be applied to settlements with similar urban geometry, density of use, and climatic characteristics, as shown in previous studies.

Recently, as academics in Turkey have recognized the importance of this topic, studies have increased, and studies are still ongoing. Examining the results of these studies, it has been concluded that the correct application of the design and planning principles learned and taught since undergraduate education in the discipline of Landscape Architecture actually positively impacts thermal comfort conditions. Unfortunately, these planning and design principles, neglected during rapid urbanization, have negatively impacted outdoor thermal comfort in our lives today and exacerbated the effects of climate change, making these issues a pressing concern. Therefore, reframing the planning and design principles of landscape architecture in line with current urbanization trends is a critical necessity for creating sustainable, climate-sensitive urban environments.

Abstract

Climate change is causing an increase in the frequency and severity of climate-related hazards, particularly extreme heat events, floods, forest fires, forest fire smoke, and ozone air pollution. Today, cities, public spaces, and infrastructure assets such as street furniture are forced to adapt to this change. Smart street furniture in the urban landscape can be defined as urban accessories that meet new urban needs and contribute to sustainability through technological advancements. Sustainability and climate change are inextricably linked, and mitigation and adaptation strategies can contribute to sustainability.

Many global cities have developed ambitious green and sustainability strategies and plans to achieve their goals of mitigating climate change. This paper focuses on street furniture, which plays a crucial role in urban landscapes to enhance urban livability under changing climate conditions. This study examines examples of various street furniture designs within the framework of current street furniture design, sustainability and climate change, and climate anxiety and adaptation. As a result, it has been demonstrated that new technologies and attractive aesthetic designs in urban furniture can increase the livability and effectiveness of existing services such as solar energy, smart technology, and thermal regulation in the urban landscape.

Keywords: Climate change, urban furniture, urban landscape, sustainability

1. Introduction

Human activities, which accelerated with the industrial revolution, are causing global warming and climate change. Climate change projections produced with scenarios predicting greenhouse gas emissions indicate that these changes will continue on the same trajectory into the future (Şerifzade 2022). Cities' climates have a structure that directs, directly affects, and changes the planning, design, and usage processes of the city. Urban furniture, an integral part of the urban landscape and the functional use of public spaces, must also adapt to this change. Smart urban furniture, which has a significant impact on the urban landscape, can be described as urban accessories that respond to new needs in cities with the development of technology and contribute to the sustainability of the city.

Urban furniture is defined as equipment or structures in public spaces that have no specific user base, have open-space functionality, and generally provide fixed services (Najafidashtape, 2018). Urban furniture is a uniquely designed product placed in public spaces such as streets, avenues, roads, parking lots, and squares. It meets needs such as seating, protection, shelter, transportation, orientation, lighting, waste collection, rest, and entertainment, and provides protection from sun, wind, rain, and other external factors (Aksu, 2012). Many global cities have developed ambitious green and sustainability strategies and plans to achieve their goals of slowing climate change. This study focuses on urban furniture as a tool for improving urban livability in changing climate conditions.

Urban Furniture Design Today

The design of urban furniture, which has a wide user base, generally requires three factors. These factors are: functional, psychological, and technological. Functional criteria include sizing appropriately for users' anthropometric characteristics and ease of use. Psychological criteria include considering the diverse cultural characteristics of societies. Technological criteria include producing urban furniture using durable materials and technologies appropriate for function and form (Hacıhasanoğlu, 1991).

In recent years, due to the climate and environmental challenges experienced in urban environments, in addition to the aforementioned basic criteria, urban furniture design has been prioritized to support urban living conditions and ensure sustainability. In this context, it is expected that urban furniture will adapt to changes within the scope of environmental design and develop innovative solutions to provide healthy and sustainable living conditions.

Urban furniture with durable, aesthetic, and flexible designs offers a solution in this regard in the urban landscape. In this solution, biophilic design offers an interesting intersection between sustainable materialism and beauty (International Living Future Institute, n.d.). Biophilic design is the integration of nature into built environments. Biophilia is the idea that humans are instinctively connected to nature and that increasing natural elements in urban environments enhances their mental well-being (McCain, 2020). In the context of street furniture in urban landscapes, biophilic design elements can include planting trees, shrubs, or flowers next to benches. This also means that natural shapes, patterns, and colors can be incorporated into designs.

Sustainability and Climate Change

Sustainability can be defined as a process that ensures the coordinated and prudent use of all resources—social, cultural, natural, human, and scientific—(Galdwin, 1995). Sustainable development is a multifaceted approach to creating a built environment that considers economic, social, and environmental concerns.

Sustainable development is a key component of any strategy to support the planet's growing population and can be achieved by constructing new infrastructure and buildings that reduce environmental impact by reducing carbon pollution. Sustainability and climate change are inextricably linked, and mitigation and adaptation strategies can facilitate sustainability.

Mitigation aims to reduce and offset greenhouse gases that trap heat in the atmosphere (NASA, n.d.). For urban furniture, mitigation strategies include reducing vehicle dependency by increasing access to sustainable transportation through public transportation and active modes of transportation such as walking or cycling. Mitigation strategies will also include the use of greener construction practices such as recycling, lighter-weight buildings, and zero-emission buildings. Adaptation is an approach that must be agile and flexible to adapt to the unpredictable weather events brought on by climate change. Adaptation offers the City an opportunity to examine how street furniture, a key element of public infrastructure, can be integrated into community resilience (City of Vancouver, 2024).

Climate change is causing an increase in the frequency and severity of climate-related hazards, particularly extreme heat events, floods, wildfires, wildfire smoke events, and ozone air pollution. These events cause emergencies resulting in illness, injury, and, for some, death (Vancouver Coastal Health, n.d.). By using both mitigation and adaptation strategies to guide

the management of public spaces and infrastructure assets such as street furniture, cities can see the impact of immediate and long-term resilience in action. Climate resilience addresses approaches and trends in street furniture and social amenities related to sustainability and equity. These approaches represent both mitigation and adaptation strategies.

2. Examples of Urban Furniture Designs Concerned with Climate Concern and Adaptation

This section examines some examples of urban furniture designed to support sustainability in today's cities, driven by climate concern and adaptation. Smart technology can be integrated into urban furniture to provide services such as Wi-Fi, emergency buttons, wayfinding, or charging stations.

Transportation Stops

The opportunity for cities to install data sensors at public transit stops means generating qualitative data that will inform planning decisions and aid climate adaptation. For example, if an air pollution sensor indicates high levels at a particular intersection, trees or shrubs can be planted or air filters installed in that area.

A 2020 study, "Thermomodulating Effects of Bus Stops and Tree Shade on Public Transit Ridership," examined the effects of both temperature and shade on public transit ridership in cities across the United States, particularly in Austin, Texas (Lanza and Durand, 2021). The authors found that, despite the decline in ridership in many cities due to high temperatures, sheltered bus stops carried more passengers on these hot days than sheltered stops on cold and heavy rainy days. Trees can be planted at bus stops to provide shade, considering shade as a type of infrastructure from every perspective, or urban furniture can be designed to provide shade (Flores, 2019). Trees are excellent shade sources, contributing to rainwater management, filtering air, providing shelter for biodiversity, blocking winds, and contributing to human well-being through biophilia (TerraMai, n.d.). Additionally, there are many approaches to adapting urban furniture through technological interventions. For example, in extremely hot climates, misting systems are an option for transit shelters, ideally in addition to shade. Fogging requires connection to a water source, which presents a challenge in cities experiencing drought (City of Phoenix, n.d.). The Phoenix shelter (Figure 1) is one example, providing misting, ventilation, and shade.

Figure 1. A transit shelter with a fogging feature in Phoenix (City of Phoenix, n.d.).

In Chongqing, China, foggers designed to spray cooled mist at bus stops to cool bus passengers. In Victoria, British Columbia, foggers were installed on fire hydrants (Chan, n.d.). The "Vegetal Bus Stop" is one example of a smart bus stop (Figure 2). The stop was designed to support the growth of declining vegetation in urban areas. The street furniture, which can be used as a bus or tram stop, is considered a symbolic piece of urban furniture that is effective in encouraging public transportation use, thus limiting the greenhouse effect and gas emissions. The design also incorporates environmentally friendly solutions such as rainwater collection and the use of low-consumption lighting (designboom, n.d.).

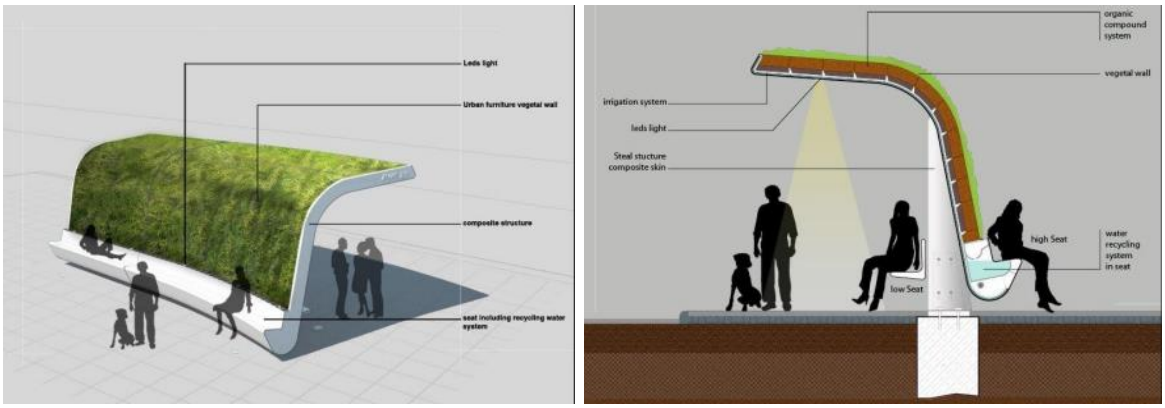

Figure 2. The appearance and operation of the "Vegetable Bus Stop" smart bus stop (designboom, n.d.).

Green and Cool Roofs

An effective way to reduce urban temperatures on unused roofs. There are two popular strategies: green and cool roofs. A green roof is a permanent rooftop vegetation system or a type of vegetation. In addition to reducing the urban heat island effect, these roofs can support biodiversity, absorb pollutants and CO2, and increase rainwater retention. Cool roofs are made of highly reflective materials and are very effective at cooling the interior of a building.

According to the authors of the book Energy and Buildings, cool roofs provide three times more effective cooling than green roofs and are generally more cost-effective than green roofs. However, cool roofs require more maintenance than green roofs because they require frequent pressure washing to maintain their solar reflectance (Sproul et al., n.d.). Derby, England, uses the roofs of bus shelters (Figure 3) to create areas for native plants that will attract bees and other pollinators (Derby City Council, n.d.).

Figure 3. A green roof installed on a transit shelter in Derby, England.

One of the biggest advantages of solar-powered street furniture is that it doesn't require electrical wiring connected to the public grid. As batteries and technology improve each year, even dark and rainy climates will benefit from solar energy (BC Hydro-Power Smart, n.d.). They also require regular maintenance, which can become a significant expense if subject to constant vandalism. Some cities are using solar energy at public transit stations. For example, Edmonton has had solar-powered public transit stations since 2012 (City of Edmonton, n.d.).

For example, the Telford transit station (Etesian Green Shelters, n.d.) is powered by both wind and solar energy. The station will be grid-independent and will generate enough electricity to power both its lights and advertising panels.

Seating and Smart Charging Units

The "Smart Tree" smart seating element is another example of an application developed by the same company (Figure 4). The seating element was inspired by nature and designed like a smart tree. This urban furniture piece, which features smart benches, also provides users with the opportunity to sit in the shade under a tree (Strawberry Energy, n.d.).

Figure 4. "Smart Tree" smart seating (Strawberry Energy, n.d.).

The smart seating element, called "Digital Break," is an example of urban furniture that offers flexible use, is suitable for working with a laptop, provides internet access, and provides news and city information via its digital screen (Figure 5). The green roof on its eaves is intended to create the illusion of a garden in the urban environment (Dezeen, n.d.).

Figure 5. The "Digital Brake (Escale Numérique)" smart bench (Dezeen, n.d.).

The "Artificial Tree" seating unit is another urban furniture unit developed to filter polluted air in cities (Figure 6). In addition to serving as seating and lighting, the urban furniture can also emit fresh scents and natural sounds, and its digital display can provide access to information in the city (Jordi Hans Design, n.d.).

Figure 6. "Artificial Tree" smart seating and lighting application (Jordi Hans Design, n.d.).

The other product is called City Tree. This particular product claims to have the nitrogen dioxide absorption capacity equivalent to 275 trees. The seating also includes Wi-Fi, charging, and solar-powered sensors that can detect a lack of humidity and, when necessary, activate a water pump located behind moss walls, cooling the area within a 5-meter radius. The product is currently being piloted in Paris, Oslo, Berlin, and Brussels, where nitrogen levels have decreased by 15%. Brussels, experiencing higher than normal temperatures, required additional water for its irrigation system after sensors detected low humidity.

Similarly, Canopee, shown in Figure 7, uses live plants in locations where trees are unsuitable. This particular product also creates a canopy with a minimal footprint. Canopee has been installed in cities such as Paris, Marseille, Bordeaux, and Nantes, as well as in Spain, Morocco, the Gulf States, and most recently, Australia. The system also collects rainwater, and irrigation is controlled remotely using humidity sensors. The product is also solar-powered (Plastics Le

Mag, n.d.). This design would be useful in areas with high pollution, where shade is needed, and where the area would benefit from biophilic elements.

Figure 7. A canopy creates a self-contained canopy with integrated irrigation.

Sidewalks

According to the C40 leadership group, cool sidewalks could be considered along bus routes and in waiting areas. This approach to heat adaptation aims to create cool streets by reflecting heat and solar radiation from the sidewalk. The theory is that reflective paint will redirect radiation, thus cooling the urban heat island. This strategy is being explored by the Los Angeles Department of Streets. In 2017, they launched a pilot program using solar reflective paving on residential blocks (Figure 8). The goal is to reduce the citywide average temperature by 1.7°C by 2035.

This strategy is used in conjunction with cool roofs and green infrastructure. A study on this program, "Solar Reflective Pavements—A Policy Solution for Heat Mitigation?", found that paving alone is ineffective and requires additional shade interventions to maximize its impact (Li et al., 2020).

The findings also show that asphalt concrete reduces heat transfer compared to cement concrete in the late afternoon, but increases human heat load. Critics of the plan cite reflective energy absorbed by people walking on it, which is up to 7°C warmer than asphalt (Bloomberg, 2019). The surface appears to work best in conjunction with additional strategies, such as shade from tree canopy.

Figure 8. Solar reflective pavements showing the difference between absorbent dark asphalt and light-colored reflective pavement (Bloomberg, 2019).

Car and Bicycle Rental Elements

The "Cigogne Bicycle Shelter," featuring smart bicycle charging elements, is designed to provide a safe space for bicycles and protect them from adverse weather conditions and vandalism (Figure 9). This area, which holds 20 bicycles, also offers services such as electric bicycle charging and tire inflation. These modules aim to facilitate and support cycling within the city. The shelter developed by French rail vehicle provider Altinnova is an example of a project designed to reduce urban air pollution and encourage cycling (Paris de l'Avenir, n.d.).

Figure 9. Example of a bicycle storage unit (Bike Box, n.d.).

Smart Waste Collection Systems and Trash Cans

It has been noted that in traditional urban waste collection systems, route planning without knowing the needs at the station leads to problems such as wasted labor and time and increased greenhouse gas emissions. As a solution, smart trash cans and waste system solutions are being developed and implemented in some cities. Smart trash cans, with features such as a sensor indicating when they are full, counting the amount of use or damage to a piece of furniture, or adjusting the lighting, will not provide effective solutions in public spaces. Smart waste collection systems prevent unnecessary traffic of waste collection vehicles in the city, thus

reducing carbon emissions (Demir, 2018). The "Ecube Lab" smart waste booths are one of the smart energy applications in Amsterdam (Figure 10). Trash is compressed in the compression chambers of solar-powered waste containers, the fill level is displayed, and ultrasonic technology can detect all types of materials (Noe, 2020).

Figure 10. Operation of the "Ecube Lab" smart waste collection booth (Noe, 2020).

3.Conclusion and Suggestions

Climate change significantly impacts people and will continue to do so on a larger scale. The city has developed numerous plans and policies to mitigate its impacts now and in the future. All departments should consider how they contribute to sustainability and climate resilience. Sustainability, a dual approach of mitigation and adaptive strategies, is crucial in building climate resilience. Mitigation will include prioritizing carbon strategies and carbon sequestration elements such as vegetation.

Another mitigation strategy is to increase bus ridership and active transportation by making these experiences more accessible and improving the visual quality of the landscape. Adaptive strategies include cooling measures such as shade and mitigating the effects of extreme heat events by reducing solar radiation. Creating shade will help protect the most vulnerable in our city from the effects of the Urban Heat Island Effect. In the absence of vegetation, artificial shade elements protect people from rain and sun.

New technology and attractive aesthetic designs in urban furniture can increase the livability and effectiveness of existing services, such as solar energy, smart technology, and thermal management. Creating comfortable spaces where people want to spend time will increase resilience by building community and providing infrastructure that supports all aspects of urban life. Some suggestions for this include:

• Sourcing sustainable materials if existing assets need to be replaced.

• Collaborating: Investigating how sustainability and embodied carbon strategies influence street furniture procurement, design, and installation.

• Conducting more detailed reviews of material options to achieve the target.

• Conducting a shade and rain cover audit that considers both artificial and natural shade elements.

• Continue exploring smart technology and how it can be used. Integrating Wi-Fi and charging stations into street furniture to improve the user experience.

• Focusing on equality for all segments of society regarding social accessibility.

• Utilizing concepts such as biophilia and placemaking to improve spaces to encourage active transportation and public transportation use for social resilience.

Examples of climate-concerned street furniture approaches can be seen in many global cities. According to a literature review, sustainability and climate resilience have been cited as important components of street furniture strategies for many cities. Street furniture is a vital part of urban life and can be an integral part of cities' climate resilience and sustainability.

Abstract

Daylight is a major factor in the architecture of any building. It does more than just lighting the building, as it affects the building's look, interior design, visual comfort, energy efficiency, and in fact, each stage of the whole design process. From an architectural point of view, daylight is a major factor in energy-saving. When natural light is used effectively, the need for artificial lighting is minimized by the user, thus the consumption of electricity is lessened and the designer is able to achieve the goal of creating a sustainable design. Proper daylight in a room is beneficial for the psychological and physiological health of the users, and it also helps their biological rhythms to be regulated.

Therefore, in order to substantially improve the efficiency of the light, that is, the amount of light entering the room, leading figures in modern architecture such as Le Corbusier, Tadao Ando and Renzo Piano have in a very considered manner utilises a variety of opening elements such as windows, skylights, light shelves, and light tubes in their works. This utilisation ensures that daylight reaches interior spaces to the maximum extent, increases visual comfort, decreases the need for using artificial lighting, elevates the aesthetic value of the space, and enriches the user experience. Comparative studies on the openings used have been conducted to provide a comprehensive understanding of the effective role of daylight in the design process.

Skylights and roof lights are designed to allow direct daylight to get in, whereas light shelves and light tubes are used to transport light to the back areas of the room. Subsequently, interiors are more evenly lit, color perception is improved and the feeling of space is greatly increased. Overall, it is a significant study that presents a compelling perspective on the importance of daylight.

Keywords: Modern architecture, daylight, housing

1.Introduction

1.1. The Historical Development of Light

In looking at the historical background, it can be stated that the first artificial light source discovered was fire. Over the years, due to technological developments and environmental conditions, some artificial lighting elements were encountered that were used at the user's desire and purpose and that were portable. Initially, people tended to the development of a portable light source by using torches. In later periods, lighting tools that were user-adaptable to geographical, seasonal, and climatic conditions were developed.

In antiquity, lamps and candles based on animal fats tended to be widely used. The Ancient Egyptians and Romans made their contributions to lighting technology with the introduction of candles from beeswax and animal fats. These developments were followed by gas lamps, leading to significant innovations in urban lighting. Subsequently, the invention of electrical lighting systems, fluorescent lamps, and light-emitting diodes (LED) introduced another significant energy efficiency in the area of lighting.

Today, smart lighting systems, sensor-equipped lamps, and artificial light sources using solar energy are widely used (Özkum, 2011). Figure 3 presents an overview of the development of light.

Figure 1. Colour temperature and white balance (Erikli & Yıldırım, 2021)

2. Types of Lighting

2.1. Types of Lighting Based on Light Source

Light is an essential form of energy, not only for the process of vision but also for the sustainability of life, technological advancements, and day-to-day requirements. Light is incredibly relevant to a space. Based on usage intentions, spatial dimensions and user needs of an indoor or outdoor space, the lighting in a space can be split into two categories natural and / or artificial light sources. Natural lighting depends solely on day lighting; whereas, artificial lighting is one of the inventions created by the hands of man. Each of these two concepts exists together in various sections below.

2.1.1. Natural Lighting

Natural lighting refers to natural light that arrives on Earth through rays produced by the sun. Sunlight contains ultraviolet rays, and also contains visible light. Sunlight, in fact, is the primal source of natural lighting that regulates biological rhythms and provides efficiency in energy-saving lighting options. It can also contribute to healthier and more liveable architecture. Daylight can be integrated into architectural spaces in a controlled manner. Natural lighting is a mix between sunlight and sky light and varies according to seasons, weather and time of day. The defining characteristic of daylight is that it is not stagnant, it is dynamic by continuously changing. This dynamism creates diversity in terms of light intensity, colour, contrast, richness and liveliness. This diversity can be observed in space and within the psyche (Özkum, 2011; Bayhan, 2018).

According to the Turkish Language Association (TDK, 2023), natural lighting can be defined as a form of lighting that is integrated with nature, while it can be said to be the opposite of artificial lighting. Natural lighting is fundamentally achieved by distributing daylight in the most effective way, and is provided in the space through openings such as windows, doors and roof lights. A natural lighting scheme that works well will, to a very large extent, eliminate the need for lighting during daylight hours altogether, including regardless of the building material. Natural lighting—which has been used since ancient times to the present day—is seen most impressively in the Pantheon Temple in Rome. The only lighting available in the building was a circular opening at the top. In modern architecture Louis Kahn's Bangladesh Parliament Building was designed with the intention of bringing natural lighting into the space. Adequate natural lighting enhances visual comfort as users will become aware of their surroundings and

be able to move about. Similarly, a good function of natural light will reduce the use of artificial lighting by about 70% and reduce energy use. It is significant, considering lighting uses 25% of a daily energy use, to note attention to natural lighting (Etli, 2013).

Sunlight is a form of directional light that will vary in direction throughout the day, creates sharp and definite shadows, and shifts from orange to white in tone. The sun, as a natural light source, produces light with a colour temperature of about 1800 K during sunrise and sunset and between 5000–5800 K at midday. The primary benefit of using a natural form of lighting is that it allows us to see things in their true texture, warmth, and purest form (Özkum, 2011). Example of natural lighting, shown in Figure 2.

Figure 2. Natural Lighting (Personal Archive)

In designing an architectural space, the atmosphere of the location is as critical to the light you are layering into the space. Based on the orientation of daylight on the surface of the earth, and depending on the latitude and longitude of the specific location, spaces are exposed to different qualities of light and quantity of light, which directly impact the identity of the space. Therefore, in space design, the intended use of the buildings, where you are located, the climate and seasonal conditions must be considered. Daylight in architecture is important, both in terms of aesthetics and function.

2.2.2. Artificial Lighting

Artificial lighting refers to electrical systems with artificial light sources designed to illuminate spaces without relying on daylight. Such provided lighting utilizes a range of light sources, including lamps, LED replacements, fluorescent lamps, and bulbs. In concerning the lighting process created in these spaces, artificial lighting is employed in environments deemed inadequate for daylight provision. In indoor spaces where daylight lighting and distribution are limited, artificial lighting technology has sought to create user preference in a wide range of factors relating to human psychology, including light intensity and colour temperature.

Artificial light has become an integral part of modern existence for animal and plant life and overarching production solutions that improve functionality across a multitude of areas of production. Advances in technology have brought about a notably more efficient, longer-lasting, and environmentally sounding artificial lighting system application. Such applications

are used in spaces with poor daylight or underground (tunnels, basements, caves, etc.), spaces where an improved productive working environment is required, garden lighting, ornamental/decoration lighting that can add aesthetically pleasant enhancements to art or in built form to interiors, stage lighting used in concerts, affected theatres, and alternative event events, health and therapeutic applications, lighting and artificial lighting application in the entertainment industry, advertising - most recently including the recent advancements in visual arts through new technologies. Figure 3 shows a visual diagram of artificial lighting.

Figure 3. Artificial Lighting (Personal Archive)

As Le Corbusier stated in 2000, 'Architecture is the appropriate and beautiful game of volumes assembled by light. Everything around us, is a unity, with light and shadow.' (Fitoz, 2002)

Methods of Utilising Daylight in Buildings

Daylight Openings in Buildings

Daylight openings are openings in the building envelope through windows or roofs that allow daylight to be brought into the indoor space. These openings maximize both visual comfort and energy efficiency. Several techniques have emerged that encourage effective daylight use, such as light shelves, light tubes, and various types of glass are now more commonplace than before.

When designing day lighting systems, it is important to consider the location of the building, including the geographical and climatic aspects. Moreover, considering the elements of the design techniques that will be used will be useful in this assessment. (Yıldırım, 2021; Erikli, 2021)

Windows

Buildings are sleeves designed to insulate humans from outside conditions. However, humans need light, air and also interaction with the environment in order to exist on this planet. In that sense, windows that started out as structural elements have transformed into elements with

infrastructural qualities without prominent considerations in design, due to technology. (Karalurt, 2008).

Windows are apertures in the exterior walls of buildings that admit light, air, and views into the inner space. Supported by various components, such as frames, glass, and curtains, windows also perform functions of insulation, security, and connecting areas (Bulut, 2001). Windows, which are one of the primary elements of natural lighting design, are placed according to climate and light direction (Yener, 2008; Yıldırım, 2021; Erikli, 2021).

Windows at eye level, located at the eye level of a sitting or standing person, provide a pleasant view of the outdoor scenery. Windows at eye level enhance the visual interaction with nature which improves user performance, relaxes the eye muscles, and provides psychological relief. Typically preferred in living areas, windows at eye level provide support for natural light to be distributed homogeneously throughout the space. Its brightness level may be high in the areas proximate to the window while being lower in the depths of the space. Therefore, proper shading elements must be designed to minimize the negative effects of direct sunlight. The sun's changing position throughout the day and the year is a determining factor for developing shading strategies for the window orientation as required for energy efficiency and higher user comfort (Yener, 2008).

To sum up, windows are not just an opening letting in light and air, but also significant elements to integrate light and air and aesthetics and energy performance in architecture. Thoughtfully integrated, windows can improve the quality of a space and comfort of the user. Figure 4 represents the window appearance and Figure 5 represents the plan and section distribution of the window.

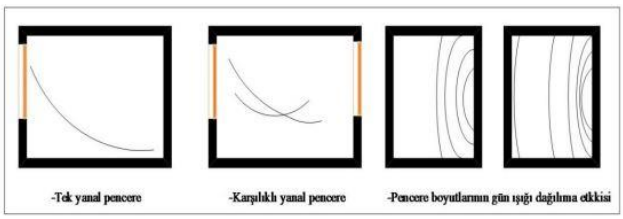

Figure 4-5. Window appearance and daylight distribution in plan and section (Özhancı & Özyılmaz, 2013)

Roof Skylights

A roof skylight refers to a horizontal or sloped opening in roofs of buildings; this includes openings which are continuous, lanterns, as well as sloped windows meant to bring daylight aesthetically into spaces from above. Their primary purpose is to not only bring daylight through above as well as allow the light to be modulated to ensure the best use of natural day-lighting (Tekbıyık, 2018).

Roof skylights are often placed on sloped roofs and are common in the form of single transparent openings in saw tooth forms. The daylight and its distribution to the aesthetic space depend both on the size and placement of the skylights. While certainly common and seen in industrial spaces, they're also a common option in spaces with large volume, such as schools, hospitals, and the lobby of a building. In some designs roof skylights can only provide natural lighting, whereas some roof skylights can also provide a natural ventilation option by contributing to clean air-flow (Tekbıyık, 2018).

Alternatively, skylights are sections that have glazing on all sides to provide light from multiple directions, but they may contribute to glare because of these qualities. In sunnier climatic regions, skylights that are orientated north-south may be better than horizontal openings. In contrast, east-west oriented skylights provide a more balanced amount of light throughout the day. (Tekbıyık, 2018). An example of a roof skylight is shown in Figure 6.

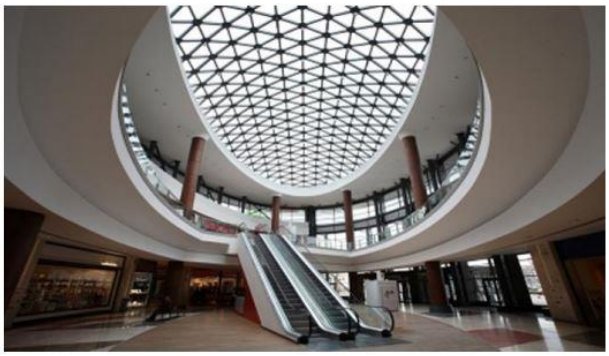

Figure 6. Continuous roof skylights example (Tekbıyık, 2018)

Advanced (Contemporary) Daylighting Systems

Light shelves

A light shelf consists of a horizontal architectural feature typically situated on the interior or exterior sides of the window and is intended to inhibit daylight or direct daylight onto the ceiling. The light shelf system could be designed to be part of the façade or constructed as a retrofitted element free-standing on top of the façade. Light shelves can mitigate the harshness of sunlight on areas immediately near a window while reflecting light up to the ceiling for illumination across the room allowing daylight to be utilized effectively. By manipulating and distributing sunlight, the daylight level at the edge of the window is lowered while a higher daylight level is achieved in the depth of the room. This also yields homogenized light distribution across the space as illustrated in Figure 7 (Tekbıyık, 2018).

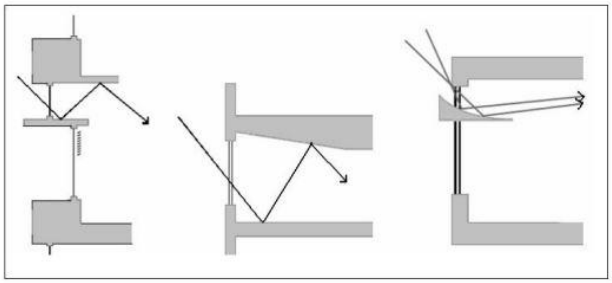

Figure 7. Bringing natural light into the space (Tekbıyık, 2018)

It is acknowledged that the angle of sunlight, especially areas that face north from the south, enables better control of daylight; creating a significant benefit in terms of architectural design. In addition, the use of atriums along with daylight from skylights within the roof are also significant in bringing natural daylight into a space and providing passive cooling; promoting the maximum utilisation of daylight in the space (Tekbıyık, 2018). For an illustration of this condition see Figure 8.

Figure 8. Shading elements applied to the transparent upper coverings of atriums (Tekbıyık, 2018)

Light Tubes

Light tubes are systems designed to facilitate the entry of daylight through openings in the roof that can be transmitted to the interior space using pipe-shaped elements covered with reflective materials at some angles. These systems, called light tubes or sun tubes, are particularly effective in public buildings and spaces where direct daylight is unable to reach. They provide daylight equally in the space to ensure balanced lighting of the space in open-plan offices. Light tubes also reduce reliance on artificial lighting, thus providing energy consumption savings and improved energy efficiency (Tekbıyık, 2018). An example of this is illustrated in Figure 9.

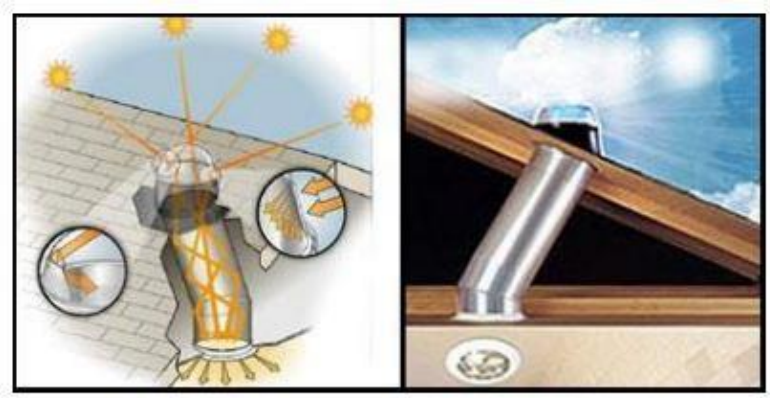

Figure 9. Light Tube (Tekbıyık, 2018)

Architectural Works By Le Corbusier, Tadao Ando and Renzo Piano

A key reason for choosing architects like Le Corbusier, Tadao Ando, and Renon Piano is because they have derived innovative principles from their focus on daylight efficiency in their architectural work. Le Corbusier, Tadao Ando, and Renzo Piano are widely recognised as leading architects of the modern era, using daylight design for symbolic and functional purposes. Both Le Corbusier and Tadao Ando created projects that articulated a holistic design

by using daylight in a way that combined beauty and function. These examples were a rich process of architecture, which developed different modalities in regard to climate conditions, building materials and the effects of daylight in interior spaces. The examination of the design principles of Le Corbusier, Tadao Ando, and Renzo Piano aims to give a different view of modern architecture and their effective use of daylight in the process of design.

Le Corbusier

Le Corbusier regards daylight as an ongoing cycle of sunrise and sunset, which he characterizes as one of the basic determinants of life. In line with this viewpoint, he employs certain design parameters to provide an effective use of daylight in his early designs, such as the Villa Falet, Villa Stotzer, Villa Jaquemet, Villa Jeanneret-Perret and Villa Favre-Jacot design cases. These approaches can be condensed into the following parameters:

- Maximize the potential of natural light: Use maximum openings on the south side; Design rooms that can collect daylight from one or two sides;
- Use L shaped corner windows, to maximize daylight entry from different angles;
- Use narrow long rectangular windows in horizontal bands;
- Use leaf shaped decorative window;
- Provide shade by using wide overhang;
- Use glass doors to enhance daylight indoor,
- Use courtyards and roof gardens to extend daylight;
- Use windows, fitted in circular projections, create light-shadow contrasts in to the interior space.

The examples of villa Le Corbusier has shown his architectural approach of daylight as a functional and aesthetic aspect (Kaya et al., 2021). The building is shown in Figure 10.

Figure 10. Le Corbusie Villas (Kaya vd., 2021)

Le Corbusier Villa Savoye

In the year 1928, Corbusier designed a vacation house for a client in the countryside close to the town called Poissy in France. This vacation house is called Villa Savoye, and it is designed in a way that offered Corbusier the opportunity to express his 'Five Principles' of modern architecture in a building. The first principle is that the project is elevated off the ground with the use of pilotis, which are columns. Second, the non-load bearing walls are true to the plan's design. Third, the principle of a load bearing structure that is independent of the façade walls. Fourth, the inclusion of ribbon windows that help illumination the building. And finally the fifth principle, the flat roof above that embraces both the building and garden. The plan of the house is designed on a square grid system and the upper floor is rectangular in shape. Overall, the building is 480 square metres of usable space and primarily uses reinforced concrete, plus the stair cases to the upper floor are circular (Varol, 2019).

Repeated ribbon windows were implemented in Villa Savoye, and open courtyards and concealed wall apertures also helped create spatial depth. The upper floor skylight and garden provide access to natural light to the interior. The light passing through the windows diffuses through the space, creating the light shelf effect and increasing spatial dynamism. Light tubes were not used. Villa Savoye is shown in Figure 11 (Kaya et al., 2021).

Figure 11. Le Corbusier Villa Savoye (Kaya et al., 2021)

La Tourette Monastery

La Tourette Monastery, situated in Lyon, France, was designed to accommodate 1,000 people. The structure consists of 100 cells, a library, a roof garden, a church, and classrooms. The monastery demonstrates the principles of Corbusier's five points of modern architecture. One principle is the structure being lifted off the ground via pilotis. The façade of the structure is made up of ribbon windows, a green roof, and clerestory windows.

The plan is a U-shaped mass that encircles the courtyard. The rectangular shape is supported by reinforced concrete load bearing elements and consists of glass surfaces with in its façade. The courtyard allows for a direct link between the outside world and the church (Varol, 2019). The adobe employs daylight and color, creating a spirit like atmosphere. The building features horizontal light shelf like openings and daylight is directed and carried to the lower spaces with upper level skylights. This method serves as a possible method, similar to the light tube processes seen in Le Corbusier.

Figure 12-13. Le Corbusier's La Tourette Monastery (Source: Varol, 2019)

Tadao Ando Azuma House

The Azuma House, also known as the Row House, was built in Osaka in 1976 and is an architectural work by Japanese architect Tadao Ando that represents a unique aspect of Japanese architecture. The two-story reinforced concrete structure is organized in three separate elements within an urban context: the front element, the courtyard, which is open to the sky, and the back element.

Ando's approach to daylight in his architectural designs is unique in terms of sparse and controlled application of daylight within his spaces. The controlled treatment of daylight is preferred for the interior atmosphere and to add richness to the space (Cengiz, 2022). The Azuma House, influenced by Japanese culture and Zen Buddhism, is intended to create an opportunity between humans and nature. In this cultural change, large glass openings were designed to allow daylight into the interior of the structure (Kaya et al, 2021).

The light courtyard, located toward the middle of the structure, allows natural daylight to enter the interior space without difficulty. Together with the glass openings on the opposite building facade, the courtyard creates an opportunity for daylight to enter deep into the space. Matt surfaces reflecting daylight can create a unique light-shadow relationship in the interior (Cengiz, 2022). The images of Azuma House by Tadao Ando in Figures 14-15. There isn't any skylight or light shelf in the building's interior, but the daylight enters vertically from the courtyard, creating a natural 'light tube effect' in the space.

Figure 14-15. Tadao Ando Azuma House. (Cengiz, 2022)

Tadao Ando Koshino House

The Koshino House, which was designed by Tadao Ando, is located in the city of Ashiya, Japan. The building is constructed on a slope and is made entirely of concrete. The Koshino House is a building that is a part of the landscape and is located in the rural countryside. (Kaya et al., 2021) The design makes extensive use of long and narrow windows that through the west façade create a contrast of light, with illumination and shadow filling the interior space. The openings in the roof take advantage of daylight entry into the building. The roof opening provides an aesthetic appearance to the design of the structure. (Cengiz, 2022) The Koshino House, designed by Tadao Ando, allows natural light to come to the interior by using a skylight that suspends between the concrete walls. In some instances, Tadao Ando's Koshino House has resulted in light that strikes and confronts the wall, creating a shelf-like effect. This is shown in Figures 16-17. The tube effect of light is observed at the ceiling height, where the light approaches downward.

Figure 16-17. Tadao Ando Koshino House (Cengiz, 2022)

Chichu Art Museum (Naoshima, 2004)

In 2004, architect Tadao Ando created an art museum on Naoshima Island in Japan that rests under a slope and has a total area of 2,300 m². The architectural approach behind this design seeks an interface that integrates nature. The project integrates views, light, and airflow into the design. The roof and windows are designed to allow natural light to enter the interior space. The underground aspect of the design also responds to the environmental aspects of the site. This is emphasized through the minimal use of materials and the use of natural materials providing harmony with the environment. The museum is designed using square, hexagonal, and triangular forms. The idea behind the design was to create varied impressions in the interior spaces (Park & Kang, 2021).

The most notable characteristic of the museum is the intention and moderation in the use of natural light. The skylights that let light through the upper ceiling of the gallery and reflective surfaces that help diffuse light across the spaces have made the use of the “light shelf” possible.

Figure 18. Chichu Art Museum, (https://avauntmagazine.com/chichu-art-museum)/

Figure 19. Chichu Art Museum, (Park & Kang, 2021)

In certain areas of the museum, significant openings function as 'light tubes'. Especially in the cylindrical voids with high ceiling heights, sunlight that comes from the ceiling helps ensure that the light is distributed evenly in the space (Park & Kang, 2021). Pictures of the Chichu Art Museum can be found in Figure 18 and Figure 19.

California Academy of Sciences, Renzo Piano, 1997, San Francisco, USA

Renzo Piano created the California Academy of Sciences in 1997, located in San Francisco, United States. The project utilized sustainable design solutions such as a natural ventilation system, green roofs, solar panels, recycled materials, aquarium, exhibit spaces, and planetarium (Özhan, 2017). The building features two domes with a total area of 3,500 m² of natural green cover. The round lighting elements hung on the domes work similarly to light tubes (Figure 20).

The building also has a terrace garden, as well as daylight, and additionally employs a rainwater harvesting system, further increasing energy efficiency. The full/empty surface relationships are particularly impactful in the overall design of the project. Renzo Piano utilized circular transparent glass openings in the dome and roof sections of the design to provide natural light to the internal spaces. The light entering the spaces through these means allows sunlight to travel in the interior spaces from the offices to the aquarium and rainforest, producing a light tube effect (Gürel & Eryılmaz, 2021).

Both the glass surfaces and the metal panels of the façade and sun-shading elements function as light shelves. The design of the system reflects daylight from the sky down to the ceiling on the interior, allowing for an equal distribution of daylighting internally.

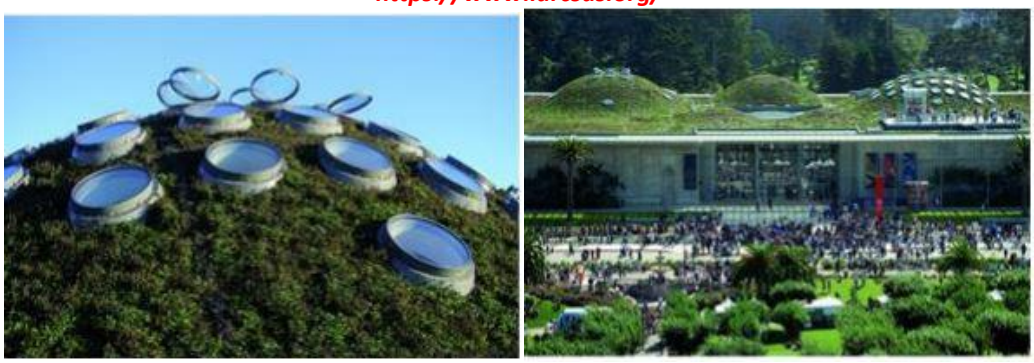

Figure 20. California Bilim Akademisi, Renzo Piano, 1997, San Francisco, ABD (Gürel& Eryılmaz, 2021)

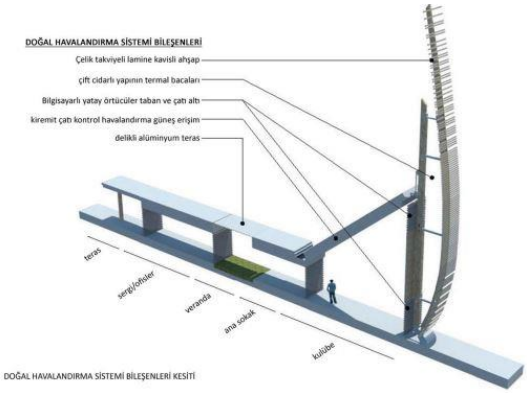
Jean-Marie Tjibaou Cultural Centre (New Caledonia, 1998)



Renzo Piano constructed the Jean-Marie Tjibaou Cultural Centre in New Caledonia in 1988, designed as large huts arranged with a settlement pattern within the natural landscape. The centre is designed with shadovoltaic glass shutters that introduce daylight to the interior in a controlled manner, as well as introduce natural ventilation while providing energy savings by reducing heat loss during winter. These shadovoltaic glass shutters contribute to the sustainability target of reducing energy usage overall.

The pavilions are designed to provide both natural daylight and natural ventilation to the interior, utilizing sloped roof details and panel systems. The roof openings supply natural daylighting to the interior, but also seem to diffuse natural daylighting in a controlled way throughout the space. The openings also function as thermal chimneys for thermal control of the conditioned interior space. Shown in Figure 21.

Figure 21. Jean-Marie Tjibaou Cultural Centre, New Caledonia, 1998 (Bedir & Mayuk, 2019)

The systems of the Jean-Marie Tjibaou Cultural Centre rely upon contemporary construction techniques but are intended to be sustainable and energy efficient. The building employs skylights, light shelves and light tube effects to provide greater visual comfort through the optimized use of daylight in the interior space.

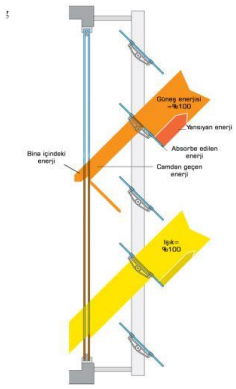


Figure 22. Facade Detail Cut, (Bedir & Mayuk, 2019) **Figure 23.** Shadovoltaic Shutter Cross-section, (Bedir & Mayuk, 2019)

Kimbell Art Museum Pavilion (Fort Worth, Texas, 2013)

Renzo Piano's architecture incorporates light as not just an aspect of a project, but part of the essence of the place. a strong illustration of this is the Kimbell Art Museum Pavilion project in Fort Worth Texas. Piano considered Louis Kahn's Kimbell Art Museum building from 1972, a concrete vaulted and dimly lit building, and designed an adjacent one that incorporates transparency and engages with daylight (ArchDaily).

The new Pavilion portion contains gallery spaces, classrooms, studio spaces, an auditorium, library and car park. In the gallery spaces, the roof system of the Kimbell Pavilion is made of tensioned fabric surfaces with incorporated wooden beams, glass panels and aluminium louvers which allow controlled daylight within the space. The daylight provided by this system can be supplemented with artificial lighting located behind the fabric walls when needed.

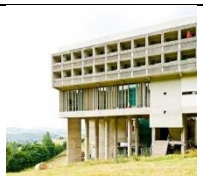
Glass panels supported by steel make up the roof system of the building, which is designed as an integrated part of the sunshades. This provides the roof with the ability to transfer daylight into the building while it has a climate control strategy that acts as an energy saving strategy. The panels of fabric on the surface of the roof act as a light shelf allowing light in to the interior evenly and gently.

The building does not have a light tube system but, like a light tube system, the vertical daylight transmission of the roof allows for reflected surfaces to reflect day light ultimately into the space. The use of light coloured wood, concrete and glass surfaces creates a better reflection of light within the space. Connected to Piano's design is landscape design and the landscape design affords the architectural integrity of the building (ArchDaily)

Figure 24. Kimbell Art Museum Pavilion Fort Worth, Texas, 2013 (ArchDaily)

Figure 25. Kimbell Art Museum Pavilion Fort Worth, Texas, 2013 (ArchDaily)

This research looks at nine significant works by important architects of modern architecture. This includes Villa Savoye, Villa Jaquemet, La Tourette Monastery, Azuma House, Koshino House, Chichu Art Museum, California Academy of Sciences, Jean-Marie Tjibaou Cultural Centre, and Kimbell Art Museum. The window, skylight, light tube, and light shelf systems shown to be effective in allowing the emergence of natural light in the space were examined in these nine structures.



The research concluded that the architect used a different relationship to light. At Villa Savoye by Le Corbusier, the architect ensured intense daylight streamed into the interior of the house via long ribbon windows, enclosed courtyards, and roof gardens. In Villa Savoye, the openings used in the staircases and ramps provided diffuse light for the interior space without a direct light tube effect. While light shelves were not used in Villa Savoye, the use of white surfaces and the ceiling expanded strongly for an indirect system of diffusing light. At Villa Jaquemet, there was purely façade windows admitting direct light into the interior, while all three artificial lighting systems (skylights, light tubes, light shelves) were not used in the house. At La Tourette Monastery, the architect used windows and skylights to allow in natural light. The indirect flow of light into the spaces was analogous to light shelf and light tube systems.

Tadao Ando's residential projects exhibit surfaces that utilize expansive glass openings to create a pronounced light-shadow interplay inside space. Rooftop openings also possess an aesthetic function in the space. The window system is typical in various works of Ando's including Koshino House, Azuma House and Chichu Art Museum. Koshino House and Chichu Art Museum also have skylights in their roofs. In Chichu Art Museum, light entering the building diffuses into the interior, demonstrating a principle of a light shelf with reflective surfaces. In this case, however, there is no particular system as a light tube. Koshino House demonstrates interior light reflected off a wall to create a light shelf appearance; also, daylight coming from an adjacent courtyard penetrated the interior vertically establishing a natural light tube appearance (Futagawa, 1991).

Projects such as the California Academy of Sciences, Jean-Marie Tjibaou Cultural Centre and the Kimbell Art Museum, designed by Renzo Piano reveal the simultaneous use of window system, skylight, light shelves, and light tube systems. These building designs capture the same goal of providing controlled amounts of natural light into the space while supporting energy efficiency and climatic comfort (ArchDaily, 2014). A comparative analysis of the architects' works is focused on in Table 1.

To summarize, most of the surveyed buildings have made use of natural lighting elements such as large glass windows, skylights, light shelves, light tubes and light wells. Nevertheless, daylight was perceived not merely as a technical lighting element but a design element that also enhances the aesthetic and symbolic values of the space.

Table 1. Analysis of architectural works by Le Corbusier, Tadao Ando and Steven Holl

Name of the Building	Location and Year	Projects	Window	Skylight	Light Shelves	Light Tubes
Villa Savoye	France 1931		+	+	+	
Villa Jaqumel	New York 2011–2017		+	+		
LaTourette Manastırı	France		+	+	+	+
Koshino House	Japonya 1984-1985		+	+	+	+

Azuma House	Japonya 1993		+			+
ChichuArt Museum	2004, Japonya		+	+	+	
California Academy of Sciences	1997, San Francisco, ABD		+	+	+	+
JeanMarie Tjibaou	1988, Yeni Kalendoya		+	+	+	+
Kimbell Art Museum	Fort Worth, Texas,		+	+	+	+

Conclusion

Daylight is now a defining criterion at every scale, from massing to architectural design, to interior organisation to the greater design. The relationship between natural daylight, the building envelope, opening ratios, material qualities and facade components contributes to a significant relationship between these critically deliberated design elements. Climate-based location will signify the importance of natural daylight controls as a part of project-based work. If considering ultraviolet rays of daylight during hot midday hours, passive design and structural interventions draw interaction from many strong design structural components seen in courtyards, eaves and grilles used in windows and walls.

Proper manipulation of natural light promotes visual comfort in a space and satisfies and nurtures the psychological and physiological needs of users. Daylight enhances mental and psychological balance with human biological clock through vitality, dynamism and richness in space. The use of daylight as a symbolic architectural element in religious, cultural and social buildings through history suggest that light is more than an architectural element in light; it is an architectural language of universal significance.

The advancements in technology have recently opened possibilities for the efficient and sustainable use of daylight. Smart facade concepts, strategic shading strategies and consideration in openings permit daylight to be delivered to every point within the building in

an efficient manner. These technological advancements will undoubtedly continue to make daylight a design variable in architecture of the future.

Daylight is not just an opportunity for illumination, but rather a means of design that expresses aesthetic, symbolic and functional values of a space. The intentional and thoughtful use of light will play an intricate role in the development of environmentally, socially and economically sustainable future buildings and spaces - both on individual scales and in urban levels.

Acknowledgements and Information Note

I would like to thank my valuable advisor Dr. Halil SEVİM, Assistant Professor, who shared his knowledge and experience with me in my undergraduate and postgraduate education and never withheld his academic support he provided me with knowledge and experience of the thesis process, as well as thanks to faculty members of the Faculty of Fine Arts at KTO Karatay University; I am grateful for everything.

I wish to express my deepest gratitude to my dear family, who have always supported me throughout my educational journey and made me feel that I am always with their presence by my side.

Abstract

The conversion of buildings with different functions into museums constitutes a significant field of study from architectural, cultural, and functional perspectives. Today, adaptive reuse practices contribute not only to the preservation of the historical identity of buildings but also to meeting contemporary functional needs. In this process, beyond the architectural features and spatial qualities of the building, the development of lighting solutions that support its new function plays a critical role. Particularly in buildings converted into museums, lighting is a decisive factor in terms of artifact conservation, the perceptibility of exhibition spaces, and the enrichment of visitor experience. Lighting design varies depending on the original characteristics of the building and the functional context to which it is adapted. In this regard, examples of military, religious, educational, administrative, residential, and industrial buildings converted into museums constitute the main focus of this study. Within the scope of the research, selected cases from both national and international contexts were classified according to their functional transformation and evaluated in terms of natural and artificial lighting systems. Data obtained through extensive literature review were systematically analyzed by applying the SWOT analysis method for each building type. These analyses reveal the strengths and weaknesses, as well as the opportunities and threats associated with the use of lighting in the adaptive reuse process. The findings demonstrate that in projects where different building typologies are transformed into museums, lighting is not merely a technical requirement but also a strategic design element that shapes the perceptual, cultural, and aesthetic values of space. In this respect, the study aims to provide guiding recommendations for the development of lighting strategies in future adaptive reuse projects.

Keywords: Lighting, re-functioning, cultural buildings, museum

1. Introduction

The inability to sustain a building's original function due to environmental, functional, or economic reasons necessitates its reevaluation for a different purpose. Adaptive reuse (refunctioning) not only preserves the existing building stock but also reduces negative impacts on the natural environment, generates economic benefits, and contributes to cultural and historical continuity (Aydın & Yaldız, 2010). For this process to be conducted effectively, the spatial qualities and physical characteristics of the building must be carefully analyzed. Particularly in buildings converted into museums, lighting constitutes a critical design parameter in terms of both the success of the exhibition function and the effective use of the space.

Throughout history, adaptive reuse has been one of the most frequently employed methods for preserving various types of buildings and transmitting them to future generations (Kaymakçı, 2022). Through functional transformation, buildings gain extended lifespans while simultaneously strengthening their significance in collective memory (İslamoğlu, 2018). In this

context, museums stand out as institutions that preserve and exhibit works of culture, art, science, and history (Özcan & Çağlar, 2020). Thus, buildings that have lost their original function are not only preserved through adaptive reuse but also become significant focal points that contribute to the touristic and cultural identity of cities (Kaymakçı, 2022).

At this point, lighting emerges as an element that both supports the new function of the building and shapes the visitor experience. Architect Tadao Ando's statement, "In all my works, light is an important control element" (ArchDaily, 2011), highlights the determining role of light in spatial perception. Human beings are constantly interacting with factors such as light, color, sound, temperature, and scent in their environments. Among these, light is the fundamental component of visual perception and the central element of lighting design (Okutan, 2012). The International Commission on Illumination (CIE) defines lighting as "the application of light to ensure the proper perception of the environment and objects" (Ünver, 2002, as cited in Öksüz, 2024). Hence, lighting is not merely a technical necessity but also a strategic design tool that supports the aesthetic, functional, and psychological dimensions of space (Kasap, 2016; Öksüz, 2024).

The multifaceted impact of lighting is directly related to the types of light used. Based on their sources, lighting systems are classified as natural or artificial; based on their purposes, as physiological or decorative; and according to the method of light distribution, as direct, semi-direct, semi-indirect, indirect, or homogeneous (Kasap, 2016; Öksüz, 2024). Natural lighting, with its dynamic structure dependent on sunlight, enables the most realistic perception of objects and spaces, while artificial lighting provides controllable and flexible illumination at the desired time and intensity. Therefore, balancing natural and artificial light in museums is of critical importance for both the conservation of artifacts and the enhancement of the visitor experience.

In the early stages of museology, artifacts were displayed under intense light; however, it was later understood that such exposure could cause irreversible damage to the objects. Today, controlled artificial lighting systems have become prominent for the purpose of artifact conservation (Yöndem & Akyol, 2017). In this context, four fundamental principles of museum lighting have been identified: (1) preventing glare to ensure clear visual perception, (2) protecting artworks from harmful radiation, (3) supplementing daylight with artificial lighting, and (4) revealing the formal, chromatic, and material properties of objects (Kurtay et al., 2003).

These principles become particularly sensitive in historical buildings. In the process of adaptive reuse, lighting design is expected to be consistent with the original character of the structure. Factors such as the building's function, volume, orientation, window openings, interior materials, and environmental conditions (light levels, surrounding natural or artificial barriers) should be evaluated together (Öksüz, 2024). In this way, lighting becomes an integrated element that both preserves the historical atmosphere of the building and supports its exhibition function.

Various types of buildings around the world and in Turkey have been converted into museums. However, these buildings have generally been examined from architectural or functional perspectives, while comparative studies focusing specifically on lighting remain limited. Although studies such as those by Çetin (2021) and Akyürek (2022) have made valuable contributions in certain respects, no comprehensive research has systematically compared different building types in terms of lighting. Therefore, this study examines museums converted from military, religious, educational, governmental, residential, and industrial structures,

analyzing the functional effects of existing and added lighting systems through the SWOT analysis method, identifying their strengths and weaknesses, and developing recommendations for future applications.

2. Materials and Methods

In this study, various building typologies that have been adaptively reused to serve as museums were evaluated based on the natural and artificial lighting strategies employed in their exhibition spaces. The aim is to present a comparative analysis of the lighting solutions adopted by buildings with different historical and spatial characteristics after being transformed into museums. In doing so, the study discusses the role of lighting in maintaining the balance between preservation and utilization, as well as in shaping the visitor experience.

Three main criteria were adopted for the selection of case studies:

- Diversity: Examination of different typologies with distinct original functions, such as military, religious, educational, governmental, residential, and industrial buildings,
- Accessibility: Focus on buildings that are documented in the literature or whose visual and technical data are available,
- Lighting Solutions: Inclusion of cases where both natural and artificial lighting applications in exhibition spaces could be observed.

Based on these criteria, the selected case studies were first introduced in relation to their historical background and architectural features, and subsequently classified according to the types of lighting used in their exhibition areas. During the analysis, factors such as the integration of daylight, window and roof openings, types of artificial lighting (e.g., spotlights, LED systems, track lighting), and their effects on exhibited artifacts were taken into consideration. These evaluations constitute the first phase of the research. In the second phase, a SWOT analysis was conducted for each building group, identifying their strengths, weaknesses, opportunities, and threats. Accordingly, the study not only examines the technical aspects of lighting design, but also evaluates its impact on visitor experience, spatial perception, and artifact conservation in a holistic manner. The buildings examined in this research are presented in Table 1, which classifies the museums according to their original functional typologies. This classification facilitates the systematic presentation of the analyses in the subsequent sections and enables comparative evaluations among different building types.

Table 1. Buildings Refunctioned as Museums

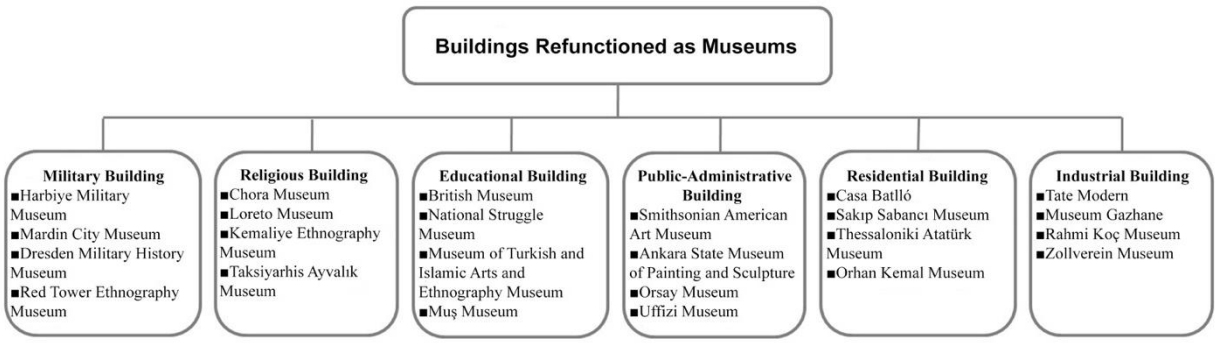

Table 1 illustrates the scope of the selected examples included in this study. According to the table, although each group of buildings possesses distinct spatial characteristics, lighting

emerges as one of the most critical design parameters in the process of transformation into a museum. In the following sections, the buildings listed in the table are examined individually in the context of natural and artificial lighting strategies, and their strengths and weaknesses are discussed through SWOT analyses.

3. Findings and Discussion

In this section, examples of buildings that have been adaptively reused as museums—originally functioning as military, religious, educational, governmental, residential, and industrial structures—are analyzed in terms of the use of artificial and natural lighting within their interior exhibition spaces.

3.1. Examples of Buildings Refunctioned from Military Structures into Museums

This subsection examines the lighting design elements used in the interior exhibition areas of buildings that have been refunctioned from military structures into museums (Table 2).

Harbiye Military Museum (Harbiye School): The building complex of the Harbiye Military Museum, originally known as Harbiye Mektebi, was constructed in successive phases between 1844 and 1893. Following a restoration process initiated in 1967, the building was opened as a museum in 1993 (Erkal, 2020; Çoruhlu, 1994; Zorlu, 2021). Natural light enters the interior through courtyard windows and roof skylights, while the exhibition areas utilize recessed and track spotlights, LED lighting within display cases, and accent lighting (Figure 1). However, reflections are observed on some display case glasses, and the showcase lighting systems operate on a timed basis, activated by visitor-controlled push buttons (Doğruer, 2020).

Figure 1. Exhibition Areas of the Harbiye Military Museum (Askerî Müze, 2014)

Sakıp Sabancı Mardin City Museum (Mardin Barracks): The barracks, dating from 1887–1891, were converted into a museum in 2009 following a comprehensive restoration (Düzenli & Düzenli, 2020). During the restoration, a controlled exhibition design was implemented using a suspended ceiling and spot lighting, while natural light was maintained at a supportive level (Figure 2).

Figure 2. Exhibition Spaces of the Sakıp Sabancı Mardin City Museum (Author's personal archive, 2025)

Dresden Military History Museum (Armory): The armory, constructed between 1873 and 1876, was reopened in 2011 with Libeskind's extension (Arslan, 2023; Özalp & Halaç, 2024). Large arched windows introduce natural light, while ceiling-mounted track spotlights allow flexible focusing, and linear LEDs provide general illumination (Figure 3).

Figure 3. Exhibition Spaces of the Dresden Military History Museum (Libeskind, 2011; ArchDaily, 2011)

Kızılkule Ethnography Museum (Watchtower): The tower, dating back to 1226, was converted into an ethnography museum following its restoration between 1951 and 1953 (Ticaret & Odası, 2016; Kültür Portalı, 2013). Limited daylight enters through niche windows, while light sources placed at the base of the walls provide texture emphasis and directional guidance. Long-term preservation considerations should be applied to objects exposed to direct sunlight (Figure 4).

Figure 4. Exhibition Spaces of the Kızılkule Ethnography Museum (Arkeogezgin, 2017)

Table 2 presents examples of former military buildings converted into museums, summarizing their functional history, current use, and interior lighting solutions (natural/artificial).

Table 2. Comparative Summary of Military Buildings Converted into Museums

CONVERTED BUILDING TYPE		MILITARY BUILDINGS			
BUILDING NAME		Harbiye Military Museum	Sakıp Sabancı Mardin City Museum	Dresden Military History Museum	Kızılkule Ethnography Museum
CONSTRUCTION YEAR		1846	1891	1876	1226
CONVERSİON YEAR		1993	2009	1897	1953
LOCATION		İstanbul/Turkey	Mardin/ Turkey	Dresden/Germany	Antalya/ Turkey
ORIGINAL FUNCTION		Military School	Cavalry Barracks	Armory	Watchtower
CURRENT FUNCTION		Military Museum	Mardin City Museum	Military History Museum	Ethnography Museum
LIGHTING	ARTIFICIAL LIGHTING	-Recessed spotlights -Movable spotlights -LED lights	-Spotlights	-Track spotlights - Linear fixtures	-Fixed spotlights
	NATURAL LIGHTING	Daylight is incorporated through windows and ceiling skylights and is supplemented by artificial lighting.	Daylight is incorporated through windows and is supplemented by artificial lighting.	Daylight is incorporated through windows and is supplemented by artificial lighting.	Daylight is incorporated through windows and is supplemented by artificial lighting.

According to Table 2, military-origin buildings, despite differences in period and morphology, tend to adopt similar lighting principles in their conversion into museums. In the artificial lighting layer, track, recessed, and fixed spotlights combined with linear LED solutions are predominant; this approach enables object-focused emphasis and flexible staging. Natural light is mostly introduced through windows and, where applicable, ceiling skylights, and is systematically supplemented by artificial lighting to maintain stable exhibition conditions. Considering the "Construction Year" together with the "Conversion Year" indicates that design decisions are influenced by the balance between preservation requirements and the integration of contemporary fixtures. In massive, low-opening typologies (e.g., towers), limited daylight results in the prominence of grazing light and localized accentuation, whereas in wide-span buildings such as barracks or armories, selective spot lighting is applied over a base of homogeneous daylight. Overall, the trend suggests that a hybrid (natural + artificial) lighting scheme enhances exhibition legibility while supporting the building's original atmosphere.

3.2. Examples of Buildings Converted from Religious Structures into Museums

This section examines the lighting elements used in the interior exhibition spaces of buildings that have been repurposed from religious structures into museums (Table 3).

Chora Museum (Church): The Chora Church, which transitioned from a monastic structure to a mosque, was converted into a museum following restoration that began in 1948 and was completed in 1958 (müzeler.org., n.d.). In this museum, where the historic building itself is also exhibited, general illumination is provided with low-color-temperature lighting, while the frescoes are illuminated with high color-rendering, warm spotlights. These are filtered and directed to ensure the long-term preservation of the paints (Önsoy, 2002) (Figure 5).

Figure 5. Chora Museum (Kariye Camii, t.y.)

Loreto Museum (Church): The construction of the basilica began in 1468 (Bellitalie, 2021). In the church lighting design, spatial elements were emphasized through varying light levels and color temperatures; the ceiling was highlighted with daylight-like illumination, while bright objects were lit in a way that minimized glare differences (Figure 6). In the building, which has been converted into a museum, lighting solutions featuring motion sensors, warm-colored light, and artifact-safe technologies were implemented to ensure both artifact preservation and energy efficiency (Önsoy, 2002).

Figure 6. Loreto Museum (iStockphoto, 2017; Bellitalie, 2021; DZ Architecture Agency, t.y.)

Kemaliye Ethnography Museum (Church): The museum was opened in 1999 through the adaptive reuse of the Surp Kiyork Church, originally constructed in 1870 (Engin, 2023). In the exhibition areas, linear LED luminaires were employed in addition to natural lighting; daylight was enhanced through large arched windows, while artificial lighting served a complementary function (Figure 7).

Figure 7. Exhibition Areas of the Kemaliye Ethnography Museum (Engin, 2023)

Taksiyarhis Ayvalık Rahmi M. Koç Museum (Church): The Taksiyarhis Church was transferred to the Rahmi M. Koç Museum and Culture Foundation in 2011 and was opened as a museum in 2014 (Akan, 2020). The circular chandeliers on the ceiling provided both decorative and functional effects through uniform light distribution; while the arched windows allowed natural light to enter, artificial lighting enhanced overall visibility. In the glass display cases, point-source lighting highlighted the details of the exhibited artifacts, whereas indirect lighting on the columns and upper sections accentuated the architectural elements (Figure 8).

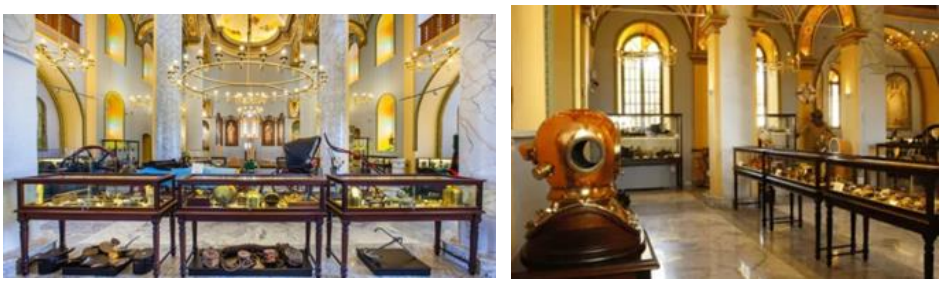

Figure 8. Interior Views of the Ayvalık Rahmi M. Koç Museum (Ayvalık Belediyesi, t.y.)

Table 3 presents examples of former religious buildings converted into museums, summarizing their functional history, current use, and interior lighting solutions (natural/artificial).

Table 3. Comparative Summary of Religious Buildings Converted into Museums

CONVERTED BUILDING TYPE		RELIGIOUS BUILDINGS			
BUILDING NAME		Kariye Museum	Loreto Museum	Kemaliye Ethnography Museum	Taksiyarhis Ayvalık Rahmi M. Koç Museum
CONSTRUCTION YEAR		4.YY	1468	1870	1462
CONVERSİON YEAR		1958	-	1999	2014
LOCATION		İstanbul/Turkey	Italy	Erzincan/ Turkey	Balıkesir/ Turkey
ORIGINAL FUNCTION		Church	Church	Church	Church
CURRENT FUNCTION		Museum	Museum	Ethnography Museum	Museum
LIGHTING	ARTIFICIAL LIGHTING	-Filtered and directional spotlights	-Sensor-based lighting fixtures -Parabolic reflector devices -Track-mounted spot lighting	-LED luminaires	-Point-source and indirect lighting elements
	NATURAL LIGHTING	Daylight is incorporated through windows and is supplemented by artificial lighting.	Daylight is incorporated through windows and is supplemented by artificial lighting.	Daylight is incorporated through windows and is supplemented by artificial lighting.	Daylight is incorporated through windows and is supplemented by artificial lighting.

According to Table 3, in museums converted from religious buildings, daylight generally serves as a primary source of ambient illumination, entering the space mostly through window openings and balanced by layers of artificial lighting. Due to conservation requirements (particularly concerning wall paintings, ornamentation, and wooden or textile surfaces) daylight has been directed, filtered, and limited, while exhibition legibility has been achieved through accent and indirect artificial lighting solutions. A comparative analysis of the examples reveals that in Kariye, filtered and directional spotlights enhance the perception of polychrome surfaces; in Loreto, sensor-supported systems, parabolic reflector devices, and track-mounted spotlights establish a dynamic balance between energy efficiency and conservation. In Kemaliye, linear LED fixtures are employed as a complement to daylight, whereas in Taksiyarhis, point-source and indirect lighting enhance both the emphasis on architectural elements and the visibility of the collection. These findings indicate that within religious typologies, hybrid (natural + artificial) lighting strategies represent a preferred, flexible, and controllable approach-supporting both artifact conservation and spatial interpretation/visitor experience.

3.3. Examples of Buildings Converted from Educational Structures into Museums

In this section, the lighting elements used in the interior exhibition spaces of buildings that have been adaptively reused from educational facilities into museums are examined (Table 4).

British Museum: British Museum was founded in 1753 (Buyurgan & Şener, 2023). Between 1994 and 2000, the courtyard was enclosed with filtered glass, creating a new exhibition area and protecting the collections from external factors. Daylight was controlled through filters and supplemented with UV-free fluorescent lamps and fiber-optic systems to provide suitable illumination for the artifacts. In the exhibition design, appropriate light levels and brightness contrasts were employed to direct visual attention toward the displayed objects (Önsoy, 2002) (Figure 9).

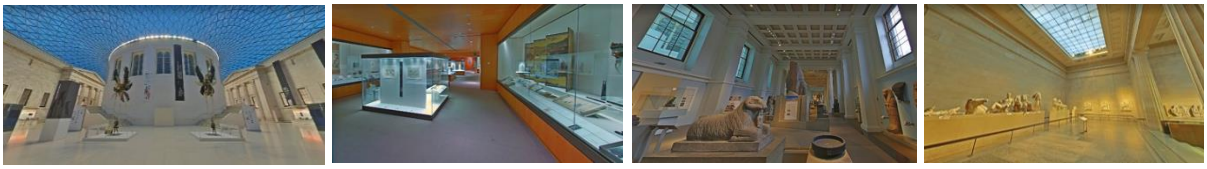

Figure 9. Exhibition Areas of the British Museum (Google Arts & Culture, t.y.-a)

National Struggle Museum (Kayseri High School): The Kayseri High School building was restored in 2012 and reopened as the National Struggle Museum in 2016 (Güner, 2017). In the museum's spatial design, the main hall was characterized by dark tones to create a dim and contemplative atmosphere, while circulation routes were emphasized through the use of materials and lighting. In the west wing, natural light was blocked, and specialized lighting systems were implemented for photographs, models, and objects. The floor was illuminated with low-level LED units, while general lighting was provided by spotlights (Figure 10). To enhance the impact of projections, a dark environment was maintained, and directional signage was supported with illuminated panels (Akyürek, 2022).

Figure 10. Exhibition Spaces of the National Struggle Museum (Akyürek, 2022)

Erzurum Yakutiye Madrasa Museum of Turkish-Islamic Art and Ethnography (Madrasa): Constructed between 1310 and 1311, the madrasa has been repurposed as the "Erzurum Yakutiye Madrasa Museum of Turkish-Islamic Art and Ethnography" following restorations carried out in 1995 and 2005 (Temur & Açıcı, 2022). In the museum layout, spotlights placed at the bases of columns highlight architectural details and guide visitor circulation. Natural light entering through the ceiling opening is supplemented with artificial lighting, while the artworks displayed on the walls are accentuated with focused illumination. Daylight is controlled for conservation purposes, and in the glass display cases, spotlights are used to provide targeted lighting (Figure 11).

Figure 11. Erzurum Yakutiye Madrasa Museum of Turkish-Islamic Art and Ethnography (Kültür Portalı, 2013; Erzurum Büyükşehir Belediyesi, t.y.)

Muş Museum (Primary School): Originally constructed in 1937 as Atatürk Primary School, the building was opened as a museum in 2021. The exhibition areas include glass display cases, informational panels, and appropriate lighting systems (Engin, 2024). Ceiling-mounted spotlights emphasize the display cases and wall visuals, while natural light is controlled using curtains (Figure 12).

Figure 12. Interior Views of the Muş Museum (Engin, 2024)

Table 4 presents examples of former educational buildings converted into museums, summarizing their functional history, current use, and interior lighting solutions (natural/artificial).

Table 4. Comparative Summary of Educational Buildings Converted into Museums

CONVERTED BUILDING TYPE		EDUCATIONAL BUILDINGS			
BUILDING NAME		British Museum	National Struggle Museum	Erzurum Yakutiye Madrasa Museum of Turkish-Islamic Art and Ethnography Museum	Muş Museum
CONSTRUCTION YEAR		-	1904	1311	1937
CONVERSİON YEAR		1753	2016	2005	2021
LOCATION		London/England	Kayseri/Turkey	Erzurum/Turkey	Muş/Turkey
ORIGINAL FUNCTION		Academy Building	High school	Madrasa	Primary School
CURRENT FUNCTION		Museum	Museum	Ethnography Museum	Museum
LIGHTING	ARTIFICIAL LIGHTING	-Point-source and indirect lighting elements -Spotlights	-Specific spot -LED lighting	-Focused spotlights - LED lighting	-Focused spotlights -LED lighting
	NATURAL LIGHTING	Daylight is supplemented with artificial lighting through the use of windows and ceiling openings.	Daylight is supported by artificial lighting in some exhibition areas through window openings.	Daylight is supplemented with artificial lighting via ceiling openings.	No natural daylight is used in the exhibition areas.

According to Table 4, lighting strategies in buildings originally constructed for educational purposes are based on a hybrid (natural + artificial) approach that aligns with exhibition scenarios and conservation requirements. In the British Museum, daylight provided through windows and ceiling openings is balanced with point-source and indirect artificial layers, establishing both ambient illumination and artifact emphasis. In the National Struggle Museum, daylight is used selectively and in a limited manner; in certain spaces, a dark-box approach combined with specific spotlights and LED solutions reinforces narrative focal points. In the Yakutiye Madrasa, ceiling openings serve as the primary source of daylight, while a combination of focused spotlights and LEDs enhances visual legibility in the exhibition. In the Muş Museum, natural light is avoided in the exhibition areas, and controlled, artifact-adapted staging is achieved through focused spotlights and LEDs. Overall, the trend indicates that the combined use of controlled/filtered daylight with targeted artificial lighting simultaneously supports legibility, visitor guidance, and conservation objectives.

3.4. Examples of Buildings Converted from Public/Administrative Structures into Museums

In this section, the lighting elements used in the interior exhibition spaces of buildings that have been adaptively reused from public/administrative facilities into museums are examined (Table 5).

Smithsonian American Art Museum (Patent Office Building): Opened as a museum in 1968, the Patent Office Building was designated as the National Museum of American Art in 1980 and renamed the Smithsonian American Art Museum in 2000 (Cook, 2019). Natural light is provided through ceiling and wall windows, while indirect lighting creates spatial uniformity. Track-mounted spotlights provide individual emphasis on each artwork, highlighting sculptures and paintings in particular (Figure 13)

Figure 13. Exhibition Areas of the Smithsonian American Art Museum (Google Arts & Culture, t.y.-b)

Ankara State Museum of Painting and Sculpture (Turkish Hearths Headquarters): Constructed between 1927 and 1930 as the Turkish Hearths Headquarters, the building was converted into a museum in 1975 (Başkan, 1989). In the exhibition areas, oil paintings are illuminated with LED luminaires that provide high color rendering and daylight-like quality, ensuring a uniform light distribution with a low UGR value (Eryurt, 2017). Ceiling-mounted spotlights are angled to focus on the paintings, while linear LEDs and light sources beneath semi-translucent panels create soft, homogeneous general illumination. Vertical roller blinds are used to control the intensity of natural light and reduce glare (Figure 14).

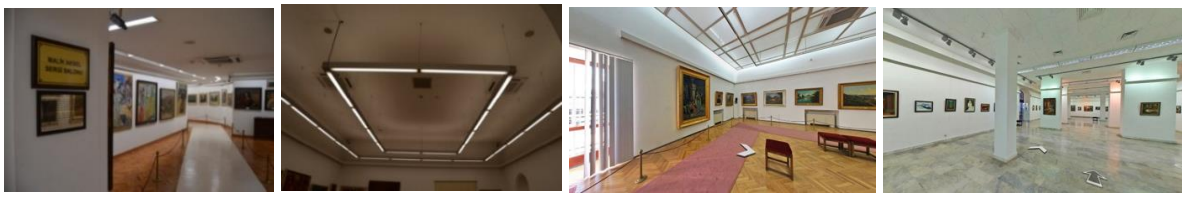

Figure 14. Museum exhibition hall and the lighting sources employed (Eryurt, 2017; Resim ve Heykel Müzesi, 2014)

Orsay Museum (Train Station): Located in Paris, the Orsay Museum opened in 1986 following the conversion of the former Gare d'Orsay train station (Güven, 2022). The main entrance is illuminated through a skylight and facade windows, while the galleries are supplemented with LED and spotlight systems (Çetin, 2021). Specialized lighting is employed for the artworks, and natural and artificial light are used in combination through ceiling openings (Yılmaz, 2024) (Figure 15).

Figure 15. Exhibition Areas of the Orsay Museum (Divisare, 2018)

Uffizi Museum: Initiated under the patronage of the Medici family in 1560 and completed in 1581, the Uffizi Palace originally housed the family's art collections and was opened to the public in 1789, serving as a model for subsequent galleries (Aslanoğlu, 2014). Natural light is controlled through semi-translucent glass panels and windows, while the exhibition areas employ linear LED fixtures, movable spotlights, and point-source lighting (Figure 16).

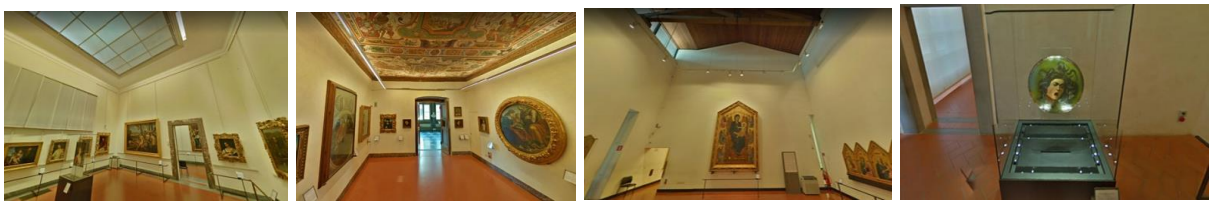

Figure 16. Exhibition Areas of the Uffizi Museum (Google Arts & Culture, t.y.-c)

Table 5 presents examples of former public/administrative buildings converted into museums, summarizing their functional history, current use, and interior lighting solutions (natural/artificial).

Table 5. Comparative Summary of public/administrative Buildings Converted into Museums

CONVERTED BUILDING TYPE		PUBLIC/ADMINISTRATIVE BUILDINGS			
BUILDING NAME		Smithsonian American Art Museum	Ankara State Museum of Painting and Sculpture Museum	Erzurum Yakutiye Madrasa Museum of Turkish-Islamic Art and Ethnography Museum	Muş Museum
CONSTRUCTION YEAR		-	1930	19.yy sonları	1581
CONVERSİON YEAR		1968	1975	1986	1789
LOCATION		Washington/ABD	Ankara/Turkey	Paris/France	Florence/Italy
ORIGINAL FUNCTION		Patent Office Building	Turkish Hearths Headquarters	Train Station	Palace
CURRENT FUNCTION		Museum	Museum	Museum	Museum
LIGHTING	ARTIFICIAL LIGHTING	Track-mounted spotlights – Indirect lighting elements	Track-mounted spotlights – Indirect lighting elements – Linear LED fixtures	Track-mounted spotlights – LED fixtures	Spotlights – Linear LED fixtures – Point-source spotlights

NATURAL LIGHTING	Daylight is supplemented with artificial lighting through the use of windows and ceiling openings.	Daylight is supported by artificial lighting in some exhibition areas through window openings.	Daylight is supplemented with artificial lighting through the use of windows and ceiling openings.	Daylight is supplemented with artificial lighting through the use of windows and ceiling openings.

According to Table 5, in buildings originally constructed for public and administrative use, lighting strategies are based on a balanced combination of the homogeneous daylight provided by large openings and overhead clerestories with track-mounted spotlights and linear LED layers. Daylight is controlled for glare and UV protection through curtains, diffusing panels, and semi-translucent ceiling solutions, while artificial lighting ensures artifact-focused emphasis, wayfinding, and accurate color rendering (high CRI). This approach simultaneously addresses conservation, legibility, and spatial identity. In specific examples: at the Smithsonian, daylight entering through ceiling and facade windows is directed toward the artworks using indirect lighting combined with track-mounted spotlights; at the Ankara State Museum of Painting and Sculpture, soft and uniform illumination is achieved under semi-translucent ceiling panels with high-CRI LEDs, while roller blinds control glare; at the Orsay Museum, the combination of skylights and facades is supplemented with selective spotlights for individual artworks; at the Uffizi, filtered natural light through semi-translucent surfaces is integrated with movable, point-source, and linear spotlights. Overall, the trend indicates that a hybrid (natural + artificial) lighting strategy provides a sustainable and flexible approach, supporting both artifact conservation and the visitor experience.

3.5. Examples of Buildings Converted from Residential Structures into Museums

In this section, the lighting elements used in the interior exhibition spaces of buildings that have been adaptively reused from residential facilities into museums are examined (Table 6).

Casa Batlló (Residential Apartment): Redesigned by Gaudí between 1904 and 1906, the building was transformed from a family apartment into a museum (Acar, 2017). Today, visitors experience the space through AR guides, video tours, and projection-based visualizations (Arslan, 2024). The exhibition areas offer varied spatial experiences through the use of pendant lamps, natural light, thematic lighting, and projection-supported light displays (Figure 17).

Figure 17. Exhibition Areas of Casa Batlló (Casa Batlló, t.y.)

Sakıp Sabancı Museum (Mansion): Established through the conversion of the Sabancı family's Atlı Mansion, the Sakıp Sabancı Museum opened in 2002 (Uçar, 2008). Hosting both the family collections and temporary exhibitions, the museum preserves the original layout of the mansion, with lighting provided by chandeliers and movable spotlights. In the corridors, paintings are highlighted with track-mounted spotlights, while books and calligraphy collections are displayed in low-lit cases (Özcan & Çağlar, 2020). The gallery's spacious hall

with a high ceiling is illuminated through glass ceiling details, and the exhibition areas connected to this upper level also benefit from skylight. Fluorescent strips are installed on the corridor ceilings, and the stairwell is illuminated through a combination of glass ceilings and wall-mounted fluorescent fixtures (Figure 18).

Figure 18. Interior Views of the Sakıp Sabancı Museum (Özcan & Çağlar, 2020)

Selanik Atatürk Museum (House): Originally constructed before 1870, the Atatürk House was converted into a museum and opened in 1953 (Anadol & Arıoğlu, 1981). Wall panels are made legible through uniform lighting, while images on window surfaces are covered with light-filtering materials, allowing natural light to contribute to the interior illumination. Soft ambient lighting is provided by wall sconces, and artifacts in display cases are emphasized with point-source spotlights (Figure 19).

Figure 19. Exhibition Areas of the Selanik Atatürk Museum (Arkeologlar Derneği, 2019)

Orhan Kemal Museum (Apartment): The Orhan Kemal Museum was converted from a residential apartment into a museum in 2000 to preserve the literary legacy of Orhan Kemal (Bektaş & Yalçınkaya, 2020; Çevik, 2021). The museum is organized around an object-focused exhibition and lighting strategy for items belonging to the author and his family, and due to the absence of interactive technologies, visitor engagement remains limited (İlbi, 2023). Lighting is provided through ceiling-mounted spotlights, which emphasize the objects, and natural light is blocked in favor of artificial illumination (Figure 20).

Figure 20. Exhibition Areas of the Orhan Kemal Museum (Bektaş, 2019)

Table 6 presents examples of former residential buildings converted into museums, summarizing their functional history, current use, and interior lighting solutions (natural/artificial).

Table 6. Comparative Summary of Residential Buildings Converted into Museums

CONVERTED BUILDING TYPE		RESIDENTIAL BUILDINGS			
BUILDING NAME		Casa Battlo	Sakıp Sabancı Museum	Selanik Atatürk Museum	Orhan Kemal Museum
CONSTRUCTION YEAR		1877	-	-	-
CONVERSİON YEAR		1906	2002	1953	2000
LOCATION		Barcelona/Spain	Istanbul/Turkey	Thessaloniki/Greece	Istanbul/Turkey
ORIGINAL FUNCTION		Family Apartment	Mansion	House	Apartment Flat
CURRENT FUNCTION		Museum	Museum	Museum	Museum
LIGHTING	ARTIFICIAL LIGHTING	-Chandelier use -Projection devices	- Track/mounted spotlights -Small spotlights -Chandelier use	-Wall sconces -Spotlights -Point/source spotlights	-Spotlights
	NATURAL LIGHTING	Daylight is supplemented with artificial lighting through the use of windows in some exhibition areas.	Daylight is supplemented with artificial lighting through the use of windows and ceiling openings.	Daylight is supplemented with artificial lighting through controlled use of windows.	No daylight is used in the exhibition areas.

According to Table 6, in museums converted from residential buildings, the lighting strategy is based on a layered and controllable design that preserves the original residential atmosphere while enhancing exhibition legibility. In most examples, daylight is limited or filtered, and in smaller spaces, focused artificial lighting—such as track-mounted/small spotlights, point-source highlights, and wall sconces—is emphasized to reduce glare and reflection risks. In specific cases, at Casa Batlló, chandeliers combined with projection-supported experiential scenarios complement daylight; at the Sakıp Sabancı Museum, movable track-mounted and small spotlights are balanced with natural light from windows and ceiling openings. At the Selanik Atatürk Museum, wall sconces and point-source spotlights provide uniform legibility in conjunction with controlled window use. In the Orhan Kemal Museum, natural light is avoided entirely, with the exhibition fully illuminated by spotlights. Overall, the trend indicates that in residential typologies, the hybrid (natural + artificial) approach tends to favor artificial lighting, which consistently supports artifact conservation, visitor guidance, and the perception of close-scale interior spaces.

3.6. Examples of Buildings Converted from Industrial Structures into Museums

In this section, the lighting elements used in the interior exhibition spaces of buildings that have been adaptively reused from industrial facilities into museums are examined (Table 7).

Tate Modern Art Museum (Power Plant): Constructed between 1947 and 1963, the Bankside Power Station was closed in 1981 and reopened as the Tate Modern in 2000 following restoration work initiated in 1995 (Yiğitoğlu, 2020). Natural light is enhanced through its semi-translucent glass roof and original windows, while different ceiling heights are supported by a variety of lighting systems. The semi-translucent glass layers filter daylight during the day and are designed to be illuminated artificially at night (Jones, 2013). The space and artworks are accentuated through linear LEDs, spotlights, and stretched ceiling lighting (Figure 21).

Figure 21. Tate Modern Art Museum (Jones, 2013; Herzog & de Meuron, 2023)

Müze Gazhane (Gasworks): Established in 1891, the Kadıköy Gas Company ceased production in 1993. The Hasanpaşa Gasworks, placed under protection in 1994, was reopened as a museum in 2021. Daylight is supplemented with artificial lighting, while the space is illuminated through electro track spot systems, linear fixtures emphasizing windows, and facade light controlled with blinds (Öztütüncü, 2023). Track-mounted spotlights are used in circulation areas, and colored illuminated panels are employed at experience stations. Spatial cohesion is maintained through linear LED fixtures integrated into the suspended ceiling. The seating area shown in Figure 22 does not receive uniform light throughout the day; reflections from transparent facade surfaces reduce the visibility of objects in glass display cases, making it more difficult for visitors to focus (Öztütüncü, 2023).

Figure 22. Exhibition Areas of Müze Gazhane (Öztütüncü, 2023)

Rahmi Koç Museum (Foundry Building): Constructed in 1703, the Lengerhane Building was converted into a museum through restoration in 1994 (Akyürek, 2022). Warm tones were preferred for the chandelier suspended from the dome and general lighting to reinforce the historical atmosphere of the space (Keçeli & Doğan, 2023). Spot LEDs in display cases and linear LEDs on walls were used to highlight both the artifacts and the building materials. Natural light was limited with roller blinds, and intensive artificial lighting was applied (Figure 23).

Figure 23. Exhibition Areas of the Rahmi Koç Museum (Geziseyahat365, t.y.)

Zeche Zollverein Museum (Coal Mine): Opened as a coal mine in 1847, Zeche Zollverein was closed in 1986 and converted into a cultural and art center during the 1990s. The complex was inscribed on the UNESCO World Heritage List in 2001 and was expanded until the 2010s to include museums, exhibition areas, and educational facilities, forming a multifaceted cultural center (Graf, 2024). Strip LEDs and high-intensity spotlights were installed on structural elements at ceiling level, while natural light was kept minimal. Artificial lighting was applied intensively to maintain the industrial atmosphere; object-focused lighting emphasized the artifacts, while background and circulation areas were left in relative darkness (Figure 24).

Figure 24. Exhibition Areas of the Zeche Zollverein Museum (Varol Can, 2024; Ruhr Müzesi, t.y.; XXI, 2018)

Table 7 presents examples of former industrial buildings converted into museums, summarizing their functional history, current use, and interior lighting solutions (natural/artificial).

Table 7. Comparative Summary of Industrial Buildings Converted into Museums

CONVERTED BUILDING TYPE		INDUSTRIAL BUILDINGS			
BUILDING NAME		Tate Modern Art Museum	Müze Gazhane	Rahmi Koç Museum	Zeche Zollverein Museum
CONSTRUCTION YEAR		1963	1891	1703	1847
CONVERSİON YEAR		2000	2021	1994	1989
LOCATION		London/England	İstanbul/Turkey	İstanbul/Turkey	Essen/Germany
ORIGINAL FUNCTION		Power Plant	Gasworks	Foundry Building	Coal Mine
CURRENT FUNCTION		Museum	Museum	Museum	Museum
LIGHTING	ARTIFICIAL LIGHTING	-Linear LED fixtures -Spotlights -Stretched ceiling lighting	-Electro track/mounted spotlights -LED sources	-Fixed and movable spotlights -Linear LED sources -Chandelier	-Linear LED fixtures -Spotlights -Stretched ceiling lighting
	NATURAL LIGHTING	Daylight is supplemented with artificial lighting through the use of windows and ceiling openings.	Daylight is supplemented with artificial lighting through direct exposure and the use of windows.	Daylight is supplemented minimally with artificial lighting, with roller blinds used on the windows.	Daylight is supplemented with artificial lighting through the use of windows in some exhibition areas.

According to Table 7, lighting in buildings of industrial origin relies on a hybrid (natural + artificial) strategy to address the scale challenges created by high ceilings and large openings; however, due to conservation and control requirements, the artificial layer often predominates. At the Tate Modern, daylight filtered through the semi-translucent roof is balanced with a combination of linear LEDs, spotlights, and stretched ceiling lighting. In Müze Gazhane, facade daylight is regulated through blinds and electro track-mounted spot systems, while linear highlights enhance circulation. At the Rahmi Koç Museum, daylight limited by roller blinds, warm-toned general illumination, linear LEDs in display cases and on walls, and chandeliers reinforce the historical atmosphere. At Zeche Zollverein, limited natural light is transformed into a "textured" industrial emphasis through strong spotlights and linear LEDs. The combination of "Construction Year – Conversion Year" reflects the integration level of contemporary fixture technologies (high CRI, glare/UV control) and the balance between energy efficiency, conservation, and legibility. Overall, the trend indicates that in large-volume spaces, layered linear and spot lighting provides flexible staging and wayfinding while highlighting the building's original industrial character.

SWOT Analyses

In this study, the natural and artificial lighting decisions in the exhibition areas of museums converted from military, religious, educational, public-administrative, residential, and industrial buildings were examined. A SWOT approach was employed to discuss the relationship between design solutions and typological differences. The evaluations are presented under the headings of Strengths, Weaknesses, Opportunities, and Threats. Each typology is addressed below along with its corresponding SWOT table, followed by a brief commentary summarizing the analysis.

Table 8. SWOT analysis of lighting elements used in the exhibition areas of museums converted from military buildings

SWOT Analysis for Museums Converted from Military Buildings	Internal Factors		External Factors	
	Strengths	Weaknesses	Opportunities	Threats
Lighting in Exhibition Areas	-Unique lighting solutions emphasize the building's original atmosphere -The large interior spaces allow flexible and convenient implementation of lighting element.	-In large spaces, uneven light distribution may result in some areas being too dark while others are excessively bright. -There may be difficulties in installing lighting fixtures due to the structural characteristics of the building.	-Custom lighting designs can enhance the military character of the space	-Insufficient funding may lead to the implementation of low-quality lighting solutions

Military-origin buildings, with their large volumes and high ceilings, offer opportunities for flexible focus and layered staging through track/recessed spotlights combined with linear LED layers, significantly enhancing the legibility of exhibits. However, risks related to reflection/glare and uneven illumination require careful consideration. Anti-reflective surfaces, glare control measures, and timed or sensor-controlled circuits (e.g., within display cases) provide opportunities for both energy efficiency and artifact preservation, whereas the use of heterogeneous or low-quality fixtures may weaken the intended atmosphere and perception (Table 8).

Table 9. SWOT analysis of lighting elements used in exhibition spaces of museums converted from religious buildings

SWOT Analysis for Museums Converted from Religious Buildings	Internal Factors		External Factors	
	Strengths	**Weaknesses**	**Opportunities**	**Threats**
Lighting in Exhibition Areas	-The use of openings of various sizes within the building enhances natural lighting and creates a more visually engaging atmosphere	-The existing lighting scheme may not adequately meet the requirements of the exhibition.	-The original lighting systems can help preserve the building's sacred or religious atmosphere.	-The original lighting systems can help preserve the building's sacred or religious atmosphere. - Wiring and installation works may compromise the structural integrity of the building.

In religious typologies, due to polychrome surfaces and ornamentation, low lighting levels, high CRI, and directed/filtered light are essential. Daylight is typically introduced in a controlled manner through window openings; sensor-assisted, indirect, or localized lighting arrangements enhance the balance between preservation and legibility. Incorrect spectral selection or excessive intensity can increase UV/thermal risks, making filtration, timing, and fixture placement critically important (Table 9).

Table 10. SWOT analysis of lighting elements used in exhibition spaces of museums converted from educational buildings

SWOT Analysis for Museums Converted from Educational Buildings	Internal Factors		External Factors	
	Strengths	**Weaknesses**	**Opportunities**	**Threats**
Lighting in Exhibition Areas	-The clear articulation of the building's sections facilitates exhibition layout design and allows for the use of different lighting systems for each exhibition.	-Excessive and uncontrolled natural light entering through large and frequent openings may cause glare problems.	-By controlling and efficiently utilizing natural light, energy costs can be reduced.	Uncontrolled lighting may lead to the deterioration or damage of the exhibited artifacts.

Educational buildings, with their compartmentalized plans and defined circulation paths, are suitable for scenario-based lighting. A combination of filtered daylight and focused spot/LED lighting reinforces narrative focal points, while glare control-particularly in large openings-is a fundamental requirement. The "dark box" approach, employing deliberate dimming, enhances legibility and conservation in multimedia and sensitive artifact displays; uncontrolled natural light can increase the risks of glare and color distortion (Table 10).

Table 11. SWOT analysis of lighting elements used in exhibition spaces of museums converted from public-administration buildings

SWOT Analysis for Museums Converted from Educational Buildings	Internal Factors		External Factors	
	Strengths	**Weaknesses**	**Opportunities**	**Threats**
Lighting in Exhibition Areas	-The flexibility of the building volumes facilitates the modernization of lighting systems according to the specific requirements of each exhibition.	-The difficulty of controlling light necessitates the implementation of more costly measures to ensure appropriate illumination conditions.	-Lighting can highlight the building's public identity and significance within the urban memory, thereby contributing to cultural tourism.	Improper placement of lighting elements may negatively affect spatial perception.

The large openings and clerestory windows in public-administration buildings provide uniform ambient illumination, which can be complemented with layered track spots and linear LED lighting to focus on exhibits. Diffuse panels, curtains, and translucent ceiling solutions help control glare and UV exposure, while high CRI enhances color fidelity. Misplacement of accent lighting can disrupt spatial perception, so light distribution, sightlines, and directional emphasis should be designed in an integrated manner (Table 11).

Table 12. SWOT analysis of lighting elements used in exhibition spaces of museums converted from residential buildings

SWOT Analysis for Museums Converted from Educational Buildings	Internal Factors		External Factors	
	Strengths	**Weaknesses**	**Opportunities**	**Threats**
Lighting in Exhibition Areas	-Lighting in human-scaled buildings can create a warmer and more intimate atmosphere. -In smaller spaces, achieving homogeneous illumination is comparatively easier.	-Due to the limited height of the structure, the lighting elements may have a restricted range of effect, potentially disrupting the overall exhibition aesthetics.	-The building's windows can serve as partial light filters for the exhibition space. -Windows proportionate to the human scale are easier to control in terms of light management.	-Excessive or uncontrolled natural light may cause damage to the exhibited artifacts.

In residential typologies, while maintaining a human scale and domestic atmosphere, focused artificial lighting (small/track spots, wall sconces, localized accents) generally complements the limited daylight. In compact spaces, beam angle, fixture-to-object distance, and surface reflectivity must be carefully adjusted to mitigate risks of excessive contrast and glare. Integrating decorative fixtures with museum-grade optics enhances the balance between originality and legibility (Table 12).

Table 13. SWOT Analysis of Lighting Elements Used in Exhibition Spaces of Museums Converted from Industrial Buildings

SWOT Analysis for Museums Converted from Educational Buildings	Internal Factors		External Factors	
	Strengths	**Weaknesses**	**Opportunities**	**Threats**
Lighting in Exhibition Areas	-Having high ceilings and larger interior spaces provides flexibility in lighting design.	-The large volumes that require illumination result in higher energy consumption for lighting.	-Natural light can be utilized to emphasize the building's original atmosphere. -The industrial character of the building can be preserved through the use of appropriate artificial lighting.	-Improper or insufficient use of light sources may adversely affect the atmosphere and the overall perception of the exhibition.

In industrial buildings, high volumes and long spans make layered linear LED and spot lighting, combined in some cases with suspended ceiling solutions, effective for scale reading and directional emphasis. Natural light is generally filtered and maintained at a supportive level; zonal or stepped dimming ensures energy efficiency and flexible staging. Incorrect or insufficient placement can create "dead zones" and perceptual disruptions in large spaces, making uniformity and glare control key performance criteria (Table 13).

Conclusion and Recommendations

This study examines the role of interior lighting within the museum conversion process of military, religious, educational, administrative, residential, and industrial buildings through a comparative framework. The findings reveal that, across all typologies, the prevailing tendency favors a hybrid lighting scheme (natural + artificial); however, the degree of control, stratification, and emphasis strategies within these hybrid systems differ significantly according to the building's original typology (Tables 2-7). In military structures, large volumes and elongated openings allow flexible scenographic arrangements through track/recessed spotlights and linear LEDs, making uniformity and luminance control critical. In religious buildings, the preservation of polychrome surfaces necessitates low illuminance levels, high color rendering (CRI), and filtered/directed light. In educational buildings, compartmentalized layouts support scenario-based configurations, occasionally embracing the "black box" approach. In public-administrative buildings, the homogeneous environment achieved through skylights is complemented by artifact-focused spot and linear lighting layers. In residential typologies, human scale is maintained through point-based highlights and the integration of decorative fixtures with museum-grade optics. In industrial structures, linear LED + spotlight systems and, in some cases, stretched ceiling solutions reinforce spatial legibility and wayfinding.

SWOT findings (Tables 8-13) confirm that lighting functions not only as a means of visibility but as a formative design parameter that simultaneously establishes the triad of conservation–legibility–identity. Strengths emphasize typology-specific spatial potentials (large volumes, skylights, defined circulation, human scale), offering opportunities for layered composition and flexible focusing. Weaknesses highlight implementation challenges such as glare/reflection,

uneven illuminance, uncontrolled daylight, and limited installation capacity. Opportunities suggest that sensor-based control, zonal or staged dimming, spectral selectivity, and anti-reflective surfaces can enhance both energy efficiency and conservation outcomes. Threats, however, stem from low-quality fixtures, inappropriate placement, and UV/thermal loads, which may compromise exhibition readability and artifact preservation. Overall, these findings emphasize the necessity of integrating measurement and verification (uniformity, luminance, lux-hour) as systematic components from the early design phase through to operation.

From a practical standpoint, the study proposes a typology-sensitive layered lighting model (ambient–task–accent) in conjunction with control and conservation protocols (filtering, shading, scheduling, sensors, zonal dimming). The role of natural light becomes safer when skylight and window systems are employed as a supportive layer, balanced with artificial components to account for diurnal and seasonal variations. The spectral content and CRI selection should be calibrated according to material sensitivity; optical and anti-reflective solutions are recommended, particularly on glazed surfaces and display cases, to mitigate reflection and glare risks. Track-based modular systems enhance sustainability by allowing quick adaptation to exhibition changes and facilitating maintenance.

The study's scope is limited by the reliance on secondary sources and visual/documentary analyses, restricting quantitative validation through on-site photometric measurements. Therefore, future research should be expanded through in-situ assessments (illuminance, glare, lux-hour) and simulation-based comparisons utilizing tools such as Radiance, DIALux, or Relux. Complementary visitor experience studies (perceived comfort, wayfinding success, eye-tracking) and energy/life-cycle analyses (impacts of control strategies on consumption and maintenance) will enable a more holistic evaluation of design effectiveness. In conclusion, through a typology-based framework and SWOT synthesis, this study advocates addressing lighting design in repurposed museums as an integrated process encompassing design–validation–operation, updating guidelines with measured and simulated data, and promoting flexible, protective, and sustainable lighting strategies in practice.

Abstract

This study examines the influence of the White Cube exhibition paradigm on interior design strategies within contemporary art museums. To explore how this approach is interpreted across different geographical and cultural contexts, the research focuses on a comparative analysis of İstanbul Modern and the Museum of Modern Art (MoMA) in New York. The White Cube paradigm advocates for presenting artworks in neutral, minimal, and distraction-free environments, aiming to direct the viewer's attention exclusively to the artwork itself. By stripping away historical, social, and spatial references, it seeks to provide a "neutral" exhibition experience. However, the implementation of this paradigm varies significantly depending on architectural choices, geographical settings, and cultural frameworks. Employing a qualitative research methodology, this study integrates literature review, architectural plan and section analyses, and visual assessments of exhibition spaces. Key evaluation criteria include spatial organization, circulation patterns, lighting design, surface materials, wayfinding elements, and visitor interaction dynamics. Findings reveal that MoMA preserves a conventional interpretation of the White Cube paradigm, characterized by white walls, uniform lighting, simplified circulation axes, and spatial neutrality. Conversely, İstanbul Modern reinterprets the paradigm within its local cultural context, incorporating natural lighting, flexible display units, multi-functional spatial configurations, and interactive elements to create a more experiential exhibition environment. In conclusion, while the White Cube paradigm serves as a universal exhibition model, its reinterpretation across diverse cultural contexts leads to spatial diversity and design innovation. This underscores the evolving role of contemporary art museums—not merely as display venues, but as dynamic cultural spaces that shape collective memory, local identity, and visitor engagement.

Keywords: White cube paradigm, Contemporary Art Museums, İstanbul Modern, New York MoMA, interior design

1. Introduction

The spaces in which artworks are exhibited are fundamental elements that directly shape the perception, experience, and interaction of the viewer with the work. Exhibition spaces are not merely passive surfaces that serve as a backdrop for artworks; they are also active design components that produce meaning, guide perception, and shape cultural experience (Duncan, 1995). For this reason, the configuration of museum spaces has played a critical role in designing audience-centered experiences in line with contemporary understandings of art. One of the most influential approaches to emerge in this transformation process is the "White Cube" paradigm. Conceptualized by Brian O'Doherty (1986) in *Inside the White Cube: The Ideology of the Gallery Space*, this paradigm advocates for exhibiting artworks in neutral, simple, and distraction-free environments. Through white walls, homogeneous lighting, and controlled spatial arrangements, the viewer's attention is directed solely toward the artwork. Thus, the work is isolated from its historical and social context, creating a "neutral" field of aesthetic

experience. However, the White Cube paradigm is not implemented in the same way in every context. Geographic location, cultural identity, architectural choices, and curatorial strategies directly influence its spatial interpretation. Therefore, although White Cube is accepted as a universal model, it has a structure open to reinterpretation and local adaptations.

From this standpoint, the aim of this study is to examine the impact of the White Cube paradigm on the interior design of contemporary art museums. The research seeks to comparatively evaluate the reflections of the paradigm in different geographical and cultural contexts through the examples of İstanbul Modern and The Museum of Modern Art (MoMA) in New York. Within this scope, the exhibition spaces of both museums are analyzed in terms of circulation schemes, lighting strategies, and material usage. Methodologically, the study adopts a qualitative research approach. Literature review, analysis of architectural plans and sections, and visual analyses of exhibition spaces constitute the main tools of the research. This multi-layered methodological framework aims to reveal not only the theoretical but also the spatial and experiential dimensions of the White Cube.

The findings indicate that the White Cube still provides an effective framework in contemporary art museums. However, it is also evident that this framework is redefined in ways that are sensitive to local contexts. Consequently, contemporary art museums are no longer merely structures for displaying works. Beyond this, they are becoming dynamic spaces that construct collective memory, represent local identity, and establish new forms of engagement with the audience.

2. Conceptual Framework

The concept of the museum has evolved throughout history from spaces where artworks were preserved into dynamic institutions that guide cultural experience, construct collective memory, and produce identity. The term originates from the Ancient Greek word mouseîon (μουσεῖον), meaning “a place dedicated to the Muses.” Today, museums are not only spaces where works of art and science are preserved but also cultural platforms that mediate the social sharing of knowledge and support public participation (ICOM, 2006). The 18th century marks a critical turning point in the evolution of museology. The establishment of the British Museum (1753) and the Louvre Museum (1793) enabled museums to assume the functions of preserving cultural heritage and making knowledge accessible to the public (Figure 1).

Figure 1. Exterior views of the Louvre Museum and the British Museum (Nugraha, 2012; Stormnight, 2006)

Since the second half of the 20th century, museums have ceased to be merely spaces where artworks are exhibited; instead, they have transformed into multifunctional institutions that strengthen cultural identity, encourage public interaction, and adopt experience-oriented exhibition approaches. Institutions such as the Centre Pompidou (1977), Guggenheim Bilbao (1997), and Tate Modern (2000) are among the pioneering examples of this transformation (Figure 2).

Figure 2. Centre Pompidou, Guggenheim Bilbao, and Tate Modern as pioneering examples of contemporary museum practice (Faléco, n.d.; Gehry, 2015; Sudjic, 2016)

Within this transformation process, one of the most significant approaches shaping the spatial configuration of contemporary art museums has been the White Cube paradigm. Conceptualized by Brian O'Doherty (1986) in *Inside the White Cube*, this paradigm advocates the presentation of artworks through white walls, homogeneous lighting, neutral surfaces, and distraction-free arrangements. This approach transforms the gallery into a sterile laboratory-like space, aiming to grant the artwork absolute visibility and autonomy. The viewer's attention is directed solely toward the artwork; the work is perceived within a "neutral" field, isolated from historical, social, and cultural contexts. Thus, the White Cube creates an aesthetic order that detaches art from environmental factors and defines the work by its intrinsic values. However, this claim of neutrality has also been interpreted by some researchers as part of an ideological construct, suggesting that beneath the invisibility of the space lies a powerful form of guidance (Figure 3).

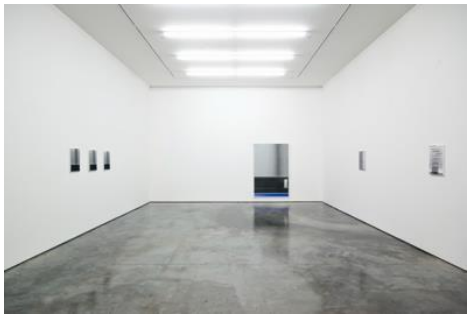

Figure 3. A typical exhibition space layout reflecting the White Cube approach (Coolimagesco, n.d.)

O'Doherty (2013) emphasizes that the White Cube is not merely a mode of display but also an ideological framework. The sterile and abstract nature of the space produces the very context that defines the object as a work of art; it detaches the viewer from environmental stimuli and invites them into a state of "pure aesthetic perception." Grunenberg (2012) describes the White Cube as "a space that presents the purity of artistic ideals within an invisible frame," while Antmen (2013) interprets it as a shell that both shapes and protects art.

The White Cube paradigm transforms not only spatial arrangements but also the relationship between viewer and artwork. Within this environment, isolated from the external world, the viewer experiences art independent of time and place. Particularly when abstract works are exhibited in such spaces, the sense of timelessness and placelessness is further intensified.

Nevertheless, the White Cube does not manifest as a uniform application in every museum. Its interpretation varies according to geographical context, cultural identity, and architectural preferences. At this point, the Museum of Modern Art (MoMA) in New York represents the

classic and canonical form of the paradigm, whereas İstanbul Modern reinterprets the approach by blending it with local context. The use of natural light, flexible display elements, and interactive arrangements with visitors in İstanbul Modern's exhibition spaces transform the paradigm into a more experiential and participatory structure (Figures 4 and 5).

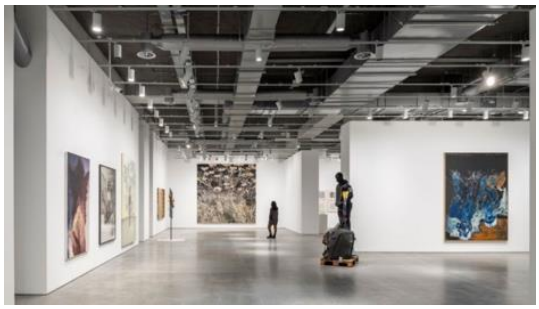

Figure 4. Exhibition layout employing the White Cube paradigm at İstanbul Modern (İstanbul Modern, n.d.)

Figure 5. Interior walls as display surfaces at MoMA (MoMA, 2025)

In conclusion, the White Cube paradigm plays a decisive role in the interior design of contemporary art museums, in the visitor experience, and in curatorial strategies. However, the paradigm's capacity to be reinterpreted across different contexts makes it less of a universal exhibition model and more of a flexible design language adaptable to local cultural dynamics. This is clearly observable in the new building of İstanbul Modern. In the structure designed by Renzo Piano, the White Cube gallery concept has been reinterpreted through a contemporary approach. The exhibition spaces were constructed with a simple, neutral, and flexible arrangement; by favoring white tones and plain forms on wall, floor, and ceiling surfaces, the design ensures that the artworks remain at the forefront (Figure 6).

Figure 6. Photography exhibition at İstanbul Modern (İstanbul Modern, 2025)

This approach, much like the ideal gallery space defined by O'Doherty (2013), aims to detach the viewer from the outside world and direct their full attention toward the artwork. At İstanbul Modern, light control, acoustic arrangements, and guiding elements are designed in ways that support this unity. In this manner, the building becomes architecturally "invisible," while the exhibition area transforms into an "artistic stage." The reinterpretation of the White Cube concept in such a way within a contemporary museum design positions İstanbul Modern not only physically but also conceptually in parallel with contemporary art museums on a global scale.

The neutrality of the walls and the overall atmosphere ensures that the artworks remain at the forefront. In particular, the orderly display of photographic and visual art pieces creates a sense of unity for the viewer; meanwhile, the glass showcases serve both as protective elements and as striking components of presentation. Lighting elements are directed specifically to highlight the artworks, while a dim overall ambiance is preferred in order to focus the viewer's attention solely on the exhibited works. The columns within the space are considered not only as structural supports but also as integral parts of the exhibition, being incorporated into the overall arrangement. In this context, the exhibition design of İstanbul Modern reinterprets the traditional "White Cube" approach through a contemporary lens, offering a simple, balanced, and interactive environment where interdisciplinary works can be displayed together (Figure 7).

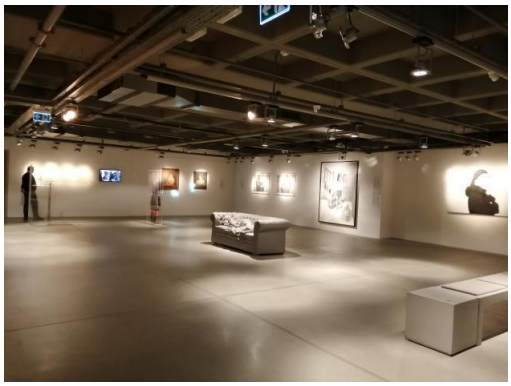

Figure 7. Photography exhibition at İstanbul Modern (İstanbul Modern, 2025)

The exhibition areas are planned with high ceilings and open spans. Gallery spaces are designed at varying heights and in flexible forms. Instead of fixed panels, movable exhibition elements and temporary walls are employed, allowing for diverse exhibition setups. In lighting design, both natural and artificial light are used together. In Renzo Piano's architecture, the relationship between interior and exterior is of great importance, and this quality is also evident within the exhibition spaces. Although the environment has been simplified in line with White Cube principles, the visual connection with the surrounding context has not been completely severed.

MoMA, however, presents a different approach. The Museum of Modern Art (MoMA) in New York adopts a simple and functional arrangement in its exhibition spaces, prioritizing the perception of artworks. The white wall surfaces, homogeneous floor coverings, and a carefully controlled balance of natural and artificial light are all designed to direct the viewer's focus directly onto the artwork. The orderly and well-spaced placement of works allows each piece to be evaluated individually, while the spatial voids create a rhythmic flow throughout the viewing process. Natural light entering through glass façades is balanced with artificial lighting

to ensure visual comfort. The interior organization of MoMA is structured around an open circulation scheme that enables visitors to move freely between artworks without requiring directional guidance. Through these features, the museum extends the White Cube approach beyond its classical boundaries, offering a modern exhibition experience that establishes a direct and uninterrupted connection between art and the viewer (Figure 8).

Figure 8. Interior walls as display surfaces at MoMA (MoMA, 2025)

In MoMA's exhibition halls, white walls and controlled artificial lighting are the defining elements. Natural light has been minimized as much as possible, thereby maintaining a uniform level of illumination throughout the entire space. The spacing left between artworks, combined with the simplicity of the environment, further highlights each piece. The White Cube approach at MoMA functions as an exhibition system that does not directly guide the viewer yet simultaneously detaches the work from its context, operating as an ideological framework. This spatial atmosphere offers the viewer an experience of "being alone with art" (Figure 9).

Figure 9. Interior walls as display surfaces at MoMA (MoMA, 2025)

3. Materials and Methods

This research was designed as a qualitative study aiming to examine the influence of the White Cube approach on the interior design of contemporary art museums. The study addresses the effects of the White Cube paradigm on the formal, functional, and conceptual configuration of exhibition spaces, focusing particularly on how this paradigm is interpreted in different geographical and cultural contexts. To this end, a comparative analysis method was adopted, and the variations of the paradigm across contexts were evaluated through the cases of İstanbul Modern and the Museum of Modern Art (MoMA) in New York.

In the first stage of the research, a comprehensive literature review was conducted. Within this framework, Brian O'Doherty's seminal work *Inside the White Cube: The Ideology of the Gallery Space* (1986) was examined in order to understand the historical development, ideological dimensions, and relationship of the White Cube paradigm with architectural design. In addition, the works of scholars such as Tony Bennett (1995), Charlotte Klonk (2009), Grunenberg (1999), and Antmen (2010) were analyzed, thereby situating the paradigm's

emergence, its role in exhibition spaces, and its effects on visitor experience within a theoretical framework.

Building upon this theoretical background, the research examined the architectural arrangements, organization of exhibition spaces, lighting strategies, material usage, and spatial configurations of İstanbul Modern and MoMA, selected as case studies. The analysis drew upon the museums' official websites, architectural drawings, exhibition catalogues, printed publications, academic articles, and theses. The use of diverse data sources allowed the study to present both the spatial characteristics and the conceptual approaches behind design decisions in a holistic manner.

In the final stage, the collected data were evaluated through the lens of comparative analysis. Within this scope, the ways in which both museums implemented the White Cube paradigm were examined in terms of circulation schemes, lighting preferences, and material usage. Thus, the impact of the White Cube paradigm in contemporary art museums has been addressed not only as a universal exhibition model but also as a flexible architectural tool adaptable to local cultural contexts.

4. Findings and Discussion

This section discusses the reflections of the White Cube paradigm in contemporary art museums through the exhibition spaces of İstanbul Modern and New York MoMA. The findings are comparatively evaluated based on the spatial organization, lighting strategies, material preferences, and curatorial approaches of both museums, while also examining the influence of cultural context on exhibition design.

4.1. The Classical Interpretation of the White Cube at MoMA

The exhibition spaces of MoMA place the artwork at the center through the use of white walls, homogeneous lighting, simple circulation axes, and an arrangement free from distracting elements. This approach directly reflects Brian O'Doherty's (1999) definition of the White Cube as an "ideological exhibition system." The principles of simplicity and clarity highlighted by Grunenberg (2012), as well as Antmen's (2013) description of the White Cube as a "protective shell for art," are observed here in their most typical form.

The exhibition areas at MoMA allow the viewer an independent circulation while simultaneously creating a decontextualized atmosphere that positions the artwork within a sterile environment. In this way, the work refers not to any social or spatial context but solely to its own aesthetic value. Thus, MoMA preserves the White Cube paradigm in its most classical and pure form, presenting an ideological stance that represents the continuity of modernist aesthetics (Figure 10).

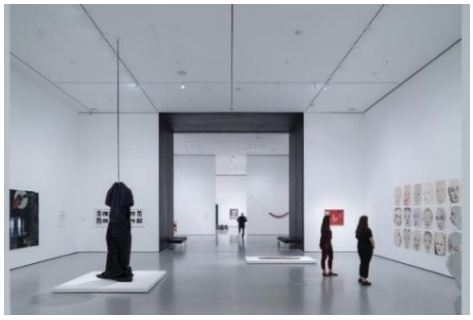

Figure 10. MoMA's New Photography exhibition (Peers, 2019)

4.2. The Experiential and Interpretive Use of the White Cube at İstanbul Modern

At İstanbul Modern, the White Cube paradigm is reinterpreted in an experiential and open-to-interpretation manner, going beyond the boundaries of its classical reading. In the building designed by Renzo Piano, galleries employ white and neutral surfaces to foreground the artwork; yet the controlled use of natural light, movable exhibition units, galleries designed at varying heights, and the integration of columns into the exhibition layout together provide the space with a multi-layered experiential dimension.

This arrangement goes beyond O'Doherty's (1999) idealized notion of a decontextualized and sterile "art space," creating instead an exhibition environment that engages more directly with the viewer. The visual relationship established with the surrounding environment and the incorporation of the Bosphorus view into the interior provide opportunities for art to form multidimensional connections with collective memory and urban identity. Thus, at İstanbul Modern, the White Cube ceases to function merely as a frame that isolates art; it transforms into an interpretive, participatory, and experiential tool of display. This not only aligns İstanbul Modern with global museum typologies but also renders it a distinctive cultural focal point (Figure 11).

Figure 11. Eye Catching / Computer video installation (Steinkamp, 2003)

4.3. Similarities and Differences Between İstanbul Modern and MoMA

Although both museums adopt the White Cube approach as a fundamental exhibition model, their modes of implementation demonstrate significant differences.

Spatial organization: At MoMA, spatial arrangement is based on white walls, homogeneous floors, and controlled circulation axes. At İstanbul Modern, by contrast, the use of flexible display elements, galleries designed at different heights, and the incorporation of columns into the exhibition design emphasize a more experiential layout (Figure 12 and 13).

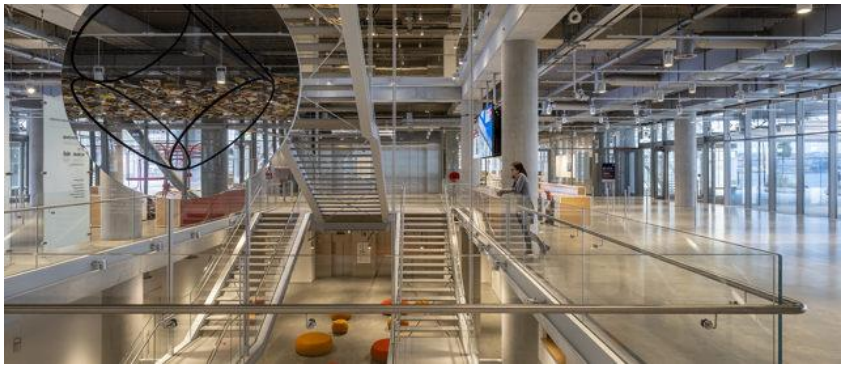

Figure 12. Foyers at İstanbul Modern (İstanbul Modern, n.d.)

Figure 13. The Museum of Modern Art (MoMA), New York (Müze Biletleri, n.d.)

Use of light: MoMA largely restricts natural light, providing artificial and homogeneous illumination. İstanbul Modern, on the other hand, incorporates natural light into the interior, balances it with artificial lighting, and creates a dynamic atmosphere (Figure 14 and 15).

Figure 14. The Museum of Modern Art (MoMA), New York (Müze Biletleri, n.d.)

Figure 15. İstanbul Modern. (Anadolu Ajansı, 2023)

Material preferences: At MoMA, white walls and matte surfaces create a sterile environment, whereas at İstanbul Modern, glass and metal panels establish a visual continuity with the surrounding environment (Figure 16 and 17).

Figure 16. The Museum of Modern Art (MoMA), New York (Müze Biletleri, n.d.)

Figure 17. Library at İstanbul Modern (İstanbul Modern, n.d.)

Curatorial strategies: At MoMA, artworks are exhibited in an independent, distanced, and neutral arrangement. At İstanbul Modern, by contrast, context-sensitive, interactive, and experiential configurations establish multidimensional relationships among art, space, and the viewer.

This comparison demonstrates that although the universal principles of the White Cube are preserved, they differ significantly in terms of spatial experience, visitor interaction, and cultural context.

4.4. The Impact of Cultural Context on Exhibition Design

Geographical, cultural, and social differences cause the White Cube paradigm to acquire distinct spatial meanings in each museum. MoMA, by adhering to the universal aesthetic principles of modernism, produces a decontextualized and timeless atmosphere through white walls, homogeneous lighting, and neutral surfaces. In contrast, İstanbul Modern draws upon its local context, incorporating the Bosphorus view, natural light, and flexible display units to create an experiential space that engages with its surroundings. While MoMA emphasizes a sterile exhibition approach independent of cultural context, İstanbul Modern develops a spatial interpretation integrated with the city's dynamic identity and collective memory. Thus, MoMA represents the continuity of universal modernist aesthetics, whereas İstanbul Modern presents an open-ended and multilayered exhibition practice that interacts with cultural context.

4.5. The Universal Model and Local Adaptations of the White Cube

Although the White Cube is recognized as a universal exhibition model in contemporary art museums, it is reshaped in every institution according to local context. The cases of İstanbul

Modern and MoMA illustrate that the paradigm is not a uniform exhibition framework; on the contrary, it can be flexibly reinterpreted according to cultural dynamics. Therefore, the White Cube functions not only as a universal aesthetic order but also as a design language capable of integrating with local identities.

Table 1. Comparative Analysis of the White Cube Paradigm at New York MoMA and İstanbul Modern

Feature	New York MoMA	İstanbul Modern
Year of Establishment	1929	2004 (new building in 2023)
Architect	Philip L. Goodwin & Edward Durell Stone (original), Yoshio Taniguchi (renovation)	Renzo Piano
Location	Manhattan, New York	Tophane, İstanbul
Building Type	Vertical, layered gallery structure	Horizontal mass connected to the sea
Gallery Layout & Spatial Configuration	Modular, enclosed, and sterile exhibition scheme; inward-looking	Flexible White Cube: contextual arrangement, galleries with varying heights
Use of Light	Controlled artificial lighting, minimal natural light	Balanced use of natural and artificial light
Façade Material	Glass, steel, and plaster surfaces	Glass and metal panels (wave/light form)
White Cube Approach	Traditional application preserving modernist aesthetics	Contemporary reinterpretation; experiential and participatory approach
Circulation Scheme	Directed, defined circulation; controlled movement	Free, non-directed circulation; flexible movement opportunities
Wall Color & Structure	Completely white, fixed panels	White surfaces supported by flexible and movable panels
Relation to the External World	Minimizes relation with the surroundings; inward-oriented spatial setup	Establishes visual connection with the city; permeable and transparent façade arrangement
Visitor Experience	Distant, sterile, and artwork-centered; viewer in a passive role	Participatory, interactive, experiential; viewer in an active role
Curatorial Strategy	Neutral presentation detaching the artwork from context; continuity of modernism	Context-sensitive, multilayered presentation; relationship among art–viewer–city
Ideological Dimension	Represents continuity of modernist aesthetics; universalist approach	Highlights local identity and collective memory; contextual approach
Level of Interpretation	Universal level; timeless and sterile exhibition concept	Localized level; exhibition concept integrated with cultural context

The comparative analysis summarized in Table 1 clearly demonstrates how the universal principles of the White Cube are rearticulated in two different museums. In the case of MoMA, the paradigm persists as a neutral and decontextualized exhibition system that represents the

continuity of modernist ideals; whereas at İstanbul Modern, the same paradigm transforms into an experiential and flexible exhibition strategy that internalizes cultural context. This reveals that the White Cube is not merely an exhibition model but also a tool that shapes the cultural identity of space, the visitor experience, and collective memory.

5. Conclusion

This study has revealed that the White Cube paradigm functions as a universal exhibition model in contemporary art museums; however, this model takes shape in different ways across institutional and cultural contexts through spatial organization, lighting, material preferences, and curatorial strategies. Initially conceptualized as an ideological framework aiming for perceptual purity by isolating the artwork from social and historical contexts, the White Cube has proven not to be a singular and absolute construct. Instead, the findings show that it is a flexible tool reinterpreted according to each institution's mission, cultural context, and architectural identity.

The case of MoMA represents the canonical and classical interpretation of the White Cube. White walls, homogeneous lighting, simplified circulation schemes, and spatial arrangements stripped of distractions place the artwork at the absolute center. This condition constitutes a direct manifestation of O'Doherty's (1999) theory of the "ideology of the gallery space." MoMA's exhibition design produces a universal sense of "timelessness" and "sterile aesthetics" by ensuring the continuity of modernist principles and the perception of art as independent from its context.

In contrast, İstanbul Modern reinterprets the same paradigm in a context-sensitive and experiential language. Renzo Piano's flexible spatial configuration, controlled use of natural light, continuity between interior and exterior through glass and metal surfaces, and the employment of movable exhibition units situate the museum in relation to its cultural and social context. Rather than isolating the artwork in a sterile environment, this approach offers a multilayered field of experience within the triangle of viewer–artwork–city. The exhibition design of İstanbul Modern transforms the White Cube from being merely a "protective shell" into a design tool that establishes active dialogue with the viewer, nourishes cultural memory, and enables public encounters.

This comparative analysis clearly highlights two dimensions of the White Cube paradigm:

- **1.Universal dimension** → A neutral system that sterilizes space, detaches art from its context, and provides the viewer with a pure aesthetic experience.
- **2.Local dimension** → Flexible and experiential applications redefined through cultural identity, geographical environment, and architectural preferences.

Therefore, the White Cube should not be regarded as a rigid and singular formula, but as a generative process of co-formation between universal principles and local contexts. The study's findings demonstrate that four design elements serve as the main levers of this co-formation:

- **Light** → At MoMA, artificial illumination creates sterile homogeneity; at İstanbul Modern, a balance of natural and artificial light produces a dynamic atmosphere.
- **Material** → At MoMA, white walls and matte surfaces dominate; at İstanbul Modern, glass and metal establish continuity with the environment.

- **Circulation** → At MoMA, undirected and simplified axes structure movement; at İstanbul Modern, flexible and experiential circulation unfolds across different heights.

- **Curation** → At MoMA, artworks are presented in an isolated, distanced, and object-centered manner; at İstanbul Modern, interactive and context-sensitive strategies allow active visitor participation.

These findings demonstrate that in contemporary art museums, the White Cube is not merely an exhibition technique but a multifaceted architectural–curatorial tool that shapes visitor experience, constructs cultural memory, and represents institutional identity. In conclusion, while MoMA's canonical implementation reinforces modernist aesthetics and object-centered perception, İstanbul Modern's experiential reinterpretation transforms space into an interface for cultural memory and public encounter. These two approaches prove that the White Cube is not a monolithic paradigm but a flexible and pluralistic design language emerging from the interaction of universal aesthetic principles and local cultural dynamics.

The results of this study contribute a new framework to the literature on contemporary museum design that goes beyond the "universal/local dichotomy." They emphasize the need to reconsider the White Cube not merely as a neutral backdrop, but as a strategic tool that directs cultural identity, collective memory, and visitor engagement. Future research may further expand this discussion by exploring how the paradigm is reinterpreted across different geographies and how it is being transformed through digital technologies such as VR, AR, and interactive exhibition design.

pelin.aykutlar@kavram.edu.tr (Responsible Author)

Abstract

The study aims to assess public space quality in Aliağa Democracy Square, located in İzmir, Türkiye, through a participatory, user-centered diagnostic process. Developed within the framework of participatory planning, the study employed spatial observation, semi-structured interviews (n=8), and structured surveys (n=60) to analyze users' everyday experiences, needs, and spatial behavior. Findings indicate that the square suffers from insufficient shaded areas, low thermal comfort during summer months (surface temperatures reaching 49°C), inadequate seating, poor maintenance, and a lack of inclusive design for elderly, children, and mobility-impaired users. Additionally, uncontrolled vehicle access and insufficient lighting have raised safety concerns. The existing water feature and street furniture were reported as dysfunctional or neglected. Most users, particularly those aged 55 and above, highlighted the need for more greenery, social spaces, and protection from extreme weather. In response, the study proposes several spatial and policy recommendations, including ecological shading elements, new seating arrangements with weather protection, accessible green areas, designated play zones, and improved urban furniture. Small-scale kiosks to support local economic activity and species-specific bird feeding stations are also suggested to improve hygiene and spatial organization. The study not only diagnoses current challenges in the square's design and use but also contributes to urban governance by offering inclusive, climate-adaptive, and user-informed strategies for sustainable public space transformation.

Keywords: Participatory planning, public space, citizen science, thermal comfort, user-centered planning

1. Introduction

In recent years, urban public spaces have gained renewed attention in the context of rapid urbanization, climate change, and growing inequalities in access to quality environments. Public squares, in particular, represent critical spatial and social nodes that reflect broader urban governance practices and serve as platforms for everyday life, democratic engagement, and socio-spatial inclusion (Carr et al., 1992; Gehl, 2010). However, many squares in contemporary cities suffer from design, maintenance, and accessibility issues that limit their potential to support inclusive and climate-adaptive urban life.

Aliağa Democracy Square, located in İzmir, Türkiye, exemplifies these challenges. While it is strategically positioned within a dense urban fabric and serves as a potential site for cultural events, informal gatherings, and social interactions, the square is currently underperforming in terms of thermal comfort, user safety, inclusivity, and ecological functionality. Surface temperatures exceeding 49°C during summer months, insufficient shaded areas, lack of barrier-free design, and degraded urban furniture significantly undermine the quality of user experience. To address these challenges, this study adopts a participatory, user-centered diagnostic approach inspired by the principles of Citizen Design Science (Müeller et. al. 2018, Özden &Velibeyoğlu, 2023). By incorporating the lived experiences of diverse users, including residents, visitors, elderly individuals, and mobility-impaired persons, this research aims to understand spatial behavior patterns, identify key barriers, and co-develop spatial improvement strategies. Drawing from structured observations, semi-structured interviews, and survey data,

the study explores how inclusive design and ecological interventions can contribute to healthier, safer, and more livable urban squares.

The research not only provides a comprehensive evaluation of the current state of Aliağa Democracy Square but also offers practical design and policy recommendations that can inform future urban regeneration projects in mid-sized cities facing similar climatic and demographic pressures. In doing so, it contributes to ongoing discussions on participatory urbanism, sustainable place-making, and citizen-led urban transformation.

2.Materials and Methods

The study employs a mixed-methods design that integrates systematic spatial observation, semi-structured interviews, and a structured on-site survey to assess user experience and public space quality in Aliağa Democracy Square, İzmir. A five-member field team from the İzmir Metropolitan Municipality and İzmir Planning Agency conducted fieldwork on August month 2025 (Figure 1).

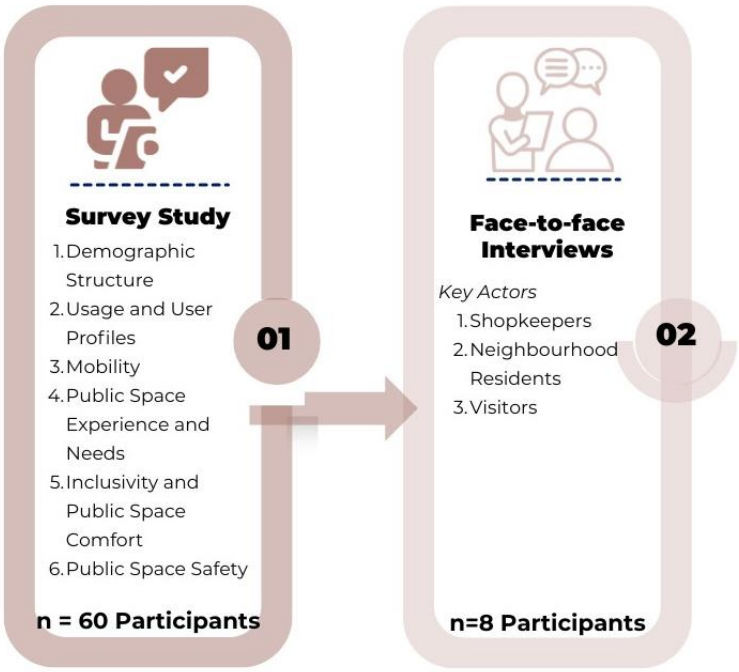

Figure 8. Methodology of the study

A concurrent triangulation strategy was adopted to enhance the validity of findings by cross-verifying qualitative and quantitative evidence (Creswell & Plano Clark, 2011). Systematic observation captured behavioral and spatial patterns in situ, interviews elicited experiential knowledge from key users, and the survey quantified usage, needs, and perceptions across a broader sample. This user-centered diagnostic approach aligns with participatory frameworks that foreground lived experience in public-space evaluation (Arnstein, 1969; Gehl & Svarre, 2013).

Spatial Context and Urban Morphology

Aliağa Democracy Square is situated within Kültür Neighbourhood, a central and densely built neighborhood in Aliağa district, İzmir. As shown in Figure 2, the square occupies a strategic

location at the intersection of major urban arteries, including Hükümet Street, İstiklal Street, and İzmir Street, and functions as both a transit node and a potential social condenser. The satellite imagery highlights two essential urban layers:

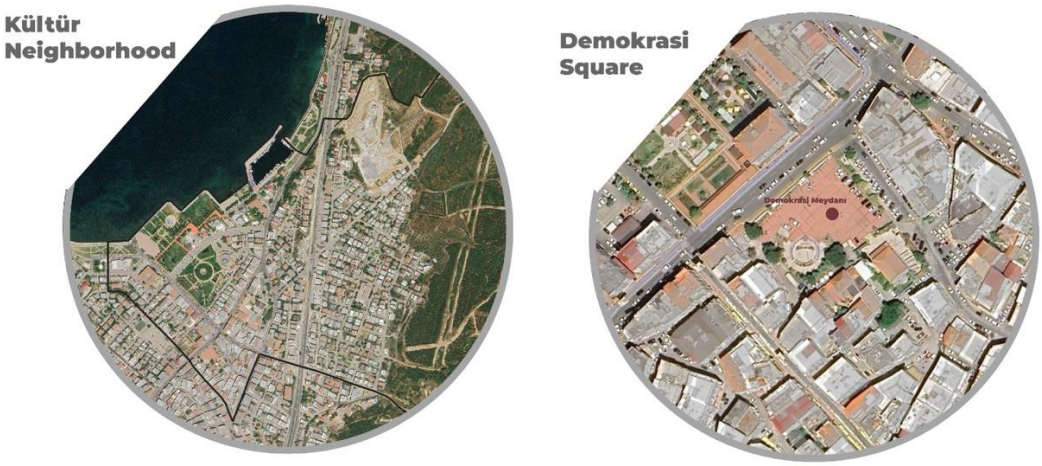

Figure 9. Spatial location and urban morphology of Kültür Neighbourhood and Aliağa Democracy Square (Source: İzmir Metropolitan Municipality Satellite Archive, 2025)

On the left, a macro-view of Kültür Neighbourhood illustrates the square's proximity to the coastal edge and the green infrastructure corridor in the north. On the right, the zoomed-in image of Demokrasi Square reveals a highly paved, compact urban texture, surrounded by civic buildings (e.g., district library, mosque), commercial units, and low-rise residential structures (see Figure 1).

This spatial duality, being embedded in a dense civic core while adjacent to natural and coastal assets, presents a unique opportunity for the square to operate as a mediator space between ecological, social, and infrastructural systems (Carmona et al., 2008). Yet, observational findings suggest that this potential remains underutilized due to the square's excessive hardscaping, lack of permeability, and poor visual legibility.

In the observed urban form, the square lacks defining edges, intuitive pathways, and inviting thresholds, which limits its symbolic and functional prominence in daily urban life. Instead of acting as a "centerpiece," the square performs more as a residual transit zone, underlining the importance of placemaking and edge activation in its future transformation (Project for Public Spaces, 2009).

The square is located within a dense urban fabric and hosts civic, cultural, and commercial functions. Following public-life study protocols, observers recorded conditions of micro-climate exposure (e.g., shade opportunities), seating supply and configuration, paving quality and accessibility, illumination, clutter and hygiene, and conflicts between pedestrian and vehicular movement (Gehl, 2010; Gehl & Svarre, 2013). Photographic documentation supported the audit of (i) neglected or dysfunctional elements (e.g., the water feature), (ii) barrier-free access constraints (damaged or uneven paving), and (iii) hygiene issues related to ad-hoc bird feeding. Observations emphasized heat-stress exposure given locally reported summer surface temperatures (~49 °C), with design implications for shade and weather protection (Nikolopoulou & Lykoudis, 2006).

Interviews: Sampling and Procedure

Eight semi-structured face-to-face interviews were conducted using purposive sampling to include key user types—shopkeepers (n=4), residents (n=3), and a frequent visitor (n=1)—representing diversity of age and gender. Purposive sampling is appropriate for capturing information-rich cases and practice-based insights (Patton, 2002). The guide probed perceived comfort (thermal and ergonomic), safety (lighting, conflicts with vehicles), inclusiveness (elderly, children, mobility-impaired users), and priorities for improvement. Interviews were recorded through detailed notes; recurring codes (e.g., “lack of shade”, “insufficient seating”, “poor nighttime lighting”, “maintenance deficits”) were identified through iterative coding to structure themes for discussion.

Survey Instrument and Administration

A structured questionnaire (n=23) was adapted from public-life survey practice inspired by Gehl’s People & Public Space studies and organized into six modules: demographics, frequency of use, mobility and access, spatial experience, inclusiveness and comfort, and safety perception (Gehl & Svarre, 2013; Gehl, 2010). The instrument comprised multiple-choice and Likert-type items, plus targeted multi-select questions to capture specific deficiencies (e.g., shade, greenery, seating). Surveys were administered on site to 60 participants using convenience sampling, a pragmatic approach in public-space intercept studies where the target population is the set of current users (Etikan, Musa, & Alkassim, 2016). Respondents represented six districts, with a majority residing in Aliağa (88%). Basic eligibility required age under 18 years old and recent use of the square. The intercept timing (mid-morning to late afternoon) was selected to capture typical daytime patterns while minimizing extreme heat exposure bias (Nikolopoulou & Lykoudis, 2006).

Data Handling and Analysis

Observation notes and photographs were compiled into a spatial audit matrix (Gehl & Svarre, 2013). Interview notes were analyzed via descriptive thematic analysis to extract recurrent constraints and user priorities. Survey data were cleaned and analyzed using descriptive statistics (frequencies, percentages) to profile users, usage patterns, perceived deficiencies, and desired interventions; cross-tabulations were used exploratorily to contextualize subgroup tendencies (e.g., age by comfort or safety perception). Methodological triangulation, comparing observational evidence with interview themes and survey frequencies, was used to consolidate convergent findings and flag discrepancies for discussion (Creswell & Plano Clark, 2011).

Ethical Considerations

All participation was voluntary, with informed consent obtained prior to interviews and surveys; data were anonymized at the point of recording. Observations were conducted in a public setting without identifying individuals, consistent with ethical guidance for public-life studies. Where visual material is used, images avoid personally identifiable information unless separate consent is documented.

3. Findings and Discussion

The findings of the study reveal a multifaceted set of spatial and experiential challenges in Aliağa Democracy Square, as perceived and experienced by users. These findings are discussed thematically under three key dimensions: (i) environmental comfort and microclimatic conditions, (ii) spatial configuration and inclusivity, and (iii) safety, accessibility, and

maintenance. The data from surveys (n=60) and semi-structured interviews (n=8), complemented by spatial observations, offer a triangulated and user-centered diagnosis of the square.

Environmental Comfort and Thermal Exposure

One of the most pressing issues reported by participants was extreme thermal discomfort, particularly during summer months. Satellite-derived thermal imaging indicated surface temperatures of up to 49°C in July 2024, aligning with observational findings of limited shade provision and inadequate microclimatic design. According to the survey, 88% of respondents stated that there is not enough shaded space in the square, while 73% reported that they could not use the space during extreme weather conditions such as heatwaves or rain.

Interviewees emphasized the absence of protective elements such as tree canopies or structural shading. Users, particularly those aged 55 and over, expressed a strong preference for shaded seating and resting areas—findings consistent with thermal comfort research in Mediterranean urban settings (Nikolopoulou & Lykoudis, 2006). This confirms the crucial role of shade in enhancing usability and inclusiveness under climate stress conditions (Johansson, Thorsson, & Emmanuel, 2014).

Spatial Configuration and User Inclusivity

The square is currently used for a variety of purposes; 57% of participants use it daily, mostly for transit, resting, or brief social interactions. However, spatial observations and interviews highlighted the inadequacy of basic urban elements. 52% of participants described seating units as dysfunctional, poorly placed, or ergonomically uncomfortable. The lack of inclusive design features such as ramps, smooth pavements, and shaded benches was especially problematic for users with mobility challenges, baby strollers, and elderly citizens.

The quality of paving emerged as a repeated concern across interviews. Observed surface degradation (e.g., cracks, slopes, water accumulation zones) limited the square's accessibility and caused safety risks. Users also pointed to a lack of greenery and ecological aesthetics, which diminishes the area's social appeal and affects its restorative potential (Kaplan, 1995). In this respect, the demand for green infrastructure (e.g., planted edges, trees, bioswales) aligns with literature emphasizing biophilic and health-oriented urban design (Beatley, 2016).

Safety, Accessibility, and Maintenance

Perceptions of safety in public spaces are shaped by both physical and social cues. In Aliağa Democracy Square, while 77% of respondents considered the square to be generally safe, 23% expressed concerns, particularly about uncontrolled vehicle entry, inadequate lighting, and presence of stray animals. Several interviewees mentioned previous incidents of vehicle conflict, particularly around pedestrian entries and paved transitions, indicating a lack of clear spatial hierarchy and protective design for vulnerable users.

Maintenance was another recurrent theme. The water feature (central fountain) was described as non-functional and unhygienic, with stagnant water and accumulated dirt. Informal practices, such as placing bowls for birds, were well-intentioned but caused sanitation concerns, as noted by both users and observers. Similarly, the lack of regular cleaning, damaged paving materials, and insufficient litter bins created a perception of neglect, affecting the users' sense of comfort and security (Carr et al., 1992).

Desired Improvements and Co-Generated Proposals

When asked about desired improvements, participants consistently prioritized:

- Shaded areas (96% mention rate)
- Increased greenery (76%)
- Better seating elements and placement (65%)
- Designated spaces for children's activities and local vendors (approx. 30–40%)

Interviewees suggested installing lightweight ecological shading structures, seasonal vegetation, weather-resistant urban furniture, and creating small-scale kiosks to promote local economic activity. These demands align with climate-adaptive, socially inclusive, and low-cost intervention strategies advocated in recent public space regeneration studies (UN-Habitat, 2020).

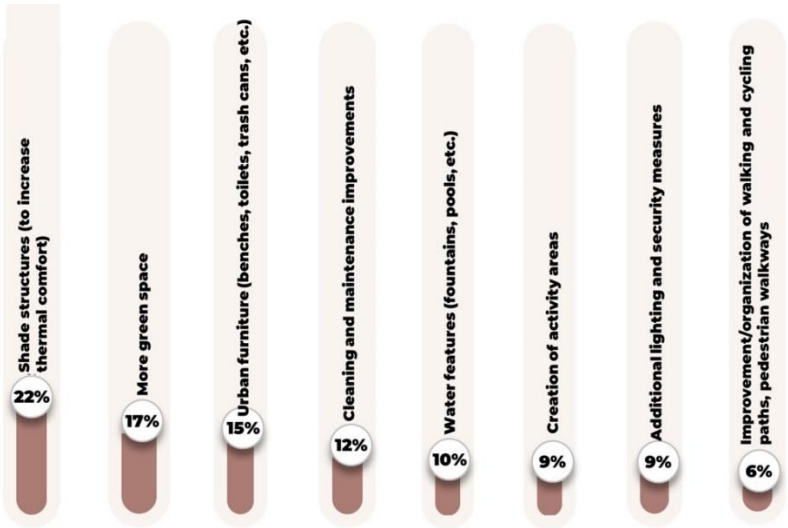

Table 1 also shows the distribution of reasons why participants could not use Democracy Square during extreme weather events. The most frequently observed problem, cited by 36 participants (80%), was the lack of overhead cover. Five participants highlighted the lack of sheltered areas against extreme weather events (11%), two participants mentioned slippery surfaces due to heavy rainfall (5%), and one participant each emphasized the lack of climate-appropriate urban furniture and infrastructure deficiencies (2%).

Table 2. Reasons for not being able to use democracy square during extreme weather events

Table 2 shows the distribution of changes participants wanted to make to make Democracy Square more attractive. The top change requested by participants to make the square more appealing is shade (improved thermal comfort), mentioned by 58 participants. Other requested changes include more green space (mentioned by 46 participants), urban furniture (mentioned by 39 participants), and improvements in cleaning and maintenance (mentioned by 32 participants).

Table 3. Distribution of participants according to the changes they want in the square

4. Conclusion and Recommendations

The study presents a comprehensive spatial and experiential evaluation of Aliağa Democracy Square, a civic public space located in the Kültür neighborhood of İzmir. By combining spatial observation, semi-structured interviews, and structured surveys, the research offers a triangulated, user-centered diagnosis of the square's current conditions and future needs. The findings highlight several persistent challenges, including poor thermal comfort, insufficient shaded and green areas, inadequate seating, maintenance deficits, and limited inclusive design features.

From a spatial justice and urban resilience perspective, the square underperforms in terms of accessibility, comfort, and social inclusion—particularly for elderly users, children, and people with limited mobility. Moreover, the lack of ecological design elements and microclimate-responsive urban furniture exacerbates discomfort, especially under increasing summer heat stress linked to climate change (Nikolopoulou & Lykoudis, 2006; Johansson et al., 2014). Despite these shortcomings, the square is intensively used by local residents and visitors, indicating its latent potential as a more vibrant and inclusive civic space.

In light of these findings, the following recommendations are proposed to guide a user-informed, climate-adaptive, and socially inclusive transformation of the square:

Design-Based Interventions

- Ecological shading structures (e.g., pergolas, tree clusters) to mitigate urban heat and improve year-round usability.
- Inclusive and weather-resistant seating arrangements, integrating shade and proximity to active zones.
- Barrier-free paving design, especially in areas with uneven or damaged surfaces.
- Green infrastructure elements, including planted borders, bioswales, and seasonal vegetation, to support visual comfort and ecological function.
- Dedicated activity zones (e.g., play areas for children, flexible kiosks for local vendors) to enhance everyday interaction and stimulate local economies.

- Species-specific bird water and feeding stations to address hygiene and spatial organization issues observed in the field.

Operational and Policy Recommendations

- Regular maintenance protocols for urban furniture, lighting, and paving.
- Introduction of participatory design workshops with community members to co-develop spatial layouts and programs.
- Integration of the square into broader green and blue infrastructure networks of the city, improving both ecological performance and connectivity.
- Institutionalization of public space monitoring tools, leveraging citizen science methodologies for continuous evaluation and adaptive management.
- Ultimately, this research underscores the value of embedding user experience, climatic responsiveness, and citizen participation in the redesign of public spaces. The case of Aliağa Democracy Square illustrates how low-cost, context-sensitive interventions, guided by local knowledge and participatory tools can transform underperforming squares into more inclusive, vibrant, and sustainable urban places.

Thanks and Information Note

The article complies with national and international research and publication ethics.

Ethics Committee approval in the study, Ethics Committee of the İzmir İnstitute of Technology dated 13.05.2025 and that it was taken with the decision no E-41752998-050.04-2500029932.

I would like to extend my sincere gratitude to Prof. Dr. Koray Velibeyoğlu, Dr. Hasibe Velibeyoğlu, Aylin Göknur and Müge Tikik for their invaluable guidance and contributions throughout the study. Special thanks are also due to all citizen participants in Aliağa who generously shared their time, knowledge, and experiences during the fieldwork.

The author declares no conflict of interest regarding the publication of this article. 1st Author %100 contributed.

Abstract

This study aims to examine the climate-related performance effects of adaptive façade designs by comparing the façade systems of three buildings located in regions with different climate types. The selected buildings are the Al Bahr Towers in Abu Dhabi, representing a hot–dry climate; the Information and Communication Technology Center in Lucca, representing a Mediterranean climate; and the Nordic Embassies Complex in Berlin, representing a humid continental climate. Each building was analyzed according to criteria such as façade type, movement mechanism, adaptation direction, materials used, and the level of thermal and visual comfort achieved. Based on the obtained data, the relationship between climate conditions and façade systems was evaluated, questioning the effectiveness of each façade design within its specific climatic context. The results revealed that considering climatic differences in façade design is critical in terms of energy efficiency, user comfort, and aesthetic coherence. In this context, it is emphasized that adaptive façade systems should be approached holistically in relation to local climatic data

Keywords: Adaptive façade, adaptive façade systems, climate-based design

1. Introduction

Today, environmental pollution and the disruption of the natural balance seriously threaten the sustainability of ecosystems worldwide. The future availability of existing natural resources has become a major issue discussed by experts from various disciplines. The American Institute of Architects (AIA) defines sustainability as the ability of a system to continue functioning properly even in cases of excessive consumption or depletion of essential resources. In this regard, sustainable design is recognized as an approach that aims to minimize negative environmental impacts while enhancing the quality of living environments. Within this framework, it is emphasized that energy consumption in buildings should be minimized, passive design strategies should be implemented, and structures should be designed in accordance with their local climatic context (Tatar, 2013).

In contemporary architecture, the rapid changes in environmental conditions and user needs make it essential for façade systems to be more flexible and adaptable. Adaptive façades attract attention as multifunctional systems with a high capacity to respond and adjust to external and internal conditions. These façades can effectively perform key functions such as balancing indoor temperatures, improving ventilation, generating energy, maximizing the use of daylight, and providing shading and humidity control by responding to environmental variables like weather conditions and solar radiation (Favoino et al., 2015; D. Aelenei et al., 2016).

2. Materials and Methods

The study aims to comparatively analyze adaptive building façades applied in different climate types and to determine the extent to which these systems respond to climatic conditions. Adaptive façade systems were evaluated in terms of their geographical location, climate type, and environmental responsiveness.

A literature review was first conducted to establish the classification, functions, and environmental interaction levels of adaptive façades. The systems were categorized based on criteria such as façade dynamism, response mechanism, control strategy (self-operating or user-controlled), and energy approach (passive or active). From this review, evaluation parameters were developed for use in the comparative analysis.

Three case studies representing different climatic zones were selected: Al Bahr Towers (BWh, Abu Dhabi) for the hot–arid climate, the Information and Communication Technology Center (Csa, Lucca) for the Mediterranean climate, and the Nordic Embassies Complex (Dfb, Berlin) for the humid continental climate. These examples were analyzed to assess how adaptive façade systems respond to local climatic needs through design and technological strategies.

Each building was examined according to façade type, adaptation direction, movement mechanism, response time, maintenance needs, material use, aesthetic quality, and overall performance. The analysis emphasized the façades' contributions to thermal, visual, and acoustic comfort as well as energy efficiency. The comparative approach revealed the functional, aesthetic, and technological potentials and limitations of adaptive façades under different climatic conditions, offering a foundation for future climate-responsive design decisions.

2.1 Overview of adaptive façade systems and typological classification

In architecture, the concept of "adaptive" refers to a building's capacity to change form or behavior in response to environmental variables or user needs—its ability to adjust to the surrounding context. The façade components or materials used in such buildings perceive physical data from the environment and respond accordingly. The main purpose is to enhance the building's functionality and improve its environmental performance.

In recent years, façade systems have increasingly been designed not merely as static and passive elements, but as dynamic systems containing active components that continuously interact with their external surroundings. In this context, adaptive façade systems transform the building envelope into a multifunctional interface capable of interacting with the outdoor environment. By performing functions such as thermal regulation, natural ventilation, daylight redirection, shading, humidity control, and even energy generation, they contribute to improving indoor comfort conditions. Owing to their flexible structures that can be modified according to users' needs, these systems can effectively respond to varying climatic conditions. (Favoino et al., 2015; Aelenei et al., 2016)

2.2 Typologies of adaptive façades: system characteristics and classification criteria Adaptive façade systems cannot be defined under a single universal description in the literature due to their diverse characteristics; therefore, they are categorized under various subheadings. Today, these systems are evaluated based on their integrated building technologies as well as their control and regulation mechanisms (Romano et al., 2018).

Table 1. Comparison of adaptive façade systems with different typologies *(Adapted from Romano et al., 2018)*

Façade Type	Definition / Characteristics	Adaptation Mode	Response Mechanism	User Interaction	Technology / Material
Active Façade	Systems that adapt to environmental changes to provide energy savings and comfort	Manual / Automatic	Mechanical	✓	System-based
Advanced Façade	High-performance façades integrated with energy systems and responsive building elements	Automatic	Integrated building systems	X	Responsive elements + control systems
Biomimetic Façade	Systems inspired by natural organisms and processes	Passive / Automatic	System-based	X	Biomimetic principles / systems
Kinetic Façade	Flexible and dynamic systems that change physically through motion	Automatic / Mechanical	Moving components	X	Mechanical / motorized systems
Smart Façade	Materials and systems responsive to environmental changes	Automatic	Sensor + control system	X	Material / system software
Interactive Façade	Systems shaped by human interaction, responding to both environment and users	Semi-automatic	User-triggered	✓	Responsive modules
Movable Façade	Systems that adjust position according to the sun's movement and enable renewable energy generation	Automatic	Mechanical	X	PV + sun-tracking systems
Responsive Façade	Systems reacting to environmental data through sensors, behaving according to specific stimuli	Automatic	Sensor + actuator	Partially	Responsive system components
Switchable Façade	Systems that alter the light transmittance or thermal properties of materials such as glass	Automatic	Smart glass / material	X	LC glass, electrochromic glass
Transformable Façade	Façades capable of physically changing their form	Automatic	Morphological transformation	X	Dynamic materials

The classification of adaptive façade systems has undergone a significant evolution in terms of scope and focus over time. Initially, in 2000, Fox and Yeh classified façades according to

material type, typology, and control mechanisms, focusing on the fundamental components of the system (Fox & Yeh, 1999). In 2005, Addington and Shodek advanced this classification to a more technical level by emphasizing the characteristics of smart materials and their energy interactions (Addington & Shodek, 2005). In 2009, the IEA ECBCS Annex 44 study highlighted the performance criteria of façade systems and their integration with HVAC systems, focusing on energy performance (Ayçam, 2011). In 2011, Ramzy and Fayed developed a more comprehensive model that included parameters such as movement type, control method, and cost (Ramzy & Fayed, 2011). Between 2013 and 2015, Loonen and his team expanded the classification framework by incorporating multidimensional criteria such as comfort, time scale, and visual impact. Finally, studies conducted in 2017 and 2018 proposed more systematic and holistic classification models that addressed adaptation factors, technology levels, and triggering mechanisms in detail (Basarır & Altun, 2017; Romano et al., 2018). This progression demonstrates that adaptive façades are now evaluated not only through material or functional characteristics but also in terms of performance, aesthetics, and technological integration as multilayered parameters.

The primary function of façades is to protect indoor environments from external influences and to ensure this protective function is achieved in the most efficient way (Johnsen & Winther, 2015). Adaptive façades respond to various external factors to maintain indoor comfort. These factors include the balanced use of daylight, control of outdoor temperature and humidity, the effects of climatic elements such as wind and precipitation, and the reduction of environmental noise. These parameters play a decisive role in façade design, both in maintaining thermal and humidity balance and in enhancing spatial comfort (D. Aelenei et al., 2016).

Table 2. Comparison of adaptive façade systems in different typologies (Adapted from D. Aelenei et al., 2016)

Thermal Comfort	Visual Comfort	Acoustic Comfort	Ventilation and Spatial Comfort
Maintains a balanced indoor temperature by adapting to changes in external temperature and humidity.	Controls daylight to optimize indoor illumination, reducing glare and thermal load.	Blocks environmental noise, creating a quiet and comfortable indoor environment.	Supports natural ventilation through adaptive movements against wind and precipitation.

3. Findings and Discussion

3.1 Comparative analysis of adaptive façade systems in different climate types

Although various methods are used to classify climates, one of the most widely adopted is the Köppen–Geiger system. This method defines climate zones based on temperature and precipitation data, as well as the relationship between these variables and vegetation characteristics (Öztürk et al., 2017).

In this study, three buildings with adaptive façade systems located in different climate types were selected. The Nordic Embassies Complex (Berlin, Germany) is situated in the *Dfb* climate type, which represents a humid continental climate characterized by mild summers, long and cold winters, and evenly distributed precipitation throughout the year (Köppen, 1930). The Information and Communication Technology Center (Lucca, Italy) is located in the *Csa* climate type, corresponding to a Mediterranean climate characterized by hot and dry summers, mild

and rainy winters, and seasonal variations in precipitation (Köppen, 1930). The Al Bahr Towers (Abu Dhabi, United Arab Emirates) fall within the *BWh* climate type, defined as a hot desert climate with high temperatures, minimal rainfall, and extremely dry conditions throughout the year (Köppen, 1930).

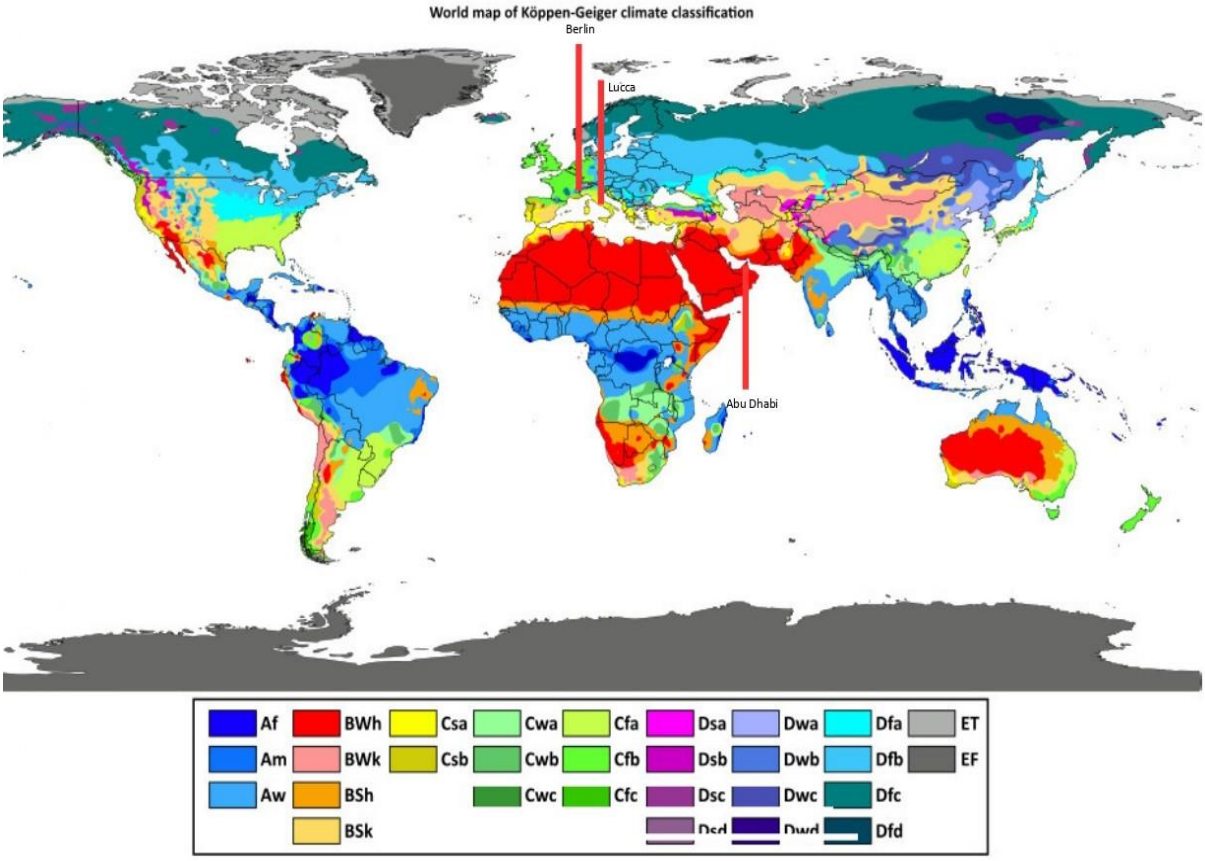

Figure 1. Locations of the selected buildings on the Köppen–Geiger climate classification map (adapted from Beck et al., 2018).

3.2 Nordic Embassies Complex (Berlin, Germany)

The architecture firm Berger and Parkkinen developed a master plan for the Nordic Embassies Complex in Berlin and led the construction of the project, which was completed in 1999. The building's plan form, characterized by sharp-angled corners, was shaped by drawing inspiration from pedestrian circulation patterns and the orientation of walkways within the urban context. The main façade of the complex is clad with horizontally arranged copper lamellas, designed to emphasize the perception of five distinct volumes corresponding to the individual embassies of each Nordic country. These lamella systems can be controlled in groups, allowing the gradual revelation of the underlying façade surface when required (Aelenei et al., 2018).

Table 3. Nordic Embassies Complex

Nordic Embassies Complex

System Maintenance Frequency	Annual

3.3 Information and Communication Technologies Center

The Information and Communication Technology Center features a dynamic double-skin façade integrating photovoltaic panels and movable shading elements to improve energy efficiency. Its 50% opaque and 50% transparent modules optimize daylight, support energy generation, and enhance thermal comfort through natural ventilation. *(Sala & Romano, 2011)*

3.4 Al-Bahr Towers

The façade of the Al Bahr Towers features a responsive system that adapts to environmental conditions. Its geometry changes according to the sun's angle, providing shading and preventing overheating by reducing direct sunlight. Controlled by sensors that monitor weather conditions, the system adjusts automatically to maintain indoor comfort and improve energy efficiency throughout the day. (Maden, 2022)

4. Conclusion and Recommendations

The findings indicate that façade systems are shaped according to local climatic conditions and optimized within their specific contexts.

•Nordic Embassies Building (Berlin, Dfb climate type): This structure features an active façade system designed to adapt to humid continental conditions. Reacting to solar radiation and seasonal temperature variations, the façade is composed of a steel frame and copper louvers. In addition to providing both visual and thermal comfort, the building stands out with its high aesthetic value that supports its public image and collective identity.

• Information and Communication Technology Center (Lucca, Csa climate type): Designed for the hot and dry summers of the Mediterranean climate, the smart glass façade system adjusts light transmittance to enhance both thermal and visual comfort indoors. The system also contributes to energy generation and provides acoustic comfort. This multi-layered performance transforms the façade from a passive protective element into an active energy component.

•Al Bahr Towers (Abu Dhabi, BWh climate type): Responding to the extreme heat and intense solar radiation of a hot-arid climate, the kinetic façade system consists of aluminum mashrabiya panels that dynamically filter sunlight, reducing indoor temperatures and energy consumption. The façade also achieves strong aesthetic value through its visual connection with traditional architectural elements.

Across all buildings, mechanical movement systems, minute-level response times, and annual maintenance requirements were observed. However, adaptation direction, materials used, and performance outcomes differ depending on the climatic context.

This study conducted a comparative analysis of buildings located in three distinct climate zones, each featuring different adaptive façade systems. The results reveal that façade systems are not merely aesthetic elements but dynamic components directly influencing climatic efficiency and indoor comfort.

Buildings in Dfb, Csa, and BWh climate regions developed distinct adaptation strategies to respond to local environmental conditions:

- In cold climates, façades are designed to maximize daylight use while responding to seasonal variations.
- In hot-summer climates, façades regulate light transmittance to limit heat gain and enhance occupant comfort.
- In extremely hot and dry climates, façades incorporate dynamic shading elements that block direct sunlight and reduce energy loads.

Recommendations:

1. Climate-Responsive Design: Adaptive façade systems should be designed with local climatic data in mind. Instead of a uniform approach, systems must be customized according to climate-specific performance targets.

2. Material and Technology Integration: The durability, maintenance needs, and energy performance of selected materials should be considered. Smart glazing, kinetic systems, and shading devices should be strategically integrated.

3. Aesthetic and Cultural Harmony: The visual impact of façade systems should align with the geographical and cultural context, reinforcing public perception and architectural identity.

4. Performance Monitoring and Feedback: Long-term monitoring and user feedback are essential for evaluating and improving façade system performance.

Adaptive façade systems offer holistic solutions in sustainable architecture by integrating environmental, technological, and aesthetic dimensions. Their wider and more efficient use in the future will represent a significant step toward enhancing energy efficiency and occupant comfort within architectural practice.

Abstact

The conservation of historical buildings is a multifaceted and multi-actor process that involves not only physical intervention but also the collaboration of various disciplines such as architecture, civil engineering, materials science, art history, and archaeology. In this context, the discipline of civil engineering plays a critical role in technical aspects such as analyzing structural systems, identifying damage, developing structural reinforcement methods, and determining appropriate intervention techniques. This study evaluates the contributions of civil engineering to the conservation of historical and cultural heritage within the framework of key principles such as authenticity, reversibility, material compatibility, minimal intervention, and sustainability. Particularly in the design and implementation phases, civil engineers are shown to actively contribute to the protection of cultural heritage through responsibilities such as preparing structural assessment reports, conducting material tests, and developing appropriate reinforcement strategies.

One of the distinctive aspects of this study is its focus on the comparative analysis of civil engineering-related courses within architectural conservation graduate programs in Turkey and Europe. Within this scope, program contents are examined to assess the extent to which interdisciplinary education is adopted and how technical knowledge is integrated into academic curricula. The findings emphasize the importance of graduate education in training conservation professionals with strong technical foundations and highlight the need for a more holistic educational approach in this field. The study ultimately aims to enhance the competencies of future conservation specialists and strengthen the visibility of civil engineering contributions in the transmission of cultural heritage to future generations.

Keywords: Historical building conservation, civil engineering, interdisciplinary approach, graduate education, structural reinforcement techniques

1.Introduction

Article 2 of the Venice Charter emphasizes that the conservation and restoration of monuments should draw upon all relevant scientific and technical disciplines (ICOMOS, 1964). This principle, while historically rooted in architecture, civil engineering, and materials science, has become even more relevant with the rapid development of technology. Today, new areas of expertise are increasingly integrated into conservation processes, enriching both the methodology and the outcomes.

In particular, software engineering has emerged as a promising field within heritage preservation. Digital tools designed for structural analysis, damage assessment, and

intervention planning provide civil engineers with valuable means to document the current condition of historic buildings and to plan appropriate engineering responses.

The 2013 declaration of ICOMOS Turkey further underlines the importance of studying load-bearing systems in conjunction with architectural documentation. It stresses that data should be gathered from historical sources, the structure itself, and through field or laboratory testing—preferably using non-destructive methods. Such assessments must also include soil characteristics and foundation structures, as they are critical to understanding the overall stability of a monument.

Earthquakes and ground movements, in particular, pose serious risks to historic buildings, often resulting in significant structural damage. This makes it essential for restoration strategies to combine traditional techniques with modern engineering solutions. Whereas earlier generations of architects relied on buttresses, ties, or partial reconstruction to address structural problems, contemporary practice now incorporates methods such as grouting, prestressing, anchorage systems, foundation enlargement, and pile foundations that reach stable soil layers (Ahunbay, 2022, pp. 92–93). Such approaches highlight that conservation is not only about safeguarding historical and cultural values, but also about ensuring structural safety and managing potential risks. Experimental studies and numerical analyses have likewise become indispensable, providing the technical evidence needed to support well-informed decisions.

For these methods to be applied effectively, however, technical expertise must extend beyond undergraduate education. It is increasingly important that engineers engaged in conservation receive interdisciplinary training at the graduate level. In both Turkey and Europe, master's programs dedicated to the preservation of historic structures now offer a growing number of courses with a civil engineering focus. This trend promises to equip future specialists with the technical competence required to meet the complex challenges of conservation practice.

2.Materials and Methods

This study employs a qualitative content analysis, focusing on a comparison of master's programs in historic preservation offered by universities in Turkey and Europe. The analysis draws on information compiled from course curricula that are publicly accessible online.

In addition, insights into engineering practices—such as the assessment of load-bearing systems, structural analysis procedures, and field observations—were gathered through a combination of literature review and an interview with Civil Engineer Volkan Aydemir, who works at the Kayseri Regional Directorate for the Conservation of Cultural Heritage.

3.Findings and Discussion

Restoration is not a simple repair task carried out with ordinary craftsmanship. On the contrary, a successful conservation process requires profound knowledge, careful observation skills, and a collaborative team approach. The planning, implementation, and monitoring of such a process cannot be achieved through theoretical knowledge alone, but must also be supported by experience and professional expertise.

As Ahunbay (2022) points out, just as a surgeon would never be authorized to perform an operation without a thorough knowledge of anatomy, an architect or engineer lacking sufficient understanding of traditional building materials, techniques, structural systems, and typologies should not be entrusted with the highly delicate responsibility of safeguarding cultural heritage.

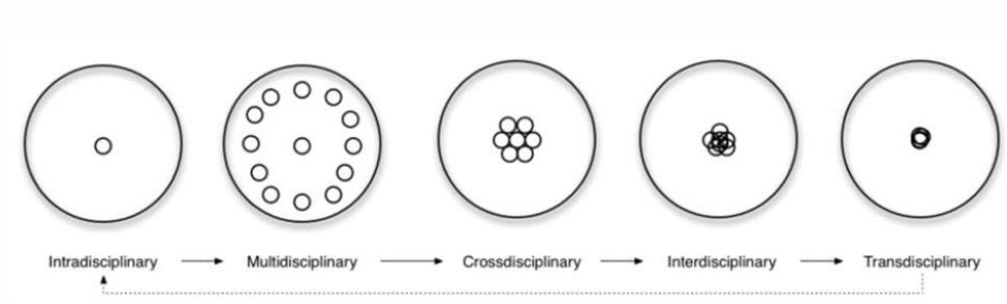

Figure 1. Diagram of Interdisciplinary Approaches (Zeigner, 1990)

In architectural practice, when sufficient communication and collaboration with other disciplines are not established, projects are often evaluated solely within the narrow framework of a single profession (an intradisciplinary approach). This frequently results in serious technical shortcomings and coordination problems during implementation. In contrast, multidisciplinary practices—where different disciplines work side by side but with limited knowledge exchange—are observed in Turkey to only a modest degree. While such an approach provides a partial basis for generating solutions, it remains insufficient for producing fully integrated outcomes.

By comparison, in advanced architectural offices, interdisciplinary collaboration is carried out more effectively. As a result, the design, engineering, and implementation stages of projects produce more holistic, reliable, and efficient outcomes.

Within this framework, the concepts illustrated in the diagram may be summarized as follows:

- **Intradisciplinary approach** refers to work conducted strictly within the boundaries of a single discipline.
- **Multidisciplinary approach** describes a model in which different disciplines work in parallel, but with limited interaction.
- **Crossdisciplinary approach** involves the borrowing of selected concepts or methods from one discipline by another, without deeper integration.
- **Interdisciplinary approach** aims to generate joint solutions through reciprocal knowledge exchange between disciplines.
- **Transdisciplinary approach** transcends disciplinary boundaries altogether, fostering the development of new areas of knowledge and methods.

This conceptual framework makes clear why interdisciplinary interaction is so vital for producing sustainable solutions in architectural and restoration projects.

3.1. Evaluating the Fundamental Principles of Historic Building Conservation from a Civil Engineering Perspective

The conservation of historic buildings involves more than preserving their aesthetic and architectural qualities; it also requires ensuring the long-term stability of their structural systems. In this regard, civil engineering provides a critical lens, examining whether proposed interventions are technically sound, structurally safe, and appropriate for the building as a whole.

From this perspective, five key principles guide the conservation process: authenticity, reversibility, material compatibility, minimum intervention, and sustainability. Each of these principles plays an essential role in shaping how engineering decisions are made, ensuring that interventions not only protect the cultural value of the structure but also secure its physical integrity for future generations.

a. Authenticity

Article 9 of the Venice Charter reminds us that restoration is not simply a technical procedure but a specialized process aimed at preserving the aesthetic and historical values of monuments. It calls for interventions to be based on authentic materials and reliable documentation. The principle that *"restoration must stop where conjecture begins"* is vital, not only from an ethical perspective but also for engineering practice. Structural interventions should always be grounded in solid technical evidence and research, leaving no space for assumptions. At the same time, any new additions should be designed to remain clearly distinguishable—both technically and visually—from the original fabric, a principle that engineers must carefully uphold in their projects.

b. Reversibility

In its 2003 document, *Principles for the Analysis, Conservation and Structural Restoration of Architectural Heritage*, ICOMOS stresses that interventions should, whenever possible, be reversible. This ensures that as new knowledge emerges, existing measures can be removed without causing harm and replaced with more appropriate solutions (ICOMOS, 2003). In practice, however, complete reversibility is not always achievable—particularly when structural safety is at stake. From an engineering standpoint, the challenge lies in striking a careful balance: protecting the authenticity of the building while ensuring the safety of those who use it. In this sense, reversibility is less an absolute rule and more a guiding principle that must be weighed against structural necessity.

c.MaterialCompatibility

Article 12 of the Venice Charter calls for missing parts of a building to be reconstructed in harmony with the existing structure, while still remaining distinguishable. For engineers, this principle translates into a conscious use of modern materials and techniques—not to imitate the historical fabric, but to ensure that interventions are deliberately recognizable. Such an approach strengthens the structural system while also safeguarding the documentary value of the monument, allowing it to be passed on to future generations with its history clearly legible.

d.Minimum Intervention

Conservation must respect the building's current state, its functions, spatial relationships, and cultural significance. As the Burra Charter puts it, the goal is to intervene "as much as necessary, but as little as possible" (Australia ICOMOS, 2013). For engineers, this principle carries considerable responsibility. Structural strengthening or repair should aim to preserve as many existing load-bearing elements as possible and to retain original materials in place. Avoiding unnecessary interventions is not only a matter of ethics but also a reflection of professional awareness. Where new structural elements are unavoidable, they should be designed in a way that avoids damaging the existing structure and leaves a clear record of their later addition.

e.Sustainability

Article 4 of the 1972 UNESCO Convention Concerning the Protection of the World Cultural and Natural Heritage places responsibility on states to safeguard their cultural heritage and transmit it to future generations (UNESCO, 1972). Within this framework, civil engineering takes on a central role. Ensuring structural safety, analyzing the properties of existing materials, and applying appropriate strengthening methods are all tasks that directly depend on engineering expertise. These technical measures contribute not only to the protection of monuments but also to their continued use and vitality—helping heritage to remain a living part of society rather than a relic frozen in time.

3.2. Roles and Responsibilities of Civil Engineers in Conservation

a. Preparation of Structural Assessment Reports

Before any intervention can take place, historic buildings must be carefully examined on site. This initial assessment involves documenting the properties of materials, identifying existing damage, and recording visible structural deterioration. When necessary, samples are taken from the building for laboratory testing to provide a clearer understanding of material performance (General Directorate of Foundations, 2021).

The type of analysis carried out depends on the building's complexity, the nature of its load-bearing system, and the characteristics of its materials. Both linear and non-linear methods, as well as static and dynamic approaches, may be employed. These analyses help to pinpoint vulnerable areas of the structure and form the basis for detailed reports outlining where and why intervention is required (General Directorate of Foundations, 2021).

At this stage, proposals for strengthening or repair are designed to respect the building's original values. Engineering solutions emphasize the preservation of existing load-bearing elements, the use of in-situ strengthening techniques, and adherence to the principle of minimum intervention. Application projects prepared in line with these structural reports aim to achieve two goals simultaneously: ensuring safety while protecting cultural heritage.

b. Supervision and Control of Implementation

Insights from Civil Engineer Volkan Aydemir of the Kayseri Regional Directorate for the Conservation of Cultural Heritage highlight the regulatory framework that guides conservation practice. According to Aydemir, two key documents shape engineering responsibilities in restoration projects.

The first is the *Guidelines for Strengthening and Repair of Historic Buildings*, published by the General Directorate of Foundations. This document provides practical guidance for protecting the authenticity of historic structures and selecting appropriate methods of intervention. The second is the *Turkish Seismic Code for Buildings* (2018), which establishes the principles and calculation methods necessary for ensuring the structural safety of historic buildings under seismic conditions.

Aydemir stresses that these two documents must be applied together. In his view, successful implementation requires balancing the ethical and cultural responsibilities of conservation with the technical demands of structural safety. This balanced approach ensures that restoration projects are both respectful of heritage and resilient in the face of physical risks.

3.3. The Role of Civil Engineering Courses in Graduate Programs on Historic Preservation: A Comparative Analysis

Graduate-level education plays a central role in preparing specialists capable of addressing the technical challenges of heritage conservation. Across Turkey and Europe, civil engineering courses are increasingly integrated into master's programs on historic preservation. These courses provide future conservation professionals with essential skills in structural assessment, materials analysis, and engineering-based intervention methods.

A comparative look at curricula reveals important differences and similarities. In Turkey, programs often focus on practical concerns such as seismic safety and repair techniques for masonry structures—reflecting the country's vulnerability to earthquakes and the prevalence of stone and brick heritage buildings. In contrast, many European programs place greater emphasis on theoretical frameworks, advanced materials research, and interdisciplinary collaboration, drawing from a broader tradition of conservation studies.

Despite these differences, both contexts highlight the same underlying need: equipping architects, engineers, and conservators with the knowledge to design interventions that are both technically sound and culturally sensitive. This integration of engineering into graduate education strengthens the professional capacity to safeguard historic buildings in a sustainable and responsible way.

Table 1. Civil Engineering–Related Courses in National and International Graduate Programs on Historic Preservation

When graduate programs in different countries are compared, it becomes clear that civil engineering courses are included in historic preservation curricula to varying degrees. In Turkey, for example, universities such as ITU, METU, YTU, and MSGSU tend to prioritize practice-oriented courses. These often address the deterioration of building materials, traditional construction techniques, and strengthening methods. While such courses are valuable, they remain largely focused on conventional practices and are not yet fully supported by analytical approaches or digital engineering tools.

European institutions present a contrasting picture. Leading universities such as Politecnico di Milano, TU Delft, UCL Bartlett, and Roma Tre University have made engineering-based content an essential part of preservation education. Their curricula include advanced topics such as structural analysis, performance evaluation, and seismic risk assessment. For instance, the

Heritage at Risk course at Politecnico di Milano allows students to explore seismic risks using digital tools, strengthening the link between conservation and engineering innovation. TU Delft's *Building Engineering Studios* and UCL Bartlett's *Historic and Contemporary Materials* courses adopt an interdisciplinary perspective that evaluates both the cultural value and technical performance of building materials. At Roma Tre University, the *Strength of Materials* course provides students with the skills to analyze material performance through fundamental engineering principles.

In the Turkish Republic of Northern Cyprus, institutions such as Eastern Mediterranean University also offer courses on structural analysis and material deterioration, further underlining the growing recognition of engineering's role in conservation education.

Taken together, these comparisons suggest that European programs use civil engineering more effectively as a tool in conservation, often supported by digital technologies and advanced analytical methods. Turkish programs, meanwhile, remain more rooted in traditional practices, with relatively limited use of numerical modeling or digital simulations. Expanding the integration of performance modeling, seismic analysis, and digital engineering tools into Turkish curricula would not only strengthen interdisciplinary collaboration but also improve the international competitiveness of these programs.

4. Conclusion and Recommendations

The conservation of historic buildings is far more than a technical exercise; it is an interdisciplinary endeavor that seeks to safeguard cultural heritage for future generations. Achieving this goal requires close collaboration and clear communication among a wide range of professionals, including architects, civil engineers, art historians, restorers, and conservation specialists. For civil engineers in particular, higher education programs that foster multidisciplinary learning are no longer optional but essential.

Equally important, the sustainable protection of heritage must extend beyond the work of experts. Broader public awareness is crucial, and the practices of countries such as Italy and the United Kingdom provide useful examples. In Italy, for instance, schoolchildren participate in field trips and on-site observation classes designed to connect them with their cultural environment from an early age. Such initiatives help instill an awareness of cultural heritage long before students choose a profession (Kishalı, 2020).

Early education of this kind lays the groundwork for future professionals—especially engineers—to adopt a holistic conservation mindset. It encourages them to value not only the structural stability of historic buildings but also their cultural meaning. This makes clear that conservation is not just about what is done on site, but also about how the next generation of experts is trained to approach their responsibilities.

A comparison of graduate programs in architecture and restoration, both in Turkey and abroad, shows that programs incorporating civil engineering and other interdisciplinary content are more effective and successful. Expanding multidisciplinary conservation education will therefore serve two purposes: it will encourage academic programs to adapt and modernize, and it will help practitioners from different fields develop a shared language. Together, these efforts will make conservation processes more coherent, effective, and sustainable.

Thanks

I would like to thank Kayseri Sugar Company for their valuable support in this study, and Civil Engineer Mr. Volkan Aydemir for generously sharing his insights during the interview process.

An Experience-Based Mapping of the Samsun City-Center

Hande ASAR [1]*

ORCID 1: 0000-0003-3201-3204
[1]Assoc. Prof. Dr., Ondokuz Mayıs University, Faculty of Architecture, Department of Architecture, Samsun-Türkiye
hande.asar@omu.edu.tr (Responsible Author)

Abstract

During and after the experience of a space, individuals encounter a multiplicity of elements that shape memory, stimulate the senses, and enrich or differentiate perception. Each encounter contributes to the accumulation of new layers of knowledge, thereby expanding one's understanding of the spatial environment. Within the architectural design process, such experiences can be framed through themes such as space–user relations, the interplay of place and space, and the influence of culture, all of which contribute to design development. This study emphasizes space as a foundational dimension of design and introduces experience-based mapping as a methodological tool. The notion of space-specificity in architectural design requires a comprehensive consideration of the multiple layers of knowledge embedded within a given site. While conventional modes of representation—such as photography, sketching, and analysis—offer valuable insights, relational representational methods are particularly effective in visualizing the continuity and stratification of experience. By synthesizing diverse perspectives and techniques, these methods parallel the multifaceted process of understanding space. Accordingly, comprehending space necessitates engagement with varied perspectives. Building on this premise, the present research examines the experience-based mapping technique as a tool for relational production and critical reflection. To this end, a case study was conducted in the city center of Samsun, offering a conceptual evaluation of its outcomes. The study concludes by highlighting experience-based mapping's potential contributions to architectural design, particularly in the context of architectural education.

Keywords: Architectural design process, architectural design education, experience-based mapping, relational representations, Samsun

1. Introduction

The architectural design process is established and carried out through multidimensional modes of thinking and making. At nearly every stage of this process, the notion of spatial experience plays a crucial role. The explicit and tacit knowledge gained during the experience of a space converges to enrich and transform the perspective of the designer/architect. Thus, each new architectural design process has the potential to become an innovative and creative domain that embraces diverse viewpoints and generates new relationships by drawing upon them. Particularly in the phases of spatial construction (such as analyses, syntheses, preliminary sketches, and interrelations among units), experiential knowledge is a significant catalyst that stimulates and sustains creative thinking. Accordingly, this study focuses on experiential knowledge and discusses how this knowledge contributes to the architectural design process through various techniques. To this end, emphasis is placed on the relational dimension of architectural representation techniques, and an evaluation of how technical knowledge can be rendered relational. Within the scope of the study, the mapping technique has been employed as a relational method. Since the technique is constructed and debated through experiential knowledge, it has been referred to throughout the study as an experience-based mapping technique.

Although the architectural design process employs broadly similar techniques and is carried out through comparable approaches, it remains a highly personal and creative field. Within professional practice, each architect forges a unique trajectory throughout their career. This trajectory, which is open to continuous development, can be reproduced in diverse ways

depending on the architect's individual approach. In architectural education, however- particularly in the early years- this is not the case. Students are introduced to various techniques and methods that shape their design trajectory during the learning process. Accordingly, the greater the number and diversity of these factual and methodological encounters, the greater the student's opportunity to develop an individual and distinctive design path.

In the context of architectural education, "in a world where uncertainty is increasing and education is becoming more personal and open-ended, abstract concepts such as intuition, common sense, emotional intelligence, a sense of responsibility, a sense of justice, flexibility, and creativity come to the forefront" (Yürekli & Yürekli, 2004). Accordingly, within the scope of this study, experience-based mapping is discussed as one of the techniques that draws upon notions such as flexibility and creativity and may assist students in constructing their own design trajectories. To further elaborate on this technique—conceived as a relational tool for both production and thinking—selected works carried out in the city center of Samsun within the course "Relational Practices in Architectural Design", taught by the author in the Department of Architecture at the Faculty of Architecture, Ondokuz Mayıs University (OMÜ), have been used as examples.

As is well known, cities offer users a multi-layered field of experience. The multiple relationships between the fixed and mobile elements of the city render the time spent in the same place at different moments unique each time. Thus, even when the fixed components of the city remain unchanged, the presence of dynamic variables mediates the formation of new experiential layers associated with that place. This condition provides designers with potential opportunities to conceive action–space relations specific to a given site within the architectural design process. To reveal such potentials, however, it is necessary to make their existing relational conditions similarly visible. At this point, the notion of relational thinking—and its translation into practice—gains significance. Relational thinking, at its core, refers to "the discovery rather than the transmission of knowledge" (Aydınlı & Avcı, 2010) and constitutes a phenomenon and practice that privileges relationships over outcomes (Kızıltoprak & Yavuzsoy Köse, 2017). Relationality is established through interaction, and interaction fields serve as catalysts for stimulating creativity. Because "(...) interactive systems do not impose a particular pattern of action; rather, they provide a space of negotiation in which individuals can exercise their 'multiple' capacities of action in creative ways" (Kocaballi et al., 2011).

Various approaches to relational thinking and relationality emerge across different fields and are drawn upon within the domain of architectural knowledge. As Kararmaz and Polatoğlu Serter (2025) state, relational thinking- developed as a response to dual paradigms in Western thought- finds its architectural foundations in Alfred North Whitehead's process philosophy, Enzo Paci's phenomenological relationality, and the deconstructive ideas of Gilles Deleuze and Félix Guattari. Today, however, the discourse on relationality has expanded further through diverse media, tools, and approaches. Actor-Network Theory (ANT), for example, addresses heterogeneous structures and the relationality of the actors that constitute them (Latour, 2005). In the context of architectural design, it is particularly valuable for reassessing the relationships between human and non-human actors from a new perspective. Furthermore, this approach is influential in transforming representational methods to capture the dynamic relations inherent in architectural design.

Relational thinking and production pave the way for transforming the architect's role, positioning them as an actor who designs relationships. To this end, the architect/designer must

also reconsider the relationship established with the tools they employ. “Relational thinking opens up a multi-possibility field for the designer-subject to benefit from, or to reveal, the potential of narrative in the architectural design process” (Asar, 2023). Among such fields, diverse representational methods can be mentioned. Within the scope of this study, the experience-based mapping technique has been addressed as one such method. The study aims to discuss experience- based mapping as a relational tool for production and thinking in architecture.

Mapping- and, as articulated in this study, experience-based mapping- constitutes one of the significant tools of the architectural design process. Because “Mappings, as one of the performative and innovative methods of the design process, are nourished by the existing condition of what is to be narrated and mediate the revelation of alternative scenarios and potentials concerning that condition” (Asar et al., 2025).

The potential of mapping lies in the mapping practitioner’s freedom to combine different design techniques and tools while incorporating personal interpretations. This acting involves engaging with multiple dimensions, such as movement and flux, as well as experiential and sensory aspects. Thus, “Beyond the physical structures and factors of a place, it is also possible to map social structures and networks of relationships in daily life” (Sarı, 2013). This situation enables mapping to function as a tool for relational thinking. Mapping, which focuses on research and discovery, relates, integrates, and structures all collected data (Kozar, 2009), facilitating an understanding of the complex dynamics of social and natural processes (Corner, 1999). In this context, “mapping can be seen as an act of rethinking architecture’s relationship with place and establishing alternative relationships with it” (Şenel, 2019).

As a tool and technique for relational thinking and the establishment of new relationships, mapping plays a significant role in both the architectural design process and architectural education, particularly because it stimulates creative processes. Various terms in the literature refer to these types of mappings. For instance, Güleç (2021) notes that “(...) creative maps are defined as mental, theoretical, formal, narrative, perceptual, imaginative, functional, indexical, relational, and interactional maps” (Güleç, 2021). In this study, since the concept of experience serves as the focal point, the maps considered are employed as experience-based mappings. Experience-based mappings are discussed as tools for relational thinking and production, drawing upon technical and experiential knowledge. Finally, the study evaluates the potential of experience-based mappings for the architectural design process within the context of architectural education.

2. Materials and Methods

The visual materials used in this study are some of the outputs from the elective course “Relational Practices in Architectural Design” (designed and conducted by the author) within the curriculum of the Department of Architecture at the OMU Faculty of Architecture, during the Spring semester of 2024–2025. The design of the final project implemented in this course is related to the approach discussed in this paper (experience-based mapping). Therefore, the outputs of this project have been utilized in this study.

In the study focusing on the experience-based mapping technique, the city center of Samsun (Figure 1) was selected as the sample area due to its multi-layered urban structure. The selected area is bounded by Saathane Square, located at one end of the historic clock tower and surrounded by Taşhan, Şifa Hamam, Süleymanpaşa Mosque and Madrasa, as well as various

commercial units, and the two streets extending from the other end of the tower **(**Kasaplar Street and Kazımpaşa Street**).** All students studied the square section collectively, while the street section was divided into two groups. This study includes works covering both streets; however, during the analysis phase, no distinction was made between them as their street characteristics were almost identical. A preliminary study was conducted in the area over two weeks (using class days and hours), and the students generated the final outputs presented in this paper by building upon the drawings produced during this preliminary work.

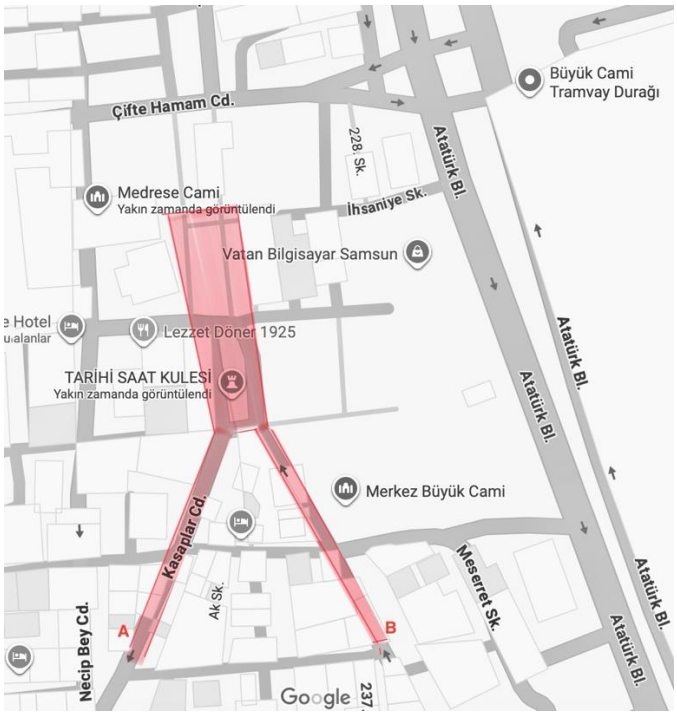

Figure 1. Boundaries of the study area (created from Google Maps)

The field study aimed for students to convey their own emotions and experiences by engaging with both fixed elements**,** such as architectural structures, urban amenities, and landscape features, and mobile elements**,** including people, activities, animals, and vehicles, within the defined urban area. The relationship between these two primary element types and their visualization was left to the students' discretion in their designs. Among the submitted works for the course (32 submissions), eight studies (Figure 2) employing different mapping techniques and visualization methods were selected. A conceptual interpretation related to the experience-based mapping technique was conducted based on these selected studies.

Figure 2. Selected mappings as samples.

Findings and Discussion

The selected studies were evaluated in terms of their implementation methods to discuss the knowledge of the technique and the information and textual expressions they conveyed to examine the understanding of experience.

An interpretation of the methods employed in the studies yields varying results. Elements such as color, perspective, textual expressions, and icons are common to all examples, and they serve as tools for creating experience-based mappings. Differences in the manner and frequency of use of these tools resulted in variations in the final outputs. A detailed examination of their application in each example highlights how the data on experiences and perceptions, which constitute personal information, diversifies. Furthermore, the students' textual expressions can be interpreted as narratives reflecting what captured their attention in the field or as means of conveying their perceptions of the place.

Figure 3. Examples of experience-based mapping I (Left: Student A; Right: Student B)

For example, in Student A's work (Figure 3 – left), a prominent route indicating the starting and ending points is depicted in yellow. Around this route, the student made each building visible by employing perspective drawings with different vanishing points. The student rendered and colored in detail the structures that represent the historical fabric and those they found noteworthy. People and sounds were represented using various icons. Textual expressions were included in the square (a couple's dinner conversation), on the street (sounds from the greengrocer), and beside the mosque (dialogues arising from traffic). The focus of this experiential mapping was the route the student established and how the surrounding fixed and mobile elements were represented.

In Student B's work (Figure 3 – right), the use of color is distributed almost evenly across the drawing. The route followed is depicted not linearly, but along the perimeters of the designated area. The square narrative is positioned on the right side of the drawing, and specific facade details of historical buildings are also included. In the drawing's double-sided representation of the street, the street is portrayed as two separate planes rather than facing each other. The use of icons, together with depictions of people's actions (such as sitting, walking, and cycling), reinforces the kinetic quality of the narrative. Similarly, the textual expressions included in the mapping (e.g., "fresh fish," "has the call to prayer been recited," and "why are you drawing here") are presented as speech bubbles, thereby conveying the experiential knowledge of the area.

Figure 4. Examples of experience-based mapping II (Left: Student C; Right: Student D)

In Student C's work (Figure 4 – left), the areas forming the focal points are represented in color. The route followed by the student is indicated with red dashed lines. Although Student C placed relatively little emphasis on mobile elements and textual expressions, the way these elements were represented distinguishes the work from others. The student draws blue lines around the icons of people and vehicles, using them to emphasize the presence of movement.

In Student D's work (Figure 4 – right), the use of color is again employed extensively. Representing all the buildings in the drawing with textures and colors highlights the structural character differences within the area. Moreover, the dense depiction of mobile elements (such as people, vehicles, and birds) conveys the intensive use of the square. The use of perspective in representing the street and its division into two planes enhances the legibility of the buildings opposite each other. The attempt to depict the mapping in two directions is further reinforced by the placement of clouds on both sides of the drawing. The limited presence of textual expressions (e.g., "*simitçi*") indicates the scarcity of site-specific experiential data.

Figure 5. Examples of experience-based mapping III (Left: Student E; Right: Student F)

Student E's work (Figure 5 – left) employs an elevation drawing technique. Another difference from previous studies is that the student uses color only in the abstractions of people and in certain textual expressions. In this representation, which is dominated by technical drawing knowledge, the dynamic nature of the city can only be inferred by including mobile elements in the drawing. While this limits the incorporation of the student's personal perspective into the mapping, it also constrains the expressive differentiation of the work.

In Student F's work (Figure 5 – right), as in Student E's, the use of color is limited; however, data related to spatial–activity relationships within the area are represented as enlarged sketches extending beyond the site's boundaries. This approach may reflect the student's intention to make certain events or dialogues (e.g., "*simitçi,*" "Aslı's drawing flew," "what are they drawing," "everyone arrived early") more visible.

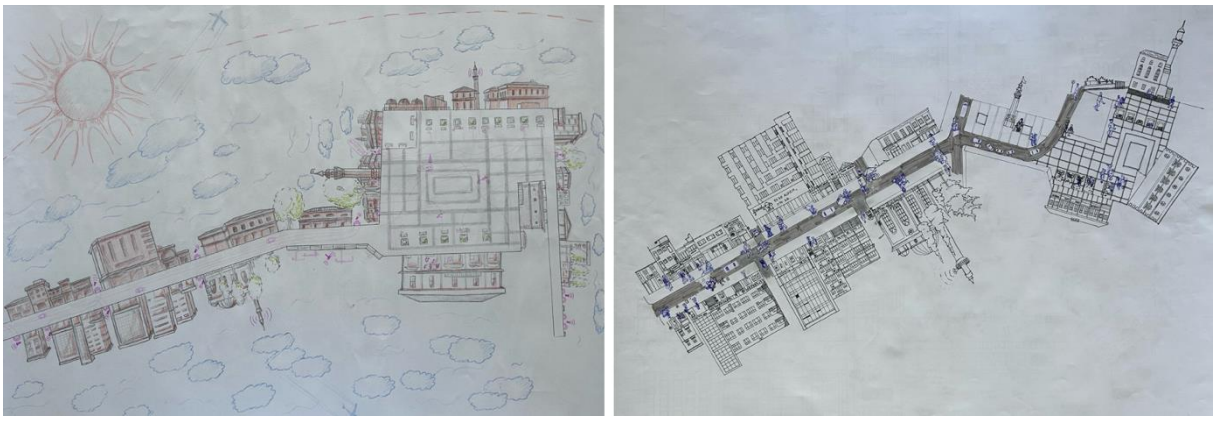

Figure 6. Examples of experience-based mapping IV (Left: Student G; Right: Student H)

In this work (Figure 6 - left), Student G attempted to have the drawing read bidirectionally, as in Student D. To this end, Student G drew clouds in both directions. In this work, Student G used a perspective drawing technique. Thus, structures perceived as one-dimensional in Student E gained dimension in this drawing. However, the absence of distorted perspectives- as in most other works- mediated the reorganization of experiential knowledge. Thus, the drawing evolved into a technique closer to existing map knowledge. In this work, we observe the use of a single color at a consistent scale, while mobile elements are represented with small icons but appear in frequently, and no textual expressions are included.

Finally, in Student H's work (Figure 6 – right), we encounter technical drawings of building elevations, as in Student E's work. However, the greater structural detail and the increased line thickness make the drawing more visually dominant. The student chose to use color only for moving elements, such as people and vehicles, while clarifying the route with pencil shading. No textual expressions are included in this mapping. Nevertheless, because the depictions of moving elements were created with attention to space–action relationships, the work provides some insight into the student's experiential knowledge.

When all the experience-based mappings used in the study are analyzed regarding their execution methods and textual expressions, similarities and divergences emerge. In some cases, where data related to experiential knowledge were incomplete, the student's chosen drawing technique resulted in a less discernible final product. On the other hand, in works where both the technical knowledge and all elements conveying experiential information are visible, multiple insights about the mapped area could be obtained.

Conclusion and Recommendations

As a relational tool for production and thinking, experience-based mapping was evaluated through the sample group addressed within the scope of this study. In this context, experience-based mapping was discussed as a process in which the designer's focus, the fixed and dynamic data of the area, and the designer's personal modes of perception, senses, and experiences converge and are represented through an individual language. In each selected case study,

students produced mappings based on their own experiences and modes of expression. However, the aspects they focused on, the elements they chose to include in their drawings, and the ways they represented fixed components such as architectural structures varied. In some instances, similar techniques and tools were observed.

Nevertheless, the similarity of representational techniques or tools did not undermine the personal language of the works. This situation highlights that even the partial inclusion of experiential data in experience-based mappings leads to differentiated outcomes. Moreover, the increased incorporation of experiential data enriches experience-based mapping in terms of its ability to convey information about both the language and the place itself.

Finally, the fact that this study was conducted specifically with architecture students positions experience-based mapping as a significant relational tool of expression and thinking within the context of architectural education. In this regard, experience-based mapping can be particularly effective in architectural education and during the early stages of the design process, as a method that facilitates the establishment of analysis-synthesis relationships and serves as a guiding approach in the design process.

Thanks, and Information Note

The article complies with national and international research and publication ethics. Ethics Committee approval was not required for the study. As the images used as examples were produced within the scope of a course conducted by the author, no separate ethics committee permission was obtained. Nevertheless, permission was obtained from the students to use the images in an academic study.

I would like to thank all the students who contributed to the course and formed the sample data for this study during the 2024–2025 Spring semester.

A Discussion on the Spatial Atmosphere: The Example of Samsun Süleyman Pasha Madrasah

Hande ASAR [1]*

ORCID 1: 0000-0003-3201-3204
[1]Assoc. Prof. Dr., Ondokuz Mayıs University, Faculty of Architecture, Department of Architecture, Samsun-Türkiye
hande.asar@omu.edu.tr

Abstract

The atmosphere of a space emerges from a range of factors, including architectural elements such as light, materiality, texture, color, and scale, as well as their interrelations and the role of the space in everyday life. In public settings, this atmosphere is also influenced by the space's relationship to the city and its integration within the historical fabric. Spatial atmosphere is thus contingent on both architectural design and the perceptions of users, requiring an understanding of its layered and complex nature. Given the openness of public spaces to diverse users, perceptions within them inevitably vary. The Samsun Süleyman Pasha Madrasah, which continues to function as a public space, was selected as the case study due to its significance within Samsun's historical fabric and daily life. The study aims to advance the discussion of spatial atmosphere by examining its formation through a conceptual framework. The distinctiveness of this study lies in addressing atmosphere at the intersection of historical fabric and everyday life. Ultimately, the study evaluates the interrelated layers that contribute to the production of spatial atmosphere.

Keywords: Samsun Süleyman Pasha Madrasah, spatial atmosphere, spatial perception.

1. Introduction

When engaging in a discussion on spatial atmosphere, it is essential to acknowledge that our modes of perceiving and experiencing space are also integral to the discourse. In this context, the act of being physically present in a space and transforming everything that occurs during that experience- including all physical realities and variables- into a perceptual act is made possible through the activation and interrelation of all our senses. This interplay gives rise to the processes of perception, sensation, and experience. With the affective responses shaped by these processes- which vary from person to person- we can begin to address the phenomenon referred to as spatial atmosphere. Although the experiential aspect of atmosphere may differ for everyone, it is also necessary to consider the physical elements that constitute spatial atmosphere, as these often exhibit shared characteristics across individuals. Accordingly, this study approaches spatial atmosphere through architectural design elements such as light, material/texture, color, and scale, as well as the relationships among these elements, in addition to factors such as the location of the space within the urban fabric, its relationship with the city in public contexts, and its position within the historical texture. For this purpose, a case study has been selected, and the concept of spatial atmosphere is examined through the structural and public characteristics of the chosen example.

Nevertheless, before addressing the concept of spatial atmosphere, it would be beneficial to explore the theoretical underpinnings of the notion of atmosphere. "Professor Gernot Böhme is one of the pioneering thinkers in the philosophy of atmospheres, along with Herman Schmitz" (Pallasmaa, 2014: 233). Due to its variability, the concept of atmosphere often appears as an ambiguous *thing*. Although Böhme adopts a similar approach, he argues that the meaning of the concept is not, in fact, unclear, and continues his argument as follows: "It is difficult, owing to the peculiar intermediary position of the phenomenon between subject and object, to define the status of atmospheres and thereby render discussion of atmospheres a legitimate concept.

However, in advancing the term atmosphere as a basic concept of a new aesthetic, it is not necessary to provide original evidence for its legitimacy because Hermann Schmitz' philosophy of the body already provides an elaboration of the term atmosphere" (Böhme, 2017: 19). The body philosophy approach mentioned here is related to everyday experiences in Schmitz's approach, that is, "(…) the experience of a tense atmosphere in a room, the oppressive mood before a thunderstorm, or the serene atmosphere of a garden" (Böhme, 2017: 20). What becomes prominent in these statements are the emotions. The affective responses that emerge through one's interaction with a spatial environment can provide a basis for discussing the atmosphere of that space. Nevertheless, making definitive claims in this regard remains challenging. The atmosphere of a given space may vary significantly depending on the temporal context, situational conditions, and narrative frameworks in which it is experienced. Thus, the same architectural setting may elicit different sensory and emotional responses, leading to a multiplicity of atmospheric readings. "Atmospheres are always spatially 'unbounded, poured out and placeless, that is, not locatable', they are moving emotional powers, spatial carriers of moods" (Böhme, 2017: 20). Because of that "Atmosphere can only become a concept, however, if we succeed in accounting for the peculiar intermediary Status of atmospheres between subject and object" (Böhme, 2013).

The concept of atmosphere can be discussed through the relationship established between the surrounding environment/place/space and bodily experience. In this regard, atmosphere is inherently related to space and, by extension, to architectural thought. The atmosphere of space holds a significant place within architectural theory and literature. Various scholars and practitioners can be mentioned who engage with this concept and shape their architectural practices with attention to the notion of spatial atmosphere. In this context, for instance, Zumthor addresses his work *Atmospheres* (2006), written around the question 'What really creates an architectural atmosphere?', in nine plus three sections, articulating the design process through a form of self-observation and by engaging with various concepts such as material, proportion, light, and poetics. Another prominent figure in this field, Pallasmaa, approaches the concept of atmosphere as follows: "Atmosphere is similarly an exchange between material or existent properties of the place and the immaterial realm of human perception and imagination. Yet, they are not physical 'things' or facts, as they are human experiential 'creations'" (Pallasmaa, 2014: 232). Böhme (2017: 20) expresses the close relationship between the concept of atmosphere and experience as follows: "For atmospheres are obviously what is experienced in the bodily presence of humans and things, or in spaces." Accordingly, the concept of atmosphere is intrinsically linked—either explicitly or implicitly—to spatial knowledge. In architectural discourse, the notion of spatial atmosphere necessitates the corporeal presence of the subject within the environment, rendering embodied experience a fundamental aspect of spatial perception. Because "Atmosphere or ambience is an epic experiential dimension or prediction, as we automatically read behavioral and social aspects- either existent, potential or imaginary- into the atmospheric image" (Pallasmaa, 2016).

Regardless of our awareness, the atmosphere of a space is an integral part of our lived experience, and discussing this phenomenon involves consideration of various factors and relational dynamics. Within this framework, the concepts of perception and sensation are crucial for critically engaging with and understanding the spatial atmosphere. Indeed, perception, defined as the transfer of the objective world to subjective consciousness through the senses (Hançerlioğlu, 1976) and described as a conscious sensory experience (Goldstein, 2010), is a cognitive and experiential process. Alongside this process, the topics of perception,

sensation, spatial perception, and spatial atmosphere can be discussed in an interrelated manner. As Pallasmaa also articulates: "… I lend my emotions and associations to the space, and the space, in turn, lends me its aura that stimulates and liberates my perceptions and thoughts' (Pallasmaa, 2016, p. 14). Within the context of this reciprocal relationship, both spatial perception and the discussion of spatial atmosphere emerge as "(...) a personal experience that varies according to the individual experiencing the space" (Asar, 2023).

Due to its multidimensional nature, the concept of spatial atmosphere can be discussed in various ways; within the scope of this study, it is primarily examined through the concepts of light, material/texture, color, and scale- elements that both constitute an architectural space and act as triggers for perception and sensation in the context of spatial atmosphere. Furthermore, since the selected case study building functions as a public space, the concept of publicness is employed to discuss the building's spatial atmosphere, drawing upon factors such as its position within the urban fabric, its historical development, and the everyday life- public space relationships contained within the building.

The case study selected for this research is the Süleyman Pasha Madrasah in Samsun, chosen due to its accommodation of diverse user profiles and its integration into everyday urban life. "Located near Saathane Square in the Kale Neighborhood, the Süleyman Pasha Madrasah is a significant building within the historical fabric of the city. Constructed in 1813, it is a two-story building made of rubble brick, shaped like a horseshoe, enclosed on three sides with a courtyard in the center. The entrance to the courtyard faces the Madrasah Mosque, with which the building forms a cohesive ensemble. Two sides of the courtyard are arcaded, and shops are situated within these arcades. The building, endowed by the Süleyman Pasha foundation, was once used as the Regional Directorate of Foundations building and later restored and converted into a business center" (Yılmaz & Gül, 2018). Today, the building functions as a cultural center.

The building, located in the historic center of the city, is the subject of this study due to its continued use within everyday life today and its inclusion of various layers that allow for a nuanced exploration of spatial atmosphere. Moreover, it is argued that the building is well-suited to address the central research question of this study: "How can the spatial atmosphere of a historic building, still in active use within contemporary urban life, be analyzed, and to what extent can this analysis inform our understanding of its publicness?" This study is unique in that it attempts to discuss spatial atmosphere at the intersection of historical fabric and everyday life.

2. Materials and Methods

The methodology of this study is based on qualitative research, incorporating phenomenological reading and spatial analysis. For this purpose, the Süleyman Pasha Madrasah in Samsun (Figure 1), considered one of the significant examples within the urban fabric of Samsun in terms of its structural language and public characteristics, was selected as the case study. The building was chosen not only because it is a part of the historical texture, but also due to its location in a key area of contemporary urban life. Therefore, it is considered to have the potential to reveal aspects of the spatial atmosphere on both structural and public scales. In this context, keywords derived from the literature on spatial atmosphere were transformed into a diagram (Figure 2), which was then used to conduct a spatial analysis of the selected building. The keywords are categorized into two main groups: in terms of structural features, they include light, material/texture- color, and scale; while in terms of public characteristics, they involve

the building's position within the urban fabric, its historical development process, and the relationship between everyday life and public space embedded in the building.

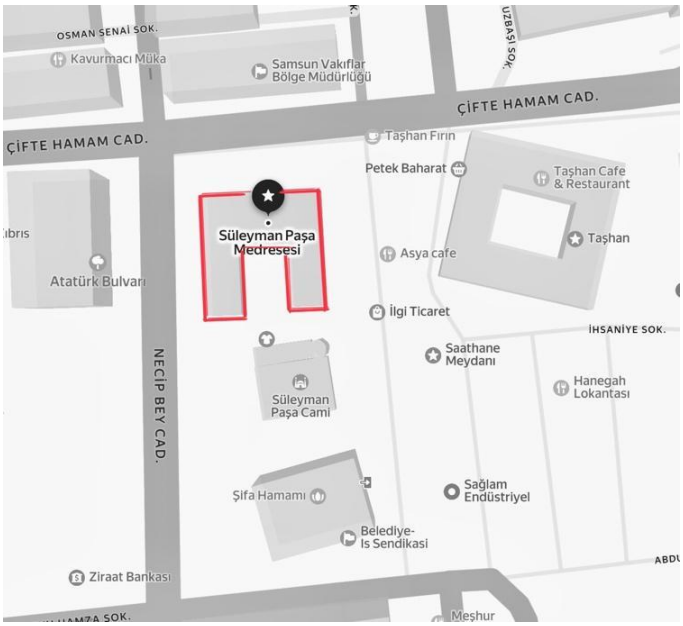

Figure 1. The location of Samsun Süleyman Pasha Madrasah in the city (Image produced from Yandex Maps)

The Samsun Süleyman Pasha Madrasah, which constitutes the material and case study of this research, belongs to the Hazinedarzade Süleyman Pasha Foundation. Located in Samsun's Saathane Square, at the corner of Şifa Bath and Taşhan, the courtyard of the building faces the entrance of the Süleyman Pasha Mosque. "The foundation date of the building is 1813. It is a two-storey structure with a horseshoe-shaped plan, constructed from load-bearing brick masonry" (URL- 1).

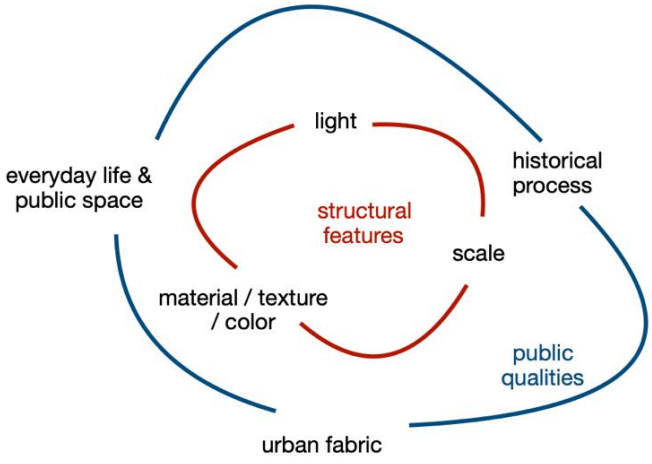

Figure 2. Spatial analysis diagram

The general information obtained about the Samsun Süleyman Pasha Madrasah is as follows: "It is known that, following the Great Samsun Fire of 1869, the original architectural configuration of the madrasah underwent significant changes and was reconstructed. (…) The building was used as a madrasah until 1914, and between 1914 and 1928, it was repurposed in

ways that did not align with its original function- first as a hotel, then as a coffeehouse *(kahvehane)*. After 1974, the building was used for a period by the Regional Directorate of Foundations and later functioned as a commercial office building. To this day, it has survived with functions that are inconsistent with its original design" (URL- 2).

"Situated within the scope of the Saathane Square Urban Renewal Project, the Süleyman Pasha Madrasah and Mosque underwent a comprehensive three-year restoration process initiated in 2016 by the Samsun Regional Directorate of Foundations. Upon completion of the restoration, the property was transferred to the administration of the Samsun Metropolitan Municipality. (…) As a result of this adaptive reuse initiative, the historic Hazinedarzâde Süleyman Pasha Madrasah- currently under the jurisdiction of the municipality- was repurposed to function as a 'Cultural House'" (URL-3) (Figure 3).

Figure 3. Samsun Süleyman Pasha Madrasah (right) and Mosque (left)

Currently functioning as a Cultural House, the building's courtyard plays a particularly significant role in discussions surrounding public space. Accordingly, the Süleyman Pasha Madrasah was chosen as the focus of this study and critically examined through the lens of spatial atmosphere.

3. Findings and Discussion

A spatial reading based on the current state of the Samsun Süleyman Pasha Madrasah has enabled a range of inferences regarding its spatial atmosphere, considered through both its structural and public attributes.

In terms of the structural element of light, the windows and their forms can be said to evoke a sense of being within a historical building, while also enhancing the visual relationship established with the surrounding historical context. The interplay of natural and artificial lighting elements further reinforces a sense of nostalgia.

When considering material/texture and color- integral and interrelated elements of any building- it can be observed that the tactile qualities of the building have become somewhat

limited, partly because of various restoration interventions. The use of white paint on both the interior and exterior façades has introduced a sterile aesthetic, slightly diminishing the historical character that the building's formal qualities would otherwise convey. On the other hand, the use of wooden materials on parts of the interior flooring, ceiling finishes, and window frames adds warmth to the space, contributing to the development of a distinctive spatial atmosphere. Similarly, movable interior elements such as wooden cabinets and patterned carpets further enhance this atmosphere (Figure 4).

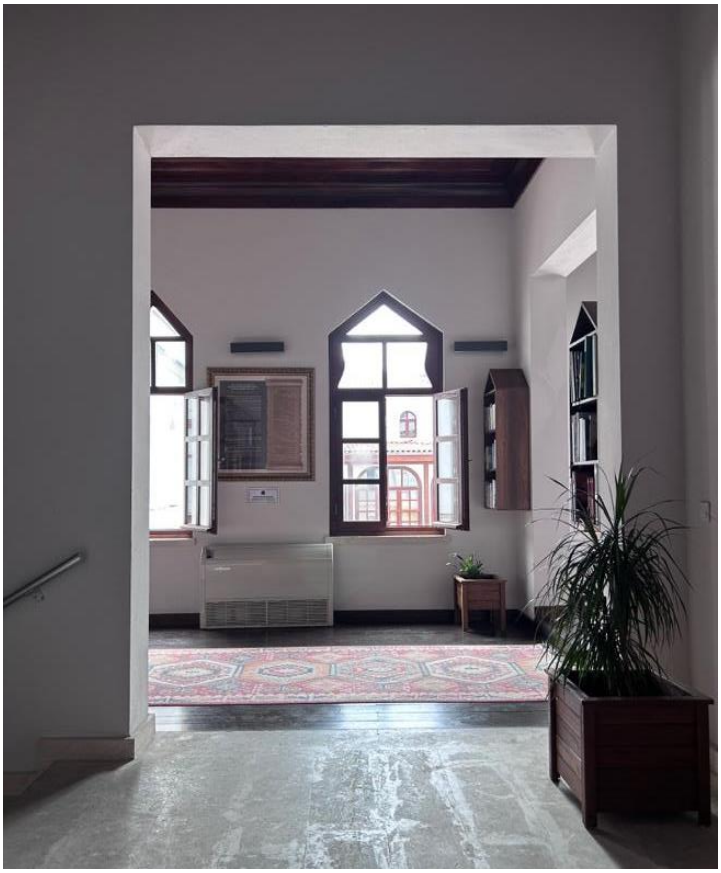

Figure 4. An example from the interior

When considering the concept of scale- the final structural element addressed in this study- the building can be regarded as a strong example of human-scaled architecture, in terms of its overall size, spatial subdivisions, and urban positioning. In particular, the courtyard element, which reinforces the spatial organization of the two-winged structure, along with the ornamental pool located at its center, contributes to a sense of human scale both formally and functionally (Figure 5).

Figure 5. Examples of the building's courtyard layout

The discussion on the public characteristics of the building- addressed as another dimension of spatial atmosphere- can also be interpreted because of the interaction between the structural features and the user. In fact, the possibility of initiating a discourse on publicness is closely related to how the building continues to be inhabited and experienced under present-day conditions. The most actively *lived* part of the building, which caters to a diverse range of users, is its courtyard. In the madrasah, which follows a U-shaped plan typology, a courtyard has been created at the center, capitalizing on the spatial potential of the layout, and an octagonal ornamental pool has been placed at its center.

The overhangs on the right and left wings of the building currently serve units functioning as tea houses, while the edges of the ornamental pool are also used for the same purpose. Due to the high intensity of use and the lack of greenery, the space faces issues of thermal discomfort, which have been partially mitigated through the installation of additional tent structures. However, these elements- being neither site-specific nor architecturally integrated- detract from the holistic spatial impact and weaken the atmosphere of the space. On the other hand, in the semi-open area near the entrance, formed by projecting elements and supported with columns, such discomforts are not observed (Figure 5).

From the perspective of its public characteristics, the building's position within the urban fabric can be considered highly significant. Although located in the historical core of Samsun, the design lacks an inviting entrance that would draw users inward, rendering the building simultaneously visible and concealed. Moreover, its spatial orientation directly across from the Süleyman Pasha Mosque contributes to the perception- particularly by those unfamiliar with the madrasah- that it is a part of the mosque complex.

The madrasah building has undergone numerous functional changes and structural interventions/restoration processes from past to present. Since its foundation date in the early 19th century, it has been affected by various disasters such as earthquakes and fires, and its function has shifted over time in response to changing social and demographic dynamics- serving at different points as a hotel and later a coffeehouse. Today, although officially functioning as a Cultural House under the authority of the Samsun Metropolitan Municipality, the courtyard continues to operate informally as a tea house.

This courtyard, primarily catering to middle-aged and older male users, becomes particularly active during prayer times. As a result, the public use of the space tends to be gender-exclusive, creating a male-dominated environment. Consequently, in terms of both usage patterns and user

profile, the building presents several limitations regarding the relationship between everyday life and public space. This condition, by reinforcing a patriarchal dynamic in the use of public space, also influences the spatial perception in a gendered manner.

Conclusion and Recommendations

When attempting to engage in a discussion about spatial atmosphere through an architectural building, it is essential to evaluate both the qualitative and quantitative characteristics that constitute that space. Elements such as light, material, texture, color, and scale- components that both shape the design process and influence spatial perception- can serve as tools for conducting an architectural space analysis through the lens of atmosphere. However, analyzing a building in isolation requires detaching it from its context. Yet, architectural works derive meaning from the contexts in which they are situated. This contextual relationship also contributes to the nature of the atmosphere that a space possesses or is perceived to possess. Therefore, factors such as the fabric in which a building is embedded, its historical trajectory, its role within everyday life, and the kinds of publicness it generates become significant. In this regard, the present study evaluates the Süleyman Pasha Madrasah in Samsun as a case study within the framework of these concepts.

Various inferences can be drawn from the spatial analysis of the building. While the formal language of the windows- as sources of natural light- creates a positive effect, the sterilized appearance resulting from successive restorations has diminished the impact of material and texture. Nevertheless, it can be observed that this effect still manifests in certain parts of the interior space. On the other hand, the courtyard, formed because of the building's U-shaped plan and its spatial organization, contributes to the building's isolation from the broader urban context. Moreover, the proportions employed in the spatial design render the building human scaled.

The forms of publicness that the building both benefits from and generates are also significant in the context of spatial atmosphere. Located in the city center of Samsun (Saathane Square) and surrounded by historical buildings, the Süleyman Pasha Madrasah and Süleyman Pasha Mosque face each other with their entrances, establishing a relationship with the square while maintaining a degree of enclosure. This spatial configuration has influenced the general user profile, transforming the courtyard- particularly after prayer times- into a male-dominated public space where men gather and use the area as a teahouse. Furthermore, the lack of greenery, which is a crucial environmental factor, has had a negative impact on both the use and atmosphere of the space.

At the conclusion of the study, it can be stated that the Süleyman Pasha Madrasah reveals both positive and negative aspects of the spatial atmosphere in the context of structural and public factors. When discussing spatial atmosphere, the discourse typically focuses on the positive elements that create the atmosphere. However, identifying and critically addressing the negative aspects of a building- especially if it is a historic building, as in the case of this study- is important for ensuring its continued use and transmission to future generations, as well as for allowing it to find a place within evolving social dynamics.

Abstract

Landscape planning is a multidisciplinary field that addresses natural resource conservation, climate change mitigation, disaster risk management, and the improvement of urban life quality. The growing volume of spatial data and increasing complexity of planning processes require advanced analytical approaches beyond conventional methods. In this context, machine learning has gained significant relevance due to its strong capabilities in prediction, classification, and pattern recognition.

This study provides a comprehensive literature review on the applications of machine learning in landscape planning, structured within a thematic framework. Key themes include green space suitability assessment, urban heat island modeling, land use and land cover classification, ecological network and species distribution modeling, integration with decision support systems, visual perception analysis, disaster and climate risk-based planning, and time-series projections of landscape change. Across these themes, major data sources—including remote sensing, geographic information systems, environmental, and socio-demographic datasets—are examined. Commonly applied machine learning algorithms such as random forest, support vector machines, and artificial neural networks are reviewed with an emphasis on their contributions to planning workflows.

The study identifies emerging methodological trends, current limitations, and potential opportunities for future research, highlighting the transformative role of machine learning in enhancing evidence-based decision-making in landscape planning.

Keywords: Landscape planning, machine learning, geographic information systems (GIS), remote sensing, land use and land cover (LULC)

1. Introduction

Landscape planning is an interdisciplinary field that encompasses multifaceted objectives such as the conservation of natural resources, mitigation of climate change impacts, management of disaster risks, and enhancement of urban quality of life. This discipline aims not only to organize the physical environment spatially but also to develop strategic decisions that safeguard the sustainability of ecosystem services, promote societal well-being, and strengthen long-term environmental resilience (Lumeng & Jianguo, 2022).

The rapid transformation of urban and rural areas, increased pressure on natural resources, the ecological threshold stress caused by unplanned land use, and growing uncertainties driven by climate change have rendered landscape planning a far more complex and data-intensive process compared to the past. Consequently, contemporary landscape planning practices require dynamic approaches built on multi-criteria decision frameworks that evaluate spatial,

ecological, climatic, socio-economic, and cultural components simultaneously, while also adapting to evolving environmental conditions (Dong et al., 2022).

Within this process, planners are expected not only to make design or land-use decisions but also to develop decision-making frameworks capable of anticipating environmental risks, preserving ecological connectivity, addressing community needs, and assessing future change scenarios.

The widespread adoption of remote sensing technologies, advances in geographic information systems, the diversification of sensor networks and environmental monitoring systems, along with advances in machine learning techniques have accelerated the production of large volumes of spatial data. Satellite imagery, LiDAR data, climate models, topographic surface analyses, land-cover classifications, population and socio-economic indicators, and even geotagged social media posts—once considered unconventional—are now integrated into planning processes (Liu et al., 2021; Yao, 2024). However, as the volume of this data ecosystem expands, its structure becomes increasingly heterogeneous; data layers vary in scale and temporal resolution and may contain noise, missing values, or inconsistencies, making integrated analysis imperative.

Traditional statistical methods, rule-based analyses, and manual weighting approaches are inadequate for modeling these multivariate, nonlinear, and dynamic structures and often perform poorly in detecting complex spatial patterns, change tendencies, and latent relationships among variables. These limitations not only result in reduced analytical capacity but also diminish the generalizability of planning decisions, hinder scalable analyses, and weaken the accuracy of spatial predictions (Neuendorf et al., 2018).

This complexity in data and analysis has significantly increased the need for more advanced, adaptive, and data-driven analytical tools within the planning discipline. As illustrated in Figure 1, machine learning stands out due to its ability to extract meaningful patterns from large and high-dimensional datasets, model nonlinear relationships between variables, learn spatial and temporal trends, and generate predictive insights from historical data (Lyons et al., 2018; Yang et al., 2025). Unlike traditional analytical approaches, machine learning models uncover the internal structure of the data without relying on predefined assumptions and can represent the dynamics of complex ecological, environmental, and urban systems within a more flexible framework (Liu et al., 2021; Shao et al., 2025).

Supervised learning, unsupervised learning, and deep learning techniques, in particular, provide high accuracy in tasks such as classification, regression, clustering, and pattern recognition, rendering decision-making processes more measurable, repeatable, and scalable. In this context, machine learning is regarded not merely as a technical analytical tool but also as a new planning paradigm that transforms intuitive decision-making processes into data-driven planning mechanisms.

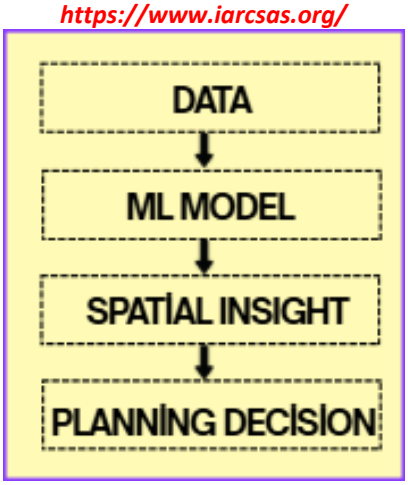

Figure 1. The Functioning of Machine learning techniquess in the Landscape Planning Decision-Making Process

In the context of landscape planning, machine learning stands out particularly through three core analytical capabilities: (1) classification, (2) prediction, and (3) pattern recognition. Classification models are used in tasks such as the automated production of land-use and land-cover maps, the differentiation of habitat categories, and the identification of landscape elements (Ouma et al., 2023; Shao et al., 2025). Prediction models, on the other hand, play a critical role in advanced analyses such as determining the spatial distribution of the urban heat island effect, generating temperature projections, calculating green space suitability potential, and modeling temporal trends of environmental variables (Tanoori et al., 2024). Pattern recognition and connectivity analysis capabilities generate strategic outputs for planning, including the evaluation of ecological network continuity, identification of biodiversity corridors, monitoring of landscape fragmentation dynamics, and detection of spatial change tendencies (Da Cruz et al., 2021). These competencies enable not only the analysis of current conditions but also the modeling of future scenarios and the pre-assessment of environmental impacts of planning decisions (Gharaibeh et al., 2023). Although the potential of machine learning in landscape planning is increasingly acknowledged, a review of the existing literature reveals that most studies focus on specific application domains, vary in methodological choices and evaluation metrics, and are not systematically integrated into a holistic planning framework. A significant portion of research concentrates on technical performance indicators (accuracy, acceptable error rates, model efficiency, etc.), while critical dimensions such as practicality within planning contexts, interpretability, integration into decision-making processes, and alignment with stakeholder needs are addressed more limitedly (Chaturvedi & Vries, 2021).

Particularly underexplored issues include how model outputs are translated into planning decisions, how social or ecological inequalities are represented within models, the sensitivity of analytical data to local contexts, and how model results can be utilized in planning practice through transparent and accountable mechanisms. Moreover, the limited number of comparative studies examining methodological overlaps or differences across themes makes it difficult to evaluate machine learning's contributions to landscape planning from a systematic perspective.

This study aims to systematically examine the use of machine learning techniquess in landscape planning processes within a thematic framework and to evaluate methodological trends, strengths, and research gaps in the literature from a planning perspective. Accordingly, the

review is structured around eight key themes that have become prominent in landscape planning: (1) green space suitability analyses, (2) urban heat island modeling, (3) land use and land cover classifications, (4) ecological network and species distribution modeling, (5) integration with decision support systems, (6) user perception and visual landscape analyses, (7) disaster- and climate risk–oriented planning, and (8) temporal landscape change and future projections. Within the scope of these themes, the study evaluates the data sources employed, the machine learning algorithms preferred, and the contributions these algorithms provide to planning processes; it also discusses critical shortcomings such as model interpretability, representation of social variables, scale compatibility, and the transferability of model outcomes to planning decisions. Thus, the research aims to offer a conceptual framework at the intersection of landscape planning and machine learning, while also providing a guiding evaluation for future studies and practical applications.

2. Materials and Methods

This study is a systematic and thematic literature review examining the use of machine learning techniquess within landscape planning processes. The aim of the research is to explain how machine learning techniques are integrated into the landscape planning discipline, to analyze the types of data and algorithms used, and to reveal trends in the literature through comparative evaluation. In this context, the study does not approach machine learning merely as a technical analytical tool; rather, it evaluates its practical value within planning, its influence on decision-making processes, and the ways in which the spatial outputs produced are translated into planning decisions. Accordingly, the literature has been examined within a framework based on analytical processing steps and the transferability of model outputs to planning decisions.

The literature search was conducted to identify studies exploring the relationship between machine learning and landscape planning. Internationally indexed databases such as Web of Science, Scopus, ScienceDirect, Google Scholar, and SpringerLink were used. During the search, keywords representing both machine learning and landscape planning processes were combined: “machine learning”, “landscape planning”, “remote sensing”, “urban heat island”, “land use/land cover classification”, “green space suitability”, “ecological connectivity”, “species distribution modeling”, and “spatial decision support”. These keywords were combined using Boolean operators (AND–OR), and studies published between 2015 and 2025 were included in the scope of analysis. However, it was observed that studies on the topic increased significantly after 2018; therefore, the review focused primarily on publications from 2018 onward. Statistical studies not involving machine learning, studies that used imagery solely for image processing without producing planning-relevant outputs, and publications without full-text access were excluded. As a result of this screening process, 112 studies suitable for thematic evaluation were identified and compiled into a dataset for analysis.

The studies obtained from the search were evaluated based on specific criteria, and inclusion and exclusion rules were established for determining which publications to analyze. The inclusion criteria were as follows: (i) application of machine learning techniquess, (ii) production of a spatial output directly relevant to landscape planning, (iii) utilization of remote sensing, GIS, environmental variables, or socio-demographic data, and (iv) publication in a peer-reviewed scientific outlet. Studies lacking contributions to landscape planning practice or focusing solely on algorithm optimization without incorporating a spatial/planning context were excluded. Additionally, studies in which model training was conducted but the transfer of outputs to planning decisions was not explained, as well as deep learning studies exclusively

devoted to image processing, were removed from the scope. This approach ensured that the review was limited to studies with practical application value for landscape planning. Following the evaluation, 76 studies that met all criteria were included in the thematic classification and analysis process. The studies included in the review were evaluated using content analysis and categorized into eight themes based on the purpose of machine learning applications within landscape planning processes. These themes are: (1) green space suitability analyses, (2) urban heat island modeling, (3) land use and land cover classifications, (4) ecological network and species distribution modeling, (5) integration with decision support systems, (6) user perception and visual landscape analyses, (7) disaster- and climate risk–oriented planning models, and (8) temporal landscape change projections.

During the thematic classification, each study was evaluated according to: (i) the types of data used (remote sensing, topography, socio-demographic data, etc.), (ii) the machine learning algorithms applied (RF, SVM, ANN, CNN, MaxEnt, etc.), and (iii) the role of the model output within the planning context (prediction, classification, pattern analysis, decision support). In this way, the planning function addressed by each study was identified and positioned under the appropriate theme. This approach makes the diversity of machine learning applications in landscape planning visible and provides a comparable structure for understanding how these methods are integrated into decision-making processes.

In this study, the literature was interpreted through a four-stage analytical framework that represents the functional workflow of machine learning in landscape planning. The first stage is data acquisition, which includes the use of multi-source data such as remote sensing, GIS layers, topographic information, climatic variables, and socio-demographic inputs. The second stage is machine learning modeling**,** in which algorithms performing classification, regression, or pattern recognition (e.g., Random Forest, SVM, ANN, CNN, MaxEnt, or LSTM) are selected based on the study's objectives. The third stage is transformation of model outputs into spatial insights, where planning-relevant layers such as suitability maps, temperature distribution surfaces, land-cover classes, risk zones, or habitat connectivity patterns are generated. The final stage involves translating these spatial insights into planning decisions**,** including prioritization of areas, scenario evaluation, identification of intervention zones, corridor planning, or policy development. This four-stage structure provided a consistent methodological basis for evaluating all studies and enabled a comparable analysis of each study's contribution to the planning process.

In the evaluation of the studies, not only the performance of the applied algorithms was considered, but also the transferability of the model to planning processes, the spatial representational power of the data sources used, the applicability of model outputs in decision-making contexts, and the reproducibility of the methods. Thus, the analysis was conducted from a perspective that prioritizes the practical relevance of the methods in landscape planning and their capacity to guide planning decisions, rather than simply focusing on technical accuracy.

However, it is acknowledged that limiting the review to accessible and peer-reviewed sources may have excluded certain local applications or reports, constituting a potential limitation. Additionally, the lack of standardization across studies in terms of data scales, sample area sizes, accuracy assessment metrics, and performance reporting formats restricted the possibility of direct quantitative comparison. For this reason, the study focuses not on one-to-one model performance comparisons but rather on identifying methodological trends, usage patterns, and planning-oriented contributions.

2 Findings and Discussion

The literature reviewed in this study demonstrates that machine learning techniquess are increasingly providing a more holistic, data-driven, and predictive analytical framework within the discipline of landscape planning. With the diversification of spatial data produced at varying scales, analyzing the complex environmental dynamics encountered in planning has become increasingly difficult to address using traditional methods alone. As a result, machine-learning-based approaches are becoming essential tools for identifying multivariate relationships, revealing spatial patterns, and generating reliable future scenarios.

The findings indicate that these methods consistently deliver higher accuracy, stronger pattern recognition capacity, and more interpretable outputs across various sub-themes of landscape planning—from ecological assessments and land-use analyses to climate-related risks and user perception studies. In this regard, the contribution of machine learning to planning processes extends far beyond technical enhancement; it establishes a new methodological plane that enables environmental decision-making to proceed in a more evidence-based, comparable, and scenario-oriented manner.

3.1. Green Space Suitability Analyses

Studies evaluated under this theme show that machine learning techniquess are becoming increasingly common and strategically important tools in the planning of urban green infrastructure. Most of the reviewed publications combine remote sensing data (NDVI, NDBI, albedo), topographic variables (slope, aspect, elevation), and socio-demographic indicators (population density, accessibility, indicators of social inequality) to determine green space potential (Gharaibeh et al., 2023). This multi-layered data approach enables machine learning models to offer greater discriminatory power compared with traditional multi-criteria evaluation methods.

Random Forest (RF) was identified as the most widely used algorithm within this theme; it is particularly preferred due to its high error tolerance, its ability to clearly reveal variable importance, and its capacity to model complex relationships. RF-generated suitability surfaces were reported to produce more stable results compared with methods such as SVM and ANN. Some studies employed hybrid models such as RF–AHP or ANN–fuzzy logic, noting that integrating multi-criteria decision-making structures with machine learning improves the sensitivity of planning outputs (Feng, 2024).

Findings indicate that machine learning–based suitability analyses perform strongly in the following areas (Gharaibeh et al., 2023; Feng, 2024):

• Prioritizing green space needs in areas heavily affected by the urban heat island effect

• Clearly identifying gaps in green infrastructure

• Making inequalities visible in social-justice-oriented green space accessibility analyses

• Enabling the comparison of spatial outcomes associated with different green infrastructure scenarios

A common limitation observed in the studies is that suitability maps are often treated primarily as model outputs, while the translation of these outputs into urban governance, policy development, or spatial planning decisions is discussed only to a limited extent. Nevertheless,

machine learning emerges as one of the most functional themes in strengthening evidence-based decision-making in green space planning.

3.2. Urban Heat Island Modeling

Most urban heat island (UHI) studies focus on estimating land surface temperature (LST), producing temperature distribution maps, and modeling the influence of urban morphology on thermal behavior. Landsat and MODIS datasets are the primary data sources, while variables such as building density, building height, impervious surface ratio, shading effects, and vegetation density are frequently used (Modjrian, 2022).

Within this theme, ensemble models (RF, XGBoost, Gradient Boosting) stand out prominently. Random Forest (RF) demonstrates high performance particularly in LST prediction, while several studies show that CNN-based deep learning models capture morphological structural features more effectively. Deep learning approaches have been especially successful in large metropolitan areas with heterogeneous urban fabrics (Zhou et al., 2025).

Findings reveal that machine-learning-based UHI models provide the following contributions (Modjrian, 2022; Ullah et al., 2025):

• High-accuracy LST predictions, with RF and CNN-based models performing particularly well

• Quantitative assessment of ecological cooling effects, highlighting NDVI as the strongest explanatory variable

• Modeling the impact of urban form components (H/W ratio, building density) on temperature

• Generating forward-looking temperature scenarios using machine learning, providing strong support for risk-oriented planning

Studies also indicate that UHI models can be directly applied in policy-making—for example, machine-learning-based scenarios estimating the cooling effects of green roofs, or LST thresholds used to identify heat-risk zones that can inform regulatory frameworks. However, many studies remain limited to the “temperature map production” stage, with relatively little emphasis on translating these outputs into adaptation strategies within planning processes.

3.3. Land Use and Land Cover Classifications

Land Use and Land Cover (LULC) classification emerges as the most common and most mature application area of machine learning within the reviewed literature. Studies in this theme frequently utilize Sentinel-2, Landsat, and WorldView imagery, while spectral bands, texture indices (GLCM), topographic variables, and NDVI constitute the most frequently used inputs (Modjrian, 2022).

Random Forest (RF) and Support Vector Machines (SVM) remain the strongest models in terms of classification accuracy. However, especially in studies published after 2020, the use of deep-learning-based models such as CNN, U-Net, and SegNet has significantly increased. These models have been shown to achieve high accuracy, particularly in urban areas where class boundaries are not clearly defined (Yashon Ouma et al., 2023).

The findings can be summarized as follows (Siddique et al., 2021):

• Machine-learning-based classification accuracies typically range between 85% and 95%, which generally meets the accuracy thresholds required by formal planning authorities.

• RF demonstrates strong performance across urban, agricultural, and natural land categories.

• The multi-purpose use of classification outputs in planning has increased—such as identifying ecologically sensitive areas, detecting land-use change, or supporting risk zoning.

• In temporal LULC series and landscape transformation studies, machine learning either complements or replaces classical models such as CA–Markov.

Limitations include a lack of standardization in classification accuracy reporting and the superficial treatment of data imbalance issues in many studies.

3.4. Ecological Network and Species Distribution Modeling

Studies under this theme focus on core components of ecological planning, such as corridor planning, habitat suitability analysis, and species distribution projections. MaxEnt is the most commonly used algorithm for species distribution modeling, while RF, BRT, and SVM are prominent in habitat suitability and landscape connectivity analyses (Modjrian, 2022). The findings highlight the following points (Mostafa et al., 2021):

• MaxEnt demonstrates stable performance even with small sample sizes, which is a major advantage for rare species.

• Using machine-learning-based suitability surfaces for identifying ecological corridors clarifies priority intervention zones against landscape fragmentation.

• Bioclimatic variables are the most influential factors in determining habitat suitability.

• The number of studies predicting habitat loss under future climate scenarios is increasing.

This theme represents one of the areas in which machine learning offers the most directly applicable outputs for conservation planning. However, only a small number of studies report that the generated corridor or suitability maps are validated through integration with on-site management practices.

3.5. Integration with Decision Support Systems

This theme represents one of the areas in which machine learning comes into closest contact with the planning process. The reviewed studies show that the integration of machine learning models with GIS-based spatial decision support systems (SDSS) is becoming increasingly widespread. The findings indicate the following (Koutra & Ioakimidis, 2023; Feng, 2024):

• The integration of machine learning and SDSS provides strong decision-making capacity, particularly in risk zoning, green infrastructure scenario development, and controlling urban growth.
• The combined use of machine learning with multi-criteria decision-making methods (AHP, ANP, TOPSIS) contributes to reducing dependence on subjective weighting in decision models.
• Studies report a significant increase in scenario generation speed when machine learning is incorporated.
• The integration offers automation opportunities that help compensate for human-resource limitations, especially in small municipalities.

A notable limitation is that many of these systems still remain at the prototype stage, and the number of real-world planning cases where they are fully integrated remains limited.

3.6. User Perception and Visual Landscape Analyses

This theme represents one of the few areas in which machine learning is integrated with social dimensions. The reviewed studies utilize street-level imagery, social media photographs, user surveys, and semantic segmentation data. CNN models stand out distinctly in visual analyses (Tian et al., 2021). The findings indicate the following (Wei et al., 2022):

• CNN-based models can automatically extract spatial aesthetic elements such as tree canopy, openness ratio, and building dominance.

• In user perception studies, RF and ANN successfully model multidimensional preference patterns derived from survey data.

• This theme provides direct feedback for policy areas such as walkability, visual quality, and satisfaction with urban open spaces.

These studies demonstrate the potential of machine learning to incorporate not only physical environmental factors but also user experience into planning processes. However, issues related to data privacy, representativeness, and sensitivity to social context remain insufficiently discussed in many studies.

3.7. Disaster- and Climate Risk–Oriented Planning Models

In studies modeling flood, landslide, wildfire, and drought risks, machine learning is used as a high-accuracy risk prediction tool. Topography, precipitation, soil type, LST, vegetation moisture, and anthropogenic pressure variables are commonly employed in this theme (Ullah et al., 2024; Toprak, 2025). The findings can be summarized as follows (He et al., 2021; Ullah et al., 2024):

• RF and XGBoost emerge as the strongest models for flood and landslide susceptibility mapping.

• In wildfire risk studies, NDVI, LST, and wind variables are the most influential predictors.

• Machine-learning-based risk maps provide more detailed zoning than traditional methods and help clarify intervention priorities.

• In some studies, combining climate projections with machine learning has enabled the generation of forward-looking vulnerability maps.

However, these outputs are often not directly incorporated into planning documents; integration of non-structural risk reduction strategies remains weak in the current literature.

3.8. Temporal Landscape Change and Future Projections

This theme focuses on modeling how landscapes change over time and how they are likely to transform in the future. LSTM, RF, Markov–machine learning hybrid models, and change detection algorithms are the most prominent approaches. The findings indicate the following (Biljecki & Ito, 2021; Ullah et al., 2024):

• LSTM-based models learn temporal patterns in time-series data more effectively than other algorithms.
• In urban growth projections, machine learning provides a more dynamic structure compared with CA–Markov models.

• Machine-learning-based models offer strong early-warning capabilities for processes such as agricultural land loss, forest conversion, and shoreline change.
• Future scenarios play a decisive role in planning land-use constraints and protected area designations.

A common limitation is that many studies lack comprehensive uncertainty analyses for their projection outputs.

4.Conclusion and Recommendations

This study demonstrates that machine learning provides a holistic framework that enhances both analytical accuracy and decision-making capacity across various thematic domains of landscape planning (Feng, 2024). The broad spectrum of applications—from green space suitability analyses and urban heat island modeling to ecological network assessments and disaster and climate risk analyses—shows that machine learning models can represent complex environmental relationships with high accuracy. In particular, ensemble-based machine learning techniquess and hybrid approaches offer predictive capabilities that exceed those of traditional analyses, owing to their capacity to capture nonlinear patterns and integrate multidimensional datasets (Biljecki & Ito, 2021).

These findings indicate that machine learning has evolved from a tool that merely evaluates existing conditions into an indispensable methodological foundation for future-oriented scenario generation, spatial prioritization, and the development of sustainable planning strategies. Future research that focuses on explainable artificial intelligence approaches—enabling more direct integration of model outputs into planning decisions—hybrid models that combine diverse data sources, and scenario-based studies centered on climate adaptation and ecological resilience will further strengthen the applicability of machine learning within landscape planning practice.

Abstract

This study aims to develop a digital twin–based approach for improving microclimatic conditions in small-scale urban areas. Kaymakkapı Square, located in Isparta, was selected as the case study area, and the effects of the existing green infrastructure on urban thermal comfort were examined. Using high-resolution orthophotos, tree crown areas were digitized, thereby quantitatively determining the current canopy cover ratio. Within the scope of scenario analyses, new afforestation interventions were proposed for the square, and the resulting changes in canopy cover ratio were identified. Subsequently, the potential effects of these changes on surface temperature were estimated using the "shading increase → temperature difference" coefficient defined in the literature.

The data obtained enabled a comparison between the current situation and the scenario outcomes through statistical analyses, maps, and tables, allowing both visual and numerical results to be jointly evaluated. The findings reveal that even small-scale design interventions can make significant contributions to microclimatic improvement. Moreover, digital twin–based approaches were shown to provide decision-makers with rapid, low-cost, and easily interpretable outputs. A key strength of this study lies in its ability to generate practical results through remote sensing and quantitative analyses without the need for field measurements. In this respect, the research offers an applicable, accessible, and replicable methodological framework for urban design processes and climate adaptation strategies.

In conclusion, this approach proposes a method that can be extended not only to Kaymakkapı Square but also to other urban areas of similar scale.

Keywords: Digital twin, microclimate, urban design, shading ratio, urban heat ısland, climate adaptation strategies

1. Introduction

As urbanization accelerates, the expansion of impervious surfaces and the reduction of natural areas produce a pronounced Urban Heat Island (UHI) effect on the urban climate. The Urban Heat Island phenomenon refers to metropolitan areas that are significantly warmer than their rural surroundings as a result of human activities. Studies conducted in Istanbul indicate that summer land surface temperatures range between 21–45 °C, with UHI intensity increasing particularly in densely built-up zones (Khorrami & Gündüz, 2017). The same study identified the NDVI value as the most influential determinant in the formation of heat islands.

International research has examined the microclimatic effects of green spaces across different spatial scales. A study conducted in the Fukuoka–Kitakyushu metropolitan region in Japan found that urbanization weakened sea-breeze circulation and caused an average increase of 0.23 °C in overall air temperature (Kawamoto, 2016). In Turkey, a study carried out in central Erzurum revealed that the relationship between Sky View Factor (SVF) and temperature is especially strong during winter months, and that shading and vegetation enhance pedestrian

thermal comfort (Yılmaz, Yılmaz, Yavaş, Mutlu, & Koç, 2016). These findings demonstrate that surface cover characteristics—such as vegetation density, ground albedo, and building ratio—are among the primary determinants of microclimate conditions even across different climate zones.

In urban microclimate management, anthropogenic heat loads play a role as critical as energy emissions and surface materials. Wagner and Viswanathan (2016) examined the impact of traffic behavior on surface temperatures using a cellular automata–based model and showed that acceleration patterns significantly increase ambient temperatures. This result indicates that micro-scale thermal mitigation strategies must account not only for vegetative cover but also for human-induced heat emissions.

In recent years, digital twin–based analyses have gained prominence as a means of evaluating these multidimensional factors simultaneously. Digital twin technology creates a virtual replica of physical systems or environments, enabling scenario-based analysis and decision-support processes. In Turkey, this technology has been integrated into urban planning applications—particularly in Bursa Metropolitan Municipality's 3D building modeling and structural inspection workflows (Aslan, 2024). According to Aslan (2024), digital twins enhance the efficiency of public resource allocation, reduce the risk of misinvestment, and have become an important tool for sustainable city management. This approach allows for the visualization and quantification of parameters such as changes in green-space ratios, shading potential, and surface temperatures in urban open spaces.

In this context, the present study conducts a digital twin–based microclimate assessment using the example of Kaymakkapı Square in Isparta. The objective is to spatially analyze the potential impact of incremental increases in green-space ratio on surface temperatures and to demonstrate the benefits that the digital twin approach can provide in micro-scale planning processes. In this respect, the study offers an original contribution to the literature in terms of both microclimatic heat management and data-driven urban design..

1.1. Microclimate and the Urban Heat Island Phenomenon

Urban microclimate is shaped by the altered energy balance and atmospheric processes that occur when artificial surfaces replace natural ground cover. This transformation gives rise to the Urban Heat Island (UHI) phenomenon, in which urban centers exhibit higher temperatures compared to their surrounding environments. According to Oke's (1982) classical definition, the UHI effect is associated with the disruption of the surface energy balance of cities and results from the interactions among surface heat fluxes, longwave radiation, air circulation, and anthropogenic heat sources, particularly within the urban canopy layer (UCL). This condition is directly linked to the high heat capacity of impervious surfaces, their low albedo values, and the reduction in evapotranspiration rates.

Subsequent studies have emphasized that the UHI effect should be evaluated not only in terms of land surface temperatures (LST) but also through atmospheric heat accumulation (Voogt & Oke, 2003). Urbanization intensity, building height ratio, surface albedo, wind flow, and the proportion of urban greenery are the key morphological parameters that determine the magnitude of the UHI effect (Santamouris, 2015). Similar patterns have been observed in research conducted in Turkey. For instance, Okumuş (2022) found that surface temperature in Istanbul is positively correlated with building density and negatively correlated with NDVI values. Saka and Atmaca (2023) reported that the mean land surface temperature in Yozgat

increased by 1.18 °C between 2012 and 2022. The LCZ (Local Climate Zone) classification developed by Sinancıoğlu (2024) further illustrated the spatial variations in UHI intensity associated with local climate zones.

These findings confirm that the energy balance principles described in Oke's (1982) theoretical framework are also valid for urban fabrics in Turkey. The interaction between the thermal properties of urban surfaces—such as albedo, thermal conductivity, and heat-storage capacity—and land-cover characteristics accelerates microclimatic heat accumulation, particularly during the summer months. Therefore, the Urban Heat Island phenomenon constitutes one of the primary parameters that must be considered in micro-scale urban planning and landscape design.

1.2. Green Infrastructure and Its Effects on Microclimate

One of the most effective strategies for mitigating the Urban Heat Island (UHI) effect is the enhancement of green and blue infrastructure components. Vegetated surfaces reduce both surface and air temperatures through mechanisms such as evapotranspiration, shading, and increased albedo, while water bodies moderate thermal fluctuations by absorbing heat during the day and releasing it at night due to their high specific heat capacity (Budzik, Sylla, & Kowalczyk, 2025).

According to a comprehensive meta-analysis conducted by Kumar et al. (2024), which evaluated more than 27,000 studies, botanical gardens (5.0 ± 3.5 °C), wetlands (4.9 ± 3.2 °C), green walls (4.1 ± 4.2 °C), and street trees (3.8 ± 3.1 °C) exhibit the strongest cooling effects among green–blue infrastructure elements. A systematic review by Budzik et al. (2025) further reported that the average cooling intensity varies by methodological approach, with remote sensing studies indicating a mean reduction of 4 °C, field measurements showing 3 °C, and numerical models demonstrating 2 °C.

The influence of green infrastructure is not limited to physical cooling; it also reduces radiative heat absorption through shading and alters wind flows to create cooling air movements known as "park breezes" (Toparlar et al., 2017). Field measurements have shown that the temperature difference around urban parks ranges between 1–3 °C, with park corridors aligned parallel to prevailing wind directions significantly enhancing cool-air advection.

In Turkey, Ortaçeşme and Zeğerek Altunbey (2022) identified green infrastructure as a "key" component of climate adaptation, while Göksoy Sevinçli and Bayrakcı (2024) emphasized its importance in strengthening urban resilience. In this context, the microclimatic benefits of green infrastructure should be evaluated not only in terms of reducing surface temperatures but also through its contributions to ecosystem services, improved air quality, and enhanced thermal comfort.

1.3. Remote Sensing and GIS-Based Microclimate Analyses

Remote sensing and Geographic Information Systems (GIS) technologies are fundamental tools in urban microclimate research, particularly for detecting thermal anomalies. Land Surface Temperature (LST) values are commonly analyzed through their correlations with indicators such as NDVI, NDBI, and albedo (Weng, 2009). The observation that areas with higher NDVI values exhibit lower LST provides quantitative evidence of the cooling function of vegetation.

Macarof and Statescu (2017), using Landsat 8 imagery, demonstrated that the NDBI–LST relationship is strongly positive, whereas the NDVI–LST relationship is negative and subject

to seasonal variation. Similar patterns have been documented in studies conducted in Turkey, where increases in NDVI correspond to reductions of approximately 0.7–1.2 °C in surface temperatures (Okumuş, 2022; Saka & Atmaca, 2023).

Remote sensing data not only supports the identification of temperature distribution but also provides the foundational database for constructing digital twins. Budzik et al. (2025) emphasized that this integration lies at the core of GIS-based spatial modeling within the "geoinformatics approach," and further argued that artificial intelligence (AI) and digital twin technologies should be prioritized in future research for the management of Blue–Green Infrastructure (BGI).

1.4. Digital Twin Technology and the Urban Planning Context

Digital twin technology is an approach that creates a virtual representation of physical systems, enabling scenario generation, monitoring, and decision-support processes. Batty (2018) describes digital twins as "dynamic digital reflections of cities," emphasizing their capacity to simulate various urban processes—such as energy, transportation, and environmental management—simultaneously.

In Turkey, Aslan (2024) examined the integration of digital twin technology into urban planning processes through the case of Bursa Metropolitan Municipality and demonstrated that this technology functions as a strategic tool for the efficient allocation of public resources. When combined with GIS-based datasets, the digital twin approach can generate highly accurate spatial scenarios for microclimate analysis, green infrastructure planning, and thermal comfort modeling.

Furthermore, Budzik et al. (2025) and Kumar et al. (2024) highlight digital twins as one of the emerging research frontiers for the optimization of green–blue infrastructure management. In this context, the digital twin is not only a visualization tool but also a critical component of data-driven climate adaptation planning.

1.5. Micro-Scale Applications and Scenario Approaches

Recent efforts to improve urban microclimates have increasingly focused on micro-scale applications such as squares, parks, and streets. Analyses conducted at this scale demonstrate that even small-scale green interventions can produce perceptible thermal effects. Measurements by Toparlar et al. (2017) identified an average air temperature reduction of 1–3 °C in urban parks, while Okumuş (2022) reported that a 10% increase in NDVI corresponds to a 2% decrease in LST values.

Kumar et al. (2024) further calculated that the combined implementation of local interventions—such as parks, green walls, and green roofs—can produce cooling effects of up to 2.7 °C at the city scale. These findings highlight the importance of GIS-based tools such as buffer analyses, vectorization, and green-ratio scenarios in micro-scale planning processes.

The digital twin approach integrates these micro-scale analyses both visually and analytically, enabling the comparison of alternative green-ratio scenarios. In doing so, it supports data-driven microclimate design in urban open spaces and provides a scientifically grounded basis for planning processes.

2. Materials and Methods

The study area comprises Kaymakkapı Square and its surroundings, located in the city center of Isparta (Figure 1). This area is a public open space characterized by intensive commercial functions, a high proportion of impervious surfaces (>60%), and limited vegetation cover. Due to increased pedestrian activity during the summer months, the square functions as a critical thermal hotspot in terms of urban microclimate. The total area is 34,350.75 m², with the existing green-space ratio estimated at approximately 39.4%. For these reasons, the square was selected as a suitable test site for urban microclimate optimization.

The methodological framework is based on a digital twin–supported GIS analysis. The workflow includes vegetation detection from satellite imagery, spatial thresholding to delineate green areas, vectorization, area calculations, and scenario-based buffer analyses (Figure 1). The resulting numerical data were subsequently used for the empirical modeling of cooling potential.

Figure 1. Study Area: Kaymakkapı Square, Isparta

2.1. Data Sources

Open-access remote sensing data and secondary datasets generated within the GIS environment were used in this study. The primary datasets include:

• Satellite imagery: High-resolution RGB satellite imagery obtained from Google Earth Pro (summer season, 2023).

• Coordinate system: WGS 84 / UTM Zone 36N.

• Climate data: According to the Turkish State Meteorological Service (MGM, 2023), the mean summer air temperature is approximately 31 °C, with maximum values reaching around 36 °C.

The secondary datasets consist of:

• Green-space vector layers, buffer analyses, and polygon area calculations, all produced in QGIS 3.34.

• All computations were performed using metric units, and the analysis scale was defined as 1:1,000.

2.2. Vegetation Digitization (ExG Method)

The Excess Green Index (ExG) method was applied to identify vegetated surfaces. This method calculates the green intensity of vegetation based on the difference between the RGB bands. The formulation is expressed as:

$$ExG=2G-R-B$$

where R, G, and B represent the red, green, and blue spectral band values, respectively (Macarof & Statescu, 2017). In the resulting raster dataset, pixels with ExG > 10 were classified as green areas. To reduce noise, small polygons smaller than 5 m² were removed from the dataset. Owing to its computational efficiency and robust accuracy, this method is consistent with comparable studies in the literature (Weng, 2009; Okumuş, 2022).

The raster data were converted to vector format in QGIS using the Polygonize (Raster to Vector) tool, and the area (m²) of each polygon was calculated. In the initial state, the total green-space area was determined to be 13,533.5 m² (≈ 39.4%).

2.3. Scenario Development and Buffer Analysis

Two scenarios were developed to model the incremental increase in vegetation coverage:

• Scenario 1 (S1): A 0.3 m buffer applied to the existing green-area polygons.

• Scenario 2 (S2): A 0.6 m buffer applied to the same polygons.

For both scenarios, the resulting total green-space area was intersected with the study area boundary, and proportional changes were calculated. Accordingly, the green-space ratio increased to 44.8% in S1 and to 49.3% in S2. These increases illustrate how small-scale surface modifications can significantly influence total green-space composition.

The buffer analyses were conducted within the spatial scenario-generation framework of the digital twin approach (Aslan, 2024; Budzik et al., 2025). This enabled different green-space configurations to be compared in a manner akin to real-time simulation.

2.4. Cooling Effect Model

In estimating the cooling effect, the empirical relationship commonly used in the literature between the Percentage of Shaded Area (PSA) and the surface temperature difference (ΔT) was adopted. According to the meta-analysis conducted by Kumar et al. (2024), each 10% increase in vegetated area results in an approximate reduction of 0.25–0.30 °C in land surface temperature.

Based on this relationship, the estimated temperature decrease for the scenarios developed in the present study—corresponding to increases in green-space ratios (5.4% → 9.9%)—was calculated using the following formulation:

$\Delta T = 0.03 \times \Delta$Green Ratio (%)

Accordingly, the cooling potential was estimated at approximately 0.17 °C for Scenario 1 (S1) and 0.32 °C for Scenario 2 (S2). These results are consistent with the field measurement ranges reported by Budzik et al. (2025) and demonstrate the direct thermal influence of vegetation cover in micro-scale urban environments.

2.5. Digital Twin–Based Spatial Modeling

The digital twin model was constructed upon a set of layer combinations developed in the QGIS environment, including ground-surface data, green-space vectors, buffer scenarios, and the raster-based heat map. This system functions as a data-driven digital replica of the physical environment. The model aims to analyze the effects of changes in green-space ratio on surface temperature distribution both numerically and visually.

In line with the recommendations of Budzik et al. (2025) and Kumar et al. (2024), the digital twin approach was evaluated as a spatial decision-support tool. The results reveal microclimatic variations across different functional zones within the square—such as pedestrian corridors, seating areas, and vegetated islands—and provide a foundation for future design interventions.

2.6. Limitations of the Method

In this study, ExG-based vegetation detection was supported through visual verification and manual boundary refinements. However, due to the unavailability of NDVI or thermal band data, direct Land Surface Temperature (LST) calculations could not be performed. Consequently, the cooling effect was estimated using an empirical model. Moreover, micro-scale wind-flow and shading analyses (e.g., ENVI-met simulations) were excluded from the scope of this research.

Nevertheless, the scenario-generation speed and visualization capabilities offered by the digital twin–based approach represent a major strength of the method, providing a simple yet effective analytical framework for decision makers (Aslan, 2024).

3. Findings and Discussion

3.1. Current Situation Analysis

The digital twin–based analysis conducted for Kaymakkapı Square in Isparta revealed that the study area covers a total of 34,350.75 m², of which 13,533.5 m² consists of green space. This corresponds to approximately 39.4% vegetated surface coverage. The majority of green areas are concentrated along the northern and western edges of the square, whereas pedestrian corridors, ground-level seating zones, and commercial frontages are predominantly composed of impervious surfaces. This configuration contributes to the formation of microclimatic hotspots, where midday surface temperatures commonly range between 35–40 °C (Okumuş, 2022).

In the raster-based ExG analysis, the areas with the highest vegetation density were identified as lawn zones and shaded areas beneath tree canopies. The shading effect was found to be particularly weak along the northeast–southwest pedestrian axis, while it was more pronounced

along the vegetated strip on the western edge. These results indicate that the microclimatic cooling potential is unevenly distributed across the site.

3.2. Scenario Analyses

The green-space enhancement scenarios (S1 and S2) were applied within the digital twin model, with each scenario evaluated as a separate spatial layer. The findings are summarized in Table 1.

Table 1. Green-Space Scenarios and Area Ratios

Scenario	Description	Green Area (m²)	Green Ratio (%)	Δ Ratio (%)
S0	Current State	13.533,5	39,4	–
S1	+0,3 m Buffer	15.392,7	44,8	+5,4
S2	+0,6 m Buffer	16.934,1	49,3	+9,9

As a result of the buffer scenarios, the green-space ratio increased by 5.4% in S1 and 9.9% in S2. Visually, the expansion of green areas was most pronounced along the edges of the vegetated islands surrounding the square and along the boundaries of the commercial axis. This increase also reduced the proportion of impervious surfaces from 60% to 51%, resulting in a more sustainable distribution in terms of surface energy balance.

3.3. Estimated Cooling Effect

According to the empirical model, the reduction in surface temperature associated with the increase in green-space ratio was calculated to be within the range of 0.17–0.32 °C (Kumar et al., 2024). Accordingly:

S1 (44.8%): $\Delta T \approx -0.17$ °C

S2 (49.3%): $\Delta T \approx -0.32$ °C

Although these values may appear small in absolute terms, they are highly significant for micro-scale open spaces. The literature indicates that even temperature differences of 0.2–0.4 °C can substantially influence pedestrian thermal comfort in small urban areas (Toparlar et al., 2017; Budzik et al., 2025).

The simulations show that the cooling effect is more pronounced in areas with high tree density, while it remains relatively limited in lawn-dominated zones. This finding aligns with the global meta-analysis by Kumar et al. (2024), which emphasizes the influence of vegetation type and canopy density on cooling performance. Additionally, the buffer scenarios contribute most effectively by connecting fragmented vegetated patches, thereby creating a more continuous green corridor. Such connectivity enhances cool-air advection along the prevailing wind direction, reinforcing the park-breeze effect (Oke, 1982; Voogt & Oke, 2003).

3.4. Spatial Distribution and Visual Assessment

In the color-scaled analysis conducted within the digital twin model (Figure 2), impervious surfaces with low green-space ratios are represented in orange–red tones, whereas shaded areas appear in light green hues. This map enabled a clear visualization of microclimatic differences across various functional zones. Notably, temperature disparities in the west-oriented seating areas and in front of ground-level cafés decreased by 7–10% under the S2 scenario. This finding

confirms the observation reported by Budzik et al. (2025), namely that "increases in vegetation density and spatial continuity expand the effective cooling range." Furthermore, the microclimatic variation of 1–3 °C observed by Toparlar et al. (2017) in urban parks appears to follow a linear pattern at the scale of this study.

One of the key advantages of the digital twin system is its ability to visually compare scenario-based differences in real time. This capability makes it possible to clearly identify which locations would yield the greatest microclimatic benefit from new green interventions.

3.5. Comparison of Findings with the Literature

The results obtained in this study are consistent with findings reported in global-scale research. Budzik et al. (2025) indicate that cooling intensity averages 4 °C in remote-sensing-based studies, 3 °C in field measurements, and 2 °C in numerical models. The 0.3 °C cooling difference observed in this study is therefore within the expected range for a micro-scale urban square.

Similarly, Toparlar et al. (2017) observed temperature differences of 1–3 °C in parks in Antwerp, and Oke (1982) emphasized that microclimatic variations of this magnitude play a significant role in surface energy balance. In the Turkish context, the model developed by Okumuş (2022) also demonstrated a linear negative correlation between green-space ratio and surface temperature ($r = -0.71$), which aligns with the findings for Kaymakkapı Square.

Furthermore, the digital twin–based analysis employed here is consistent with Aslan's (2024) concept of "data-driven decision making in smart city management and planning." In this regard, the method extends beyond traditional GIS analyses by offering dynamic scenario generation and visual impact assessment capabilities.

4. Conclusion and Recommendations

This study evaluated the microclimatic effects of increasing green-space coverage in Kaymakkapı Square, Isparta, using a digital twin–based analytical approach. The findings demonstrate that raising the green-space ratio from 39.4% to 49.3% generates a potential surface temperature reduction of approximately 0.32 °C. This outcome is largely consistent with the global meta-analysis by Kumar et al. (2024), which reports that each 10% increase in green-space ratio yields an average cooling of 0.25–0.30 °C.

Although the cooling magnitude obtained in this research is situated at the lower bound of the 3–4 °C macro-scale cooling range documented by Budzik et al. (2025), it remains fully aligned with expectations for a micro-scale urban square. Similarly, the 1–3 °C temperature differences observed by Toparlar et al. (2017) around parks support the notion that the microclimatic trends observed in this study follow a scaled but parallel pattern. Studies conducted within the Turkish context (Okumuş, 2022; Saka & Atmaca, 2023; Sinancıoğlu, 2024) further corroborate this trend, highlighting a negative correlation between NDVI and LST and confirming that increased vegetation density results in lower surface temperatures. Accordingly, the findings for Kaymakkapı Square exhibit both quantitative and qualitative consistency with national and international literature. The digital twin framework employed in this study goes beyond traditional GIS-based analysis by enabling scenario-based simulation on a virtual replica of the physical environment. This approach facilitates both numerical and visual assessment of green infrastructure interventions, particularly in micro-scale urban areas such as squares, parks, and streets (Aslan, 2024).

One of the central contributions of the digital twin model is its ability to allow real-time visual comparison between different green-space scenarios. This capability made it possible to explicitly identify the locations where additional vegetation would yield the greatest microclimatic benefits. This aligns directly with the perspective of Budzik et al. (2025), who emphasize digital twin technology as a priority research direction for future BGI (blue–green infrastructure) management.

Furthermore, the application of digital twins—previously highlighted by Aslan (2024) in the context of Turkish cities—is recognized as an instrument that enhances resource efficiency in urban planning and public administration. In this study, the use of a digital twin introduced a new analytical dimension to microclimate assessment, providing an innovative decision-support mechanism.

The research findings indicate that even small-scale green infrastructure interventions can produce meaningful microclimate improvements in urban centers. Increased vegetation connectivity contributed to the dispersal of thermal hotspots and strengthened the park-breeze effect (Oke, 1982; Voogt & Oke, 2003). This demonstrates that spatial configuration, continuity, and orientation are just as important as the total amount of vegetation in green infrastructure design. As also noted by Budzik et al. (2025), the shape complexity and spatial structure of BGI significantly influence the effective cooling footprint.

In the context of Turkish urban areas—particularly medium-sized cities like Isparta—public open spaces are predominantly composed of impervious surfaces. Therefore, micro-scale greening strategies carry a level of importance comparable to large-scale park developments. This study shows that such strategies can be quantified and monitored effectively through the integration of GIS and digital twin technologies. Overall, the digital twin–based GIS analysis demonstrated that this methodology offers a measurable, visualizable, and scenario-compatible tool for urban microclimate planning. The results clearly indicate that increasing green-space ratios reduces surface temperatures, enhances thermal comfort, and mitigates microclimatic imbalance. These findings align with global trends reported in the literature (Oke, 1982; Kumar et al., 2024; Budzik et al., 2025), confirming the applicability of digital twin technology for localized urban interventions. In conclusion, the case of Kaymakkapı Square illustrates that even modest interventions can improve urban climate quality. It also highlights that data-driven, participatory, and digitally supported planning approaches will be among the key tools for building sustainable cities of the future.

Abstract

This paper explores the spatial logic and ecological intelligence embedded in the temporary settlement practices of Yörük nomadic communities, reframing them as mobile heritage ecosystems. Drawing on an in-motion visual grammar approach, the study analyzes six transitional settlements through schematic diagrams and ethnographic documentation. The analysis focuses on three interrelated parameters—positional patterns, componential layouts, and transition paths—revealing the ways in which mobility functions as a form of resilience rather than a lack of permanence.

Findings highlight a consistent spatial intelligence across varied contexts: solar-oriented positioning, clear separation of human and animal domains, and flexible circulation paths. These recurring arrangements demonstrate inherited design strategies that embody environmental responsiveness, modular organization, and multispecies cohabitation. By interpreting these spatial logics through the lens of ecosystemic heritage thinking, the paper positions nomadic settlements as dynamic, living systems that transmit ecological and cultural knowledge across generations.

This perspective expands heritage discourse beyond sedentary and monumental frameworks, acknowledging mobility as a sophisticated cultural practice with enduring value. Ultimately, the study contributes to debates on cultural sustainability by conceptualizing ephemeral settlement systems as heritage ecosystems, where temporality, adaptability, and ecological intelligence converge. Through the integration of visual pattern analysis and ethnographic insight, it argues that the Yörük case exemplifies how nomadic heritage can be mobilized as a critical lens for rethinking spatial resilience, mobility, and cultural continuity in contemporary heritage studies.

Keywords: Nomadic heritage, yörük settlements, mobility, ecological intelligence, heritage ecosystem, cultural sustainability

1. Introduction

The ongoing discourse on cultural heritage increasingly underscores its integration within ecological systems and everyday cultural practices. Rather than being viewed as static remnants of the past, heritage is now conceived as a living, relational, and context-dependent phenomenon, continually shaped through the interactions of people, materials, landscapes, and non-human entities (DeSilvey, 2017; Harrison, 2015; Holtorf & Fairclough, 2013). This conceptual turn signals a broader paradigm shift from object-based preservation toward process-oriented heritage management, in which heritage itself becomes an active participant in sustaining identity, resilience, and ecological balance (DeSilvey, 2012).

Such an ecological orientation creates new possibilities for understanding and engaging with nomadic and pastoralist groups whose lifeways remain finely synchronized with environmental rhythms, animal welfare, and cyclical mobility (Krätli, 2015; Nori, 2019). For these

communities, spatial organization is governed less by permanence than by seasonal adaptation and the health of herds, reflecting a pragmatic environmental intelligence. Their practices also unsettle the sedentary assumptions that dominate conventional heritage discourse, revealing mobility as both an epistemic and ecological mode of existence (Rose, 2011; Viveiros de Castro, 2004).

Gilbert (2014) distinguishes multiple forms of nomadism in mobile cultures, emphasizing pastoral nomadism as a distinct form defined by movement organized around the care and management of livestock. It represents a way of life structured by ecological cycles and animal needs rather than by commerce or extraction (Barfield, 2013; Barnard & Wendrich, 2008; Zvelebil, 1980). Among groups embodying these principles, the Yörüks of Anatolia provide a particularly instructive case. Their settlements demonstrate an intricate entanglement with seasonal variation, environmental uncertainty, and multispecies coexistence (Doğan & Doğan, 2004; Ersavaş & Özkanlı, 2018; Lindner, 1983; Yeni, 2013). The Yörüks were selected for this study as one of the few remaining pastoral nomadic groups in Anatolia that continue to sustain mobility-based traditions.

To explore these dynamics, the research concentrates on transitional phases, specifically the acts of settling and departing that punctuate the seasonal cycle. These liminal moments encapsulate complex judgments about terrain, weather, and available resources, translating them into spatial and material gestures. They serve as critical thresholds where ecological awareness and collective coordination become most visible (Figure 1). While relatively stable intervals (e.g., t2–t3; t4–t5; t6–t7; t10–t11) structure daily life, this study foregrounds the transitional junctions (t1–t2 and t11–t12) where built configurations are dismantled and re-assembled. These phases offer insight into how nomadic communities evaluate sites, channel livestock movements, and coordinate communal and material arrangements.

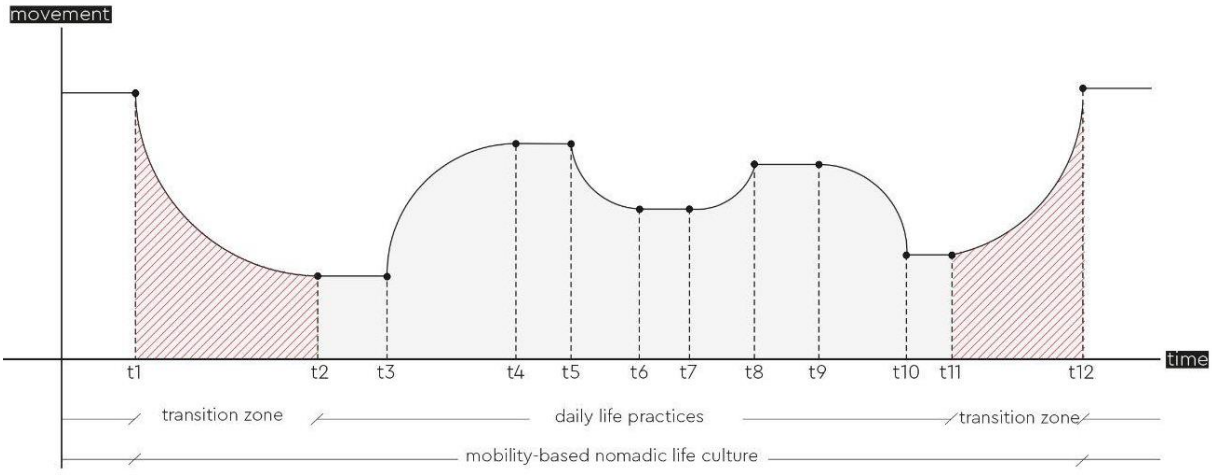

Figure 1. Thresholds of settlement and departure in Yörük mobility (Source: Authors).

Guided by this perspective, the study seeks to understand how the key moments of temporary settlement and departure within the Yörük mobility cycle reveal embedded environmental reasoning and relational heritage practices, and to explore in what ways mobility-centered

traditions can expand current understandings of heritage ecosystems while informing sustainability-oriented management frameworks.

2. Materials and Methods

The term Yörük, derived from the Turkish verb "yörü-" (to walk or move), encapsulates a lifestyle grounded in habitual movement, environmental awareness, and spatial adaptability (İnalcık, 2014). Historically, Yörük communities developed a settlement logic based on ephemeral, modular, and reparable structures that supported cyclical mobility while remaining responsive to shifting climatic and ecological conditions (Bates, 1973; Beşirli & Erdal, 2008; Ersavaş & Özkanlı, 2018). Their encampments are organized around the *karaçadır*, a portable black tent woven from goat hair, strategically positioned in response to climatic, topographic, and ecological factors (Pfeifer, 2015) (Figure 2).

Figure 2. Exterior (left) and interior (right) views of the Karaçadır, the central spatial unit of the Yörüks' mobile settlement system (Source: Authors).

Within the scope of this research, selected instances of Yörük encampments were documented through schematic visualizations focusing specifically on transitional phases, namely the acts of temporary settlement and departure. Six distinct examples were identified through ethnographic documentation, archival photographs, and field observations. Each case was subsequently analyzed to produce schematic drawings mapping the core spatial components: karaçadır tents, livestock enclosures, communal zones, and circulation paths. These drawings were standardized and compiled into a comparative visual matrix structured around variations in spatial configuration, environmental orientation, and functional zoning.

The visual dataset was developed by synthesizing ethnographic literature, archival imagery, and prior field surveys with newly constructed schematic documentation. Selection emphasized cases where both setup and dismantling phases were visible and reconstructable. Each chosen example was redrawn as a schematic plan intended to represent the spatial reasoning and morphological logic inherent in the original observation. To maintain consistency, a uniform drawing scale and north orientation were applied to all diagrams. Functional domains were classified to distinguish between areas for human habitation, animal care, and storage or resource management (Figure 3).

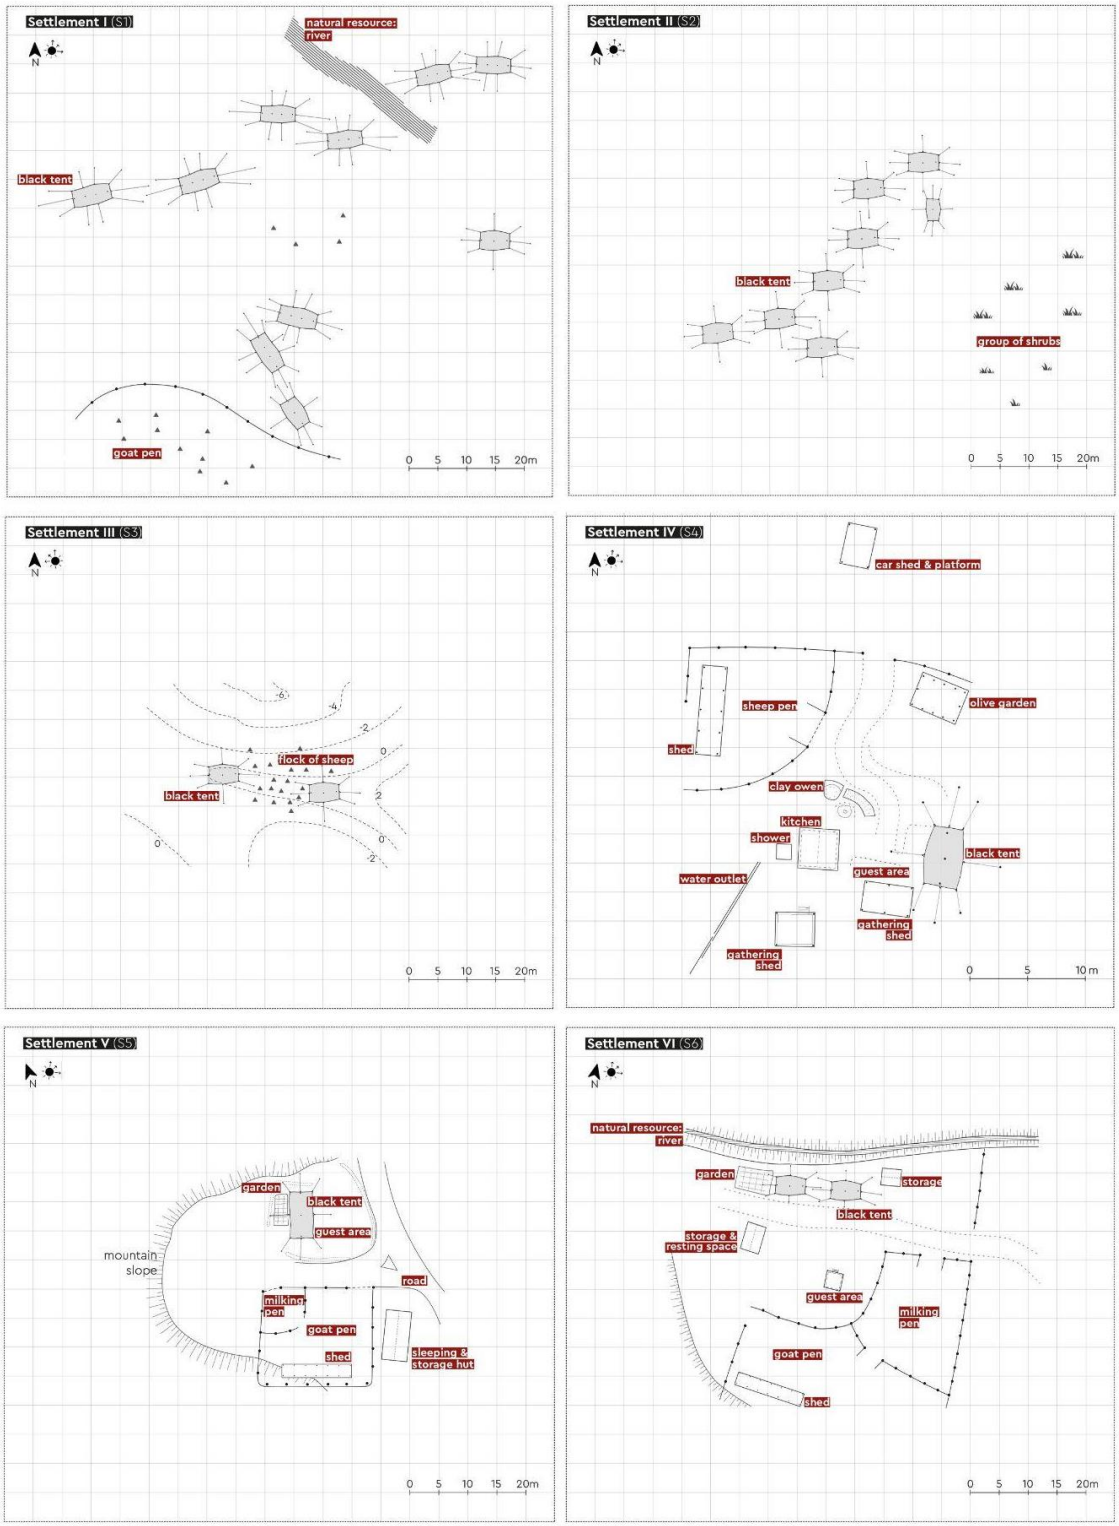

Figure 3. Matrix-based representation of six Yörük settlements (Source: Authors).

The study adopts a visual-computational framework based on shape grammars (Knight, 2000; Knight & Stiny, 2015; Stiny, 2006). Extending this method beyond morphological analysis, the framework incorporates ethnographic dimensions such as communal roles, group mobility, and

seasonal behavior. Building on previous adaptations, including the "lived-in grammar" (Rezoug & Özkar, 2023) and user-oriented models (Eloy et al., 2018; Ferreira et al., 2011; Vardouli, 2015), this study proposes an *in-motion visual grammar* that identifies recurring, mobility-driven spatial patterns revealing the embedded design intelligence of nomadic lifeways.

The in-motion visual grammar was applied to analyze the organizational principles embedded in Yörük settlements. The standardized schematic corpus provided the analytical foundation for a comparative study structured around environmental, functional, and social parameters. Through this framework, the study aimed to visually systematize the underlying logic governing how tent clusters are spatially composed and organized. Translating observed settlement configurations into schematic visual patterns made it possible to identify recurring organizational logics, adaptive strategies, and forms of environmental reasoning that characterize Yörük spatial practices.

Figure 4 conceptually illustrates how nomadic camp layouts are determined not only by social and protective factors but also by livestock movement patterns (Figure 4). It contrasts two grazing models: in the continuous grazing tract model, herds move within a single central area with tents densely clustering along its periphery, whereas in the dispersed grazing tract model, grazing zones extend over a broader terrain, producing a looser and more flexible tent configuration. This diagram underpins an integrated analysis across three spatial parameters: (a) positional patterning among tents, (b) componential relationships between human and animal domains, and (c) the flow paths required for effective herd circulation.

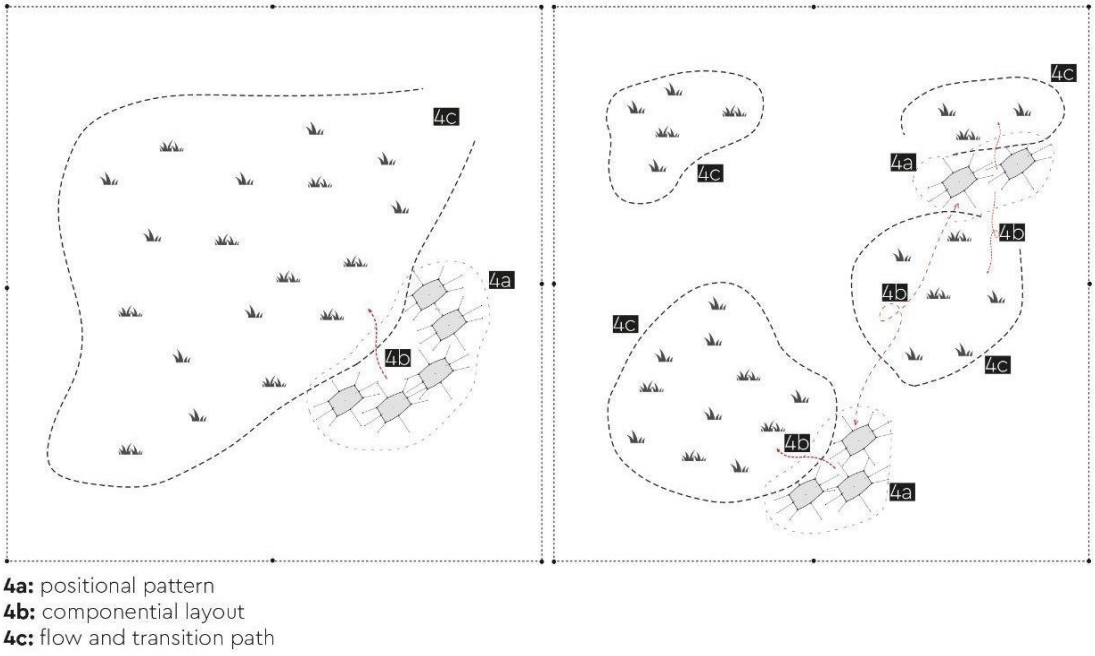

Figure 4. Spatial logic of nomadic camps: Positional patterning (4a), componential layout (4b), and transition paths (4c) (Source: Authors).

To operationalize this framework, three interrelated parameters were defined and examined across all settlement samples.

The first parameter, *positional patterning*, analyzed how tents were oriented and grouped within each camp. This included examining entrance directions relative to sunlight and prevailing

winds, as well as identifying clustering tendencies such as linear, radial, or dispersed formations. The presence of a central void and the orientation of the overall layout (inward-facing or outward-oriented) were also considered. This dimension provided insight into how climatic factors such as solar gain, wind protection, and thermal comfort informed collective settlement form.

The second parameter, *componential layout*, examined spatial relationships among principal functional elements such as karaçadır tents, livestock pens, water sources, and communal or cooking spaces. The analysis explored the grouping and separation of these components, the degree of functional segregation between human and animal areas, and their proximity to natural resources. This layer illuminated how Yörük encampments balanced ecological pragmatism with social organization through adaptable spatial configurations.

The third parameter, f*low and transition paths*, focused on patterns of movement within and across the campsite. It identified visible and implied circulation routes linking tents, livestock zones, and resource areas, and analyzed how these paths were oriented and scaled relative to daily mobility routines. Circulation was further classified as centralized, radial, or decentralized, depending on the internal organization of movement.

Collectively, these three parameters establish the analytical foundation of the proposed in-motion visual grammar. Rather than isolating single morphological traits, the analysis uncovers how orientation, zoning, and circulation interact to sustain mobile lifeways. This composite grammar articulates the interdependencies between human practice, environmental condition, and material arrangement, providing a nuanced understanding of how temporary settlements are enacted, negotiated, and maintained. Accordingly, the framework functions not only as a tool for documentation but as a generative model for interpreting the spatial intelligence embedded in nomadic heritage ecosystems.

3. Findings and Discussion

Although each Yörük settlement analyzed in this study exhibits a distinct environmental context, group composition, and degree of permanence, the spatial analysis reveals a remarkable convergence in the underlying organizational logic. Despite differences in topography and context, the camps exhibit consistent tendencies in orientation, zoning, and circulation that indicate the presence of an embedded spatial intelligence. This convergence points to a culturally transmitted yet uncodified design grammar that is pragmatically enacted through lived practice.

Across the six settlements, *positional patterns* consistently align with solar exposure, most often oriented toward the south or southeast, and reveal flexible clustering strategies shaped by terrain, herd behavior, and visibility needs. Camps alternate between open radial forms and compact linear layouts. Distributed settlements generally include a central open space, while denser ones support multidirectional access. These tendencies correspond with broader ethnographic observations. Tent clusters maintain gaps of approximately four to five meters between individual units, while wider intervals, typically 20 to 30 meters, separate clusters to facilitate grazing circulation and minimize animal mixing. Such dimensions are consistent with studies suggesting that flock maneuvering requires 10 to 20 meters of clearance. Entrances most frequently face south, optimizing sunlight and airflow while enhancing both thermal comfort and inter-tent communication.

Componential layouts reveal recurrent patterns of functional separation combined with selective integration. Human habitation areas and livestock zones are generally distinct, often divided by natural thresholds or topographical buffers. Auxiliary functions such as cooking, storage, or guest reception appear as permanence increases, yet their placement remains adaptive to terrain and group size. This modular configuration is particularly visible in the recurring spatial modules found across most Yörük camps. A central tent serves for rest, indoor cooking, and hospitality; an adjacent outdoor kitchen contains a fire area; a gathering space, open or semi-sheltered, is positioned in front of the tent; and minimal hygiene infrastructures including washing areas near water sources and toilets located toward vegetated peripheries. Some encampments also include small vegetable gardens hidden from main circulation paths and animal pens shaded by fencing. Collectively, these arrangements reveal a design intelligence rooted in ecological pragmatism, balancing hygiene, control, and efficiency through distance, slope, and modularity.

Circulation and transition logics also demonstrate recurring spatial principles. Camps with dispersed clustering feature open, non-hierarchical movement paths, whereas compact or enclosed configurations organize circulation along radial or linear axes connecting human and animal zones. Across all cases, circulation pathways emerge organically from habitual movement, shared access, and interspecies negotiation rather than from formal planning. Mobility therefore manifests as open fields of action shaped by daily routines and communal rhythms. Pathways and entry alignments influence cluster formation, directing both herd flow and social interaction through spatial porosity and permeability.

Taken together, the six settlements display a coherent set of spatial patterns operating across scales and contexts: consistent solar orientation that reflects environmental literacy and landscape attunement; functional separation between species domains that expresses multispecies agency; modular organization of auxiliary functions that reinforces resilience and cyclical continuity; and circulation systems that sustain cohabitation and shared spatial agency among human and non-human actors.

Beyond spatial efficiency, these patterns embody social flexibility. Families choose neighboring clusters according to personal preference, kinship relations, or seasonal cooperation. During collective grazing or weaving periods, especially in highland pastures, tents are reconfigured to accommodate social events such as weddings, collaborative craftsmanship, or communal herding duties. In these situations, tents act as loci of intergenerational knowledge transfer and social reproduction, demonstrating how spatial design and heritage co-evolve as dynamic, lived practices. Mobility therefore emerges not merely as a response to environmental conditions but as a cultural mechanism that sustains collective memory, reciprocity, and ecological consciousness.

These findings affirm that Yörük spatial practices are not ad hoc reactions to environmental constraints but deliberate, inherited expressions of ecological heritage intelligence. They illustrate how mobility-centered practices preserve cultural continuity not through resistance to change but by embedding adaptability into both spatial and social systems. Viewed through this lens, Yörük encampments appear as living heritage ecosystems that are dynamic, negotiated, and multispecies environments. These configurations challenge sedentary preservation models and open new pathways for sustainability-oriented heritage discourse.

4. Conclusion and Recommendations

This study has examined the spatial intelligence embedded within Yörük settlement practices by analyzing the adaptive patterns, functional distributions, and circulation logics that structure their mobile camps. Through an in-motion visual grammar, it has revealed a culturally transmitted yet uncodified design language that sustains ecological responsiveness, social cohesion, and interspecies coexistence through cyclical mobility. These findings contribute not only to the empirical understanding of nomadic spatial practices but also to a broader reframing of cultural heritage through the lens of movement, adaptability, and multispecies interaction.

Rather than defining heritage as a fixed inventory of artifacts or architectural remains, this research conceptualizes it as a dynamic ecosystem that evolves through situated interactions among humans, animals, materials, and landscapes. The Yörük example demonstrates how environmental reasoning, functional flexibility, and cyclical routines converge into sustainable forms of inhabitation, offering a model for understanding heritage as a living process. From this perspective, the Yörük encampments examined here function not as temporary dwellings but as spatial expressions of an ecological epistemology in which environmental awareness and material modesty represent sophisticated design strategies.

This discussion has particular relevance for contemporary heritage discourse that increasingly confronts climate change, forced migration, and urbanization pressures. Within this context, the heritage ecosystem can be understood not only as a descriptive model but also as a normative one, suggesting that sustainability depends less on monumental permanence and more on relational continuity, spatial resilience, and adaptive stewardship. The Yörük experience illustrates how communities can inhabit fragile environments, navigate transformation, and sustain cultural identity through flexible practices that preserve ecological balance.

Furthermore, the spatial patterns identified in this study, including solar orientation, functional separation, modular organization, and adaptive circulation, constitute a transferable grammar of heritage-making. These principles reveal how traditional knowledge systems embody spatial solutions to complex environmental and social challenges, highlighting the need for their renewed recognition within academic and institutional frameworks. Acknowledging these systems reinforces the idea that sustainability is not solely a technological goal but also a form of cultural inheritance.

Looking ahead, the findings of this study point to several directions for future research. First, heritage analysis should broaden its conceptual and methodological scope to encompass ephemeral, mobile, and relational forms of spatial knowledge. Second, interdisciplinary approaches that combine computational modeling with ethnographic inquiry can make intangible practices more visible and analyzable. Third, the inclusion of non-human actors as integral participants in heritage ecosystems should become central to conservation and evaluation frameworks.

In this light, the Yörük settlements serve not only as a subject of study but also as a conceptual resource: a living archive of ecological adaptation, heritage transmission, and communal design intelligence. Their camps are not relics of a fading tradition but examples of sustainable cohabitation that testify to a heritage ecosystem in motion. As ecological instability and sociocultural fragmentation intensify, learning from such mobile epistemologies becomes not merely an academic pursuit but an ethical responsibility.

Ultimately, this study affirms that heritage ecosystems, when understood as distributed, adaptive, and multispecies, can offer resilient alternatives to extractive and static models of preservation. Embracing mobility as both a spatial and epistemological strategy allows heritage management to move toward futures that are inclusive, sustainable, and grounded in the lived intelligence of diverse cultural practices. In this process, the insights drawn from the Yörüks are not peripheral; they are essential.

Thanks and Information Note

The article complies with national and international research and publication ethics. This study is derived from the doctoral dissertation currently being conducted by Uğur Efe Uçar under the supervision of Assoc. Prof. Ethem Gürer within the Architecture Design Computing PhD Program at Istanbul Technical University. An extended and revised version of this study has been submitted to the Journal of Cultural Heritage Management and Sustainable Development.

Abstract

Artificial intelligence (AI) has introduced new dynamics into interior design education, where linguistic articulation intersects with spatial reasoning and theoretical knowledge. As a discipline that integrates user experience, spatial configuration, and material understanding, interior design offers a fertile ground for positioning AI not only as a cognitive tool but also as a pedagogical assistant. This transformation reshapes how design knowledge is produced and transmitted, influencing students' creativity and critical engagement with design. However, how students perceive and negotiate these transformations within educational settings remains underexplored.

This study addresses this gap through a mixed-methods survey of fifteen interior design students conducted after a workshop introducing AI-based design tools. The survey focused on students' reflective evaluations rather than workshop outcomes. Findings reveal that students perceive AI as a supportive partner that assists in idea generation, enriches visualization, and facilitates narrative-driven design thinking, while also raising concerns about originality, ethics, and overreliance.

The study concludes that integrating AI into interior design curriculum requires reinforcement through critical literacy and structured pedagogical guidance, ensuring that computational assistance enriches learning in spatial representation, atmosphere, and user experience.

Keywords: Artificial intelligence, interior design pedagogy, design cognition, design thinking, reflective practice

1. Introduction

The rapid integration of artificial intelligence (AI) into design pedagogy has sparked new debates on how computational tools influence creativity, authorship, and critical thinking. In the context of interior design education, these debates carry particular weight, as linguistic articulation and spatial reasoning are deeply intertwined with designers' intrinsic values and theoretical knowledge (Brooker & Stone, 2010; Ching, 2012; Pile, 2007; Piotrowski, 2014). While existing studies have conceptualized AI as a transformative force in design cognition (Adeleye, 2023; Patel, 2024; Pfeiffer, 2018), empirical insights into how students perceive and navigate these transformations within pedagogical settings remain scarce.

This study aims to address this gap by examining students' reflections on AI-based design processes in interior design education, revealing how they conceptualize AI as a pedagogical partner following their workshop experience. Recent studies have positioned AI as a linguistic interface capable of reshaping the communicative dimension of design thinking (Agarwal, 2024; Almaz et al., 2024; Li et al., 2024). These perspectives point to a shift from tool-based to dialogue-based design processes, where AI acts as a collaborative agent in the articulation of

design intent. Complementing this view, interior design pedagogy provides a distinctive context in which user experience, spatial configuration, and material knowledge intersect with conceptual reasoning (Abercrombie, 2018; Gibbs, 2005; Uçar et al., 2025). Within this framework, AI extends beyond output generation, mediating reflective engagement that prompts students to question assumptions about creativity, originality, and responsibility.

Building upon the earlier study by Gökdemir and Kayan (2025), which examined the integration of AI as a linguistic interface in interior design education, this research shifts from process-based analysis to a student-centered reflective investigation. While the earlier study focused on how AI shaped linguistic and spatial articulation during the design process, the present research extends this inquiry toward understanding how students retrospectively interpret and evaluate those experiences. In that constructive linguistic study, a two-month workshop was conducted with fifteen undergraduate students at Istanbul Technical University, where AI tools such as ChatGPT-4o and DALL-E were used to explore text-to-text (txt2txt) and text-to-image (txt2img) generative processes for scenario-based spatial representations. The workshop demonstrated how linguistic articulation shaped spatial reasoning and how structured AI dialogues enhanced conceptual coherence, visual consistency, and critical awareness throughout the design process.

The present study builds directly on this pedagogical experiment, examining the reflections of students who participated in or were later introduced to the same AI-supported framework. To capture and assess this reflective dimension, a follow-up survey was conducted as a complementary phase rather than an independent assessment, aiming to reveal interpretive insights that were not observable during the workshop itself. Through this connection, the research explores how the same AI-driven learning environment is re-experienced by students as a pedagogical assistant that structures design communication while fostering critical thinking, creativity, and authorship awareness within interior design education. As illustrated in Figure 1, the conceptual framework of the study positions artificial intelligence as a design tool that operates at the intersection of language, communication, and interior design (Figure 1). In this context, the term ‘pedagogical assistant’ refers to AI’s active role in mediating learning processes rather than merely automating design tasks.

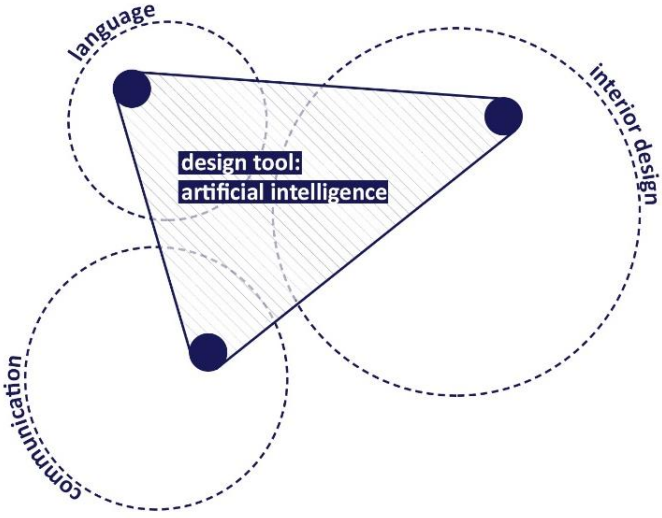

Figure 1. Conceptual background of the study.

2. Materials and Methods

The study was conducted within the pedagogical framework of a two-month AI-assisted design workshop that formed the basis of the earlier constructive research by Gökdemir & Kayan (2025). Implemented with fifteen undergraduate interior design students at Istanbul Technical University, the workshop was designed as a progressive process composed of four interrelated phases:

(a) Conceptual framing, in which students developed text-based spatial scenarios focused on historical healing environments,

(b) Initial AI integration, where tools such as ChatGPT-4o and DALL-E were introduced to visualize scenario narratives through text-to-text and text-to-image generative processes,

(c) Iterative dialogue, during which students refined their prompts through a guided model (SV + HS) designed to enhance consistency between linguistic input and spatial output,

(d) Final evaluation, where students analyzed the coherence between their narratives and AI-generated visual representations (Figure 2).

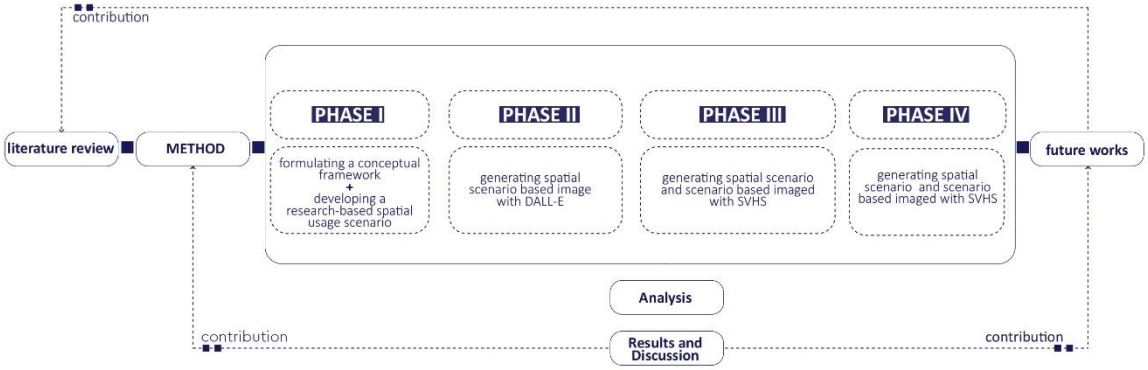

Figure 2. Workshop process.

The workshop produced a diverse set of outputs, including scenario texts, AI-generated images, and structured dialogue records that demonstrated how linguistic articulation shaped spatial reasoning. These results showed that AI could function as a linguistic co-agent in the design process, enriching conceptual clarity and visual communication. However, beyond these tangible outcomes, understanding how students perceived and interpreted these hybrid processes—how they internalized, critiqued, and reflected on AI-assisted design—became equally significant. This need led to the development of a student-centered follow-up survey as an extension of the pedagogical inquiry.

A mixed-methods survey was conducted with the same group of fifteen interior design students. Developed with reference to the Learning Object Evaluation Scale, the survey aimed to assess students' reflective evaluations of AI-assisted design processes rather than the workshop activities themselves. The Learning Object Evaluation Scale was selected because it provides a structured framework for assessing both the pedagogical and technical dimensions of digital learning environments, aligning closely with the hybrid nature of AI-assisted design education. The instrument was structured to capture both quantitative and qualitative dimensions of learning, focusing on students' perceptions of creativity, authorship, and cognitive engagement with AI-based tools. Quantitative items measured the perceived impact of AI on design learning, while qualitative questions explored students' individual concerns, expectations, and

interpretive insights. Data analysis combined descriptive statistics with thematic coding of open-ended responses to provide a comprehensive understanding of students' reflections and learning experiences.

The survey consisted of twelve questions and was completed anonymously. The first question identified participants' year of study in the interior design program, while the second examined whether they had prior experience with AI-based design tools. Questions three through nine were designed as five-point Likert scale items evaluating students' perceptions of the workshop process, the integration of AI tools, and the relationship between their scenario narratives and generated visual outputs. The final three questions (10–12) were open-ended, allowing students to provide reflective assessments of the workshop and their experiences with AI-based tools. To ensure objectivity and confidentiality, all responses were collected anonymously.

The survey was structured according to the four key dimensions of the Learning Object Evaluation Scale: educational content, design and presentation, interaction level, and technical adequacy (Leacock, 2004; Nesbit et al., 2002). Learning objects are defined as reusable, modular digital units designed to facilitate structured knowledge transfer, and their evaluation provides valuable insights into how digital tools function as pedagogical mediators (Wiley, 2002; Churchill, 2007). Within this framework, the educational content dimension assesses the clarity, alignment, and adaptability of materials with intended learning outcomes, while the design and presentation dimension concerns the visual organization and aesthetic quality that enhance motivation and comprehension (Mishra & Koehler, 2006). The interaction level refers to the extent of engagement between the learner and the digital tool, emphasizing how language, terminology, and prompt formulation influence production in AI-assisted environments (Moreno & Mayer, 2007). The technical adequacy dimension focuses on system performance, accessibility, and platform stability, all of which shape user experience and learning efficiency.

In this study, these four dimensions were applied to evaluate students' communicative and productive interactions with AI-based design tools. Each survey question corresponded to at least one dimension, encompassing subthemes such as content knowledge, scenario-oriented production, linguistic structure, and technical experience. Through this correspondence, the survey provided a multidimensional assessment of students' cognitive, technical, and communicative engagement within the learning process. The results, therefore, offered a holistic understanding of the pedagogical potential of AI-based design tools as learning objects within interior design education (Figure 3).

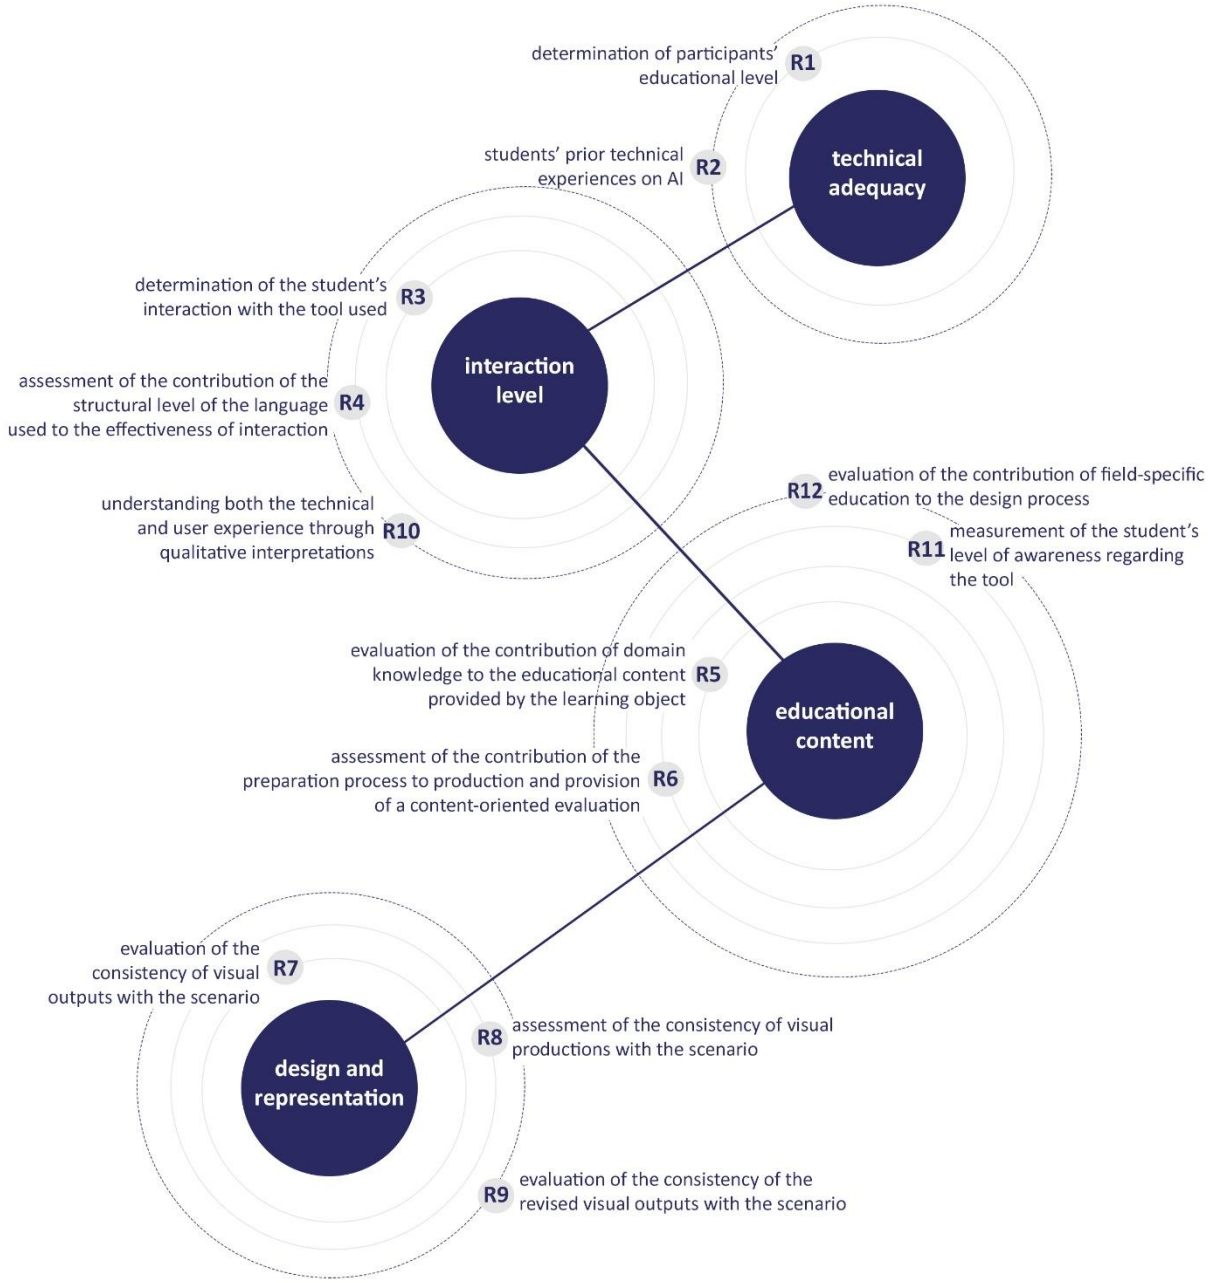

Figure 3. Evaluation of the survey content (R1-12) in parallel with the learning object evaluation scale.

3. Findings and Discussion

Building upon the reflective phase described earlier, this section operationalizes the theoretical shift from conceptualizing AI as a linguistic interface to understanding it as a pedagogical assistant. Through students' reflective evaluations, the empirical analysis translates this theoretical link into concrete educational insight. By doing so, this section presents and discusses the empirical findings derived from the mixed-methods survey conducted with 15

interior design students. Although the participant group was limited to fifteen students, the consistency of responses across both quantitative and qualitative dimensions strengthens the internal validity of the findings. The results are organized thematically to illustrate how students perceived, interpreted, and reflected upon the role of AI within the design learning process. Quantitative data provide an overview of students' general attitudes toward AI-assisted design, while qualitative reflections reveal deeper insights into their cognitive, linguistic, and ethical considerations. The discussion integrates both dimensions to outline how AI was experienced not only as a technical tool but as a pedagogical agent mediating creativity, authorship, and reflective thinking in interior design education.

The quantitative findings reveal how students perceived the communicative and procedural dynamics of AI-assisted design learning. Table 1 summarizes these results (Table 1). Overall mean scores ranged between 4.00 and 4.50 out of 5, indicating a consistently positive evaluation of linguistic, conceptual, and iterative dimensions of the process.

	student 15	5	5	5	4	4	4	4

The quantitative results of the survey, based on questions 3–9, reveal that students developed a strong awareness of the linguistic, cognitive, and iterative dimensions of AI-assisted design learning. Overall mean scores ranged between 4.00 and 4.50, indicating a predominantly positive perception of the AI-supported process.

When asked "Do you think the language you used was effective in communicating with the AI-based design tool?", most students agreed that the wording of their prompts was crucial in guiding the AI's responses. The mean score of 4.20 demonstrates that language functioned not merely as a medium of instruction but as a generative mechanism that shaped design decisions and spatial reasoning. This suggests that students actively recognized the relationship between linguistic precision and the quality of the design outcomes. Similarly, in response to the question "Do you think the sentence structures you used were effective in communicating with the AI tool?", the average score of 4.13 indicated that syntactic clarity and well-structured expressions contributed meaningfully to the effectiveness of AI-assisted production. Taken collectively, these linguistic parameters—clarity, syntax, and terminology, illustrate how students gradually developed communicative agency in directing AI outputs. Students observed that carefully composed and goal-oriented sentences helped translate abstract design ideas into coherent visual and narrative outputs. This result also reflects the pedagogical need to cultivate grammatical awareness and linguistic structure as integral components of design literacy.

The highest average score (4.47) emerged in response to "Do you think the terminology you used was effective in communication with the AI tool?". Students acknowledged that the correct use of disciplinary terminology not only improved AI comprehension but also added conceptual depth to their design reflections. They emphasized that terminological accuracy strengthened both communicative precision and cognitive coherence, confirming that technical vocabulary operates as a form of design knowledge in itself. Regarding preparatory research, students answered the question "To what extent did your preliminary research before using AI influence your communication with the design tool?" with a mean score of 4.13, suggesting that independent investigation prior to engaging with AI tools enriched their conceptual framing and scenario development. They highlighted that the process of research fostered a deeper understanding of the project context and improved their ability to formulate meaningful prompts aligned with design intentions.

The stage-based questions provided further evidence of progress in text–image consistency throughout the workshop. For the second stage—"How well did the AI-generated visuals correspond to your scenario?"—the mean score of 3.93 reflected initial challenges in aligning narrative intent with visual representation. In the third stage, this value rose to 4.00, and by the fourth stage "How well did the AI-generated visuals correspond to your scenario in the final phase?" the mean reached 4.47, demonstrating significant improvement. This upward trend confirms that students gradually refined their prompting strategies and achieved greater conceptual alignment between textual input and visual outcome.

Taken together, the overall improvement in mean scores highlights the development of multimodal literacy, where students combined linguistic and visual reasoning into a coherent reflective practice. Within this process, according to students' reflections AI emerged not merely as a technical instrument but as a collaborative cognitive partner which students practiced linguistic precision, conceptual articulation, and reflective authorship.

The qualitative findings, derived from students' open-ended responses, complement the quantitative results by illuminating how they interpreted and internalized their experiences with AI-based design tools. The thematic analysis identified two major domains of reflection: (1) communicative parameters influencing the quality of interaction and (2) design contributions highlighting AI's pedagogical role in the design process.

When reflecting on the communicative dimension, students consistently emphasized the importance of language clarity, accurate word choice, disciplinary terminology, and prompt structure including the length and number of commands. They noted that the clarity of expression directly determined the reliability and relevance of AI-generated results. Many respondents described effective collaboration with AI as dependent on both linguistic precision and conceptual understanding, stating that even small ambiguities in sentence formulation could significantly alter visual outcomes. These remarks strongly corroborate the quantitative results, particularly the high ratings assigned to language, sentence structure, and terminology.

On the design side, students articulated a wide range of areas where AI contributed to their creative and cognitive processes. They highlighted its role in concept generation, scenario writing, creativity enhancement, idea development, visualization, and atmosphere design. Several participants noted that AI served as a stimulus for imagination, especially in the early stages of ideation, helping them break through conceptual barriers and explore alternative solutions. At the same time, they recognized AI as a facilitator of reflection, enabling them to iteratively test and refine ideas rather than accepting initial outputs at face value.These reflections underscore that students perceived their interaction with AI not as a command-response mechanism but as a dialogic and reflective exchange. They learned to view the AI-assisted process as one that required continuous critical engagement, linguistic precision, and ethical awareness. Many also warned that uncritical dependency on AI could limit personal authorship, indicating an emerging sensitivity toward responsible design practices. These insights underscore the need to integrate ethical reflection into AI literacy within design curricula, ensuring that critical awareness accompanies creative experimentation.

The thematic mapping illustrates the relationship between communicative parameters and design contributions, showing how linguistic factors such as clarity, terminology, and conceptual mastery correlate with design outcomes like creativity and scenario coherence (Figure 4). This relationship reinforces the effectiveness of the language-driven pedagogical model applied in the workshop.

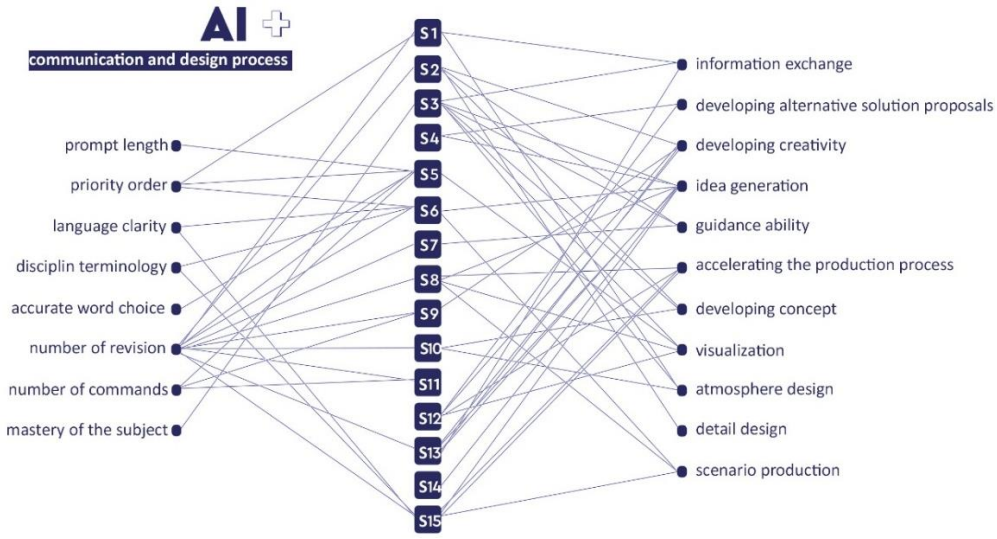

Figure 4. Thematic mapping of qualitative findings

Overall, the qualitative findings depict AI as a pedagogical assistant that supports self-reflection, conceptual awareness, and linguistic literacy rather than replacing human creativity.

When embedded within a structured and ethically guided curriculum, such tools can nurture students' reflective capacity and strengthen the dialogic nature of interior design education.

Together, the quantitative and qualitative analyses demonstrate that AI-assisted learning fosters linguistic sensitivity, iterative reasoning, and reflective authorship—key competencies for cultivating a critically engaged and communicative design pedagogy.

4. Conclusion and Recommendations

This study explored how interior design students perceive and negotiate the integration of artificial intelligence in design learning, reframing AI from a cognitive tool to a pedagogical assistant. The findings revealed a dual perception: while students recognized AI as a catalyst for idea generation, visualization, and narrative thinking, they simultaneously expressed concerns about originality, authorship, and ethical responsibility. These tensions illustrate the necessity of embedding AI within a structured pedagogical framework that fosters both creativity and critical literacy.

The originality of this research lies in its focus on interior design education—a field where linguistic articulation, spatial reasoning, and user experience intersect. By analyzing students' reflective responses through the lens of the Learning Object Evaluation Scale, the study expands the discussion of AI beyond efficiency or aesthetics, situating it within communicative and cognitive dimensions of learning. It demonstrates that AI can mediate reflective engagement, linguistic awareness, and multimodal literacy when pedagogically contextualized.

Nevertheless, the study's scope remains limited to a single institutional context and a small participant group, restricting the generalizability of its findings. Future studies could extend this framework across different educational settings, longitudinally investigate how students' perceptions evolve over time, or examine the role of AI dialogue interfaces in cultivating design authorship. Building upon the current results, further research should explore how AI tools can be integrated into interior design curricula without diminishing reflective depth, what forms of pedagogical scaffolding can balance computational assistance with creative autonomy, and how AI-mediated communication might transform design studios into more dialogic and participatory learning environments.

Ultimately, this research contributes to the emerging discourse on AI-integrated design pedagogy by offering a model for interpreting computational tools as communicative and pedagogical interfaces rather than as mere productivity enhancers. Its theoretical contribution lies in redefining the relationship between linguistic articulation and spatial reasoning within design cognition. Practically, it provides an adaptable framework for instructors aiming to integrate AI tools into interior design education in ways that maintain critical, ethical, and creative balance.

In conclusion, the study emphasizes that the future of AI in design education depends not solely on technological advancement but on cultivating reflective, linguistic, and ethical literacy—qualities that preserve the interpretive depth of design learning while enabling meaningful collaboration between human and artificial intelligence.

Thanks and Information Note

This study is derived from the doctoral dissertation currently being conducted by Gözde Gökdemir under the supervision of Assoc. Prof. Hande Zeynep Kayan within the Interior Architecture PhD Program at the Graduate School of Mimar Sinan Fine Arts University. The

authors would like to express sincere gratitude to Prof. Dr Ervin Garip at Istanbul Technical University for his invaluable support and contributions throughout the workshop process, particularly for providing the educational framework in which the study was conducted. The authors are also grateful to students who participated in the workshop for their active engagement and creative productions, which significantly enriched the outcomes of this research.

The authors declared no potential conflicts of interest with respect to the research, authorship, or publication of this article and all authors contributed equally to the article.

The article complies with national and international research and publication ethics. The study was approved by the The Ethics Committee of the Mimar Sinan Fine Arts University (Ethical Clearance Reference Number: 202583) on October 15, 2025. Abstract

Landscape Character Analysis (LCA) is an essential methodology for comprehending and overseeing the intricate interconnections among the biological, cultural, and perceptual characteristics of landscapes. LCA seeks to advance sustainable land utilization and the preservation of biodiversity. Recently, it has emerged as a novel planning approach aimed at addressing the unintentional exploitation of environment and its associated issues. The Palandöken rural settlement area served as the basis for this model. Raster files, including geology maps, main soil group maps, contour maps, Corine land use maps, and vegetation maps, from the 575 km² research region were digitized with ArcGIS 10.2. The digitized maps were consolidated for the application of the LCA approach. Consequently, these groups revealed two distinct elevation zones, fourteen geological formation kinds, three principal soil groups, three vegetation types, and five land use categories. The use of the LCA technique via on-site observations in the study region found 78 landscape character types and 10 distinct landscape character patterns in the Palandöken rural settlement area. Recommendations were formulated for several prospective applications of the research area based on the acquired results.

Keywords: Palandöken, landscape character analysis, landscape pattern

1. Introduction

Landscape character is defined as the distinct and perceivable pattern of natural, cultural, and historical elements that distinguishes one landscape from another. It provides a framework for spatial planning, heritage conservation, and the sustainable management of human-environment interactions. The landscape character of an area or region can be defined as a distinct and recognizable pattern of elements within the landscape, focusing on managing landscapes sustainably rather than simply preserving their texture (Zhao et al., 2023; Hong et al., 2024). Landscape character analysis (LCA), on the other hand, is a systematic methodology used to assess and describe the unique physical, cultural, and visual attributes of a landscape, which are essential for informed planning and sustainable development (Öztürk et al., 2020). It uses quantitative techniques such as clustering and segmentation, as well as qualitative assessments, to identify distinct landscape character types and areas (Wang et al., 2023). Practitioners use LCA to support rural settlement management, heritage conservation, and spatial planning by mapping variables ranging from landforms to cultural heritage features. This process informs decisions that balance ecological sustainability with socioeconomic needs (Öztürk et al., 2020; He et al., 2024). In this context, LCA integrates natural and human dimensions into a coherent framework that guides development, resource management, and the protection of distinctive landscape values in various environments (Wang et al., 2023; Pihler et al., 2021). Through this integration, it offers a multifaceted package of benefits that enhance spatial planning, sustainable development, community participation, and tourism management. Another of the

key benefits of LCA is the ability to identify the unique biophysical and cultural characteristics of a landscape, thereby informing decision-making, and that it allows providing a structured framework for spatial planning (Teh et al., 2017; Oliveira and Guiomar, 2016). By identifying the distinctive spatial patterns and intrinsic qualities of a given area, LKA facilitates tailor-made management strategies that are compatible with the objectives of the European Landscape Convention and respect natural beauty and local heritage (Oliveira and Guiomar, 2016; Morrison et al., 2018). This analytical process increases the capacity of planners and policy makers to integrate ecological, cultural, and social dimensions into environmental management, optimizing resource allocation and informing politicians (Teh et al., 2020; Morrison et al., 2018)

Erzurum is a province encompassing diverse landscape compositions due to its geographical location. Palandöken, located close to the Erzurum central district, reflects the province's general characteristics. This study aims to determine the landscape character analysis and potential of Palandöken, a location with a natural and cultural landscape potential and an area of 575 km².

2. Materials and Methods

The material of the study area is located in the Palandöken border, which is located at the coordinates of 39°50′56″N 41°17′03″E in Erzurum province and has an area size of approximately 575 km² (Figure 1). The Palandöken study area has an altitude of between 3200 and 2100 m.

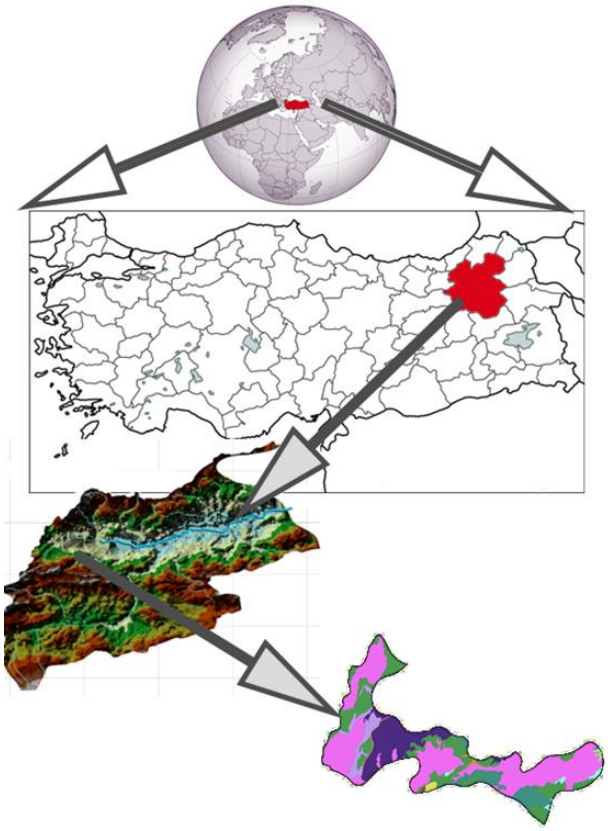

Figure 1. Map showing the location of the study area

2.1 Determination of landscape types of the study area

Typologies based on the association of essential landscape variables—topography, land use, predominant soil groups, geological formations, and land capacity classes—were modified from Wascher 2005 and Atik et al. 2015 (Figure 2). The "Landscape Character Method," utilized in the context of the European Landscape Character Initiative (ELCA), was applied to identify local landscape character types. A five-letter coding system was implemented to classify the landscape character types in the Palandöken Landscape Character Area, situated inside Erzurum Province.

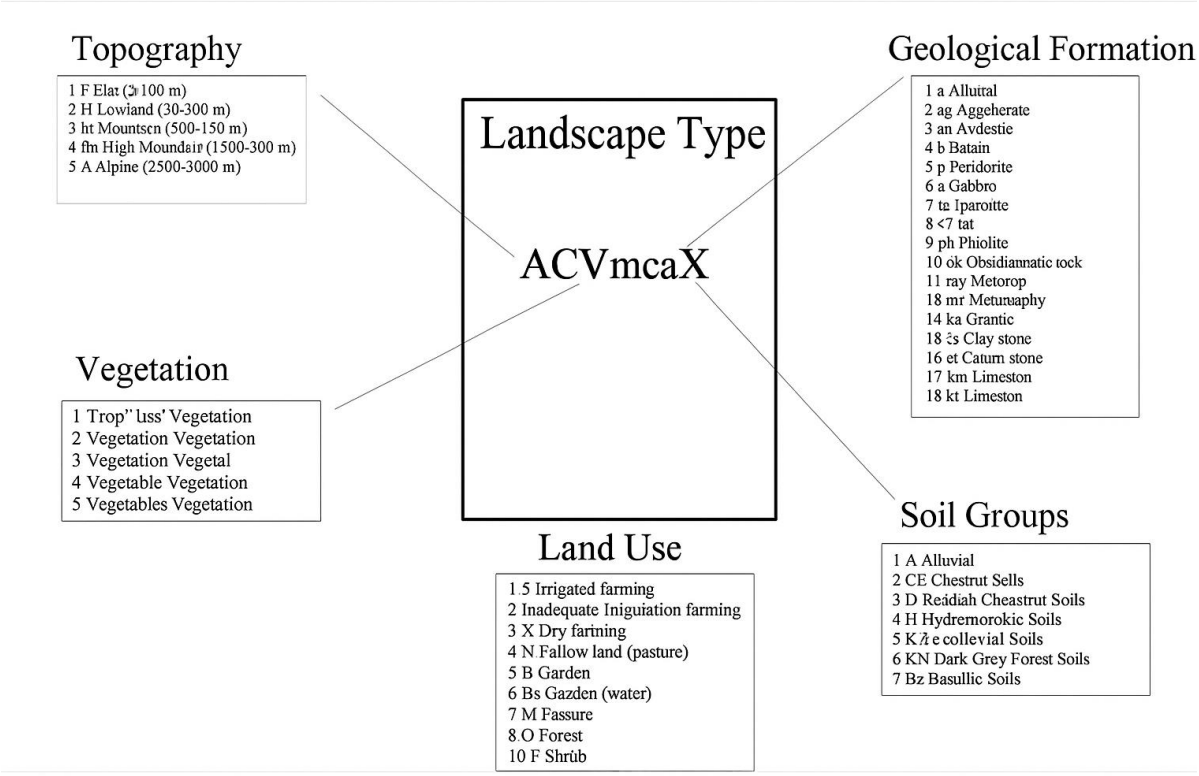

Figure 2. Landscape type classification system (Washer 2005; Atik et al. 2015)

2.2 Utilization of Geographic Information Systems (GIS) Tools in the Study Area

Subsequent to the formulation of the landscape classification type for the study region, the resultant data was digitized using Arc-GIS 10.2. The topography, soil types, soil classifications, vegetation, geological context, and land use layers were superimposed. A landscape typology map was generated using the superimposed maps.

A model was developed in the Model Builder of Arc-GIS 10.2 to intersect the typology maps for the creation of the landscape typology map. To reduce the inaccuracy in this model, the overlays were constructed from vector maps. The Intersect submodule in the Overlay layer of the Analysis Tools module was utilized to superimpose the vector maps. Subsequent to utilizing the module, classifications of landscape types were produced. Microsoft Excel was employed to categorize these classes. Subsequent to grouping, the raster landscape typology maps were imported into the attribute table in Arc-GIS and subsequently generated within the Classification module (Figure 3).

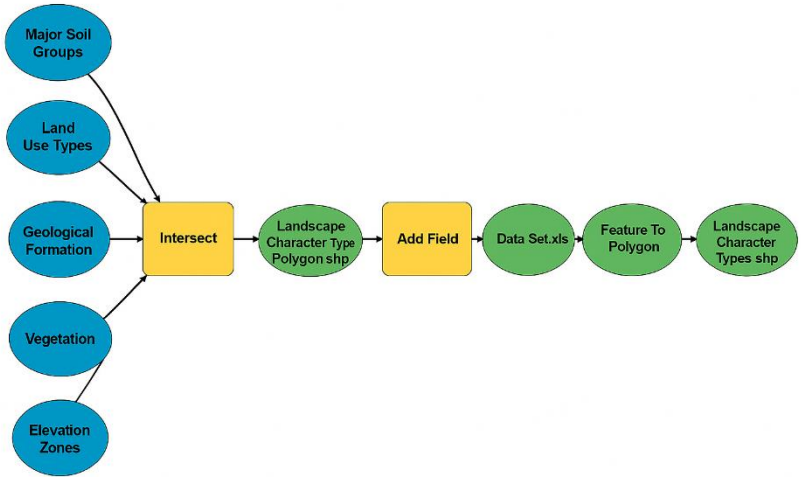

Figure 3. Model used to create landscape typology maps

3. Findings and Discussion

In the analysis of the Palandöken landscape character region, which spans 575 km², 78 landscape character types were discovered, and 10 landscape patterns were delineated (Figure 4). The predominant landscape type in the Palandöken landscape character area is classified as AMvManX, characterized by alpine topography, prevalent pasture vegetation, primary land use for pastures, and geological formations of andesite layers, with basaltic soils as the principal soil group. Simultaneously, it was shown that natural meadows and shrublands predominated the Palandöken Landscape character region within the landscape patterns identified in the CORINE type 2 land classification (Figure 6).

From 2014 to 2017, intermittent field studies were conducted in the Palandöken landscape character area throughout various time intervals. The field research revealed that the land possessed a rough structure. Consequently, the existence of herbaceous plants and a limited quantity of broadleaf woods may be noted in the area.

Table 1. Data from the Palandöken landscape character area

Number of Character Types	Number of Landscape Patterns	Area Covered (Km²)	Number of Area Uses	Altitude Zone	Geological Formation	Great Land Group	Vegetation Number
78	10	575	5	2	14	3	4

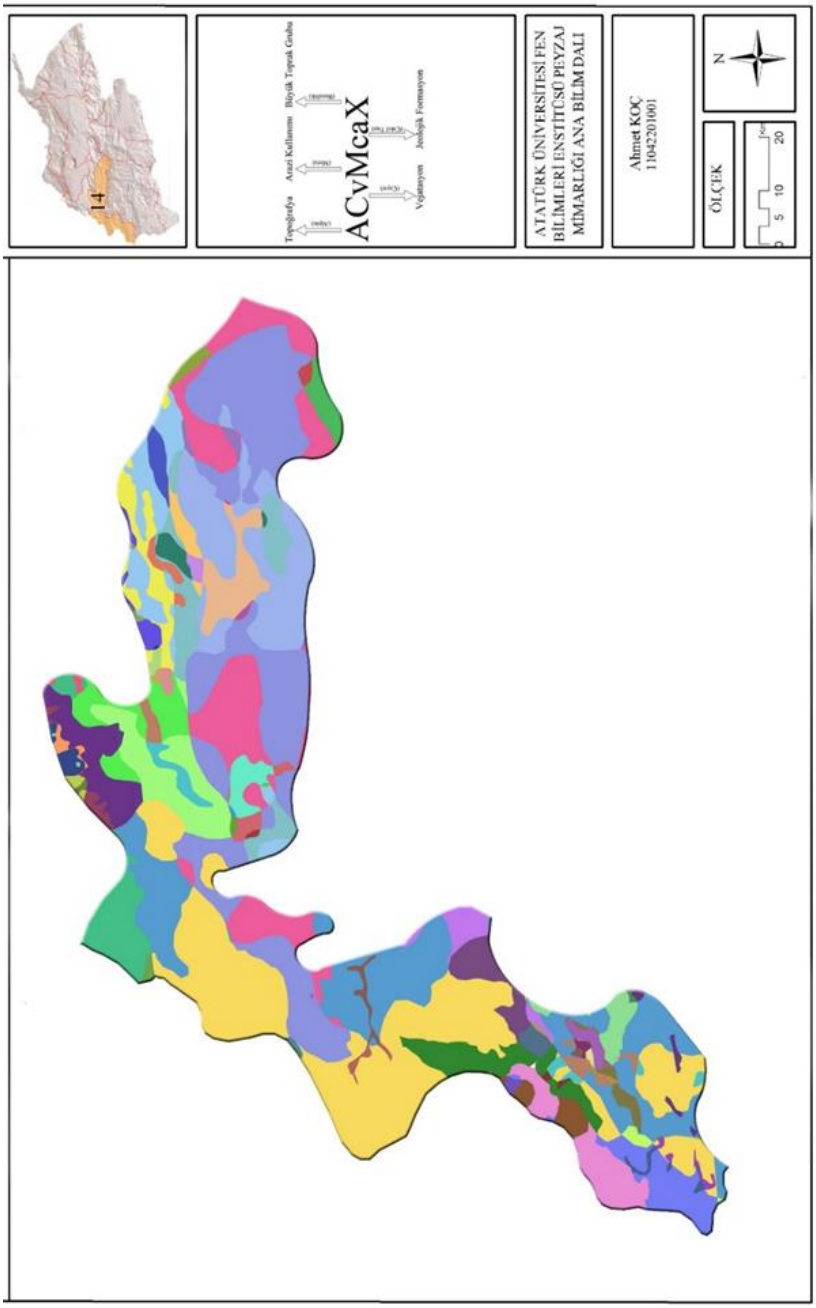

Figure 4. Palandöken landscape character types

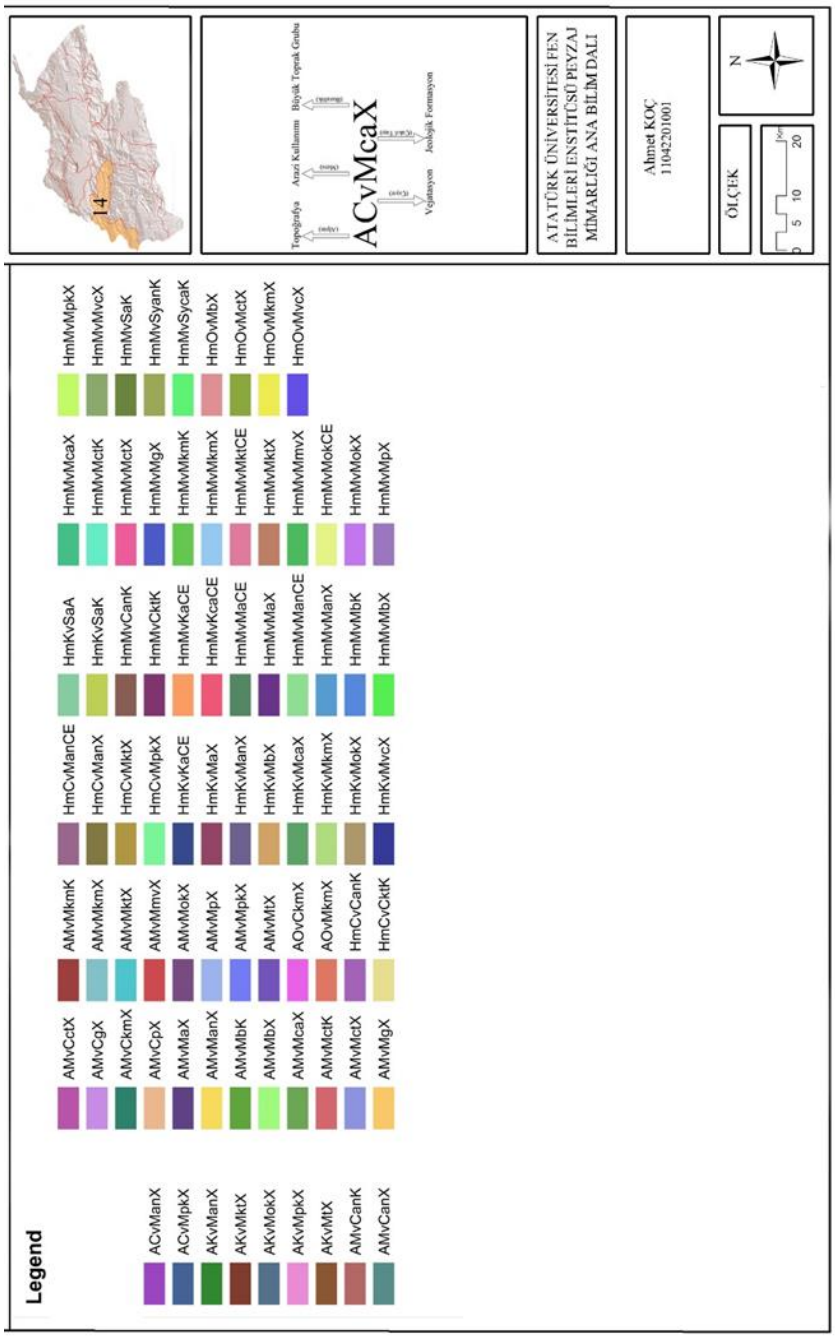

Figure 5. Palandöken landscape character types legend

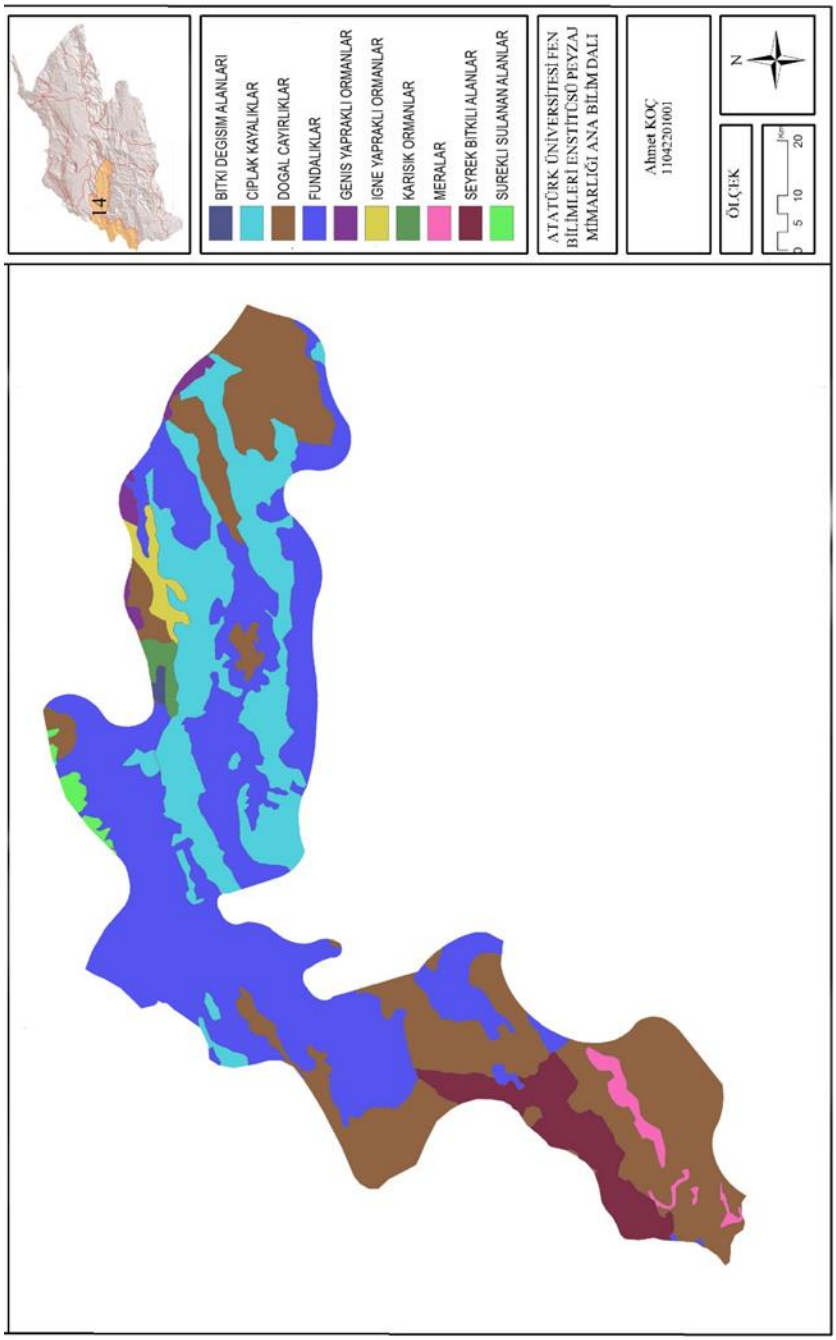

Figure 6. Landscape patterns of the Palandöken landscape character area

Conclusion and Recommendations

Types of landscape character in the research area: In the Palandöken rural settlement region, 78 landscape character categories and 10 distinct landscape character patterns were found. The spatial distribution among these landscape types ranges from 0.002 km² to 23.08 km². In the entirety of the research region, the predominant landscape character type is HmKvSaA, characterized by high mountainous topography, cultural vegetation cover, irrigated agricultural

land use, geological formations with alluvial layers, and an alluvial soil group. This predominant landscape character type encompasses an area of 23.08 km², or approximately 2.1% of the total area.

A further issue observed in the research area is the emergence of regions designated as pastures, modified by anthropogenic vegetation, indicating areas transformed by human activity. Amendments were enacted to Pasture Law No. 4342 on February 25, 1998, which ensured optimal utilization of pastures. Nevertheless, human involvement has caused the vegetation type to revert to a culturally predominant form.

Landscape character evaluations are crucial in basin planning and management. Öztürk (2011) asserts that effective basin management and planning necessitate the collaborative efforts of several professional specialties. Nevertheless, for the sustainable development of basin regions and the preservation of natural and cultural resource values, landscape character analysis studies will establish a basis for future efforts to safeguard the basin's resource values and promote the advancement of the adjacent community.

Abstract

Ergonomics, defined as the adaptation of the physical environment to human needs, is closely related to interior design through a human-centered approach. In educational contexts, students spend a significant portion of their time at classroom desks; therefore, anthropometric compatibility and functionality constitute critical factors for comfort, attention, and learning. However, desks designed according to standard measurements do not adequately accommodate variations in students' physical characteristics, which may result in discomfort, distraction, and potential health risks. In Turkey, the most comprehensive anthropometric study in this field was conducted in 1937, and contemporary research on ergonomically optimized educational furniture remains limited. This study investigates classroom desks in the Interior Design Department at Kayseri University Technical Sciences Vocational School from an ergonomic perspective. The methodology involves the collection of 18 anthropometric measurements from 80 students, documentation of existing desk dimensions, and administration of a user experience survey. The data obtained are utilized to generate design proposals through three-dimensional modeling software. The study aims to develop adjustable and inclusive desk models that correspond to students' anthropometric characteristics. Such models are expected to minimize discomfort, enhance concentration, reduce health risks, and improve spatial comfort in educational environments. By prioritizing evidence-based and human-centered approaches, the research seeks to contribute to the advancement of ergonomic and equitable furniture design in higher education. The outcomes are intended to be disseminated at international conferences in order to support the wider implementation of adaptable classroom solutions.

Keywords: Ergonomics, interior design, anthropometry, educational furniture

1. Introduction

Ergonomics, which can be defined as the process of adapting the physical environment to the human body, originates from the Greek terms ergon (work, labor, product) and nomos (law, rule). Ergonomics applies theories, principles, data, and methods to design in order to enhance human well-being and optimize system performance (Weerdmeester, 2001). The primary aim of ergonomics is to make human life easier and more humane by improving living conditions, eliminating potential hazards, and promoting human health (Güler, 1997). As a multidisciplinary science, ergonomics examines every field in which humans are involved and seeks to ensure that individuals work more efficiently with less physical strain. The term was first introduced by Wojciech Jastrzebowski in 1857, and the foundational developments in the discipline were initiated by experts in experimental psychology (Yararel, 2019). Münsterberg's Psychology and Industrial Efficiency (1913) became one of the pioneering works in this field, followed by the establishment of the first laboratory of experimental psychology at Cambridge University in 1921. During World War II, significant losses caused by the lack of attention to human factors in rapidly developing weapons and machinery led to extensive studies on

human–machine systems. In the United States, the term human factors is widely used instead of ergonomics (Yararel, 2019).

In 1949, during a meeting at Oxford University chaired by Murrell, researchers from various disciplines—including anatomy, anthropology, physiology, psychology, engineering, and design—recommended the use of the term ergonomics (Köksüz, 2019). Anthropometry, one of the fundamental scientific bases of ergonomics, examines human body measurements and forms the basis for designing spatial and product dimensions. In interior architecture, anthropometric data are classified as static (body measurements in still positions) and dynamic (measurements of movements such as reaching and bending) (Kahya et al., 2018). Designing environments in accordance with the anthropometric characteristics of societies contributes significantly to the physical and psychological well-being of future generations. When the national literature on ergonomics in interior architecture and interior design is examined, only a limited number of graduate theses and articles are encountered. Existing studies largely focus on smart home systems, office spaces, or the effects of color, texture, and spatial organization in preschool and primary school interiors. Although related works—such as the theses titled The Effects of Environmental Graphics and Wayfinding Design in School Spaces for Children with Disabilities and Interior Space Design and Student Interaction in Primary Schools—provide broad perspectives, they do not focus specifically on school desk design (YÖK National Thesis Center, 2023). Yet, students spend most of their school time seated at desks, making this topic highly important and academically underexplored. In educational environments, ergonomics refers to organizing teaching and learning settings to maximize efficiency for both teachers and students. Education is broadly defined as a process of behavioral change, which requires suitable physical, social, and psychological conditions (Uşan, 2010; Dönmez, 2008). Considering that compulsory education occupies a major portion of children's developmental years, classrooms must be designed in accordance with the anthropometric characteristics of the society. International studies—such as The Effects of Standing Desks Within the School Classroom: A Systematic Review and The Role of School Desks on the Learning of Graphic Skills in Early Childhood Education in Brazil—demonstrate that classroom desk design significantly affects both physical development and learning performance.

Despite the availability of various desk models in the furniture industry, many designs lack scientific grounding and do not account for different user profiles or regional anthropometric data. This study therefore conducts an ergonomic evaluation of different desk types used in the design classrooms of the Technical Sciences Vocational School of Kayseri University and proposes an ergonomically optimized studio desk design suitable for design-oriented departments. The study aims to contribute to national literature, provide foundational data for the furniture industry, and raise awareness among students and practitioners, highlighting its originality and significance.

2. Materials and Methods

In this study, the methodological process involved several sequential stages. First, the necessary anthropometric measurement instruments were procured, along with a set of colored table covers to support observational analyses. A comprehensive literature review on ergonomics, anthropometry, and educational furniture design was conducted to establish the theoretical framework. Subsequently, the anthropometric measurements of the participating students were collected, and these data—together with their calculated averages—served as the basis for developing an ergonomic classroom desk design. To examine the influence of color on the

learning environment, classroom sessions were conducted using desks covered in different colors, followed by a survey administered to determine which color elicited the most positive student responses. The selected color was then integrated into the proposed desk design. Finally, all collected insights informed the creation of a 3D digital model of the desk, for which detailed renderings were produced to visually communicate the final design proposal.

Figure 1. Measuring instruments (Ecevit, 2025)

A comprehensive literature review was conducted to determine which anthropometric measurements are required for classroom desk design and how these measurements should be collected in accordance with ergonomic standards. The review focused on identifying the specific body dimensions necessary for developing an ergonomic desk suitable for students, including both static and dynamic anthropometric parameters. Based on the findings, the essential measurement set was established, and the complete list of required dimensions is presented in Figure 2.

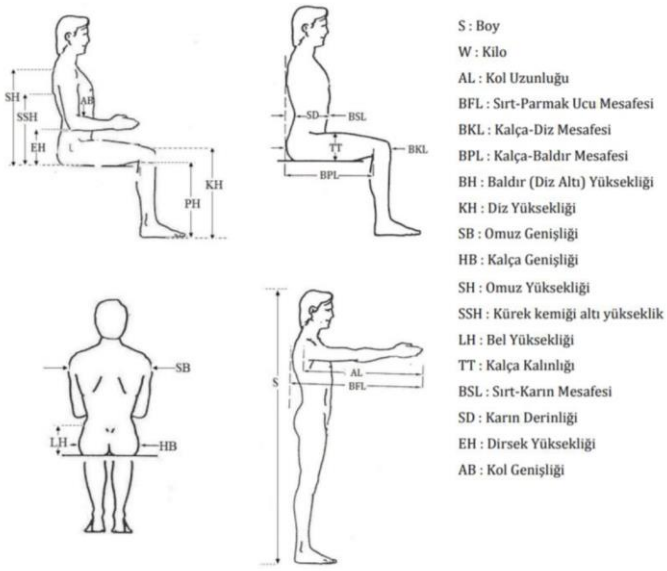

Figure 2. Series of eighteen anthropometric measurements (Kahya et al., 2018: 62)

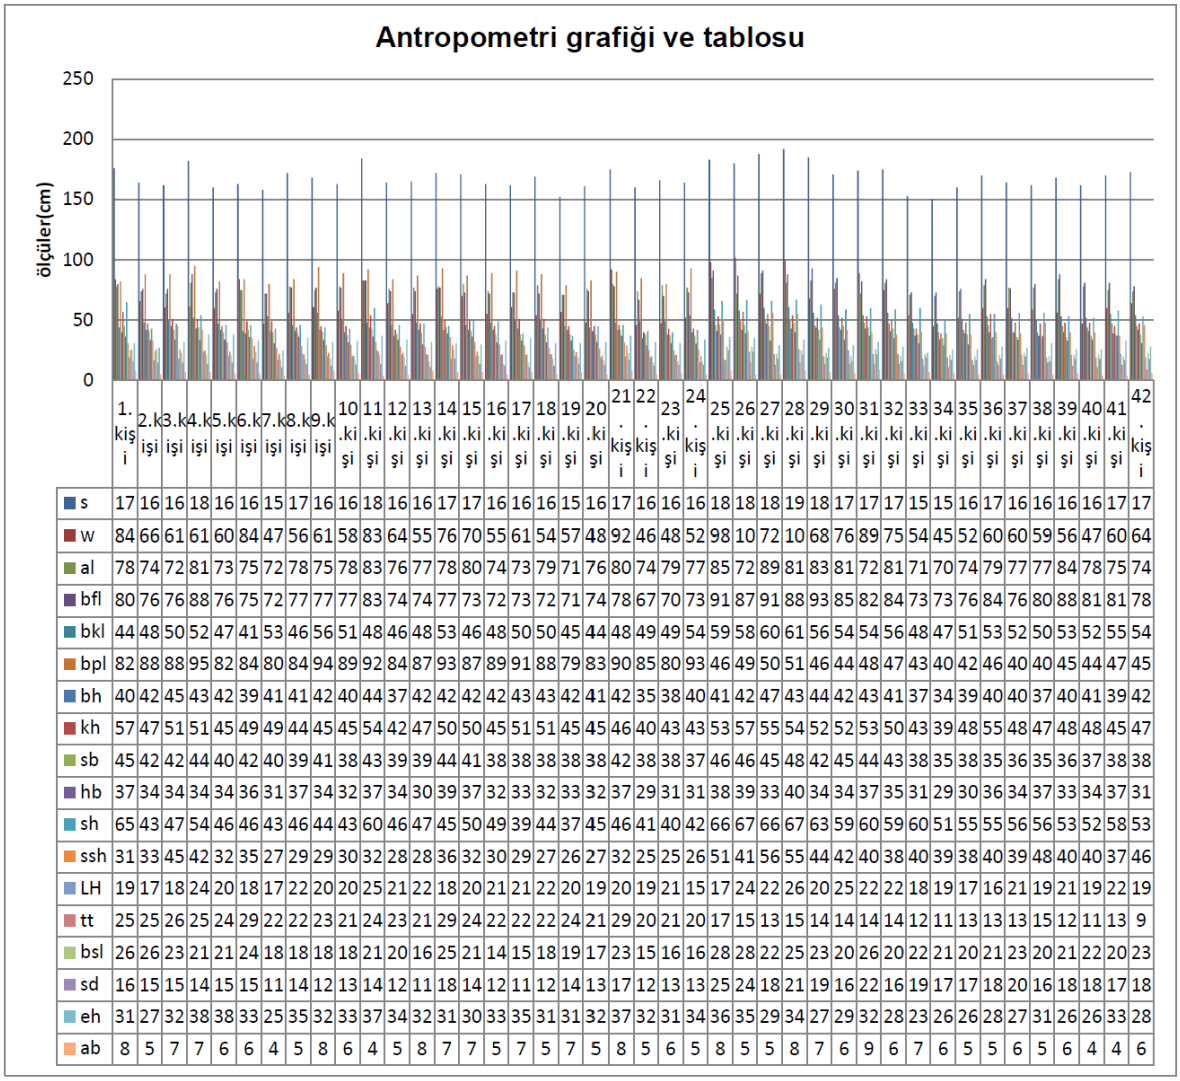

3. Findings and Discussion

The anthropometric measurements collected from students were recorded, tabulated, and visualized through graphical representations (Figure 3). The mean values of these measurements were subsequently calculated, organized into tables, and presented graphically. These measurement results and their averages were then compared with anthropometric data obtained from the literature to conduct a preliminary ergonomic evaluation of the classroom desk design. Based on this comparative analysis, initial conceptual sketches were developed to establish the fundamental formal structure of the proposed desk (Table 1-2.).

To determine the appropriate color for the final desk design, a series of observations was carried out using table covers in different colors. These covers were applied weekly to different student

groups during courses offered in the Interior Design Program at Kayseri University Vocational School of Technical Sciences. Through this process, the effects of color variations on students' attention levels and psychological perception were observed and documented (Figure 4).

Figure 4. Interior design students' color analysis (Ecevit, 2025)

4. Conclusion and Recommendations

The entire project plan was successfully implemented in this study. Surveys and anthropometric measurements collected from students revealed that existing classroom desks do not adequately meet ergonomic and anthropometric requirements. Based on these findings, a more ergonomic and comfortable prototype was developed to support healthy postures both during forward-leaning and upright sitting, and to facilitate comfortable work on both desk surfaces and computers. Although commonly used seating arrangements are generally considered suitable for computer-based activities, desks with fixed surfaces are often inadequate for tasks such as writing, drawing, cutting, or other tabletop activities. When the desk surface cannot be adjusted for inclination, users tend to lean forward to see and work comfortably, which can lead to poor posture and potential physical issues, including spinal deformities.

In this design, a seating element was developed to allow users to work comfortably both at the desk and on a computer, providing healthy posture support when leaning forward and adequate support when sitting upright. The seat is adjustable in height, width, and depth according to the average anthropometric measurements of the users. The desk features an adjustable inclined surface, enabling comfortable performance of various activities such as drawing, writing, cutting, pasting, and computer use. The designed desk incorporates adjustable height and tilt, integrated lighting, power outlets, a solar panel, an adjustable footrest, a front compartment for project bags, and a dedicated section for pens and small stationery. The seating element offers adjustable height and tilt, a contoured backrest providing spinal support, and knee rests to enhance ergonomic comfort. The resulting design is manufacturable and suitable for mass production. Furthermore, the study provides a foundational framework that can be extended to different user groups and work environments in future research, facilitating more comprehensive ergonomic data collection (Figure 5.-6.).

Abstract

A city can be defined as a spatial whole formed by the convergence of settlement systems that have emerged over time and in different periods, shaped by geographical conditions. The memory of cities is formed by the memories, experiences, and spatial spirit they offer to their inhabitants. This memory plays an active role in shaping the city's identity by undergoing processes of acceptance, transformation, or rejection over time. Therefore, socio-economic, cultural, and social dynamics are among the factors that directly influence the formation of the city's identity. Within the urban fabric, there are concrete arteries that define the identity and facilitate the lives of city dwellers. Streets and avenues are the most prominent examples of these arteries, offering users and researchers important clues about the city's memory and identity based on periodic changes. These spaces sometimes connect the city's districts along a linear axis, while at other times they are characterized by labyrinthine streets that emerged as a result of organic development. It is not only physical structures that determine urban identity; migration movements, natural disasters, regime changes, and the social, economic, and spatial transformations they cause also play a decisive role in this process. Throughout history, streets and avenues have been regarded not only as transportation axes but also as cultural and sociological transition points. These arteries are concrete axes that reflect the spatial memory and identity of cities. Their locations, the areas they surround, and the structures built on them reveal historical stratification and contribute to the city's identity continuity. Therefore, streets and avenues are considered key elements shaping the city's identity due to their historical, cultural, and spatial qualities in terms of urban memory.

Keywords: City, identity, Gaziantep, street.

1. Introduction

Place plays a connecting role at the center of the material and spiritual relationships users establish with their surroundings, forming the most fundamental component of spatial meaning (Togay, 2002). Place emphasizes its importance as an identity carrier, as an experiential space strengthened by social and cultural contexts. In this sense, place constitutes a dimension that acquires meaning in people's memories, beyond being merely a physical entity (Relph, 1976).

Space, on the other hand, can be defined as a broader perspective than place, as an area where individuals live their lives, where social interactions take place and gain meaning. It can be stated that space is a phenomenon enriched by historical and socio-cultural contexts, beyond its material characteristics. As a carrier of social memory, space contributes to shaping the relationships between individuals and society. In this context, spaces enriched with historical meanings play an important role in connecting both individuals and societies with the past (Ahunbay, 2009).

The city, as a multidimensional organization of space, is a complex system of structures shaped by social, economic, cultural, and political processes (Lynch, 2016). It emphasizes that cities gain meaning not only through physical spaces but also through the historical and cultural accumulation these spaces contain. The city occupies an important position not only as part of individuals' daily lives but also as a stage where social memory and identity are shaped (Kuban, 2001). In this context, analyzing urban structures and processes can determine the effects on a city's identity and memory (Hasol, 2017).

Identity encompasses the ways in which individuals and communities define and express themselves. Social and cultural identity is a reflection of historical processes and spatial relationships. In this context, identity is constructed through the interaction of the individual and society with historical, socio-cultural, and spatial contexts. In social science literature, the concept of identity is central to understanding the effects of social structures and processes on individuals (Çekindir & Aktan, 2021). Urban identity is the sum of a city's historical, cultural, social, and physical characteristics. Preserving urban identity is of great importance in terms of transferring historical and cultural heritage to future generations during modernization processes. In this process, the preservation of historical structures and spaces, in particular, plays a critical role in maintaining the unique identity of cities (Ahunbay, 2009). Gaziantep can be considered a concrete example that supports this view with its rich historical heritage; in particular, its historic bazaars and inns both bear the traces of the past and strengthen the city's identity by bringing these traces together with modern life.

Urban identity gains meaning both through the preservation of the physical environment and through the perpetuation of this environment's place in social memory (Eczacıbaşı Art Encyclopedia, 2008). When urban identity is passed on to the future, it draws attention to the functionality and preservation of historical spaces. (Eryazıcıoğlu & Markoç, 2018) Urban identity reflects the unique character and spirit of the city. This character can be examined through a wide range of aspects, from street layout to architectural structures, art, and traditions. On the other hand, urban memory shows the change and evolution of this identity over time and how it has established itself in the minds of city dwellers. Concepts that form the cornerstone of the development and growth of cities are included. Among these, value emphasizes the economic, social, cultural, and aesthetic importance of the city, while sustainability refers to the balanced and conscious use necessary to preserve these values and pass them on to future generations. In Turkish cities, streets and avenues are not only transportation axes but also spaces where social relationships and neighborhood culture are shaped(Bektaş, 1981). On the other hand, trade is a fundamental factor supporting the economic and social vitality of the city. It enables the city's growth and strengthens its global connections. Along with these, urban planning is also extremely important for making city architectures more livable, accessible, and sustainable.

2. Materials and Methods

This research was conducted to examine the effects of Karagöz Street, located in the city center of Gaziantep, on the city's identity and memory. Based on Lefebvre's (1991) approach to the social production of space, the city was considered a dynamic system that shapes individuals' cultural relationships and social characters. The study evaluated monumental structures, public spaces, and street fabric directly related to urban memory as a whole; the effects of building restorations and renovation processes on the street silhouette and spatial integrity were observed. Karagöz Street and the Karagöz Mosque, Nuri Mehmet Paşa Mosque, Eski Camlı

Kahve, and Nakıp Cinema/Hotel located on it were taken as material; fieldwork, photographic documentation, archive scanning, and comparative spatial analysis methods were used. In this regard, the aim of the study is not only to examine the buildings themselves, but also to reveal the role of the system formed by these buildings together on the city's identity and to contribute to urban axis-centered assessments that are lacking in the literature.

3. Findings and Discussion

3.1. The History and Development of Gaziantep City

Gaziantep Province, one of the oldest and most deeply rooted settlements in Anatolia, has been home to many different empires and civilizations throughout its historical process. Its historical significance lies not only in being a city of users but also in being an important commercial area. Located on the Silk Road trade route, Gaziantep occupies an important position both economically and culturally (Utanır Karaduman, 2023).

The city's historical fabric has formed a unique identity by bearing the traces of various periods. In this context, the Gaziantep City Plan prepared by Herman Jansen in 1938 is an important work that combines the traditional structure of the city with a modern urban planning approach (Keleş, 1996).

In this plan, Jansen aimed to preserve the character of narrow streets and historic neighborhoods while adding new transportation axes and squares to the city. Thus, the goal was to protect Gaziantep's cultural heritage and ensure its adaptation to the modernization process. This plan envisaged preserving the city's values inherited from the past while supporting its development in line with contemporary urban planning principles.

Gaziantep's contributions from the past to the present have had a noticeable impact both regionally and nationally. Structurally, the city also has a silhouette where traditional and modern lines comfortably coexist. These formations and changes have had a significant impact on shaping its identity (Kuyucu, 2019).

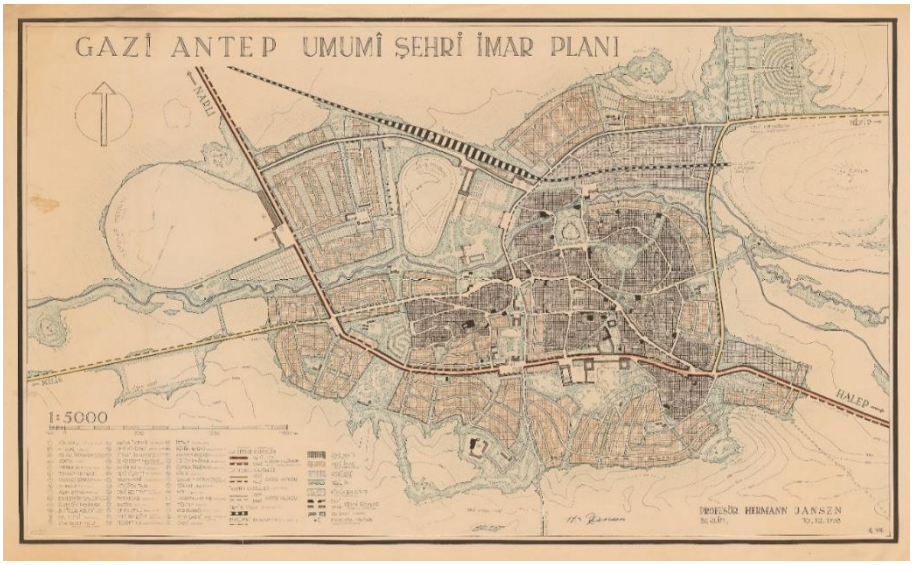

Figure 1. Hermann Jansen's Gaziantep Plan (Jansen, 2024) (1869-1945)

Gaziantep's contributions from the past to the present have had a noticeable impact both regionally and nationally. Structurally, the city also has a silhouette where traditional and modern lines comfortably coexist. These formations and changes have had a significant impact on shaping its identity (Kuyucu, 2019).

3.1.1. Historical Background

Historically, Gaziantep is known to be located in a rich geography that has been home to many different civilizations. Its origins date back to the Neolithic period around 3650 BC. The city was home to the Hittites, Persians, and the Hellenistic period. The most prominent traces of the city can be seen in the Roman and Ottoman periods. During the Roman period, due to its geographical location, it became a stopping point for trade caravans and was able to achieve economic and social development linked to trade. As a result of this development process, it became a regional administrative center and increased its fame (Sönmez, 1995).

During the Ottoman Empire, the city became a cultural center, influenced by trade and social development dating back to the Roman period. The impact of trade led to the development of handicrafts, carpet weaving, and copperware industries that continue to this day. With the development of industry, the direction of trade changed, and economic growth was observed. In addition to these, the urban architecture characteristic of Ottoman Empire culture, with its narrow streets, stone walls, and residential buildings, shaped a unique urban identity. With the proclamation of the Republic, an industrial revolution took place without disrupting the city's traditional structure, accelerating the city's development (Söylemez, 2018).

Today, it is a cradle of great civilizations that bears the historical signatures of its past. Markets specializing in copper, carpets, and handicrafts, whose foundations were laid during the Ottoman period, are located here. These markets are active both as tourist attractions and commercial centers. In addition, Gaziantep has made significant developments in the field of gastronomy and has become globalized.

During the Ottoman period, Gaziantep gained importance as a center of trade and culture. Traditional handicrafts in the city, particularly carpet weaving, copperwork, and food industries, flourished, and trade was largely shaped around these areas. The urban structure of the city during the Ottoman period is characterized by narrow streets, stone-paved avenues, and residential buildings. This structure of the city created an urban identity where the people interacted intensively and small shops and workshops were common. With the advent of the Republican era, the city began to industrialize rapidly, with the textile, food, and metal industries coming to the fore. This industrialization led to the city's growth and accelerated urbanization processes (Söylemez, 2018).

Today's Gaziantep is a modern city shaped by its rich historical heritage, possessing a structure that encompasses both its traditional architecture and its industrialization process. The city's development, parallel to growth in both trade and industry, reflects the evolution of its social fabric and way of life.

3.1.2. The Importance of Streets and Alleys in Gaziantep City

Gaziantep consists of narrow streets and alleys paved with basalt stone, particularly influenced by the Ottoman period. These streets and alleys have not only been used as means of transportation but have also been distinctive in shaping the city's identity with their historical structure. Today, narrow streets are not very practical. However, in order to preserve the

historical structures and prevent damage to the city's identity, the streets in the city center have mostly been left untouched. Streets and alleys that have worn out and deteriorated over time have been restored to their former appearance through restoration work.

The streets of Gaziantep feature a complex structure where traditional and modern architecture intertwine. This complexity allows visitors to breathe in the traditional architecture and feel the historical textures, while also providing the opportunity to experience modern world structures (Kuyucu, 2019). Throughout history, they have been trade centers where people interacted. These streets and avenues, which have been shared spaces, have greatly contributed to the city becoming a trade center. This has shaped the city's dynamics. Today, streets that have retained their traditional architecture are considered the city's social centers because they are home to the most distinctive and widely accepted structures that represent the city's identity. These factors, which form the fabric of the city, have persisted and been reshaped throughout history (Şahin, 2016).

One of the most important elements that make a city a city is its historical system. The concrete structures and street system are what best describe how it has evolved from the past to the present and the struggles it has endured along the way. One of the streets that fits this description for the city of Gaziantep is Karagöz. The street has a direct physical, historical, cultural, social, and economic relationship with the city. In terms of location, it is situated in the direction of the traditional and historical bazaar that the city has used for centuries. Used for commercial and social activities since its inception, this street is now a vital structural axis for the city.

3.1.3.City Memory and Karagöz Street

Memory is the social memory system that shapes the city's identity from past to future.City memory is not limited to physical elementsbut is also directly related to the socio-cultural and socio-economic infrastructure.It is organized by individuals' concrete or abstract experiences with the city,lifestyles and practices applied according to traditions and customs.Gaziantep, a city known for its cultural and historical richness, is of great importance for preserving memory, developing identity, and protecting social memory.Known for its cultural and historical richness,the city of Gaziantep is of great importance for the preservation of memory, the development of identity, and the protection of social memory. The street is located in a settlement pattern that intertwines traditional and modernstructures. With its change and development over time, it occupies an important place for the city's memory and identity.

The collective memory that encompasses the culture, history, identity, and values of societies stretching from the past to the future can be referred to as social memory. Memory exists in a visible, tangible form through cities, streets, buildings, and other concrete cultural assets. Gaziantep's Karagöz Street is one of the main elements that make up the city's social memory. This street bears traces that can be understood by the city's users or tourists visiting the city from outside. These traces are located on the Karagöz street axis as evidence of great struggles and successes.

The street reflects the social dynamics, cultural structure, and commercial life of the city. The commercial and social structures along Karagöz Street are user-oriented. It is located in a position that can be described as a gateway to the center of the city bazaar. It serves as a brief summary of the bazaar for users. The street axes branching off from the street are related to each other but do not run in the same direction. For example, one branch leads to the Nuri Mehmet Paşa Mosque, while another branch opens onto an area where an old synagogue is located. Similarly, the same situation may apply to the Nakıp Cinema and Paşa Hamam. Due to its comprehensive structure, the street remains dynamic and vibrant in the memory of the community (Karadayı Yenice, & Ararat, 2022).

Figure 2. View of Karagöz Street from Maarif Junction (1925) (Biçer, 2017)

Figure 3. View from a Location Similar to Karagöz Street (2024)

Preserving a community's memories, culture, and history is of vital importance. Memory is the fundamental element that dynamically connects the city, its individuals, and its structures, linking body and space. The streets of a city can convey the experiences of those who lived there before to its current users. Accordingly, the preservation of memory is achieved both through the continuation of cultural activities (customs and traditions) and through physical restoration.

Space has the ability to keep memories alive in the body. For this reason, the most important element in preserving memory is the restoration of historical structures and spaces. However, preservation can be achieved not only physically but also through the preservation of abstract values. The foundations of these abstract values are strengthened by giving them experience and vitality through traditional, commercial, and social structures located on the street.

Conclusion and Recommendations

When examining the historical development and spatial structure of the city of Gaziantep, it is evident that the relationship between the city's identity and its memory is most tangibly observed along historical axes such as Karagöz Street. Urban memory is not limited to physical structures; it is a dynamic system that reflects the sum of individuals' social, cultural, and economic relationships. In this context, Karagöz Street has become a focal point that nourishes the city's identity by carrying traces of the past.

The research highlights the importance of preserving historical fabrics, carrying out restoration work that reflects the original identity, and addressing traditional spatial organization in a manner consistent with modern planning approaches in order to ensure the continuity of urban memory and identity. Preserving the street as a "memory space" from both historical and social perspectives is critical to sustaining Gaziantep's local identity.

Ultimately, the city's identity and memory are shaped at the intersection of the physical environment and human experience. In this context, historical spaces such as Karagöz Street are not merely physical entities representing the past; they are also carriers of social memory and cultural bridges that ensure the continuity of identity. Preserving these axes and integrating them into urban life in planning processes for the city's future will strengthen both historical continuity and identity awareness.

Abstract

Cinema and architecture offer unique experiences to viewers or users by creating spatial narratives. Both disciplines consider space not only as a physical entity but also within an emotional and semantic context. The aim of this article is to analyze and interpret the perceptual, experiential, imaginative, and memorizational relationships of fictional spaces in the 2015 film "Room." More than half of the film takes place in a single location. In this context, the aim is to understand how a single space, the limited space within the room, is conveyed to the audience through the characters, through comparisons between the spaces of the outside world. Another aim of this article is to analyze the emotional and psychological impact of the differences between the spaces in the film and to reveal the contributions of space to the narrative and character development. The analyses were conducted by considering the factors that influence spatial perception, particularly the concepts of scale, experience, imagery, and memory. Using a literature review method, the study explores the physical and psychological factors that influence spatial perception, experience, imagery, and memory, and then explores how the fictional spaces in "Room" relate to these criteria. The film's main characters' emotional connections to places have been revealed. The results indicate that the characters' relationships with and perceptions of space vary significantly. This highlights how the perception of space is based on an experience imbued with personalized, memorized images and emotions.

Keywords: Cinema, fictional space, perception, image, memory

1. Introduction

Architecture has interacted with various disciplines since the past. Cinema, which emerged in the late 19th century and continues to develop with technological advancements, is a significant discipline intertwined with architecture through its treatment of space and time. Cinema's reconstruction of physical spaces on a digital platform, its characterization of architecture with its fictional structures, and its definition of spaces that do not exist in the real world as virtual architectural fields illustrate the interaction between cinema and architecture (Us, 2023).

Cinema is an art form created by combining many elements. One of these elements is the construction of space, a fundamental subject of architecture. Cinema always requires a space and organizes it in various ways. For example, cinema can design a new space, utilize or modify an existing space, and create space at the interior or urban level. Therefore, in every film, an architectural representation is created through the images of space presented (Yıldırım Yargıcı, 2021).

All events occur and develop within the framework of time and space. Space is a concept encountered in every field. Disciplines such as painting, philosophy, cinema, and architecture, influenced each other with their evolving understandings of space, considering the concept of

space and producing it in different ways. While architecture shapes spaces in the concrete world, cinema presents these spaces to the audience along with stories. Although processed differently in both disciplines, the concept of space forms a bridge between the two.

Cinema and architecture share similar characteristics in terms of conceptualization, production, planning, and presentation techniques (Güleç & Çağlar, 2014). As in architecture, in cinema, various dimensions of space -such as time, form, concept, and sensation- are constructed through space. Both disciplines utilize space and time. In cinema, space is sometimes used as a tool, and sometimes it can be the goal. In the early years of cinema, space was generally the focal point. However, over time, story became more prominent. With the rise of storytelling, space began to be used more as a tool (Akyol, 2019).

Just as each image in cinema has a purpose, each space also has a specific purpose and inherent meaning. The primary goal is to achieve effects appropriate to the script and to strengthen the narrative. Thoughts and emotions intended to be expressed are conveyed through spaces. For example, narrow, confined, and dark spaces can be used to convey negative emotions such as fear and tension, while spacious and bright environments are preferred to represent peace (Akyol, 2019).

Juhani Pallasmaa emphasizes that there is no film that cannot be connected to architecture. He states that the fundamental function of architecture is the production of space, and that the organization of space, scale, void, and light are intertwined with cinematic expression (Pallasmaa, 2007).

According to Graham Cairns, the moment cinema's visual narrative entered our lives, a new visual language emerged. This innovation influenced architecture and raised questions about how the environment is perceived. This has opened new perspectives in building design and presentation, while offering architects an area of experimentation at the interior and urban scales (Cairns, 2013). Consequently, many researchers recognize that cinema and architecture interact and influence each other.

Both disciplines have a way of influencing mental perception through the meanings they embody, as well as the physical characteristics of space. In the film "Room," the focus will be on the rendering of space and the perception of space conveyed from the visual to the mental.

The 2015 film "Room" is the primary focus of this study. The aim of this study is to examine how the intended message within the context of the relationship between cinema and architecture is conveyed through space and to evaluate the spaces used in the film in terms of perception.

2. Materials and Methods

2.1 The Use of Space in Cinema

The use of space in cinema is a fundamental element of filmmaking. Space is not just a physical location; it is also an emotional and semantic narrative tool. The careful selection and use of space in films offers the audience a profound experience and makes cinema a powerful means of expression.

The spaces seen in cinema can be real, existing spaces, or, depending on the director's wishes, virtual or recreated spaces. Existing spaces can be used in their original form or reorganized according to need (Us, 2023).

Cinema has the power to tell a story and create emotional engagement through the use of space. Space is one of the cornerstones of a film, and filmmakers aim to create the desired emotion in the audience by utilizing the physical characteristics and atmosphere of the space. The colors, textures, architecture, and lighting of the space determine the film's atmosphere and are used to convey a specific emotional state to the audience.

Fictional space is considered in two main categories: real and virtual space. In cinema, in addition to physical real spaces, sets and spaces designed within the virtual world are also used. These freely constructed spaces can be more creative because they are shaped independently of real-world constraints. Diverse architectural structures in film productions demonstrate the connection between architecture and various disciplines, environmental elements, and social structure. In cinema, space is a tool used to achieve realism. These environments determine the flow of time and the movements of the characters in the film (Selvitop, 2017).

When the use of space in cinema is evaluated from the perspective of the discipline of architecture, carefully designed spaces can evoke various sensory and cognitive perceptions in the viewer. Films created with these perceptual architectural approaches deepen the film's theme through the spaces created, contributing to the development of the story (Köseoğlu & Yücel, 2023). Cinematic space is not merely a physical location; it is also a tool that conveys the relationships, emotional states of the characters, and the fundamental elements of the story. The choice of location can emphasize the relationships between characters, increase tension, or convey a dramatic image.

Spaces are important elements that reflect the characteristics of society and the individual. This applies not only to everyday life but also to movies. In cinema, space is the cornerstone of visual structure and significantly influences a film's atmosphere, emotion, and story. Furthermore, locations play a critical role in shaping a film's atmosphere. For example, in horror films, dark and abandoned locations aim to heighten the tension and influence the audience. In a romantic film, warm and romantic settings facilitate the establishment of an emotional bond. Locations guide the audience in understanding the relationships between the film's events and characters (Ersoy, 2010).

2.2 The Perception of Space

An individual is in a complex network of relationships with their environment, with which they constantly interact. This process encompasses the behaviors behind the individual's responses, the needs that form the basis of these behaviors, and a series of processes and concepts within the perceptual system that aims to understand the environment. Individuals must recognize and understand their environment in order to make the most of it, adapt, or adapt it to their needs. Perception of the space we inhabit involves a complex process that begins with the emission of stimuli to various sensory organs (Koç, 2012). The way individuals understand the physical environment, the meaning they ascribe to it, and how these elements influence designs and behaviors play a significant role in determining an individual's interaction with their environment.

Perception, cognitive processes, and behavior constitute the main components of a complex interaction model. Perception involves acquiring environmental information through sensory stimuli, while cognition involves interpreting this information, storing it in memory, and understanding emotional states. Behavior refers to the process by which an individual uses this information to exhibit various responses aimed at achieving goals (Gür, 1996). Cüceloğlu

defines perception as the process of organizing and interpreting sensory data to give meaning to objects and events (Cüceloğlu, 1996).

Perception is an active process and does not assume a passive role. It acquires meaning by integrating with what is perceived and the behaviors that result from this perception. Perception cannot be explained simply by automatic responses to stimuli. Human-environment interactions are dynamic. An individual's perception of the environment depends on past experiences as well as current situations. Past experiences contribute to the individual's process of reconciling current situations with their own needs. Perception is shaped by expectations, experiences, and personality traits (Lang, 1987).

Perception is the process of processing information obtained through various senses and constructing a concept of the external world. This process is the result of an individual's effort to understand and interpret their environment. Perception has an ever-changing structure because it is a temporary system, open to new data and amenable to constant inquiry and experimentation. Perception can evolve and strengthen with incoming information, or it can weaken and give way to another theory. Individuals personalize their theory of perception based on their own experiences and experiences, emphasizing that perception is a highly subjective process. Concepts such as colors, sounds, time, and size vary from person to person (Aydoğan Şahin, 2019).

Perceived space does not merely refer to a physical environment; it can also be considered as a space observed, experienced, and perceived by the person in it. Space is not merely comprised of the physical characteristics of the external world; it is also shaped by internal experiences, subjective values, and personal meanings. In this context, perceived space is a rich and personalized field that emerges from the combination of both a stimulus reflecting the objective characteristics of the external world and the subjective experiences of the individual viewing this stimulus. This two-way interaction of perceived space encompasses not only the physical dimension of the space but also the emotional and mental experiences of the individual within it (Aydınlı, 1986).

Humans naturally desire to live in harmony with their environment. This tendency causes environmental influences to have a greater impact on individuals. Factors such as the color of a room, the lighting, and the size of the environment are factors that influence an individual's perception. Individuals acquire a wealth of information using visual perception and store this information in their memory. During this storage process, the mind evaluates the information obtained and shapes emotional responses. Scientific research has confirmed the emotional responses that design elements of architectural space, such as form, color, and texture, visually evoke in individuals. Human perception can be manipulated by shaping these effects in the desired way. The power of architectural space is highlighted by the role of visual elements in directing emotional responses (Aydoğan Şahin, 2019).

2.3 Spatial Experience, Image and Memory

Spatial experience is the totality of sensory, physical, and mental interactions an individual experiences during their perception, exploration, and time spent in a space. This experience provides insight into how an individual perceives a space, interacts with objects within it, and evokes an emotional response to the space. Imagery and memory play a key role in the formation of spatial perception. The ability of perception to integrate with the multifaceted

elements expressed reveals the interaction between concepts such as imagery and experience (Hekimoğlu, 2021).

Imagery can derive from different thinking approaches using an individual's memory. In the thought process, in addition to fundamental elements such as experience, memory, and knowledge, factors such as perception and the subconscious can also influence the internal dynamics of image formation. An individual's past experiences, learning, and emotional states can shape the content of the image created (Hekimoğlu, 2021). Although images contain the physical characteristics of their objects, they are shaped by the individual's internal experience and are distinct from the object itself. The image-making process is shaped by an individual's unique life experiences and knowledge (Burnett, 2007).

An image is a visual, auditory, or emotional representation that emerges in an individual's mind. In spatial perception, an image forms a mental map of a space. For example, when a person passes the entrance door to their home, an image of this passage is formed in their mind. This image is associated with their previous experiences with their home, their emotional attachments, and the design of the space. Imagery enriches the perceptual structure of a space and has the potential to add meaning to the user. An image is enriched by references from memory, and thus, the space becomes part of a personal story. For example, a café, which holds significant memories for a person, acquires meaning not only through its physical features but also through the special memories spent there.

Spatial memory refers to an individual's ability to recall experiences related to the spaces they have lived in and to make connections between these spaces. Memory contains the concrete traces of previous spatial experiences, combined with individual, social, and cultural values in the individual's thoughts, and constructs the spatial memory. Spatial memory emerges as a result of individuals' emotional and semantic experiences related to spaces. The stimuli that trigger a person's association with the mental and experiential experiences they have gained throughout life during the understanding of a space correspond to the traces left in the memory by the space. Therefore, a person's perception of space is not only mediated by visual perception, but also by their previous experiences and the characteristics and meanings of each stimulus they encounter (Sayar Avcıoğlu & Akın, 2017).

Memory is a mental archive that stores past experiences. In spatial perception, memory helps an individual recall experiences they have had in previous spaces and interpret new spaces within this context. For example, if a person remembers a park they frequently visited in childhood, this memory influences their mood when they step into a new park. By connecting a space with past experiences, memory contributes to deepening perception and gaining personal meaning.

3. Findings and Discussion

3.1 The Film “Room”

“Room” (2015) is a drama film directed by Lenny Abrahamson and adapted from Emma Donoghue’s novel of the same name. The film tells the story of a young woman, Joy (Brie Larson), and her five-year-old son, Jack (Jacob Tremblay), living in a confined room. Joy is kidnapped by a mysterious man they call Old Nick and imprisoned in the room for years. Jack was born and raised in the room, growing up with only what he saw on television about the outside world. Joy, unable to tell her son, who held her captive, that they were imprisoned here and that there was a world outside the room, created an imaginary world for him where only

the two of them lived. Unwilling to disappoint Jack by telling him a life she couldn't give him, she allowed him to believe the rest of the world existed only on television. Jack grew up believing that only he, his mother, and the room were real. The story is told through Jack's eyes, and his life in the room is the only place he believes represents the real world. When Jack turns 5, Joy tells her son the truth, but Jack can't believe there's a life outside the room. Joy devises a plan to escape. She tells Old Nick that Jack is dead, prompting Jack to escape. After escaping, Jack tries to tell the police what happened, and Joy is rescued. Later, Jack and Joy begin living at Joy's mother's house.

The film focuses on the room through Jack's eyes and how he perceives this limited space. It also emphasizes that our perception of life is limited by our experiences, but imagination knows no bounds. The room is Jack's universe, his world. His reality lies within the walls of this limited space. Everything within the room constitutes his perception of the real world. This limited space is the center of Jack's existence, and all his knowledge and perceptions come from it. However, Joy and Jack's escape attempt and subsequent reconnection with the outside world reshape his perception of the room and its reality. In this process, it becomes clear how limited the space actually is, yet how profoundly it impacts human perception. The room, in addition to being a protective space for Jack, can also be seen as an emotional and psychological prison.

The film "Room" goes beyond the physical boundaries of a space by examining how space shapes human perception and psychology. The room represents the characters' inner worlds, emotional bonds, and perspectives on life, while also showing the audience how human perception relates to space. Elements such as the room's structure, furniture, colors, and lighting shape the perceptual experiences of the characters and the audience. These elements reflect not only the physical boundaries of the space but also the characters' emotional states and mental processes.

47 minutes of the 117-minute film take place in the same room. This article also focuses on spaces belonging to the outside world, outside the room. The spatial elements that appeal to perception in the design of the space and how the space strengthens the story are examined. The spaces used have different qualities and meanings, and it is anticipated that the spaces discussed will provide various data for evaluating spatial perception. Jack is in direct relationship with the spaces. The room occupies a central position in the film, and Jack's relationship with these spaces is a focal point throughout the film. The room is also mentioned in dialogue between Jack and other characters. This demonstrates that film can explore not only the physical dimensions of space but also its mental and emotional dimensions. In this context, the film offers a significant opportunity for analysis of how space influences human perception and how it is represented in the human mind.

3.2 Evaluation of The Perception of Spaces in The Film "Room" in The Context of Experience, Image and Memory

The room, the characters' living space, is approximately 20-25 square meters. It contains a bed, television, nightstand, bathtub, toilet, sink, small kitchen area, table, and two chairs.

Pictures drawn by Jack are displayed on the wall. A skylight in the ceiling provides natural light. Jack and Joy's perceptions of space are quite different. From Jack's perspective, the room represents the entire world, while for Joy, it symbolizes a form of captivity. This contrast demonstrates how subjective perceptions of space can differ. In this context, it emphasizes how characters create meaning and value within a space beyond its physical dimensions. This

demonstrates to the audience that space is not only physically definable but also how it is reflected in a person's mental and emotional world (Figure 1).

Figure 1. The room interior

A dark theme is generally used in scenes set in a room. This creates a gloomy perception of the space. Colors are known to affect the perception of space's size. Therefore, when elements such as the walls and ceiling are of the same color tone, the viewer perceives the space as small. The colors used create a sense of space as cramped and cramped, far from spaciousness. The brown and tan tones seen throughout the room may be intended to emphasize the safety of Jack and Joy's family and the fact that this room is Jack's reality.

When examining the textures used, the first thing that strikes the eye is the soft sound-absorbing material covering the entire walls and ceiling. Rough and soft surfaces direct the perception of the space towards a warm atmosphere while simultaneously creating a sense of distance. These textures offer the viewer an emotional and perceptual experience of the space's characteristics. Different textures are known to contribute to children's sensory development and their interaction with the environment. In the film, there are scenes where Jack tries to recognize and make sense of his environment through tactile stimuli in his first encounters with the outdoors (Figure 2).

Figure 2. Jack's encounter with the outdoors

The room's elements, such as the small kitchen area, a single bed, and a small two-door closet, are in harmony with its size. The room's small size is evident by examining its constituent elements (Figure 3). The room's narrow and confined physical dimensions emphasize the

character's lack of freedom. The mental dimension of the space is more prominent than its physical dimensions. Because he hasn't experienced the outside world, Jack's room isn't confined to him. The space is his world. Despite its narrowness, some scenes, due to the shooting angle, make the ceiling appear high, emphasizing the inaccessibility of the outdoors—that is, freedom.

Figure 3. Elements in the room

Additionally, the colorful and childlike appearance of the plates in this scene strengthens the relationship between Jack and the room, but also gives the audience the impression that Joy doesn't belong there.

The skylight is a feature that helps the characters see the outside world. The light from the skylight and the shadows on the sides that aren't are used as important storytelling tools. Light is associated with freedom and the outside world (Figure 4).

Figure 4. The use of light in the room

Jack's reality in the room is limited to what he perceives from the outside world. This affects Jack's imagination and understanding of reality. Jack's knowledge and experiences of the real world are limited. He cannot conceive of a reality outside of his room. There is a potted plant in the room. He accepts the plant's reality, but since he has only seen trees on television, he doesn't believe it is real. His remark that the people on television are flat demonstrates that his three-dimensional perception is also underdeveloped.

Jack's statement demonstrates not only that Jack cannot physically see the outside world, but also that he has no mental perception or understanding of it. Because Jack grew up within the confines of his room, his perception of the world was shaped by his relationship with space. Joy's statement, comparing the room they were in to the outside world, highlights Jack's

limitations in terms of understanding. For him, the world, like space, can be an unknown and incomprehensible concept because he only knows the room. This comparison between the outside world and space demonstrates how limited Jack's perception of space is, and how, for him, the outside world is an incomprehensible and distant concept.

Because the room constitutes Jack's entire existence, it appears he cannot grasp the magnitude and diversity of the outside world. In this context, Jack's relationship with space has also influenced his perception of the concept of dimension.

For Jack, the room is his living space, his playground, and his entire universe. As a safe, familiar, and controllable space, the room plays a central role in Jack's perception. Jack finds the objects in his room familiar and meaningful. Every object in the room holds a significant place in his daily life, and he makes sense of the world through these objects. The room provides him with a controllable and safe haven, safe from danger. His desire to return to his bed the first moment he goes outside demonstrates this view. For Joy, the room is perceived as a factor that restricts her freedom. At the same time, living in the room carries a sense of danger for her and her son Jack's safety. This demonstrates that she perceives the room not only as a physical space but also in a psychological context, such as safety or danger.

Figure 5. View of the room from outside

During his escape with his mother, Jack encountered the outside world, entering different spaces, and these experiences led to a significant shift in his perception of space. The hospital room, the first space he encountered, is quite different from the space the characters had spent so long in. In this space, Jack experiences large windows, abundant daylight, and a large space for the first time, and he appears to have a reserved attitude toward other people. The light colors and lighting used in the space contrast with the other spaces. The smooth surfaces convey the viewer's sense of the cold atmosphere (Figure 6). While Joy feels familiar and safe in the hospital room, Jack feels cold, frightening, and unfamiliar. He still carries traces of the other space in his memory and interprets the new spaces he encounters according to this spatial memory. For example, he questions why the bathtub in the "room" is not present in this hospital room.

Figure 6. Hospital room

"I've been in the world for 37 hours. I've seen pancakes, stairs, birds, windows, and hundreds of colors. I've seen people of different faces, sizes, and smells talking together. The world is like a TV planet. All at once. That's why I can't look and listen. There are doors and more doors... and behind all those doors, there's another inside and outside. Something's constantly happening, and it never stops. Everything in the world gives way to brightness and harshness."

This line from Jack expresses his experiences and the shift in his perception of space after stepping outside the limited space he inhabits throughout the film. Encountering the stairs, birds, windows, and different colors causes Jack's perception of space to suddenly expand. These elements are real and concrete experiences, different from the world he had previously seen only on television. Jack's statement, "The world is like a TV planet. All at once," suggests that the world he sees through television is limited and orderly, while the real world has a complex and constantly changing structure. This represents a paradigm shift in spatial perception. The line, "There are doors and more doors, and behind all the doors, another inside and outside," demonstrates Jack's understanding that he is no longer simply inside a space, but in a world where spaces and passages are interconnected. This highlights the evolution of his perception of space to a complexity he had never experienced before and the shift in his perception of size. Jack's statement, "Everything in the world gives way to brightness and hardness," emphasizes the diversity and density of the outside world, in contrast to Jack's confined room. With these new experiences, Jack enriches his perception of space and realizes that the world is real, tangible, and multidimensional.

Jack's inability to figure out how to descend the stairs after going outside is an experience he hadn't experienced before in the confined space he had lived in. Jack is seen to be surprised by the staircase, which he sees for the first time. This scene illustrates the audience's reaction to a child's previously unfamiliar spatial element (Figure 7).

Figure 7. Stairs

Even though Jack experiences new environments, he remembers the room he grew up in, a place etched in his memory where he felt safe. It's known that children enjoy being in spaces that are appropriate to their own scale. However, because he feels comfortable in the familiar dimensions of the room in his spatial memory, he appears to prefer the dressing room, a smaller space than other rooms in the house, for play (Figure 8).

The color palettes, textures, spatial dimensions, lighting, and spatial elements used within the spaces also support the story being told. Dark color themes contribute to the perception that the space is narrow and cramped. It has been observed that the use of color affects the perception of size within the space. The color palette, created with brown and tan tones, is used to emphasize the family's security and Jack's reality. The light color themes used contrast with the "room" space, conveying the contrast between the spaces to the audience. Color, theme, textures, and visual elements reveal how the characters' unique perspectives influence the space, revealing that the space holds symbolic significance beyond being merely a physical space.

Figure 8. The dressing room where Jack plays

The relationship and perception of space between Joy and Jack, the main characters in the film "Room," are seen to be very different. For Jack, the physical and mental dimensions of the space are quite different. For Jack, the inside, the room, represents trust, the world, reality, and the bond of love between him and his mother, while for Joy, it evokes captivity, resistance, and fear. The outside, all spaces outside the room, For Jack, it evokes unfamiliarity, uncertainty, excitement, and fear, while for Joy, it evokes the real world, hope, and the security of being in familiar space. The outdoors represents freedom for both of them. The skylight in the room symbolizes freedom for Joy, while Jack, having not yet experienced the outdoors, symbolizes uncertainty. While the walls are a boundary that restricts Joy's freedom, they are a dream world where Jack hangs his drawings. The hospital room is a familiar space for Joy, but for Jack, it is

a space he feels unfamiliar with. This difference demonstrates how a space influences human perception and how it can be represented in different ways in the human mind (Figure 9).

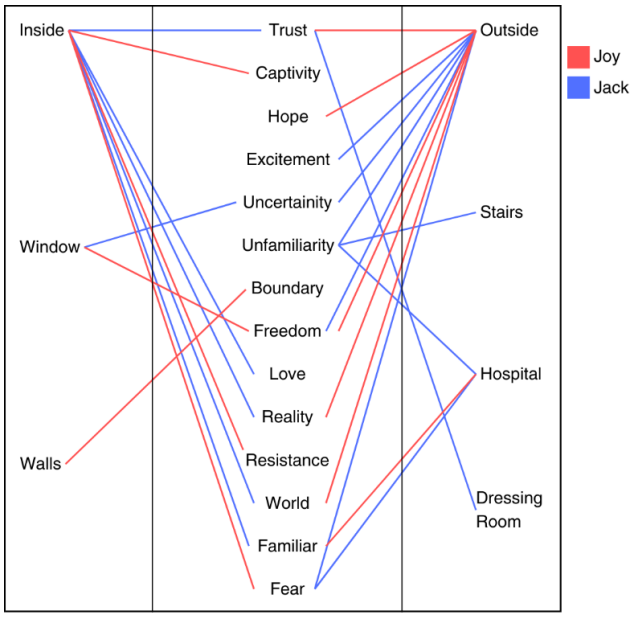

Figure 9. The relationship of the main characters with the space (Tokuç, 2025)

Conclusion and Recommendations

Cinema and architecture are two art forms that share similar characteristics in terms of the use and expression of space. Both aim to create atmosphere by influencing spatial experience. In cinematic works, space interacts with architecture through the representational power of cinema. Spaces are used as a significant tool in the cinematic language to strengthen fictional narratives and convey emotional expressions. In cinema, spaces can be used as a part of the story, reflecting the inner worlds and relationships of characters. At the same time, architectural elements and environmental details contribute to the audience's emotional connection and understanding of the story's atmosphere.

Space perception is a complex process that involves the integration of sensory information from multiple sources. It involves the process of evaluating the details, dimensions, colors, textures, sounds, and overall atmosphere within a space. Various elements such as space organization, color selection, lighting, sound, and smell can influence an individual's perception of space. Furthermore, factors such as an individual's personal history, cultural background, age, and emotional state can also determine spatial perception. This concept goes beyond the physical characteristics of a space and aims to understand and explain individuals' experiences related to that space. The perception of space offers an understanding of an individual's interactions with space, its meanings, and emotional responses.

In cinema, spaces function as carriers of the story told through their color palettes, textures, dimensions, lighting, and other elements. These elements determine the atmosphere of the space and the emotional states of the characters, imbuing the audience with a deeper meaning. In this

context, the spatial design and color palette used in the film "Room" serve to support the story and emphasize the characters' perception of space.

The film "Room," which serves as the sample for this research, emphasizes that spatial perception is a subjective and individual experience through Joy and Jack's relationship with space. For Jack, the room is not just a physical space but also a symbol of his world, his trust, and his loving bond with his mother. In this context, the interior is seen as an expression of security and belonging for Jack. Conversely, for Joy, the same space symbolizes captivity, resistance, and fear. For Joy, the exterior represents the real world, hope, and the security of a familiar space, while for Jack, it reflects unfamiliarity, uncertainty, and excitement. The research results demonstrate that the relationships and perceptions of space of Joy and Jack, the main characters in the film "Room," are quite different. This emphasizes that the perception of space is a personalized, emotional, and meaningful experience. In this context, the power of space to influence individuals' perceptions and the potential to explore different meanings associated with space itself come to the fore.

The findings of this study emphasize the personal and emotional dimension of space perception, providing a perspective on spatial design and use in architecture. Understanding how the spaces in the film are perceived by characters with different backgrounds and perspectives can contribute to the field of architecture by evaluating sensory elements and emotional experiences within space during design processes. In this context, understanding space not only through its physical boundaries but also through its emotional and semantic depths allows for more effective and meaningful design decisions. This article provides an important reference for researchers and designers seeking to understand the impact of space on individuals and integrate this knowledge into their design processes.

Abstract

The rapid growth of the human population, its mobility, demand, and supply have a significant impact on land use/land cover (LULC) dynamics. Especially, LULC changes appear as biodiversity loss, deterioration of water quality, increase in greenhouse gas emissions, carbon cycle disruption, and decrease in livelihoods, and these changes are among the frequently discussed issues in scientific studies. Geographic Information Systems (GIS) are frequently used in scientific studies to predict the consequences of damage resulting from LULC and to reveal future management strategies. A new tool, Molusce (Land Use Change Assessment Modules), is used to understand the factors affecting historical, current, and future changes in LULC and the significance of these changes. Molusce is a plugin for QGIS that facilitates the exploration, modelling, and simulation of LULC changes. In this study, the aim is to reveal the importance of the QGIS plugin Molusce in spatial and temporal change analysis of land cover and future scenario modeling. In this context, the pros and cons of the Molusce tool in LULC change analyses were revealed and opened for discussion.

Keywords: Land use/land cover change (LULC), remote sensing, Molusce, QGIS

1. Introduction

Land cover is defined as the surface landscape, such as bare rocks, soil, vegetation, and water surfaces that can be seen with the naked eye and observed through satellite images, and is formed based on natural environmental features (Demir, 2021). Land use, unlike land cover, is difficult to observe and means that people utilize the surface landscape for specific purposes and through human activities such as agriculture, settlement, and mining (Ebenezer et al., 2018; Selcuk et al, 2021). Today, land cover data has an important place as a basic base of information for sustainable resource management, land use and planning, and land use data for strategy development and planning studies (Demir, 2021).

Humankind has directly or indirectly affected and changed the land cover (Buğday & Buğday, 2019). The rapid increase in the world population has caused the demand and supply of human beings on the existing land cover to diversify and increase day by day. However, land is a limited resource (Muhammad et al., 2022). Overexploitation of existing resources in land cover has significantly impacted ecosystem services worldwide (Polasky et al., 2011). For example, it affects many natural ecosystems such as the world's biogeochemical cycle, nutrient cycle, soil carbon structure, water availability, etc. (Song & Denk, 2017). Costanza et al. (2014)

examined land cover/land use (LULC) changes in forests and wetlands in China between 1997 and 2011. They found a 3.59% decrease in forest areas and a 0.14% decrease in wetlands. Deforestation, desertification, soil erosion, and other forms of environmental degradation in the world are caused by the overuse of land cover (Bhattacharya et al., 2020). This situation is increasingly important for determining the spatial and temporal changes of existing resources in comprehensive LULC for sustainable land resource planning and management to achieve local, national, and international targets of countries that provide food security, economic development, and energy supply in pristine lands.

Remote sensing (RS) and geographic information system (GIS) are the best tools used to manage LULC research and natural resources (Kamaraj & Rangarajan, 2022). In spatial and temporal analysis of LULC changes, UA and GIS help in efficient preparation of natural resources and also in land management and monitoring long-term change dynamics (Ebenezer et al., 2018; Bhattacharya et al., 2020). On the other hand, LULC is often an important tool in research to reveal when and how often changes will occur and to produce predictions for the future (Guidigan et al., 2019).

Remote sensing (RS) and geographic information systems (GIS) are fundamental tools used in many scientific studies and fields that enable the display, analysis, and interpretation of geographic data. GIS technology is a frequently used tool today due to its easy accessibility and functionality, open source software, and wide range of plug-ins. QGIS is an important GIS program known for its user-friendly interface, powerful features, and participatory development community (Albut, 2024).

Molusce (Land Use Change Assessment Modules) is a QGIS plugin designed for LULC analysis, modeling, and future LULC simulation using land cover images from various time periods (NetGıs, n.d.1). It is a QGIS plugin frequently used in LULC analyses today. Molusce, a QGIS plugin with an easy-to-use interface, is used by many researchers to investigate, model, and simulate LULC changes created with the Cellular Automata (CA) model. In this study, the QGIS plugin Molusce was examined and its place and importance in GIS system tools were tried to be revealed. The features of the plugin are mentioned, and the pros and cons it provides to researchers in LULC change analyses are mentioned.

2. QGIS plugin MOLUSCE

Scientific developments in Geographic Information Systems, as well as their methods, have gained momentum day by day. One such method is the Multilayer Perceptron (MLP) Neural Network. This method is used for various purposes, such as distinguishing surface changes, planning land suitability maps, and so on. It can be done using the Multi-Layer Perceptron (MLP) Neural Network method in the Geographic Information System. This method is performed in the QGIS software, which includes the Modules for Land Use Change Simulations (Molusce) modules.

Molusce is a QGIS plugin and stands for Land Use Change Assessment Modules. Molusce includes well-known algorithms used in LULC analysis. It is an open-access resource and has been developed for QGIS 2.0 and above by Asia Air Survey Co., Ltd (AAS) since 2012 (Gismondi et al., n.d.1).

Molusce is primarily used for the following (Thanekar & Krishna, 2021):

- Analyze land use and changes,

- Model land use transition potential and areas at risk,
- Create simulations of future land use/land cover changes.

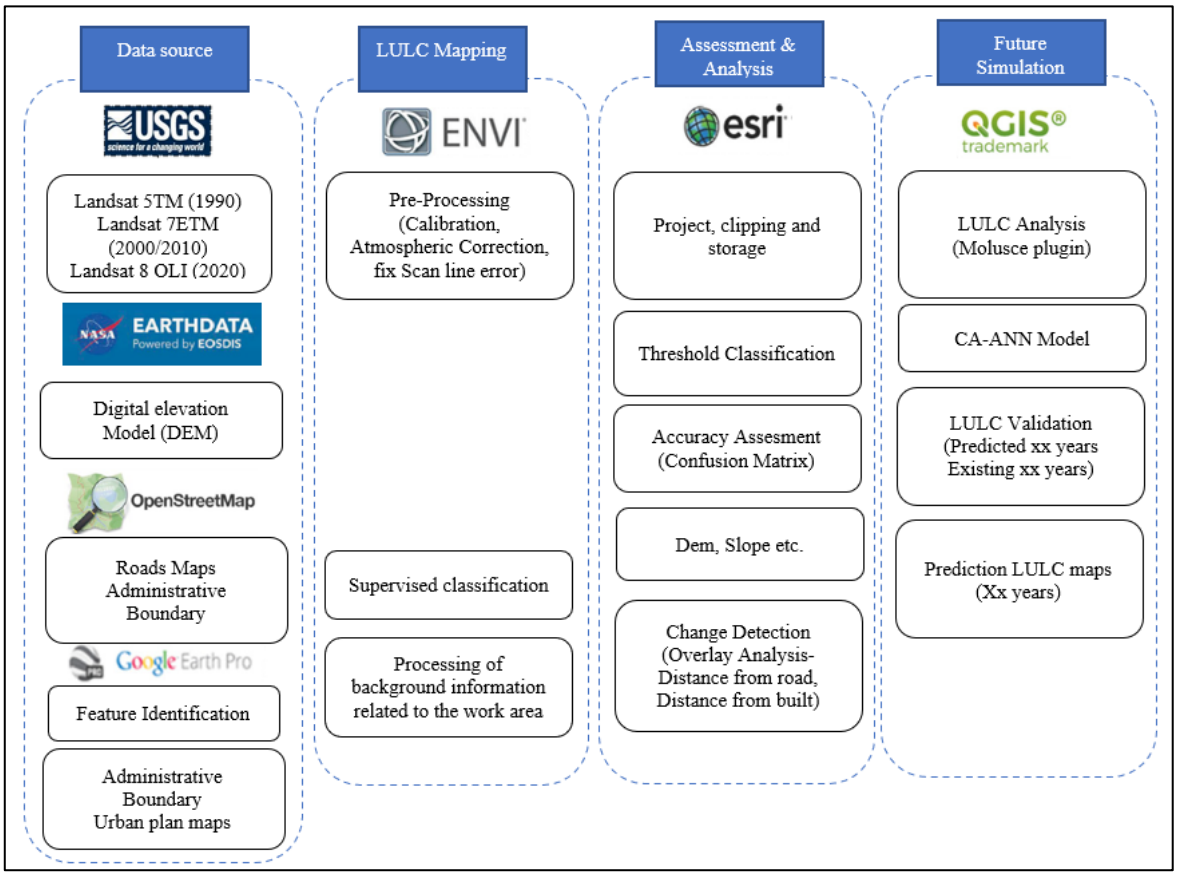

Figure 1. QGIS Molusce methodological workflow

Molusce is a software that simplifies LULC modeling and simulation processes. The software includes three algorithm plugins for modeling and simulation. The auxiliary modules incorporate several well-known algorithms, such as cross-tabulation techniques and algorithmic modules (e.g., Artificial Neural Networks (ANNs), Multi-Criteria Evaluation (MCA), Weights of Evidence (WE), Logistic Regression (RL), and Monte Carlo Cellular Automaton (MCA) models).

The program's interface consists of seven main components. These main components are (Gismondi et al., n.d.1):

1. Inputs
2. Evaluation correlation
3. Area change
4. Transition potential modelling
5. Cellular automata simulation
6. Validation
7. Messages'dır.

3. Using QGIS MOLUSCE: Data Loading and Model Training

Inputs: LULC maps for the initial (Time1) and final (Time2) periods, and spatial changes such as elevation, slope, population density, road networks, and demographic information are loaded into QGIS. All this data is used to model and simulate the LULC change. All spatial datasets loaded here must have the same geometry (coverage and spatial resolution). If the spatial data is not identical, a "Check geometry" function is available in the "Inputs" tab.

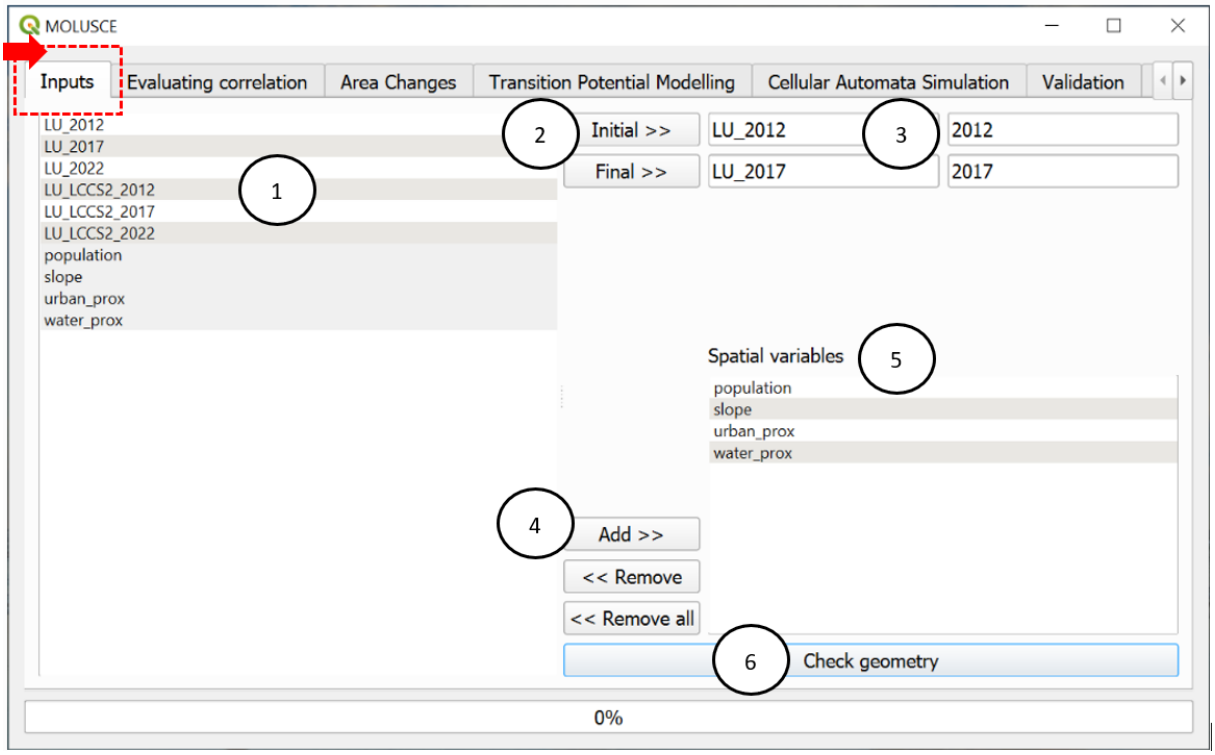

Figure 2. QGIS Molusce data loading phase

Step 1: This is the step where all raster data required for the LULC transformation is imported.

Step 2: This is the step where the Time 1 and Time 2 LULC maps are imported. The geometry of all files, including pixels, scaling, and projection, is created here.

Step 3: This shows the study years of the LULC transformation maps. If the plugin doesn't automatically add them, you can add them manually.

Step 4: This is the step where you add/remove the spatial variable data you want to add to the LULC transformation. This step includes adding or removing variables such as geographic data (slope, elevation, etc.) and cultural data (population, etc.).

Step 5: This is the tab where the LULC transformation spatial variables are displayed.

Step 6: This is the "Geometric Verification" button for the spatial data. This step checks whether the same geometry (spatial resolution) of the raster data is compatible.

Evaluation correlation: LULC checks the spatial changes correlation with three methods: Pearson Correlation, Crammer's Corfficient and Joint Information Uncertainty. In this tab, the extent to which spatial factors are related to each other is calculated. If the correlation between two factors is very strong, using only one may be sufficient.

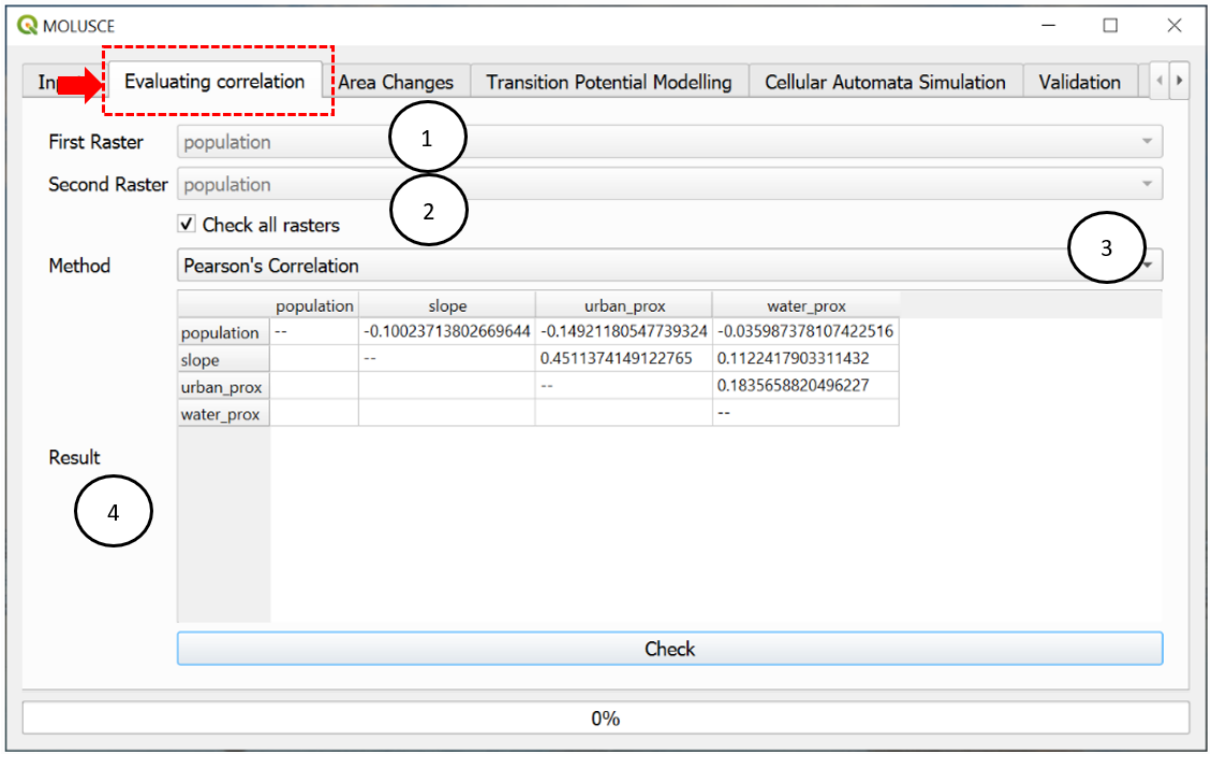

Figure 3. Calculating correlations of spatial data

Step 1: This is the step where the raster spatial data for the Time1 and Time2 periods are selected.

Step 2: This is the step where the spatial raster data for which the correlation is to be performed is selected.

Step 3: In the Method button, one of the three correlations is selected: Pearson Correlation, Crammer's Corfficient, and Joint Information Uncertainty.

Step 4: This is the tab where the correlation results for the spatial data are displayed.

Area change: It calculates the LULC change and transition probabilities between two time periods (T1 and T2). Transition matrices and land use change maps are generated for LULC. LULC data can be expressed in square meters, square kilometers, and hectares.

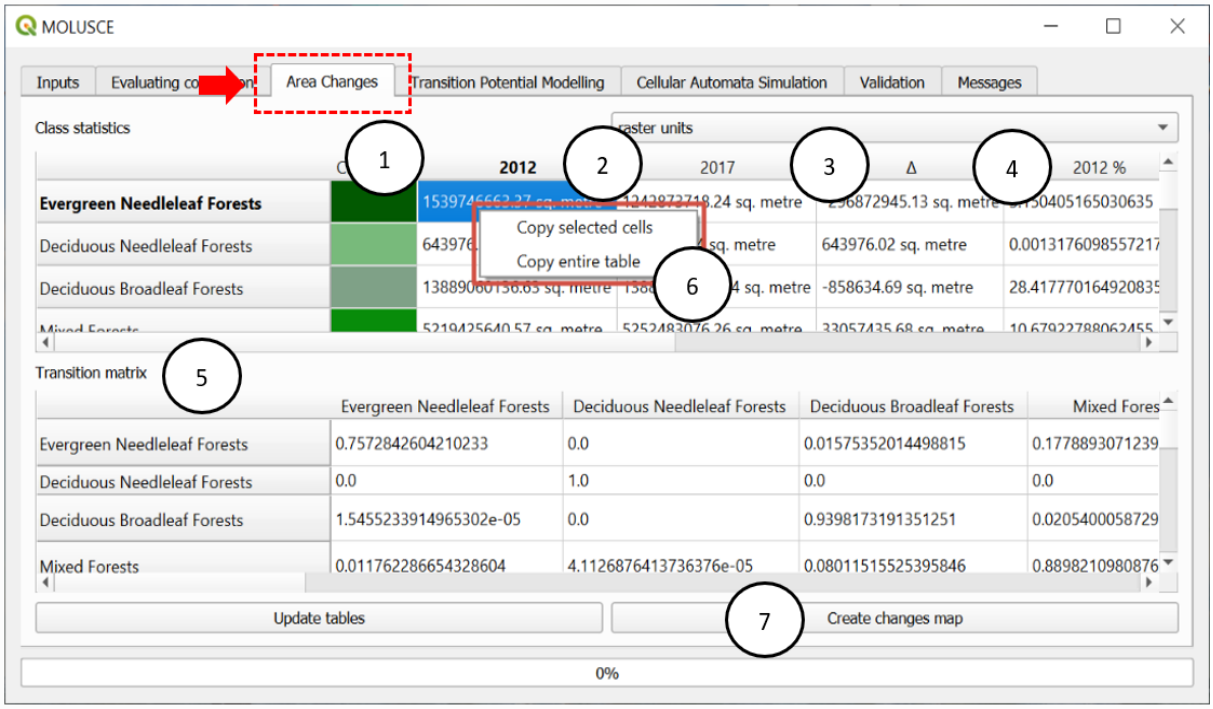

Figure 4. LULC area change table

Step 1: This gives the LULC areas at Time 1 in meters, hectares, etc.

Step 2: This gives the LULC areas at Time 2 in meters, hectares, etc.

Step 3: This gives the rates of LULC land cover changes at Time 1 and Time 2 in meters, hectares, etc.

Step 4: This gives the percentage of land cover changes between Time 1 and Time 2.

Step 5: This gives the percentage of land cover changes from Time 1 to Time 2, indicating the change in meters, hectares, etc. of each land cover.

Step 6: This shows the context menu by left-clicking on any cell, and the tables can be copied as a GeoTiff.

Step 7. This creates a map of LULC land change classifications from Time 1 to Time 2.

Transition potential modelling: One of four methods, namely Artificial Neural Networks (ANN), Logistic Regression (LR), Multi-Criteria Evaluation (MCE), and Weights Evidence (LR), is used to estimate the probability of LULC land cover transitions. Each method is used as input to calibrate and model the LULC spatial changes. The LULC estimate will ultimately show the value of kappa validation of the spatial change results.

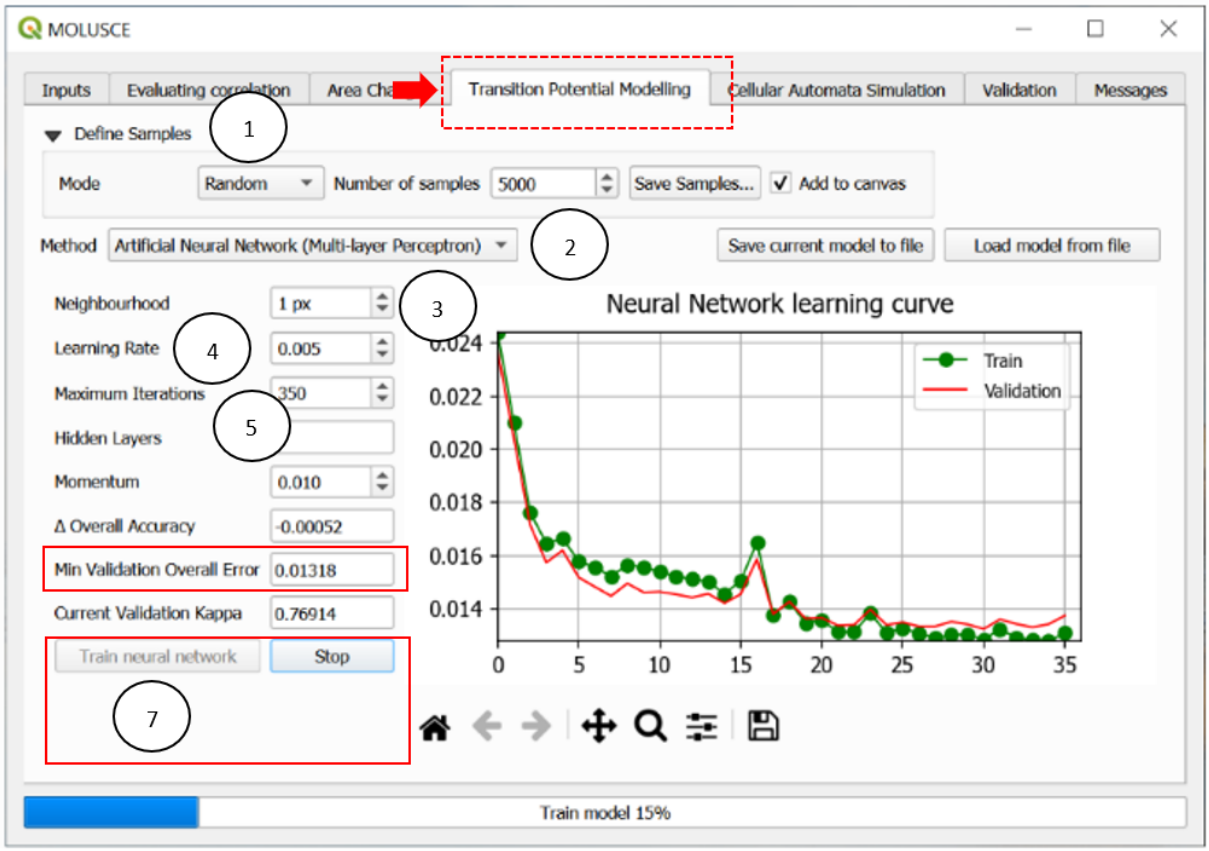

Figure 5. Training a neural network and typical learning curves

Step 1: This is the step where the model's sample parameters are selected to estimate the probability of land cover transitions. Here, the number of samples can be configured to configure the model's accuracy.

Step 2: Here, one of the four methods offered by the model is selected. Artificial Neural Networks (ANN) were selected in this step.

Step 3: Neighborhood; defines the number of neighboring pixels around the current pixel (typically, values of 1 or 0 are used).

Step 4: Learning rate (lower values result in a more accurate model).

Step 5: Maximum number of iterations; number of learning cycles. If the value is too high, overfitting may result.

Step 6: Hidden layers define the complexity of the model.

Step 7: Click Train neural network. You will see the learning curve and error curve in the graph. If you notice that training is not going well, you can click Stop and adjust the parameters. If training is successful, both curves will slope downward smoothly, and the current Validation Kappa value is around 0.8 or above.

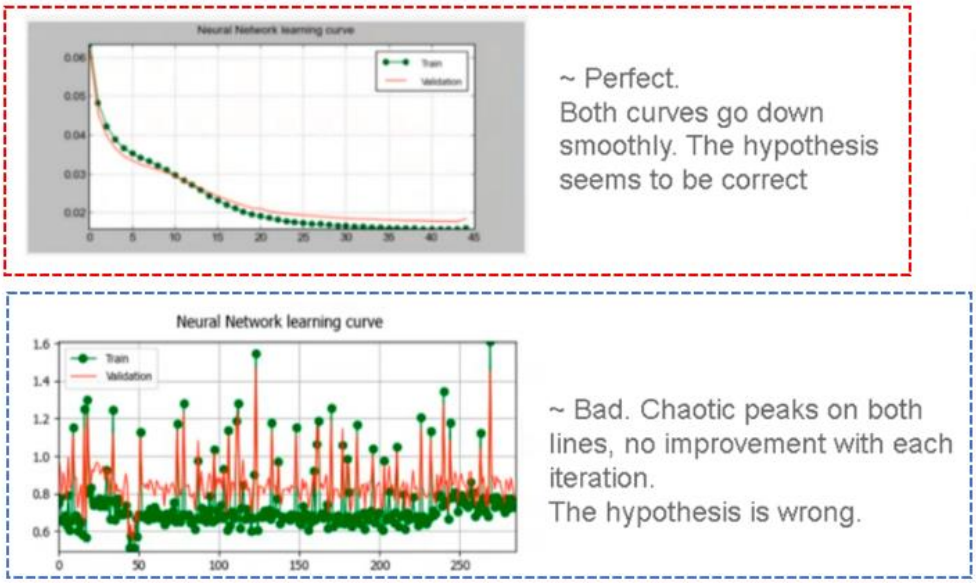

Figure 6. Typical learning curves (Source: NetGıs, n.d.1)

Cellular automata simulation: Shows transition potential maps, confidence function (experimental), and results of simulated LULC change maps. An estimated LULC map is produced by a modeling approach based on the Monte Carlo algorithm. This can be done after the kappa value in the previous stage meets the evaluation standard.

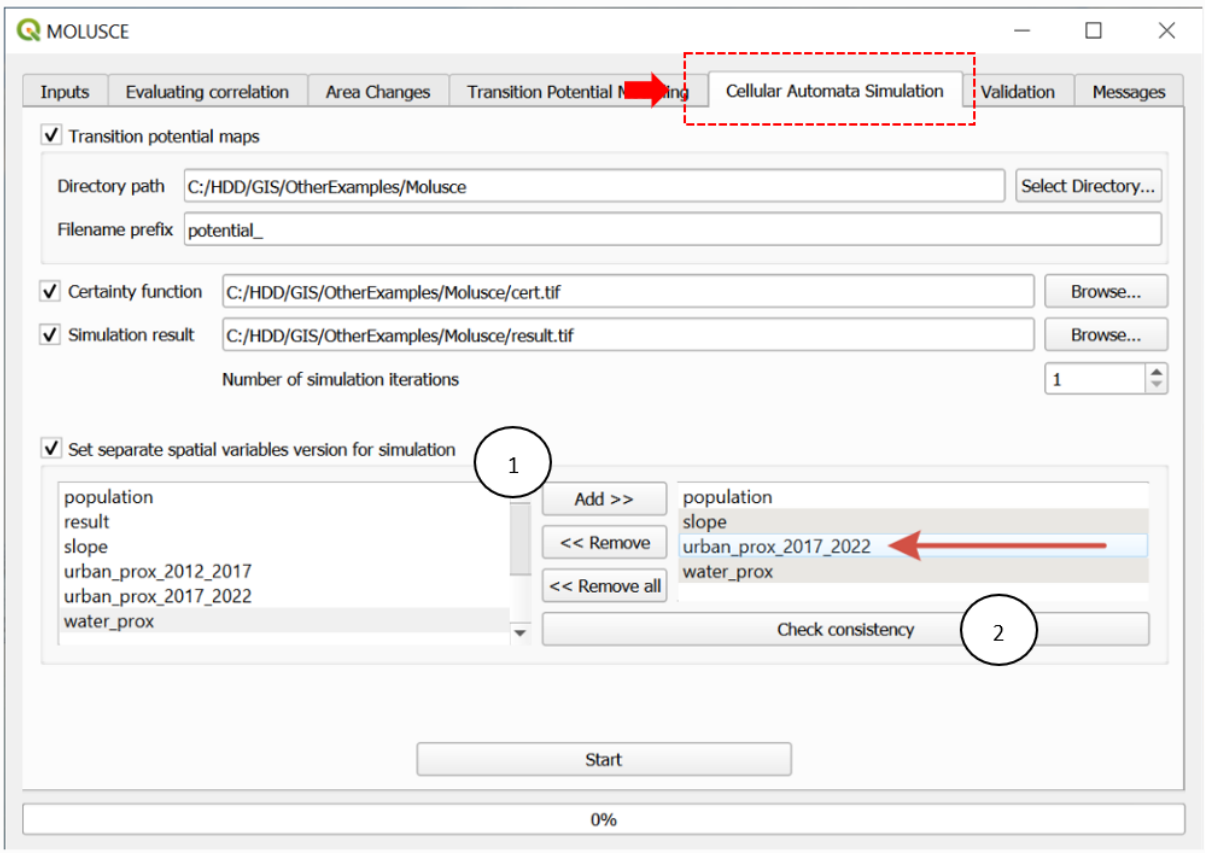

Figure 7. Simulation Settings

Step 1: LULC variables are selected in the input section.

Step 2: Click the start button to start the simulation. To start the simulation, the kappa value in the previous training model must be 0.8 or higher.

In this step, in addition to the simulated land use/cover map (NetGıs, n.d.1):

-The transition potential map indicates the probability or potential for a transition from one land use/cover class to another. Values range from 0 (low potential) to 100 (high transition potential).

-The precision function indicates the degree of estimation certainty. Values range from 0 (low precision) to 100 (high precision). A low precision probability means that a particular transition type was not sampled.

Validation: Verification of the performed transactions is determined by the Kappa statistics. Kappa values are a step that increases the transaction success statistic by alerting users to recalculate the accuracy of the transactions if they meet the standards.

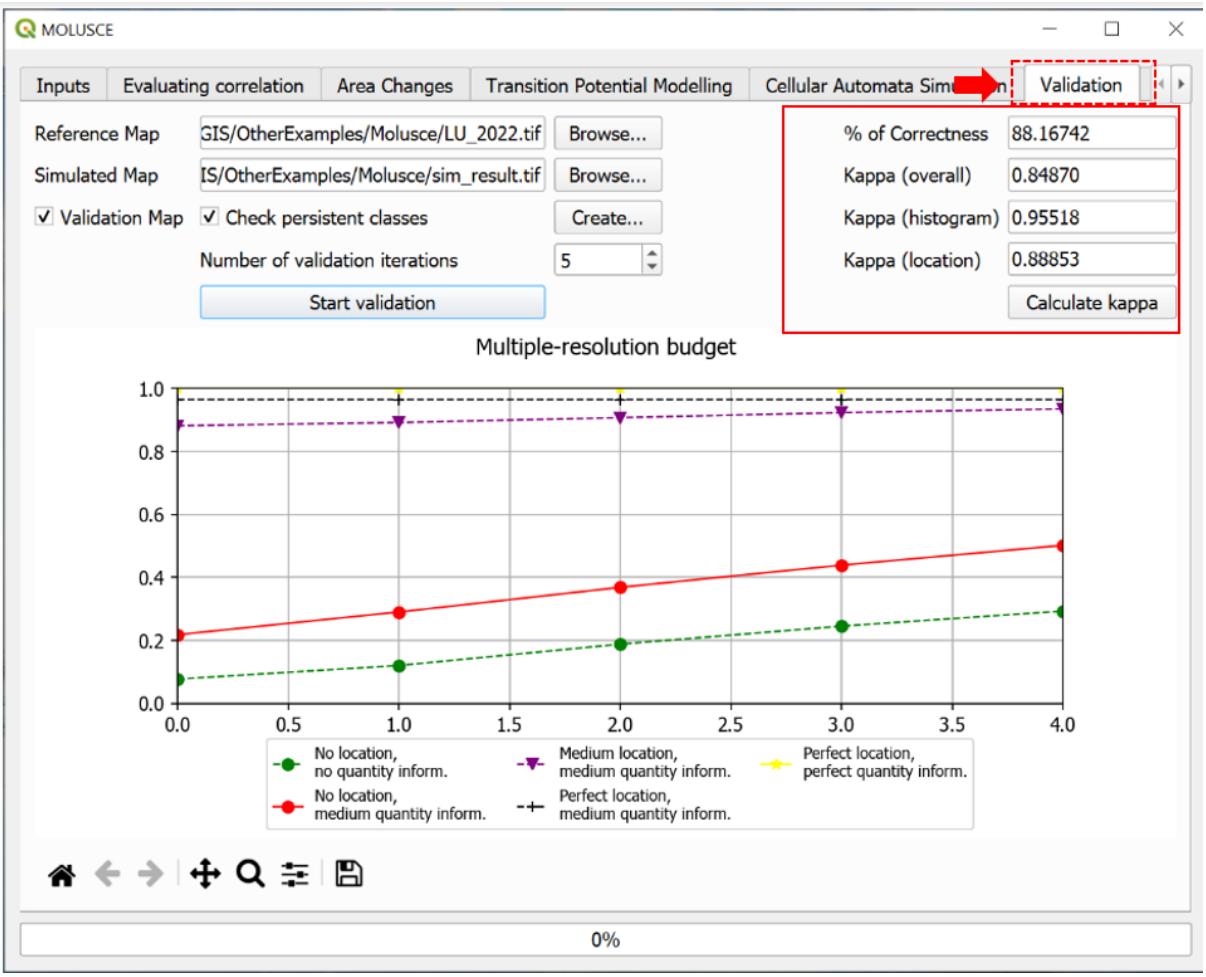

Figure 8. Mollusce kappa Validation

Messages: This tab is used to provide error messages or warnings to the user during modeling or simulation progress. It helps users access the margin of error and kappa success indicators by alerting them during process steps.

4. The pros and cons of the QGIS MOLUSCE plugin

Advantages offered to the user by the QGIS plugin Molusce:

- Molusce is an open-source software product of the QGIS program.
- Molusce is an easy-to-use and understandable software program.
- Molusce ASS is constantly developing the program. ASS offers new add-ons, technical support, and training opportunities.
- LULC provides convenience in determining temporal and spatial changes in change maps. It particularly enables the acquisition of data on temporal and spatial changes in land cover in terms of meters, hectares, or percentages.
- LULC facilitates the acquisition and creation of maps as well as statistical information for the future.
- LULC facilitates the acquisition of more accurate data by calculating not only high-resolution satellite images but also spatial changes such as elevation, slope, population density, road networks, and demographic information in obtaining spatial and temporal changes and future data.
- It includes Artificial Neural Networks (ANN), Logistic Regression (LR), Multi-Criteria Evaluation (MCE), and Weights Evidence (LR) methods that have been proven accurate and frequently used in scientific studies in obtaining future LULC data.
- Molusce warns the user when obtaining future data with LULC spatial and temporal change data, ensuring that the error margin and kappa success indicators ensure more accurate data acquisition.
- It presents data on future-oriented LULC maps in an easy-to-understand format. Providing tables of LULC data in meters, hectares, or percentage change significantly simplifies the interpretation of these data by urban planners, landscape architects, politicians, and decision-makers working in this field, making it easier to make sustainable urban planning decisions.

Disadvantages of the QGIS plugin Molusce:

- Preprocessing of the underlying spatial data used to generate LULC spatial and temporal data is necessary. For example, creating maps such as satellite imagery, DEM, and so on, based on the study area boundaries, land use classification of satellite imagery, processing into transportation maps, and other spatial map preprocessing are necessary.
- The pre-processing stages of the base spatial data used to create LULC spatial and temporal data are very time-consuming.
- The base used to create LULC spatial and temporal data causes the program to be unusable or take too much time if the spatial data is high resolution and there is not enough technical infrastructure.
- The geometric (coverage and spatial) resolutions of the underlying spatial data used to create LULC spatial and temporal data must be the same. Otherwise, Molusce LULC spatial and temporal data cannot be created.
- The Molusce program user must be proficient in one of the following methods: Artificial Neural Networks (ANN), Logistic Regression (LR), Multi-Criteria Evaluation (MCE), and Weights Evidence (LR).

5. Conclusion and Recommendations

In the 21st century, the increasing population, economic expansion, and the resulting urbanization process have seriously changed the existing land cover. The current change in land cover is primarily triggered by physical and socio-economic factors such as geography, increasing population, and economic expansion. However, socioeconomic development has a greater impact on urban expansion than overpopulation (Muhammad et al., 2022). The acceleration and growth of land cover change have raised concerns about climate change, food security, natural resource scarcity, etc. Therefore, LULC estimation plays a vital role in formulating plans to balance conservation, competing users, and development pressures (Kamaraj & Rangarajan, 2022). It is also inextricably linked to geography and development policies. Therefore, QGIS, a GIS tool, is an important tool for policy makers to analyze the change in LULC density and the socio-economic factors affecting it, with spatial and temporal land cover change and future LULC outcomes. Consequently, the QGIS plugin Molusce will help them to monitor spatial and temporal land cover change and future LULC data to promote environmental protection, sustainable development, and policies.

gulguzel@beykent.edu.tr

Abstract

Historical buildings are important works that provide information about the region's past, such as culture, architecture, socio-economic status, and way of life. However, these structures may experience material damage and deterioration over time. In this case, historical buildings can be re-functioned in a way different from their former use. In this study, traditional houses of Urfa were re-functioned for tourism and culture purposes and different design, function and concept suggestions were put forward. Şanlıurfa's historical architectural texture, consists of mansions and traditional Urfa houses. Urfa houses generally consist of two parts: the "harem" and the "selamlık" sections. In the selamlık section, there is a small courtyard, an iwan, and a large stable. The harem, the main section of the house where the household resides, is larger than the selamlık. Within the scope of this study, two separate registered houses were examined. These new functions include an ethnography museum, a restaurant and a boutique hotel. It is important that the interventions to be made are distinguishable from the original and preserve the characteristics of the historical building. In this regard, the designs have been made contemporary but compatible with the historical texture, identity, and culture of Urfa.

Keywords: Traditional Urfa Houses, re-functioning, interior architectural design

1. Introduction

Historical houses provide information on many topics, such as the architecture of the region where they are located, its past, the way of life of its people, its socio-economic status, the richness of its past living culture, and the level of technology achieved. However, these structures are not suitable for the contemporary life of today's people and cannot adequately meet their changing needs.

In order for these structures to keep pace with contemporary life, their layout plans are being disrupted by poor additions, many are being abandoned, and material damage is occurring. In this case, these historical buildings can be restored and re-functioned in a way different from their former use. These structures need to be protected to ensure their continuity and to be passed on to future generations, making them sustainable and livable. (Kutlu & Ergün, 2021, Hattap 2023, Aydın & Okuyucu, 2009).

In the re-functioning processes, the basis was to preserve the building in accordance with its original construction state and to determine compatible functions that would also carry the identity of its period. It is also important to preserve the characteristics of the historical building and to distinguish the interventions from their original state during the restoration and re-functioning processes. (Kutlu & Ergün, 2021).

In this study, traditional houses in the central Eyyubiye district of Urfa were re-functioned for tourism and culture purposes and different design, function and concept suggestions were put forward in accordance with the Conservation Development Plan.

Şanlıurfa is one of the oldest settlements in Mesopotamia, located in the center of GAP in the Southeastern Anatolia Region. Due to its proximity to rivers and its location on trade routes, it has maintained its strategic importance throughout history. (Yıldız & Rızvanoğlu 2012, p. 17,

Yıldız & Rızvanoğlu, 2014, p. 22). It has also gained importance in the field of tourism with its historical, cultural, and religious significance.

Excluding monumental structures the historical architectural texture of Şanlıurfa consists of mansions and traditional Urfa houses. More than 500 of these houses are registered as ancient monuments by the Ministry of Culture and Tourism (Kürkçüoğlu & Kürkçüoğlu, 2017, p.67). These structures have a history of 100-120 years.

Traditional Urfa Houses are located in a complex and adjacent layout. The width of the streets varies from 2.5 to 3.5 meters, which provides protection from high temperatures in summer. The houses in Şanlıurfa are entered through quite magnificent doors from narrow streets. (Akkoyunlu, 1988).

Urfa houses generally consist of two parts: the "harem" and the "selamlık" sections. In the selamlık section, there is a small courtyard called (hayat), an iwan, (eyvan), a large camel stable (develik) and a toilet. Urfa houses are planned as introverted, closed spaces. The harem section, which is the main part of the house where the household lives, is larger and more equipped than the selamlık section. In the middle of the courtyard, there is a marble pool, a well, and a "flower bed" containing one or more trees such as fig, mulberry, pomegranate, orange, oleander, and vine. (Kürkçüoğlu & Kürkçüoğlu 2017, p.67, Orhun, 1999).

The main determining element of the plan in the Traditional Urfa House is the iwan. The iwan is a rectangular space, a few steps above the courtyard level, with an open and arched facade facing the courtyard, windows on the side surfaces, a closed rear surface, and usually covered with a vault. On the north side of the harem courtyard, there is a “winter iwan” facing south with a room on either side, while on the south side, symmetrically, there is a “summer iwan” facing north with “living rooms” on either side. The iwans and rooms are sometimes 1-1.5 meters above the ground and in their lower parts there are cellar rooms called "zerzembe". In traditional Urfa houses, no other part of the house is given as much importance as the eyvan.

On the other sides of the harem courtyard, there are sections such as the kitchen (tandırlık), the bathhouse (hamam) and the woodshed. (Kürkçüoğlu & Kürkçüoğlu, 2017, p.67). The main building material of the load-bearing masonry walls of Urfa houses is white colored limestone. Windows and doors are wooden (Akkoyunlu, 1988).

2. Studio Works

Within the scope of this report, two separate houses named Abuzer Duran and Bakır Dellalbaşı, located in the areas specified as II. Group Registered Immovable Cultural Heritage in the Şanlıurfa Conservation Development Plans were examined.

Students of Akdeniz University Department of Interior Architecture and Environmental Design were asked to detail and re-function the restoration projects as interior architecture projects. As a result, Urfa's traditional houses were re-functioned for tourism and cultural purposes, and different design, function, and concept suggestions were put forward.

2.1. Abuzer Duran House

It is the first house examined.

It is a 2-storey building. On the ground floor, there are 3 iwans, 2 large living rooms, 2 cellars (one small and one large), a stable, a kitchen and a large courtyard. The terrace on the upper

floor is accessed via a stone staircase, and the main room is also accessed from this terrace. The other spaces have a soil roof.

There are two suggestions for this house. In the first suggestion, it was decided that the function would be an ethnography museum and its concept would be the tree of life. This choice was made because Urfa has hosted many civilizations, and the tree of life motif was used in these civilizations. The tree of life forms the vertical symbolism of life ever-evolving, ascending to heaven. Trees symbolize settledness and rootedness because they are rooted and settled in a certain area and cannot migrate. They symbolize life, beauty, eternity, the immortality of the universe and the axis of the earth. The tree of life form has been used in various stylized motifs in stone, wood, pottery, tile work, weaving, glass, illumination, miniature, literature and music. (URL 1) The tree of life motif has also been stylized and used in our carpets and rugs (Figure 1).

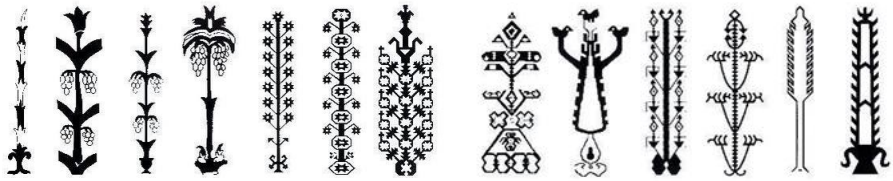

Figure 1. Tree of life motifs in Turkish carpets and rugs (URL 2)

The tree of life in this project, was used abstractly as a partial top cover of the courtyard and on the walls. (Figure 2, 3, 4, 5).

Figure 2. Section from the courtyard, Tree of life on the top cover and walls

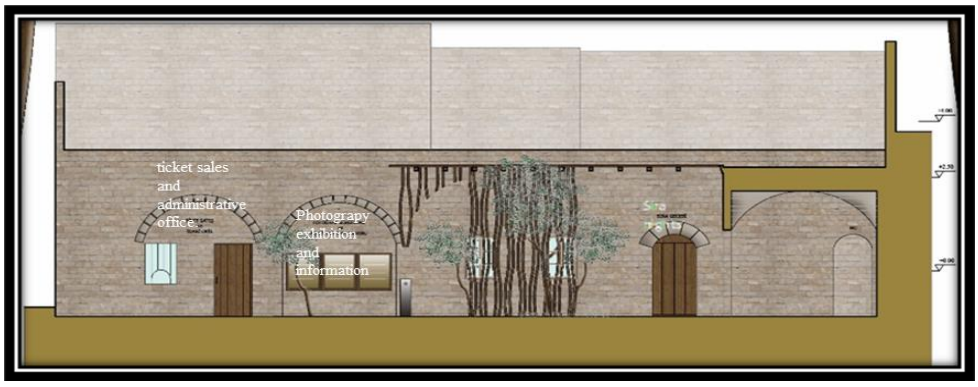

Figure 3. Section from the courtyard, Tree of life on the partial top cover of the courtyard and on the wall

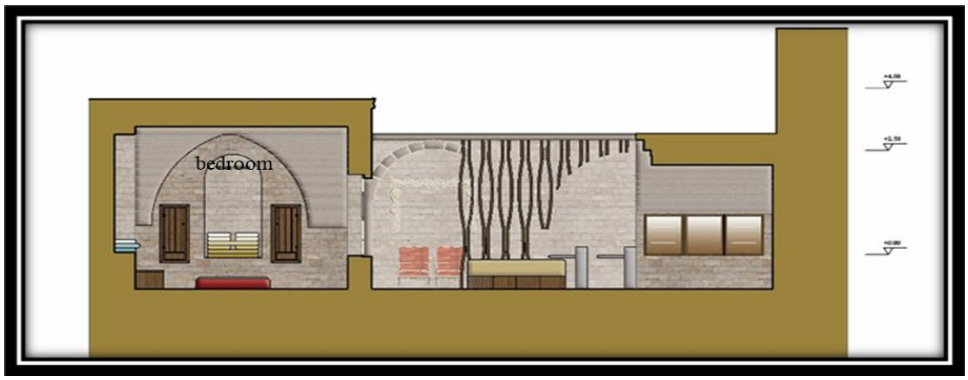

Figure 4. Section from the courtyard and iwan. Tree of life motif in the courtyard

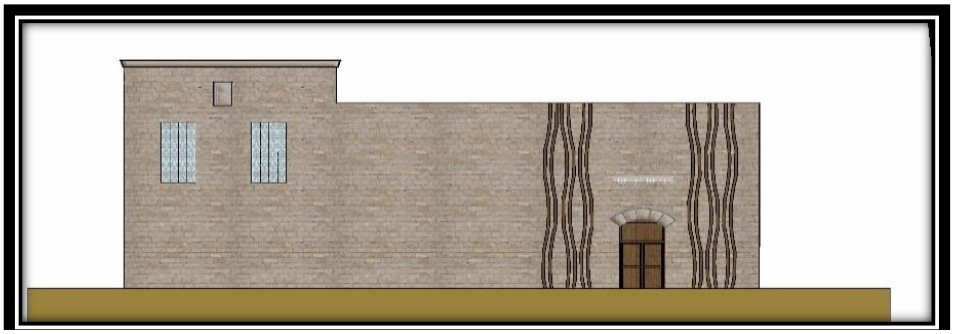

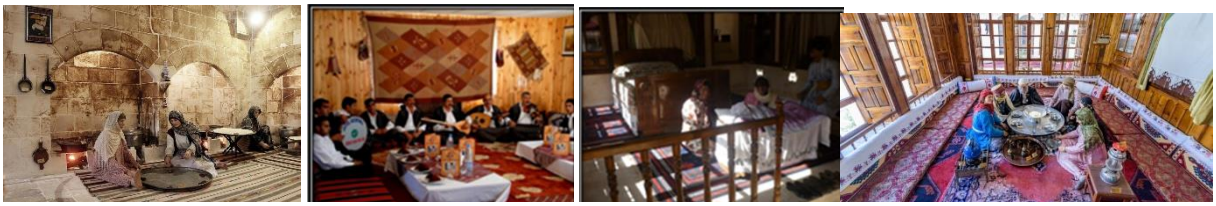

Figure 5. Elevation from the street. Tree of life motif on the outer wall

In this museum, an attempt was made to reflect the house culture of Urfa; kitchens, the sira nights (sıra gecesi), bedrooms, and living rooms held in Urfa were described (Figure 6). In Şanlıurfa, "sıra nights" refers to gatherings where a group of friends meet once a week. These gatherings are a learning environment where music is taught and performed according to the master-apprentice tradition (Kürkçüoğlu & Kürkçüoğlu 2017, p.93). The goal is to create a museum that appeals to all five senses rather than an ordinary museum.

Kitchen Sira Night Bedroom Living and

Figure 6. House Culture of Urfa (URL 3, URL 4)

In this project one of the three iwans on the ground floor has been preserved as a photography area with local costumes, the second as an exhibition area, and the third as a photography exhibition and information area. The small cellar was used as men's and women's toilets, and the stable was used as a place for sira night and folk dances. The living room is decorated as a dining and sitting, and the other living room is decorated as a bedroom. The large cellar was designed as a souvenir shop, and the kitchen was designed as a ticket sales and administrative office. The bathhouse is arranged as a local clothing wardrobe. There are orange, lemon and vine trees in the courtyard (Figure 7).

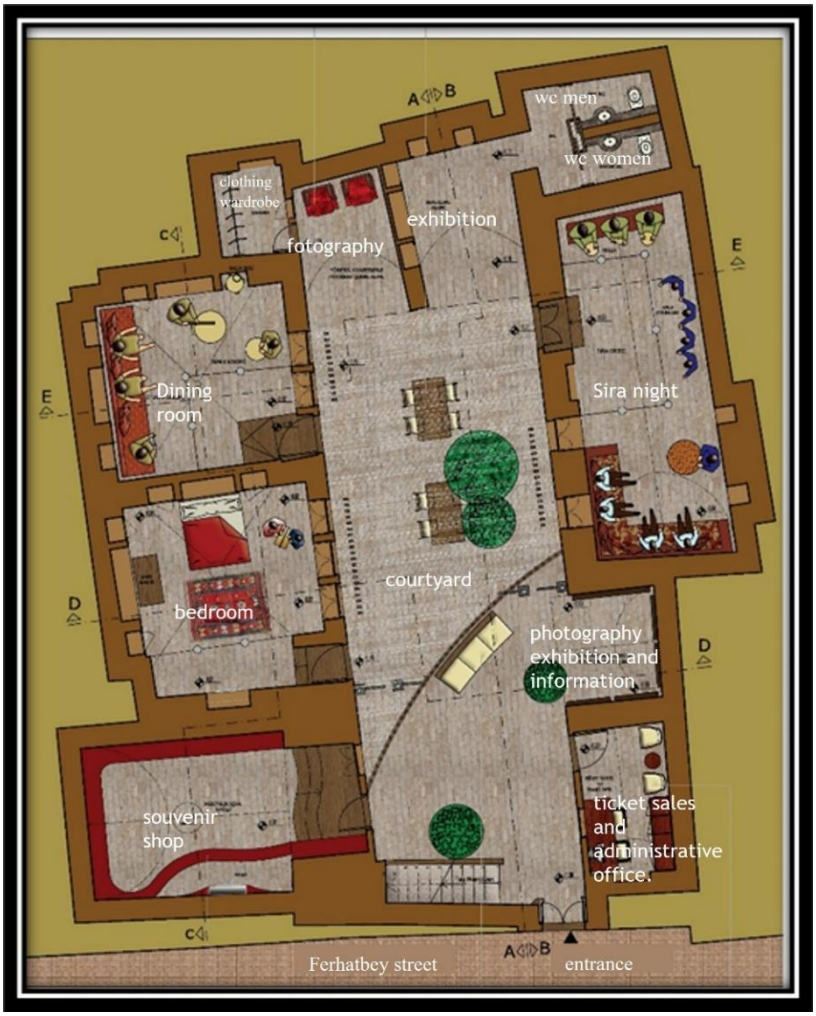

Figure 7. Ground Floor Plan

The main room on the upper floor is used as a food and beverage sales and the terrace in front of it is sherbet serving place. On this floor, the partial upper cover of the courtyard, symbolizing the tree of life, is also seen. (Figure 8)

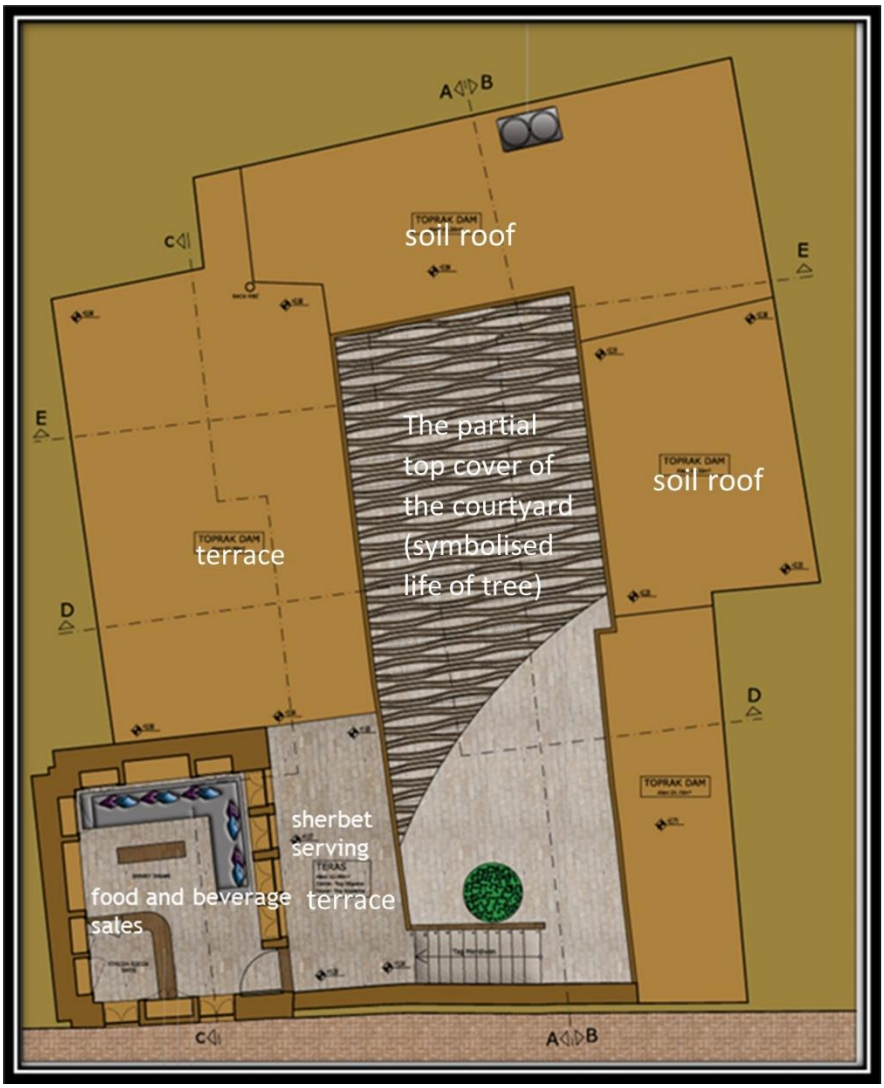

Figure 8. Upper floor plan

In the second suggestion for the Abuzer Duran House, it was decided that the function would be a restaurant and that its concept would include biorhythms and lines. This concept was chosen by establishing its association with food and beverage rather than with Urfa. When people are hungry, their biorhythm balance may change, they may have difficulty in mental perception, show physical weakness, and become aggressive in terms of sensitivity. Therefore, when people eat, their feelings of hunger disappear, and their mental and physical sensitivities improve. In the project, rhythmic line designs were also applied partialy to the cover of the courtyard, and walls, the interiors of the iwans, wall niches, and the legs of tables and coffee table, taking inspiration from biorhythm lines (Figure 9, 10, 11, 12).

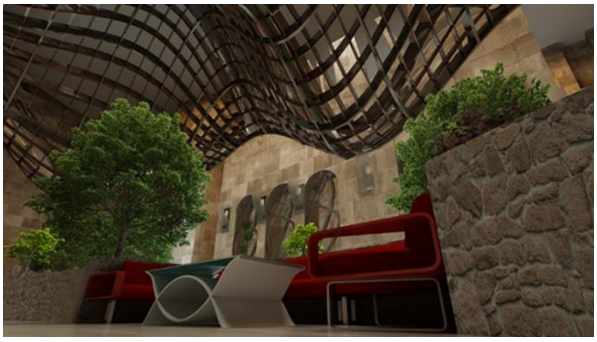

Figure 9. Elevation from the courtyard, biorhythm lines on the top cover

Figure 10. Biorhythm Lines in the Iwan

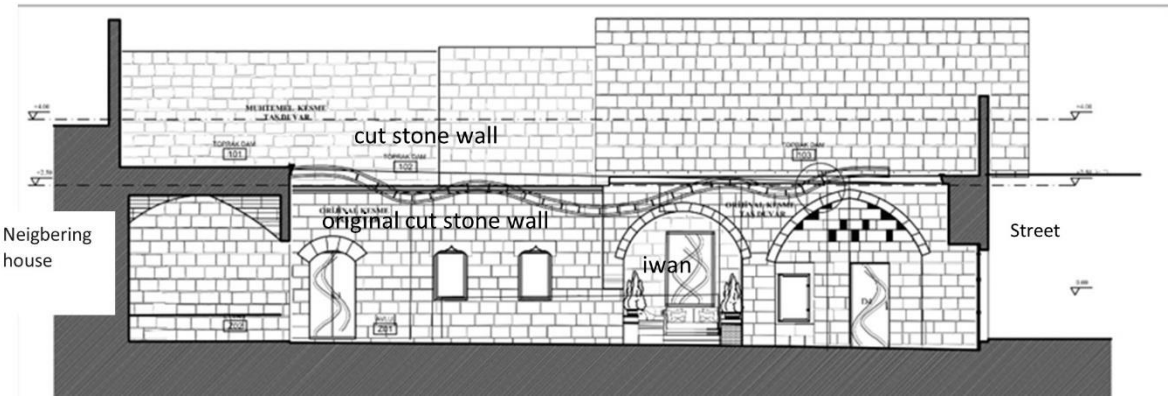

Figure 11. Section from the courtyard. Biorhythm Lines on the top cover and iwan

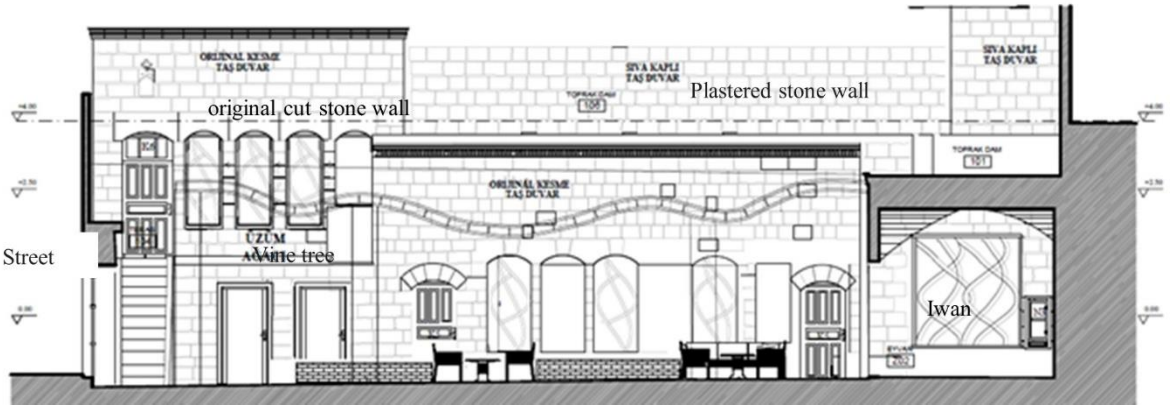

Figure 12. Section from the courtyard, biorythm lines on the top cover and iwan

Three of the iwans are designed as tea and coffee drinking and resting areas. The two living spaces were combined by opening a doorway in the wall between them and decorated as the main dining area. The front part of the large cellar is designed as a men's and women's toilets, the back part accessible from the main dining room is designed as a dining area with cedars (sedir). The stable was designed as the main kitchen, the small cellar designed in its original

function, the kitchen as the cass register place. The courtyard was also designed as an open eating and drinking area, preserving the trees (Figure 13)

Figure 13. Ground Floor Plan

The main room on the upper floor was used as the manager and accounting room (Figure 14).

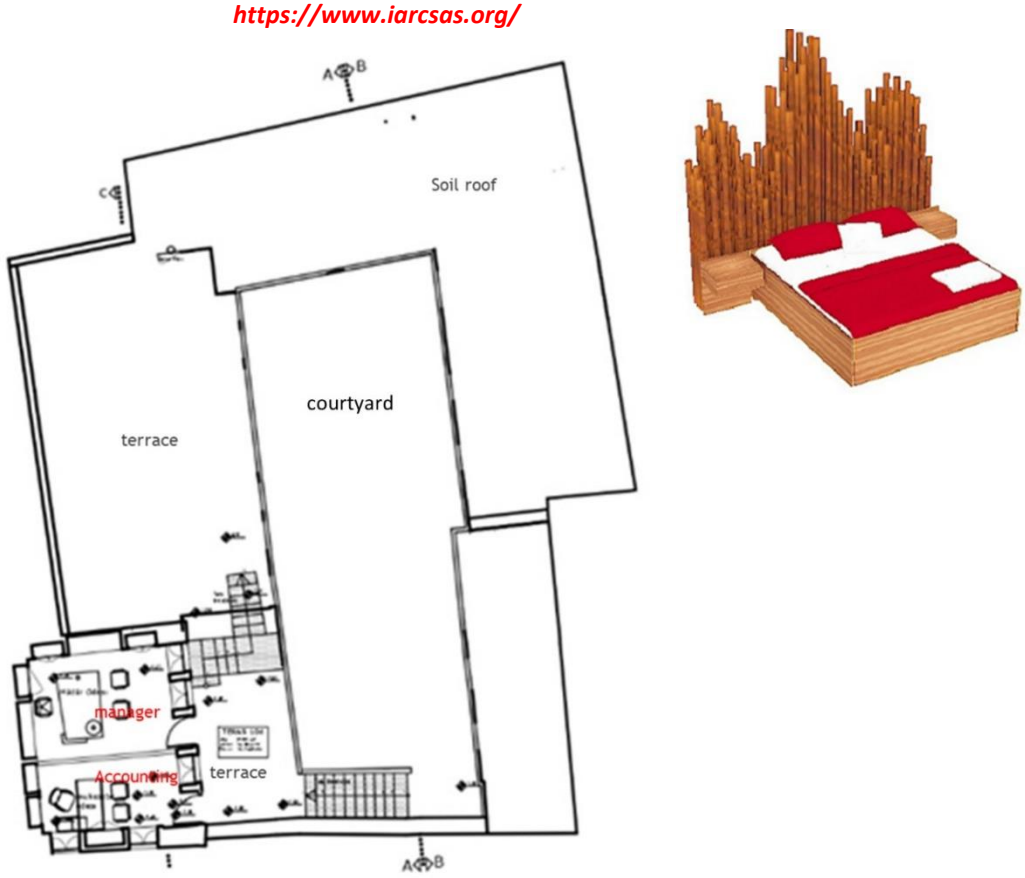

Figure 14. Upper Floor Plan

2.2. Bakır Dellalbaşı House

It is the second house examined.

It is a 3-storey building. On the ground floor, there is one iwan, two rooms on either side, six additional living rooms, a kitchen, a toilet and bathroom, and a large courtyard with a mandarin tree in the middle. Access to the upstairs rooms and terrace is provided by a stone staircase in front of the bathroom and toilet. The other rooms on the ground floor have a terrace above them. There is also a cellar in the basement, accessed via a stone staircase.

In this project, Boutique Hotel was chosen as the function and fire and water as the concept. According to the legend from the Babylonian period, Prophet Abraham was thrown into the fire by the Babylonian ruler Nimrod. When Abraham was about to fall into the fire, God said, "Send coolness and safety to Abraham," and the fire retreated in all directions and turned into water (Kürkçüoğlu ve Kürkçüoğlu, 2017, p.92). Based on this event, fire and water were symbolized in the design. While the spread of fire is from the ground upwards, the flow of water is from top to bottom. For this reason, fire form was used in the ground floor rooms and water form was used in the upper floor rooms.

Zigzag forms were obtained during the abstraction process, and these forms were achieved in the rooms on the ceilings with wooden pipes that create a warm effect. Wood has also been chosen for the furniture (Figure 15, 16)

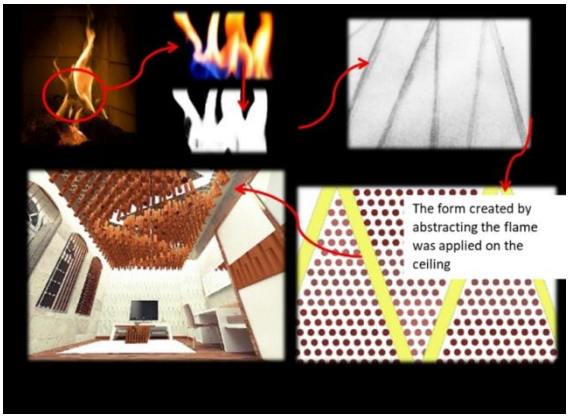

Figure 15. Fire abstraction process and design approach

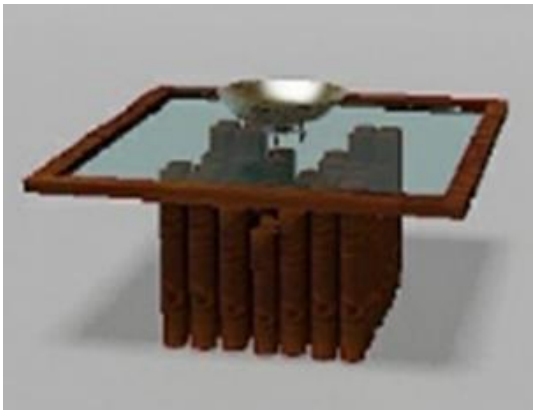

Figure 16. Wooden bed and coffee table symbolizing fire

The wave motion of the water theme is achieved with metal and glass materials on the ceilings and with light effects, aiming to create a water-like sensation. The furniture in these rooms is also made of metal and glass (Figure 17, 18).

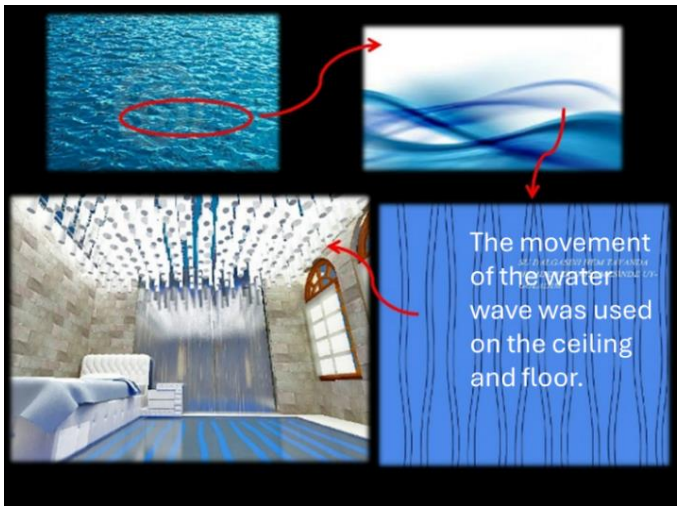

Figure 17. Water abstraction process and design approach

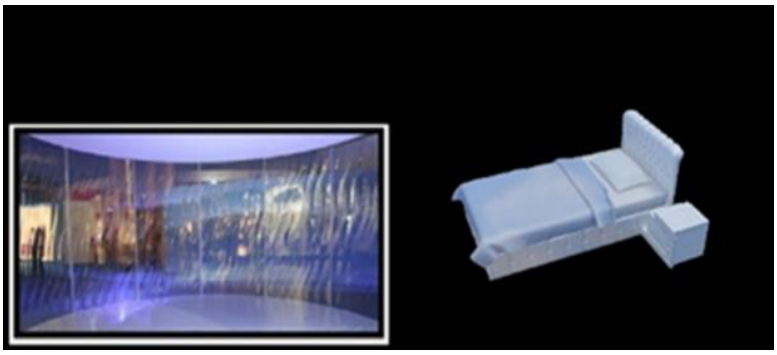

Figure 18. Metal and glass furniture symbolizing water

The rooms on the ground floor have been converted by adding a bathroom to each, resulting in two standard bedrooms and two suite rooms. The iwan has been preserved as a resting place, and one of the rooms on either side has been designed as an administrative office. The bathroom and toilet is arranged as a reception and a suite room's bathroom. The space that was originally a kitchen was left with the same function. Courtyard was preserved with the tree inside, creating an open dining area (Figure 19)

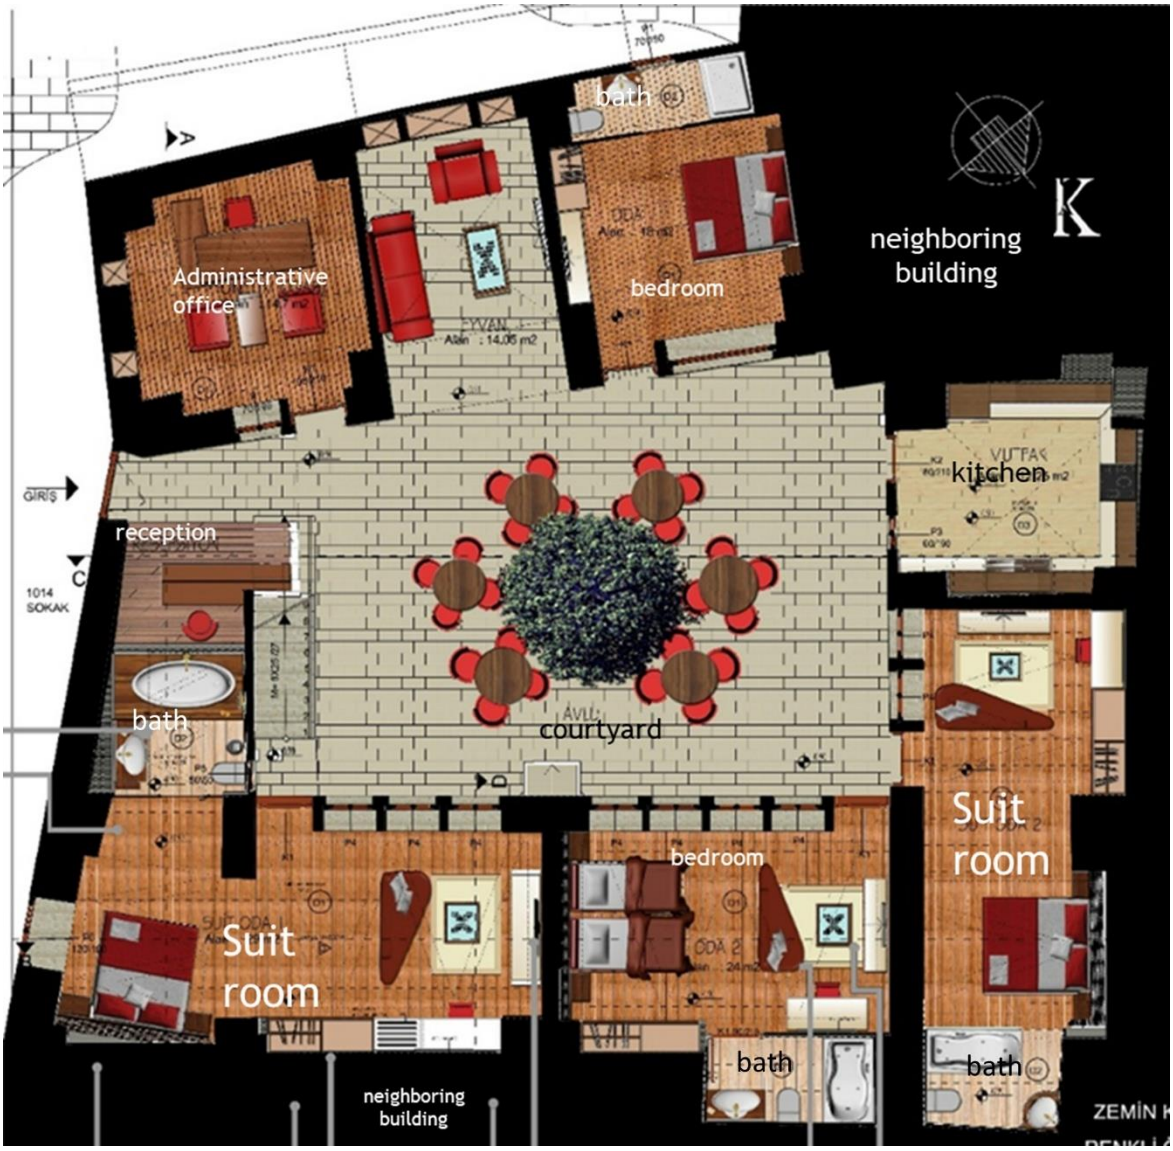

Figure 19. Ground Floor Plan

The two rooms on the upper floor are also arranged as bedrooms with bathrooms, and the water concept is also processed on the ceiling with tempered glass and metal suspended ceilings (Figure 20)

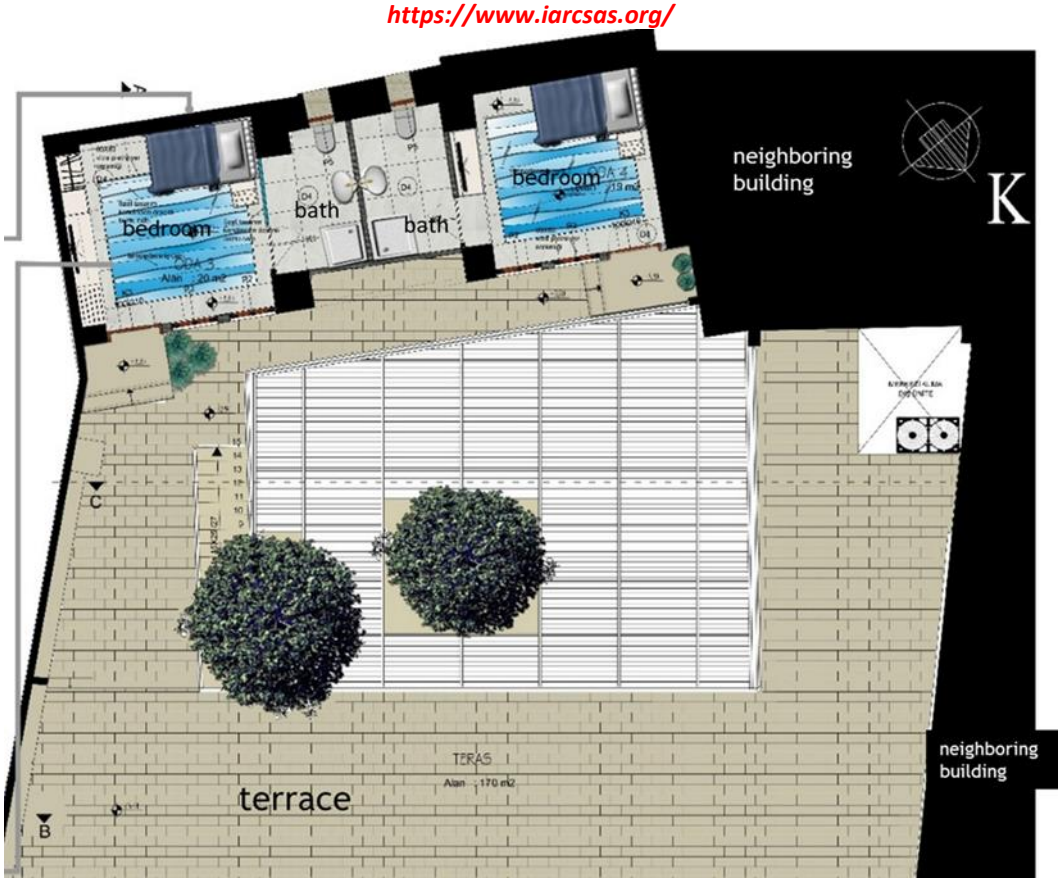

Figure 20. Upper Floor Plan

The cellar, which is descended from the courtyard via a stone staircase, is also furnished as the hotel's restaurant, with both table seating and corner seating (Figure 21)

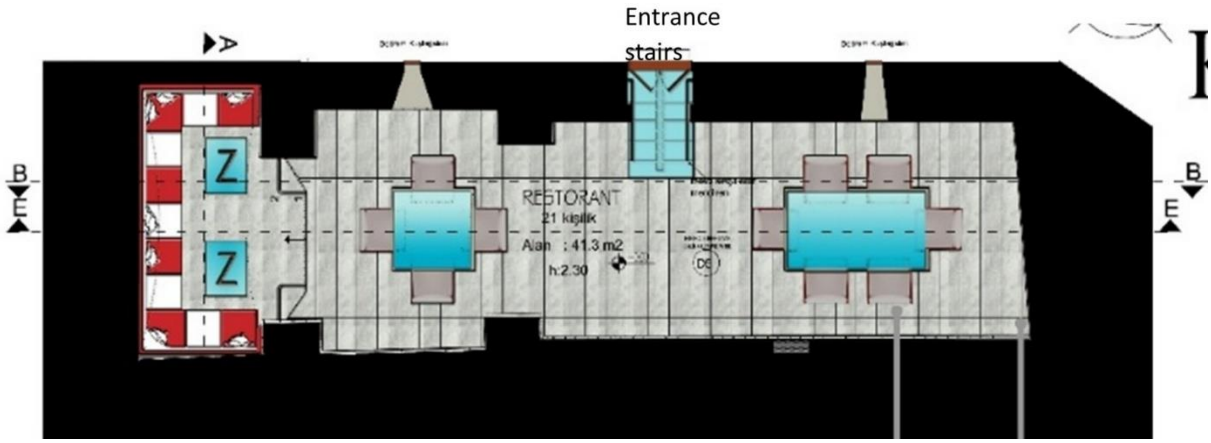

Figure 21. Basement Floor Plan

Findings and Discussion

Function and concept suggestions were made for two separate traditional Abuzer Duran and Bakır Dellalbaşı houses examined in the study. It is important that these suggestions comply with the traditional architecture of Urfa. The ethnographic museum, restaurant and boutique hotel suggestions have been re-functioned without changing the plan schemes but in accordance with modern life. If these houses are not restored and are abandoned, they are subject to structural deterioration. For this reason, it is important to restore these structures and introduce them to public and tourism. Therefore, in this study, interventions and functional changes appropriate to the architecture were made based on the characteristics of traditional Urfa houses with interior architectural designs.

- It was ensured that the selected concepts were specific to Urfa and compatible with the function.
- No load-bearing walls were demolished; Only in the main dining room of the restaurant project, a door has been opened in the wall between the two living rooms.
- The iwans were not closed and were carefully preserved.
- Only partial and perforated roof coverings have been added to the courtyard, the trees within have been preserved, and its contribution to the overall design has not been lost.
- An effort was made to ensure architectural compatibility of interventions and functional changes according to the characteristics of these traditional buildings.

Conclusion and Recommendations

Urfa traditional houses are generally low-comfort spaces where poor people stay as tenants. Many of the homeowners were forced to abandon their homes to their fate because their economic situation was inadequate and they were unable to carry out the restoration work required. (Aras & Yıldırım, 2003). Most of these houses were divided, especially due to inheritance, with the selamlık section remaining in the hands of one heir and the harem section remaining in the hands of another heir. As a result, unsanitary toilet, bathroom and kitchen extensions had to be built. If these houses are not restored and are abandoned, they are subject to structural deterioration. For this reason, it is important to restore these structures and introduce them to public and tourism. In Şanlıurfa, there are many examples of registered mansions and houses that have been converted into museums, boutique hotels, and restaurants. Some of these mansions and houses have been restored by the Şanlıurfa Education, Culture, Arts, and Research Foundation (Şurkav), some by the Şanlıurfa Governorship, and some by the Şanlıurfa Municipality.

The other unrestored residences should be taken up by relevant organizations or dedicated businesspeople as soon as possible, preserved as cultural heritage, and re-functioned when necessary, which will contribute to Urfa's identity as a tourism and cultural center.

In this study, re-functioning was carried out based on the principle of preserving the building in its original form and determining compatible functions that would also carry the identity of the period. It is of great importance that the interventions to be carried out preserve the characteristics of the historic building.

Finally, with new functions and concepts suitable for contemporary living we concluded that the design of the Ethnography Museum, Restaurant and the Boutique Hotel could contribute to the preservation and sustainability of the building and to culture and tourism.

Thanks and Information Note

I would like to thank Akdeniz University Interior Architecture and Environmental Design students for their dedicated work on this project.

Abstract

Life cycle assessment is an environmental management tool that holistically and systematically analyzes and evaluates the impacts on the environment of a product, system, or building elements. LCA includes all activities from raw material extraction to end-of-life disposal. The construction sector plays a significant role globally in terms of energy consumption and environmental emissions, and the contribution of transportation to environmental impact is a factor that must be considered. This study aims to examine the environmental impact of the transport factor in the context of transportation distances and to investigate the impact of transportation scenarios on the environmental impacts of load-bearing systems. In this study, alternative structural systems are analyzed for different transport distances. GaBi thinkstep LCA software is used as the analysis tool. The data obtained show that transportation distances have a significant impact on the environmental performance of structural systems. It is an important factor that affects the advantage of structural systems compared to each other. In this respect, the importance of including transport effects in LCA analyses is emphasized.

Keywords: Structural systems, life cycle environmental impact, transport factor.

1. Introduction

The construction industry accounts for 40% of carbon emissions and 36% of global energy consumption, and this rate is increasing. In addition, a significant part of the built environment consists of buildings. In this direction, the construction sector has great potential and importance in minimizing its carbon footprint and maximizing its environmental performance (Guggemos & Horvath, 2005; Kim et al., 2013; Oladazimi et al., 2020). Compared to other building elements, structural systems constitute the largest percentage of a building (Stek et al., 2011). In this respect, the evaluation of structural systems in terms of environmental impact is of great importance. Measuring and evaluating the environmental impacts of a building element or component is provided by life cycle assessment (LCA) as a powerful environmental management tool. Life Cycle Assessment Principles and System Boundaries are defined in EN 15978:2011 (Figure 1).

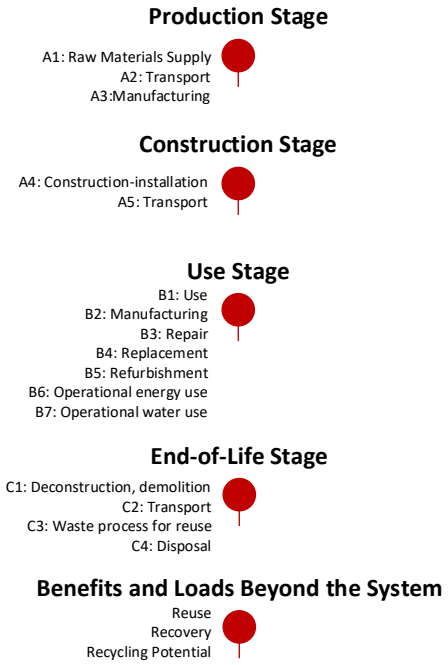

Figure 1. Life Cycle Assessment Principles and System Boundaries in EN 15978:2011 (European Committee for Standardization, 2011)

The transport factor, which is included in almost all modules of the life cycle systematics, is a parameter that must be clearly evaluated (Dvorsky et al., 2023). Transport factors can remain implicit in LCA studies. Studies evaluating transport effects are quite limited. In this respect, the study investigates the effect of the accessibility factor on the life cycle environmental performance of load-bearing systems.

2. Materials and Methods

First of all, the life cycle assessment system boundary for structural systems is defined. The basic modules and sub-parameters that constitute the system are explained. In line with the defined framework, two structural system alternatives, steel and reinforced concrete, are analyzed for two different transportation scenarios using GaBi thinkstep LCA software. Transport scenarios are shown in Table 1. The GaBi is an LCA software developed to contribute to sustainability and reduce environmental emissions (e.g., carbon emissions) (Sphera, n.d.). The findings obtained within the scope of environmental impact are evaluated and explained.

Table 1. Transport Scenarios for Structural Systems LCA Analysis

Scenarios	Transportation to Construction Site	Transportation to Recycling Areas	Transportation to Landfill Areas
Scenario 1	100 km	100 km	100 km
Scenario 2	1000 km	1000 km	1001 km

3. Findings and Discussion

The life cycle assessment framework for the structural systems defined within the scope of the study is shown in Figure 2. The framework does not include the use module (B1-B7). Structural systems do not directly affect the operational energy of a structure. Furthermore, the inclusion of modules such as maintenance and repair in the assessment requires a static performance analysis for structural systems. The International Energy Agency (IEA) states in its Annex 57 that scenarios regarding maintenance, repair, and reuse of structural systems must be planned (IEA ANNEX 57, 2016). In addition, the lifespan of a structural system is considered one hundred (100) years in international standards, and the lifespan is generally accepted as fifty (50) years in the life cycle approach. The framework defined from this perspective includes the production, construction, lifespan, LCA energy, and emission recovery modules.

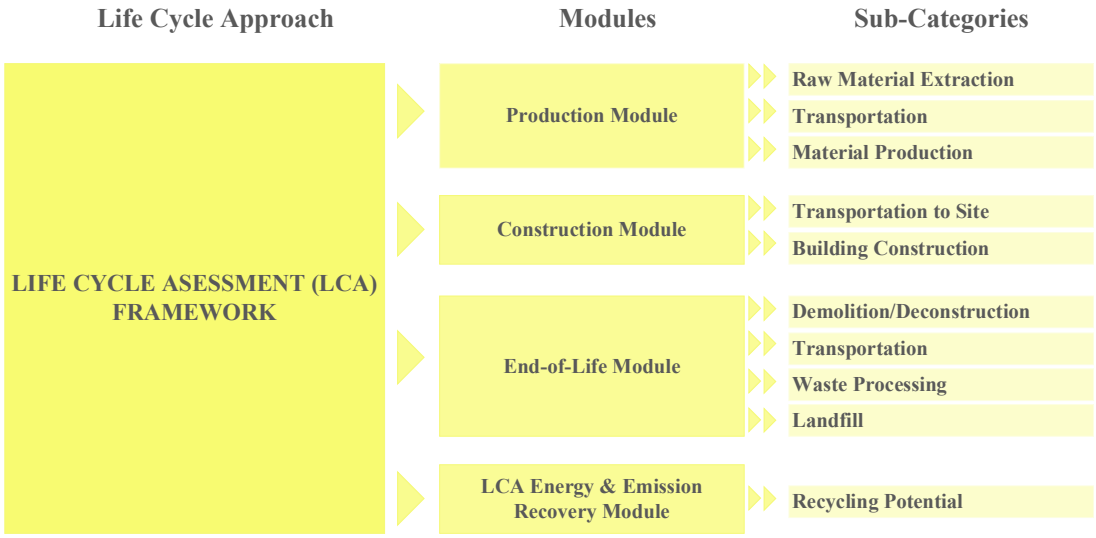

Figure 2. The life cycle assessment system boundary for structural systems (Created by the authors)

In line with the defined system, the steel and reinforced concrete structural system is analyzed in terms of lifecycle energy and carbon emissions using the GaBi thinkstep software. Information regarding steel and reinforced concrete frame structures is shown in Table 2. The modeling of the reinforced concrete structural system in the GaBi software is shown in Figure 3, and the modeling of the steel structural system is shown in Figure 4.

Table 2. The life cycle assessment system boundary for structural systems

Parameter	R.C. Framed Building	Steel Framed Building
Building type	Residential Building	Residential Building
Study period	50 years	50 years
Gross area	600 m^2	600 m^2
Building story and total height	8-story and 24m	8-story and 24m
Structural frame type	R.C. Frame	Steel Frame
Structural materials	Concrete, rebar	Structural steel, bolt

Building core	Reinforced Concrete	Steel
Core materials	Concrete, rebar	Steel, bolt
Flooring type	R.C. flooring	Composite flooring
Flooring materials	Concrete, rebar	Concrete, rebar, steel sheet
Concrete amount (t)	4726 tons	2000 tons
Rebar amount (t)	98 tons	33,9 tons
Structural Steel (t)	-	260 tons
Bolt connection amount (t)	-	0,5 tons
Steel sheet amount (t)	-	38, 4 tons

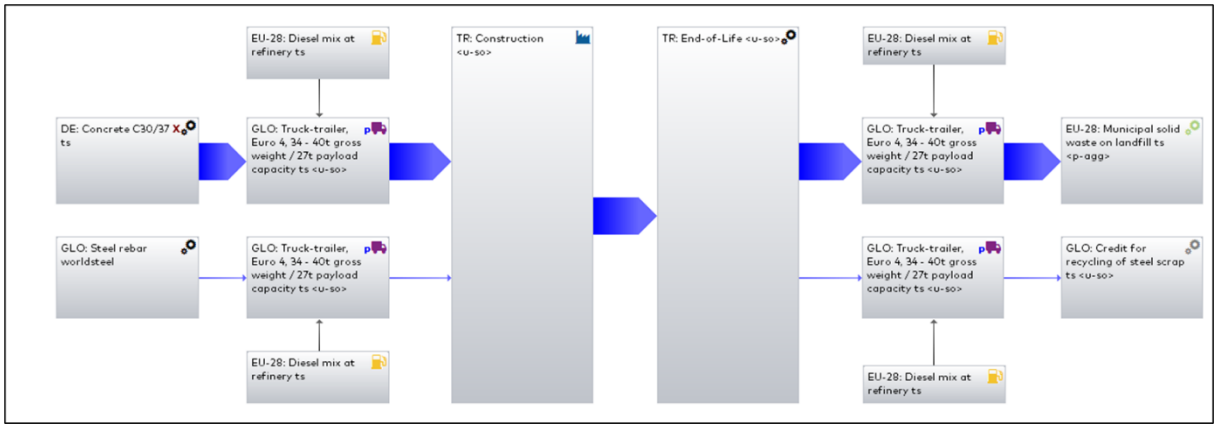

Figure 3. Reinforced Concrete Structural System Modeling in GaBi Software (Created by the authors)

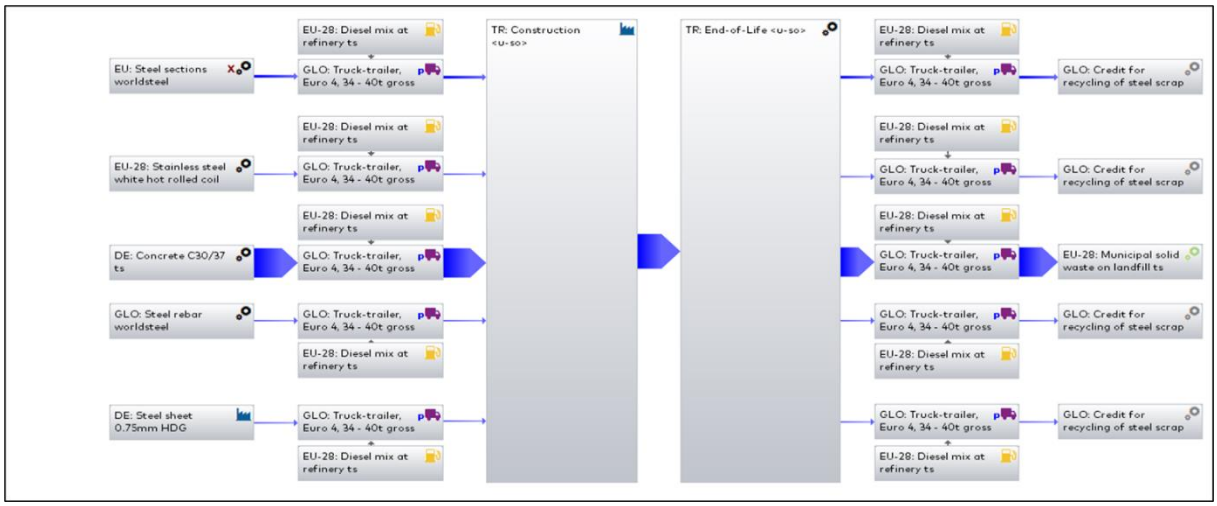

Figure 4. Steel Structural System Modeling in GaBi Software (Created by the authors)

The life cycle environmental performance results of steel and reinforced concrete structural systems for scenario 1 and scenario 2 are shown in Table 3. Annual embodied energy values per square tetrameter for scenario 1 and scenario 2 are shown in Figure 5, and embodied carbon values are shown in Figure 6.

Table 3. Alternative Structural Systems' LCA Results

Scenarios	Indicator	R.C. Framed Building	Steel Framed Building
Scenario 1	Embodied Energy (Mj)	8,54E006 Mj	8,57E006 Mj
	Global Warming Potential (GWP) (kgCO2-eq)	5,14E006 kgCO2-eq	2,65E006 kgCO2-eq
Scenario 2	Embodied Energy (Mj)	8,54E006 Mj	1,2E007 Mj
	Global Warming Potential (GWP) (kgCO2-eq)	5,14E006 kgCO2-eq	2,91E006 kgCO2-eq

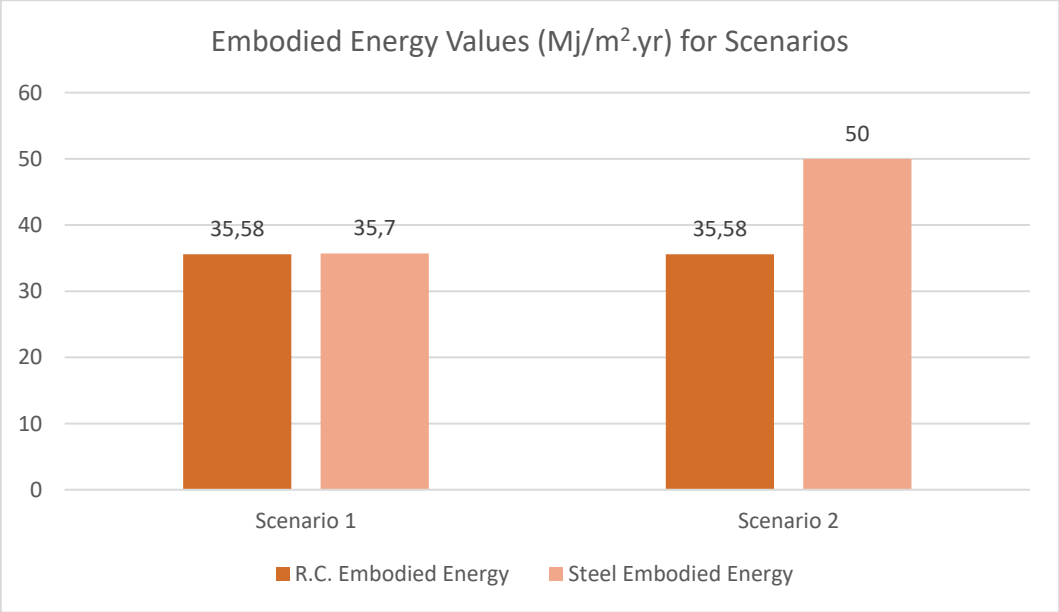

Figure 5. Structural Systems Embodied Energy Values for Scenarios (Created by the authors)

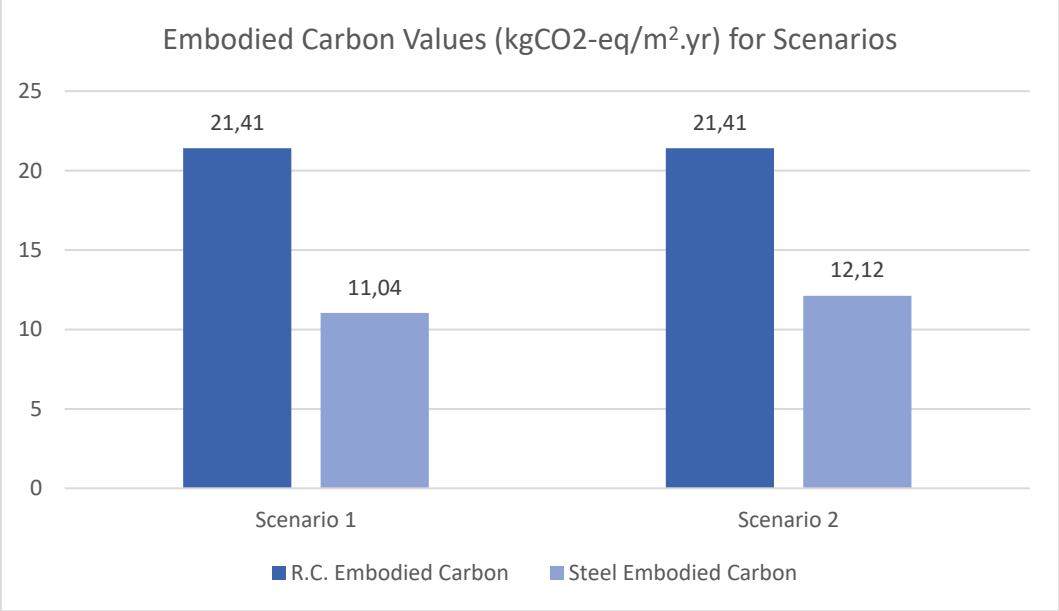

Figure 6. Structural Systems Embodied Carbon Values for Scenarios (Created by the authors)

In terms of embodied energy values, the structural systems have almost identical values in Scenario 1, while the reinforced concrete frame becomes more advantageous in Scenario 2. In terms of embodied carbon values, the values of the structural systems are similar in both scenarios. Here, energy consumption will influence whether structural systems are advantageous. The results indicate that the transport factor is a powerful parameter that can influence the selection of a structural system.

4.Conclusion and Recommendations

This study aims to contribute to a better understanding of the environmental impacts of transport factor in LCA analyses of structural systems. In this direction, LCA analyses are conducted for two different scenarios, and the findings show that the transport factor has a significant impact on the environmental performance of structural systems.

Consequently, transport distances have a significant impact on life cycle environmental performance. Local characteristics affect transport distances. Transport, on the other hand, has a significant impact on the decision-making mechanism for alternative structural systems. Therefore, it is an LCA parameter that should be evaluated in LCA studies.

Especially in a period where urban transformation is on the agenda and for Türkiye, which has a building stock that needs to be revised at a high rate, it is of great importance to select a structural system by evaluating its life cycle environmental performance with each parameter.

Thanks and Information Note

This study is produced within the scope of the project titled "Development of a Decision Support Model for Structure Selection in the Context of Earthquake and Environmental Impact (24/ÖAP/06)" supported by the Scientific Research Projects Coordination Unit of Mimar Sinan Fine Arts University, led by Prof. Dr. Ümit ARPACIOĞLU. We would like to thank the MSFAU Scientific Research Projects Coordination Unit for their contributions to the study.

The article complies with national and international research and publication ethics. Ethics Committee approval was not required for the study. All authors contributed equally to the article. There is no conflict of interest.

Abstract

The acceleration of rapid urbanization and intensive construction since the Industrial Revolution has caused significant ecosystem degradation, transformation of the urban landscape, and disruption to the environmental balance. These changes have a negative impact on both human health and urban quality of life. In this context, restoring green infrastructure and integrating blue, green and grey components into urban planning is essential for the sustainable development of cities. This study examines the spatial distribution of these infrastructure components and the impact of green cover on air quality in Darıca Millet Garden in Kocaeli, Turkey. A comprehensive literature review was conducted and ArcGIS 10.8 was used to map the park's blue, green and grey infrastructure elements. The results show that the green infrastructure covers 184,374 m², the grey infrastructure covers 77,576 m², and the Marmara Bay coastline represents the blue infrastructure. Ecological assessments using i-Tree Canopy reveal that approximately 91.6 tons of carbons are sequestered annually and significant amounts of air pollutants are removed. Specifically, the park removes 7.92 kg of CO, 31.30 kg of NO_2, 377.32 kg of O_3, 67.55 kg of SO_2, 19.70 kg of $PM_{2.5}$ and 151.30 kg of PM_{10} each year. These findings demonstrate that Darıca Millet Garden functions as both an urban recreational space and a vital green infrastructure element that contributes to improving air quality and promoting environmental sustainability.

Keywords: Darıca Millet Garden, air quality, ecosystem services, green infastructure

1. Introduction

Following the Industrial Revolution, rapid population growth and intense urbanization led to large-scale transformations in urban landscapes and significant disruptions to environmental balance. In particular, the rapid increase in the building stock reduced green spaces and destroyed natural ecosystems, thereby weakening ecological functions and diminishing the overall quality of urban life (Aktaş, Öztürkci & Tanyaloğlu, 2022; Kurt Konakoğlu et al., 2024). This process has not been confined to city centers; urban expansion has also affected peripheral rural areas, causing them to become rapidly urbanized and lose their natural characteristics (Bengston & Youn, 2006; Çatalbaş, 2016). As rural areas have gradually disappeared, environmental problems such as air and water pollution and biodiversity loss have increased, making it difficult to establish healthy and balanced living environments in cities (Tokuş, 2012; Selim, 2015; Shakouri, 2016; Aktaş, 2023).

To mitigate these adverse effects and ensure the sustainability of ecosystems, it is essential to adopt an ecosystem services approach, which emphasizes the benefits that nature provides to human life (Pamukcu, 2015; Uygur Erdoğan, 2020; Liu et al., 2021). Within this context, green infrastructure has emerged as a key planning concept for creating sustainable living environments, preventing environmental degradation, maintaining ecological balance, and establishing healthier, more livable spaces (Mell, 2009; Sokolova et al., 2024).

Ecosystem services represent a fundamental framework describing nature's multifaceted contributions to human well-being, highlighting the interdependent relationship between ecosystems and quality of life (Costanza et al., 2014; Tokgöz, 2018). These services encompass essential elements such as clean air and water supply, climate regulation, biodiversity conservation, and recreational opportunities—making them indispensable components of sustainable urban living. However, unplanned urbanization and rapid industrialization have degraded natural ecosystems and caused the loss of landscape areas, leading to a decline in the availability of ecosystem services as urban areas become increasingly covered with impermeable surfaces (Aksoy & Ergun, 2010; Temiz Topsakal & Sağlık, 2024). This in turn triggers environmental problems such as air, water, and soil pollution, the urban heat island effect, and climate change—all of which negatively affect human health and overall well-being.

The concept of green infrastructure has therefore emerged as a comprehensive planning approach designed to ensure the continuity of ecosystem services (Benedict & McMahon, 2002; Yaralıoğlu & Asilsoy, 2021). It provides an integrated framework that generates ecological, social, and economic benefits across multiple spatial scales, from city centers to rural landscapes, and is grounded in nature-based solutions (Shakouri, 2016; Serdar Yakut & Erdem Kaya, 2020; Akay, 2022). Green infrastructure aims to preserve the value that nature adds to urban life through the efficient use of natural resources (Parlak & Atik, 2020; Karaismailoğlu, 2024). By restoring the functionality of ecosystem services in cities, it helps reduce environmental problems and enhance human well-being. Thus, the interdependent relationship between ecosystem services and green infrastructure establishes a vital strategic foundation for sustainable urbanization and the creation of living environments that coexist harmoniously with nature (Tülek & Ersoy Mirici, 2019; Duru et al., 2022).

Green infrastructure enhances urban resilience and livability by generating economic, social, and ecological benefits aligned with the United Nations Sustainable Development Goals (SDGs) (Korkou et al., 2023; Ashinze et al., 2024). Economically, green infrastructure promotes the efficient and responsible use of natural resources, reduces energy consumption and costs, optimizes infrastructure investments, and ensures more efficient resource management (Gedik, 2020; Karaismailoğlu, 2024). Moreover, by increasing land value and minimizing environmental impacts and financial burdens through energy efficiency, it supports economic sustainability (Bolat, 2022; Akay, 2022). From a social perspective, green infrastructure contributes to improving quality of life and enhancing individuals' physical, emotional, and psychological well-being (Lehtonen, 2004; Güneş, 2017). It also strengthens social cohesion by creating healthier environments, expanding spaces for social interaction, and providing diverse recreational opportunities (Bramley & Power, 2009; Yıldırım, 2024). Ecologically, green infrastructure mitigates environmental degradation by maintaining natural balance, reducing the urban heat island effect, improving air quality, and conserving biodiversity (Bithas & Christofakis, 2006; Gómez-Baggethun & Barton, 2013; Tunç, 2023).

Importantly, green infrastructure represents a multi-layered, strategic approach that extends beyond merely quantifying natural elements in urban settings. It focuses on the ecological, aesthetic, and functional integration of these elements and their interconnections at various spatial scales (Monteiro et al., 2020; Arslan, 2022). At the micro scale, green infrastructure encompasses components such as green roofs, green walls, and rain gardens (Tzoulas et al., 2007; Demirören Civan, 2022). At the neighbourhood scale, it includes parks, roadside trees, permeable surfaces, and residential gardens. At the urban scale, it incorporates rivers, large public parks, cemeteries, and botanical gardens. At the regional scale, the focus shifts to forests, wetlands, and green corridors, which help reduce environmental threats, conserve biodiversity, and ensure ecosystem connectivity (Semiz, 2016; Özçelik, 2023). These systems are not merely physical components of the landscape—they function as critical urban infrastructure that delivers a range of ecosystem services (Baylan, 2025).

For example, they restore the natural water cycle through effective storm water management, thereby reducing flood risks and enabling the replenishment of groundwater resources (Kasprzyk et al., 2022). They also help regulate the microclimate by mitigating the urban heat island effect and improving air quality through the filtration of atmospheric pollutants (Aksu, 2021; Kayar & Kutlu, 2022). Thus, green infrastructure serves as a strategic element that enhances the resilience of urban ecosystems, promotes environmental sustainability, and directly contributes to human health and quality of life through its ecosystem services (Coşkun Hepcan, 2019; Ortaçeşme & Zeğerek Altunbey, 2022; Demirören Civan & Görmüş Cengiz, 2023).

This study focuses on Darıca Millet Park, located in the Darıca district of Kocaeli province. The research identifies the park's blue, green, and grey infrastructure components at the urban scale and evaluates their contribution to air quality. As part of the study, a comprehensive literature review was conducted, and the park's blue, green, and grey infrastructure elements were identified and analyzed using ArcGIS 10.8. The park's existing green cover was quantified using the i-Tree Canopy application, and its contribution to air quality was assessed. The spatial distribution of green areas and hard surfaces was also calculated to reveal the park's ecological and environmental contributions to the city's identity and urban life. Based on these findings, recommendations were developed to improve the management of the park's blue, green, and grey infrastructure and to enhance its ecosystem services-specifically improving air quality, increasing carbon storage capacity, and reducing the urban heat island effect.

2. Materials and Methods

The Darıca district is located in the province of Kocaeli, Türkiye, lying between 40°45'–40°46' N latitude and 29°23'–29°24' E longitude. Situated approximately 56 km from the central district of İzmit, Darıca covers a total area of 114 km² (Orman, 2023). The district has a 16 km-long coastline along the Sea of Marmara and is particularly renowned for its coastal landscape and zoological park (Figure 1). The terrain rises from the low-lying coastal areas towards the interior, displaying a gradual elevation pattern. The district experiences a hot and dry climate in summer and a cold and rainy climate in winter (Özyurt & Gürses, 2020; Darıca Municipality, 2025; Republic of Türkiye Darıca District Governor's Office, 2025).

Figure 1. Study area boundaries

This study focuses on the boundaries of Darıca Millet Garden (also known as *Martyr Er Gökhan Hüseyinoğlu Coastal Park*), which is located in the Darıca district of Kocaeli province. The park covers an area of approximately 261,950 m², situated between Darıca Beach and Eskihisar Beach. It features a variety of social and recreational spaces, including walking and cycling paths, viewing terraces, rest areas, themed 'hobbit' houses, sports fields, food and beverage areas, children's playgrounds, and beaches. The park was developed on land formerly used for military purposes, and during its design process, most of the existing mature trees were preserved. While the first and second phases of the park have been completed, work on the third phase is currently ongoing (Darıca Municipality, 2025; Kocaeli Metropolitan Municipality, 2025).

The main objective of this research was to evaluate the contributions of blue, green, and grey infrastructure components to air quality improvement within the first and second phases of Darıca Millet Garden. The study began with a comprehensive literature review to establish the theoretical and conceptual framework. Subsequently, spatial analyses were carried out using ArcGIS 10.8 software to examine the spatial configuration of the park's infrastructure components. The i-Tree Canopy online tool was employed to quantify the existing green cover, which was then used to assess its contribution to air quality. The distribution of green areas and impervious (hard) surfaces was also calculated to evaluate the park's ecological and environmental contributions to the urban fabric and city identity.

Based on these analyses, recommendations were formulated to enhance the management and sustainability of Darıca Millet Garden, with particular attention to the integration of its blue, green, and grey infrastructure components. In addition, quantitative assessments were performed to determine the ecosystem services provided by the park's green infrastructure, including air quality improvement, carbon storage enhancement, and mitigation of the urban heat island effect.

3. Findings and Discussion

The findings of the study are as follows:

The blue infrastructure of Darıca Millet Garden is represented by the Marmara Gulf, which defines the park's coastal boundary. The green infrastructure of the park consists of trees, shrubs, and grass areas, covering a total of 184,374 m². The grey infrastructure includes roads,

squares, and buildings, with a total area of 77,576 m². By analyzing the spatial distribution of green and hard surfaces within the park, the study revealed the ecological and environmental contributions of Darıca Millet Garden to the city's identity and urban life. Considering Darıca Millet Garden as both an urban park and a green infrastructure component at the city scale, spatial analyses were performed using ArcGIS 10.8 to identify the blue, green, and grey infrastructure components. The results are illustrated in Figure 2. Based on ArcGIS analysis, the park's green and grey infrastructure elements were classified into five categories, each represented by distinct colours.

- The Tree/Shrub category constitutes the largest area, covering approximately 93,445 m². These areas include former military zones where existing trees were largely preserved and complemented with newly planted tree and shrub species.
- The Grass/Grassland category covers approximately 77,846 m², consisting of extensive open green spaces designed for public use and recreation.
- The Hard and Soft Ground category includes pedestrian, bicycle, and vehicle paths, as well as squares and viewing terraces, covering an area of 71,979 m².
- The Unfinished Landscape and Sand Areas category, where planting arrangements have not yet been completed, covers 13,083 m².
- The Buildings category accounts for 5,597 m², representing structural elements such as service units and facilities within the park.

Figure 2. Darıca Millet Garden, ArGIS 10.8, Blue-Green-Grey Infrastructure Components, Area Distribution

The ecological benefits provided by the blue, green, and grey infrastructure components of Darıca Millet Garden were further evaluated using the i-Tree Canopy online tool. Random sampling points were distributed within the park boundaries to assess the proportion and contributions of these infrastructure elements to the urban ecosystem, particularly in relation to air quality improvement, carbon storage, and climate regulation (Figure 3).

Figure 3. Darıca Millet Garden I-Tree Canopy Point Distribution

Figure 3 presents the results of the land cover analysis conducted using the i-Tree Canopy application. An examination of 10,000 randomly distributed points within Darıca Millet Garden identified six distinct land-cover categories (Figure 4).

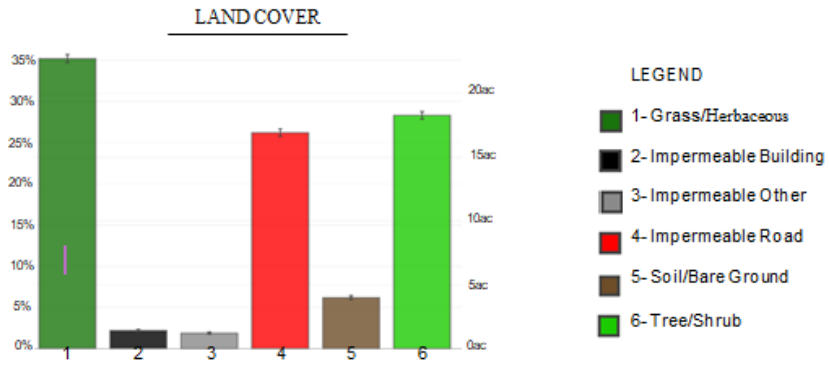

Figure 4. Distribution of 10,000 points randomly placed within the boundaries of the study area

The Grass/Herb category, representing green infrastructure, accounted for the highest proportion of points, with 3,521 points (35.21%) corresponding to extensive open green spaces suitable for public use and recreation. The Tree/Shrub category ranked second, with 2,832 points (28.32%), encompassing areas previously under military use where existing vegetation was largely preserved and supplemented with newly planted trees and shrubs.

The Impervious Road category, representing grey infrastructure, ranked third with 2,621 points (26.21%). This category includes pedestrian, bicycle, and vehicle paths, as well as squares and viewing terraces that provide access and circulation within the park.

Areas where planting arrangements have not yet been completed, along with sand-covered recreation zones, were classified as Soil/Bare Ground under green infrastructure. These accounted for 619 points (6.19%) of the total.

The Impervious Building category, also under grey infrastructure, comprised 220 points (2.20%), representing former military structures, daily service units, symbolic hobbit houses, certain residential areas, and security facilities within the park.

Finally, the Impervious Other category of grey infrastructure included rubber-coated surfaces, retaining walls, and other structural reinforcement elements, accounting for 187 points (1.87%).

Table 1. Areas Covered by Analyses Conducted Using ArcGIS 10.8 and I Tree Canopy

ArcGIS 10.8 (Blue-Green-Grey Infrastructure Components)	i-Tree Canopy (Ecosystem Services-Based on 10,000 Points)
Trees/Shrubs (93.445m2)	Grass/Herbaceous (%35,21- 3521 Points)
Grass/Herbaceous (77.846m2)	Tree/Shrub (%28,32- 2832 Points)
Hard/Soft Ground (71.979m2)	Impermeable Road (%26,21- 2621 Points)
Soil/Bare Ground (13.083m2)	Soil/Bare Ground (%6,19- 619 Points)
Building (5.597m2)	Impermeable Building (%2,20- 220 Points)
	Impermeable Other (%1,87- 187 Points)

Table 1 compares the results of the blue, green, and grey infrastructure component analyses conducted in ArcGIS 10.8 with those obtained from 10,000 randomly distributed points in the i-Tree Canopy online application.

In the ArcGIS 10.8 analysis, the spatial classification method (or "painting method") was used. In this approach, areas containing trees or shrubs were directly classified under the "Tree/Shrub" category, which led to an overrepresentation of this category in the final results. In contrast, the i-Tree Canopy application employed the point sampling method. When multiple points intersected a tree-covered area, both the tree canopy and the underlying grass or herbaceous vegetation was recorded separately. This approach provided a more realistic and detailed representation of the Grass/Herbaceous category.

As a result of these methodological differences, the ArcGIS analysis ranked the "Tree/Shrub" category first and the "Grass/Herbaceous" category second, while the i-Tree Canopy analysis produced the opposite order—placing "Grass/Herbaceous" first and "Tree/Shrub" second.

In both analyses, surfaces such as roads, squares, and viewing terraces were included under comparable categories: classified as "Hard/Soft Ground" in ArcGIS and as "Impervious Road" in i-Tree Canopy. The fourth category in both tools was "Soil/Bare Ground," and the fifth was "Structure." Unlike ArcGIS, however, the i-Tree Canopy application introduced an additional sixth category, "Other Impervious," which includes small-scale impermeable surface features such as walls, rubber-coated areas, and various structural elements identifiable at the point level. This distinction indicates that i-Tree Canopy provides a more detailed and nuanced classification of surface cover types within the study area.

Within the context of the Tree/Shrub category under the green infrastructure heading in Darıca Millet Garden, the preservation of existing olive trees and other native vegetation from the area's former use as a military zone was prioritized. In addition, the park's design incorporated newly planted tree and shrub species, thereby enhancing both ecological diversity and aesthetic value within the site.

The tree and shrub category within the green infrastructure component makes a significant contribution to urban ecosystem functionality. These plants absorb carbon dioxide from the atmosphere and release oxygen, acting as carbon sinks that play a critical role in mitigating climate change. In addition, they improve air quality by filtering harmful gases and particulates, and they help to alleviate the urban heat island effect, thereby reducing ambient temperatures and lowering energy consumption. From an aesthetic perspective, trees and shrubs enhance the visual diversity of the urban landscape and provide spaces for relaxation and recreation. Interaction with nature has been shown to produce psychological benefits, including reduced stress and improved mental health. Thus, trees and shrubs simultaneously contribute to both environmental sustainability and social well-being.

Within the scope of green infrastructure in the study area, the grass/herbaceous category comprise open green spaces, including flat grass areas, picnic sites, resting zones, and viewing terraces. These areas not only enhance the aesthetic quality of the urban landscape but also provide essential ecological services, such as improving air quality, supporting biodiversity, and preventing soil erosion. Owing to its coastal location, Darıca Millet Garden exhibits a natural transition from green to blue infrastructure, creating a visually harmonious environment. Furthermore, these grass and herbaceous zones contribute to social functionality by supporting recreational activities such as sitting, walking, exercising, eating, and socializing. Consequently, this category enhances urban livability from ecological, aesthetic, and functional perspectives.

The grey infrastructure components within the study area include walking and cycling paths, children's play areas, sports fields, squares, viewing terraces, amphitheater zones, and car parks, collectively classified as hard or soft ground. These areas meet the recreational and social needs of urban residents by providing spaces for walking, cycling, sports, and entertainment, thereby improving the social quality of urban life. However, most of these surfaces are impermeable, including parking lots, paths, rubber-coated play areas, amphitheater, and sports fields. In contrast, permeable pavements are used in squares and stepping-stone pathways, allowing rainwater infiltration. The prevalence of impermeable surfaces in Darıca Millet Garden restricts water absorption, which may increase the risk of flooding and surface runoff. Therefore, the use of permeable materials is vital for sustainable urban water management and environmental resilience.

Within the green infrastructure category, areas of bare ground, vegetated soil, and sand-covered zones—such as beaches and open parks—provide spaces for various recreational activities, including walking and swimming, which enhance physical health and promote social interaction. The permeability of the soil enables rainwater infiltration, supporting natural drainage and groundwater recharge, while also reducing flood risks. Additionally, soil surfaces can absorb and dissipate heat through evapotranspiration, thereby lowering environmental temperatures, mitigating the urban heat island effect, and improving the microclimate. These functions demonstrate how soil-based surfaces contribute to urban ecosystem resilience and enhance environmental sustainability.

In the grey infrastructure areas of Darıca Millet Garden, there are former military structures as well as food and beverage facilities, hobbit houses, toilets, and a mosque. These structures meet basic daily human needs, such as access to food, water, and sanitation, thereby ensuring the continuity of social life and improving urban quality of life. Architecturally, the hobbit-house structures are particularly noteworthy for their green-roof designs, which blend harmoniously

into the landscape and contribute to energy efficiency and microclimate regulation—thus serving as an example of integrated green infrastructure within the built environment.

From a holistic perspective, Darıca Millet Garden functions as a significant urban park that enhances psychological and physical well-being through its wide range of recreational activities and green open spaces. Spending time in such environments positively affects individuals' mental state, helping them cope with urban stress and social isolation, while also encouraging physical activity and healthier lifestyles. Urban parks like Darıca Millet Garden play a vital role in supporting environmental sustainability by providing ecosystem services such as heat island mitigation, local climate regulation, air purification, and biodiversity conservation.

In this context, Table 2 presents the amounts of carbon captured and stored through canopy cover as part of the regulating ecosystem services in Darıca Millet Garden, as calculated using the i-Tree Canopy application. The amount of carbon (C) sequestered annually by trees in the study area was found to be 24.98 tonnes, while the total carbon storage was estimated at 627.40 tonnes. These findings confirm the park's important role in urban carbon management and its contribution to climate regulation.

Table 2. i-Tree Canopy application benefit estimates and analysis results

DEFINITION	C (Carbon) QUANTITY(t) ± SS	VALUE ($) ± SS
It is stored in trees every year	24.98± 0,40	10.811 $ ± 172
It is stored in trees	627.40± 9,98	271.495$ ± 4.319

Table 3. i-Tree Canopy application benefit estimates and analysis results

ABBREVİATİON	POLLUTANTS	QUANTİTY (kg) ± SS	VALUE ($) ± SS
CO	Carbon Monoxide (Annual)	7,92 ± 0,13	$12 ± 0
NO_2	Nitrogen Dioxide (Annual)	31,30 ± 0,50	$5 ± 0
O_3	Ozone (Annual)	377,32± 6,00	$243 ± 4
SO_2	Sulphur Dioxide (Annual)	67,55 ± 1,08	$1 ± 0
PM2.5	Particulate Matter (Annual)	19,70 ± 0,31	$511 ± 8
PM10*	Particulate Matter (Annual)	151,30 ± 2,41	$1127 ± 18
TOTAL		**655,08 ± 10,42**	**$1899 ± 30**

According to the assessments presented in Table 3, the tree and shrub cover within the study area removes approximately 655 kg of atmospheric pollutants each year, providing a key ecosystem service that contributes to the improvement of urban air quality in Darıca Millet Garden.

Among the pollutants removed, the quantities of carbon monoxide (CO) and nitrogen dioxide (NO_2)—both primarily emitted from motor vehicle traffic (Korkmaz, 2023; Dikenli, 2024)—were found to be 7.92 kg and 31.30 kg, respectively. The amount of ozone (O_3), a major pollutant contributing to global warming (Nur Aydın, 2024), removed from the atmosphere was determined to be 377.32 kg. In addition, sulphur dioxide (SO_2), which forms mainly as a result of the combustion of fossil fuels, was removed at a rate of 67.55 kg.

Particulate matter emissions ($PM_{2.5}$ and PM_{10}) originate from both natural sources (e.g., volcanic activity, dust, and sea salt) and anthropogenic activities such as industry, fossil fuel combustion, and waste management (Çakır Göktepe, 2024). The respective quantities of these particulates removed from the atmosphere were 19.70 kg for $PM_{2.5}$ and 151.30 kg for PM_{10}.

In a comparative study, Pace et al. (2018) used the i-Tree Canopy model to analyses Munich's Englischer Garten, a 330-hectare park, and determined that it stores 6,225 tonnes of carbon and captures an additional 214 tonnes annually. In comparison, Darıca Millet Garden, covering an area of 28 hectares (approximately 12 times smaller), was found to store 627.40 tonnes and capture 24.98 tonnes of carbon per year. When these values are normalised according to area, the results obtained for Darıca Millet Garden are proportionally similar to those of Englischer Garten, suggesting that the park exhibits high ecological efficiency relative to its size.

Pace et al. (2018) also assessed air pollutant removal, reporting that Englischer Garten removed 2,610 kg of O_3, 845 kg of NO_2, 186 kg of $PM_{2.5}$, 171 kg of SO_2, and 62 kg of CO, with O_3 and NO_2 identified as the leading contributors. In the present study, the respective pollutant removal values for Darıca Millet Garden were 7.92 kg of CO, 31.30 kg of NO_2, 377.32 kg of O_3, 67.55 kg of SO_2, and 19.70 kg of $PM_{2.5}$, with O_3 and SO_2 showing the highest contributions. The consistency between the two studies indicates that ozone (O_3) is the most effectively removed pollutant in both cases, reflecting similar vegetation-based pollutant absorption dynamics. However, while SO_2 ranked second in the Munich study, NO_2 was the second-highest contributor in Darıca Millet Garden, likely due to its proximity to urban traffic sources.

Similarly, in a study conducted at Altınpark, located in the Altındağ district of Ankara, Şahin Körmeçli (2023) employed the i-Tree Canopy application and determined carbon sequestration and storage values of 74.58 tonnes and 1,873.10 tonnes, respectively. In comparison, the corresponding values for Darıca Millet Garden were 24.98 tonnes (sequestration) and 627.40 tonnes (storage). Although Darıca Millet Garden is approximately half the size of Altınpark, the carbon values obtained are proportionally lower, indicating lower vegetation density and reduced carbon storage potential.

When comparing pollutant removal capacities, Altınpark was found to remove 24.63 kg of CO, 134.32 kg of NO_2, 1,377.85 kg of O_3, 84.65 kg of SO_2, 65.01 kg of $PM_{2.5}$, and 448.11 kg of PM_{10}, with O_3 and PM_{10} contributing the most. A similar trend was observed in Darıca Millet Garden, where O_3 also showed the highest removal rate. However, the overall pollutant removal quantities were significantly lower in Darıca Millet Garden, a difference likely attributable to variations in vegetation cover, climatic conditions, and urban air pollution intensity.

4. Conclusion and Recommendations

Rapid urbanization today continues to exacerbate environmental problems such as air pollution, climate change, and the urban heat island effect, all of which have significant adverse impacts on urban livability. Increasing population density and the concentration of employment in city centers, coupled with the ongoing loss of natural areas, have intensified traffic congestion and motor vehicle use, thereby worsening air quality. These challenges negatively affect human health and threaten the sustainability of ecosystems. Consequently, adopting ecologically based planning approaches has become essential to enhance the environmental resilience of cities and improve quality of life.

Green infrastructure represents one of the key strategies of such approaches. It contributes to mitigating air pollution by creating carbon sink areas, moderates microclimatic conditions, and

reduces the urban heat island effect, while also serving as a strategic tool for achieving sustainable urbanization goals. Within this context, Darıca Millet Garden stands as a significant example of an urban park that enhances the urban ecosystem through its diverse green infrastructure components. Furthermore, technological tools such as the web-based i-Tree Canopy application, developed by the United States Department of Agriculture Forest Service, enable the environmental benefits of urban green spaces to be assessed scientifically. By quantifying trees' carbon storage capacity and their potential to remove atmospheric pollutants, these tools support more informed and sustainable urban planning processes.

Urban parks provide recreational spaces and social interaction areas, while simultaneously supporting environmental sustainability through the ecosystem services they deliver. They help regulate local climate conditions, reduce air pollution, and contribute to biodiversity conservation. In addition, parks have profound psychological and physical health benefits—reducing stress, alleviating social isolation, and encouraging healthy, active lifestyles through outdoor activities such as walking, cycling, and sports.

Darıca Millet Garden offers a wide range of recreational opportunities, including walking, cycling, sports, picnicking, and social gatherings, which enhance both the physical and social well-being of residents. The park's diverse tree and shrub species also enrich the urban ecosystem and promote biodiversity conservation, demonstrating its dual function as both a recreational space and an ecologically valuable green area that contributes to environmental sustainability.

The integration of ArcGIS 10.8 and i-Tree Canopy analyses provides a multidimensional perspective on the environmental contributions of urban parks by assessing the blue-green-grey infrastructure components. The results from Darıca Millet Garden indicate that the existing green infrastructure—particularly the mature tree canopy inherited from its former military use—possesses high carbon storage and pollutant filtration capacity. Newly planted vegetation, while not yet mature, is expected to significantly enhance the park's ecosystem service potential over time.

This finding suggests that the park's ecological contributions will increase as the vegetation develops, thereby strengthening its role in urban environmental sustainability. The park's blue infrastructure (water features) and grey infrastructure (paths, terraces, and seating areas) complement the green components by enhancing user experience and functional diversity. However, to improve comfort and resilience, it is recommended to increase tree planting along walkways and resting areas to provide additional shading, which will reduce heat stress during the summer months and increase park usage efficiency.

Analyses further reveal that while the park's green infrastructure is robust in environmental, aesthetic, and functional terms, improvements are needed to reinforce sustainability and ecosystem service provision. Increasing the diversity of tree and shrub species would strengthen biodiversity, enhance carbon sequestration and air filtration, and contribute to visual richness. Conversely, assessments of the grey infrastructure indicate that many paths and open spaces are composed of impermeable surfaces, limiting natural water infiltration and elevating flood risk. Replacing these with permeable materials would restore the natural hydrological cycle and improve environmental sustainability.

Overall, Darıca Millet Garden has the potential to significantly enhance urban quality of life by combining ecological functionality, aesthetic value, and public health benefits. This study

underscores the critical role of urban parks in mitigating air pollution, heat island effects, and climate change, especially in densely built environments where natural green spaces are diminishing. Strengthening urban green infrastructure—by increasing park numbers, enhancing vegetation density, and diversifying plant species—is therefore vital to achieving sustainable urban development goals.

Abstract

This study focuses on the Amasya University campuses located within the central district of Amasya, including the Hakimiyet, Yeşilırmak and İpekköy campuses. Situated in the interior of the Central Black Sea region, the city spans 5,628 km² with an average elevation of 1,200 m and a population of 148,908 (2023). Using Google Earth imagery and Adobe Photoshop, the spatial distribution of green, grey, and blue infrastructure components was mapped, followed by ecological assessments with the i-Tree Canopy application to evaluate ecosystem services. Green infrastructure covers 235,088 m², including forested areas, open green spaces, and afforested areas, while grey infrastructure comprises buildings, social facilities, and sports units; no blue infrastructure elements were identified. i-Tree Canopy analyses revealed that these green areas annually sequester 17.15 tons of carbon, store a total of 430.71 tons, and remove significant amounts of air pollutants: CO (5.14 kg), NO_2 (25.74 kg), O_3 (237.75 kg), SO_2 (25.71 kg), $PM_{2.5}$ (13.53 kg), and PM_{10} (97.28 kg). The total annual economic value of ecosystem services provided by campus green areas was estimated at $194,122. These findings highlight the critical role of green infrastructure in mitigating air pollution, supporting sustainable urban development, enhancing biodiversity, and improving quality of life. The study emphasizes the need to integrate quantitative assessments of ecosystem services into spatial planning, expand nature-based solutions, strengthen management capacity, and promote participatory design to maintain ecological integrity, carbon storage, and the social, environmental, and economic benefits of campus green areas.

Keywords: Amasya University, ecosystem services, green infrastructure

1. Introduction

Green infrastructure is defined as a network of strategically planned and interconnected green spaces composed of natural habitats, parks, green corridors, and conservation areas. Designed and implemented by considering the ecological, social, and economic benefits derived from the natural resource values it contains, this system aims to strengthen the ecological structure of cities. In contemporary urbanization processes, green infrastructure emerges as a holistic planning approach with objectives such as protecting ecosystem health, maintaining biodiversity, and enhancing urban quality of life. This approach contributes to the integration of the ecosystem services perspective into spatial planning processes by ensuring the

preservation of ecological balance and enabling the services provided by urban ecosystems to become more visible and manageable (McMahon & Benedict, 2000; Yanık, 2023).

The primary advantage of green infrastructure planning lies in its emphasis on connectivity and multifunctionality. This structure, which ensures the continuity of ecological corridors, contributes to the conservation of natural and cultural resources at the urban scale, strengthens local landscape character, and enhances the sense of place (Güneş & Şahin, 2015; Demirkır, 2019). Considering that cities have historically evolved in line with changing settlement values and functions, open and green spaces have become a determining factor in shaping urban character. In contemporary cities, the spatial diversity that supports essential activities such as living, working, resting, and recreation is directly related to urban quality of life. The quality and quantity of open-green spaces, therefore, constitute significant indicators of this quality (Gül & Küçük, 2001; Geray, 1998; Yakın İnan & Sönmez, 2019).

Open-green spaces are critical not only due to their recreational functions but also because of the ecological roles they assume in maintaining the sustainability of the urban ecosystem. Through functions such as air quality regulation, carbon sequestration, microclimate control, biodiversity support, and the continuity of ecological networks, they contribute to the integrity of the urban ecosystem (Keleş, 1998; Öztürk & Özdemir, 2013). Since urban ecosystems are shaped by human–nature interactions and integrated with socio-economic and cultural processes, the accurate assessment of ecosystem services within these areas is a vital requirement for effective planning and management (Degefu et al., 2021; Görmüş et al., 2021).

In this context, the Millennium Ecosystem Assessment (MEA) categorizes ecosystem services into four main groups: provisioning, regulating, cultural, and supporting services. These services encompass a wide range of functions, from food and raw material supply to climate regulation, from recreational opportunities to the sustainability of biological processes (Pamukçu et al., 2015; Felipe-Lucia & Comín, 2015; Akkurt & Akten, 2021; Çağlayan et al., 2020; Esringü et al., 2021).

In today's cities, where the pressures of urbanization are increasing, scientifically evaluating the ecosystem services provided by large open spaces—such as university campuses—offers valuable insights for sustainable planning. Accordingly, the Hâkimiyet, Yeşilırmak, and İpekköy campuses of Amasya University present a suitable study area for assessing the spatial distribution of green infrastructure and identifying ecosystem services. In this regard, the aim of the study is to identify the green infrastructure components within the Amasya University campuses, quantitatively evaluate the ecosystem services provided by these areas, and offer implications for sustainable campus planning based on the findings obtained.

2. Materials and Methods

This study covers the Hâkimiyet, Yeşilırmak, and İpekköy campuses of Amasya University, located within the boundaries of the central district of Amasya province. Situated in the inland part of the Central Black Sea Region, Amasya is bordered by the provinces of Yozgat, Tokat, Çorum, and Samsun. The total surface area of the province is 5,628 km², and according to the Address-Based Population Registration System dated 31 December 2023, the population of the central district is 148,908. The city center has an average elevation of 392 m, while the

provincial average is 1,200 m; the highest point in the province reaches 2,061 m. Amasya is located in the valley formed by the Yeşilırmak River between the Canik Mountains, offering a characteristic settlement pattern at the regional scale due to its topographic and hydrological features (Republic of Türkiye Amasya Governorship, 2024) (Figure 1).

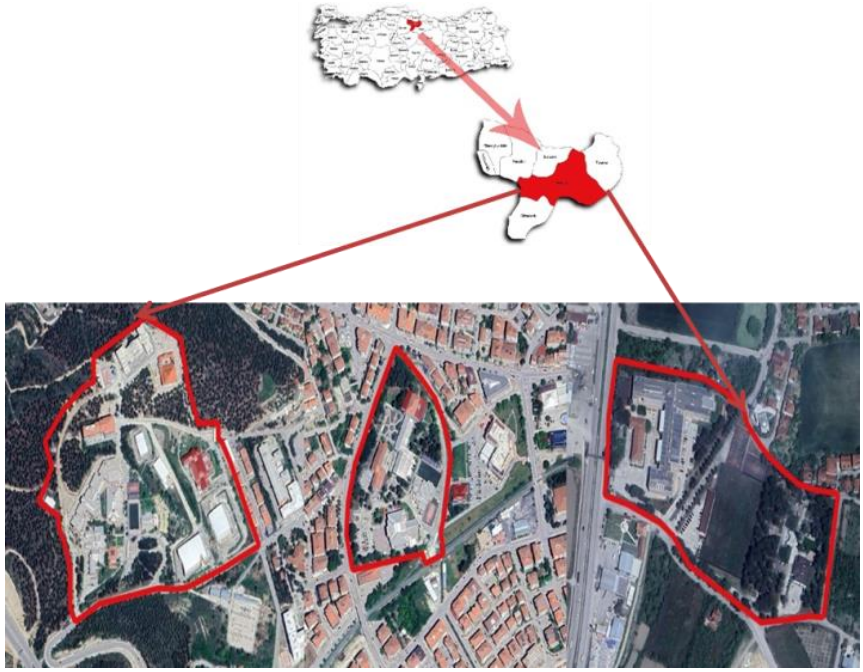

Figure 1. Yeşilırmak, Hakimiyet and İpekköy Campuses located in the Central District of Amasya

The primary materials of the study consist of boundary data for the Hâkimiyet, Yeşilırmak, and İpekköy campuses, Google Earth satellite images, and supporting visual materials used for land cover classification of the study area through the i-Tree Canopy software.

In this research, the i-Tree Canopy model—developed by the United States Department of Agriculture Forest Service (USDA) and based on a random point sampling approach—was employed. The method consists of three main stages:

1. Defining the Study Area Boundaries: Campus boundaries were digitally delineated using the i-Tree Canopy interface.

2. Identification of Land Cover Classes: Six land cover classes available in i-Tree Canopy and suitable for the study area were evaluated:

(1) Tree/Shrub: Tree and tall shrub vegetation,

(2) Grass/Herbaceous Plants: Areas covered by herbaceous vegetation,

(3) Soil/Bare Ground: Soil surfaces with little or no vegetation cover,

(4) Impermeable Buildings: Built-up areas,

(5) Impermeable Roads: Asphalt- or concrete-covered transportation units,

(6) Other Impermeable Surfaces: Parking lots, sidewalks, and similar impermeable areas.

3. Random Point Sampling and Classification: The software performs the analysis by assigning each randomly generated point within the study area boundary to one of the defined land cover classes. Through this process, land cover ratios were determined, and ecosystem service outputs—such as carbon sequestration, carbon storage, and removal of air pollutants—were generated using i-Tree Canopy's automatic calculation modules.

3. Findings and Discussion

In this study, green, gray, and blue infrastructure components were identified at the campus scale using the example of Amasya University's Hâkimiyet, Yeşilırmak, and İpekköy Campuses, and the land cover distribution was analyzed through the i-Tree Canopy application. Satellite images obtained from Google Earth Pro were processed in Adobe Photoshop to classify the infrastructure components within the campuses. The findings provide important insights into the ecosystem service potential of the campus areas.

The analyses reveal that green infrastructure occupies a considerable portion of the campuses. Specifically, green infrastructure components include 185,576.99 m² of forested areas, 22,538.93 m² of open-green spaces, and 26,971.68 m² of afforested areas. In contrast, gray infrastructure elements consist of 6,010 m² of social facilities, 9,590 m² of sports units, and 38,700 m² of built-up areas. No data corresponding to blue infrastructure components were identified within the study area, indicating a limited capacity of the campuses in terms of water-based ecosystem services.

A total of 10,000 random points were evaluated in the i-Tree Canopy application, and land cover was analyzed across six classes. The distribution of these points is as follows (Figure 2-3, Table 1):

- Tree/Shrub: 1,845 points
- Grass/Herbaceous: 2,094 points
- Impermeable Buildings: 1,925 points
- Impermeable Roads: 2,732 points
- Other Impermeable Surfaces: 348 points
- Soil/Bare Ground: 1,056 points

Based on this distribution, the percentage of land cover across the campus is as follows:

27.32% impermeable roads, 20.93% grass/herbaceous vegetation, 19.25% impermeable buildings, 18.45% tree/shrub areas, 10.56% soil/bare ground, and 3.49% other impermeable surfaces. These results indicate that impermeable surface areas are particularly high across the campuses, while vegetation cover is distributed at varying proportions.

Figure 2. Amasya University Yeşilırmak, Hakimiyet and İpekköy Campuses i-Tree canopy point distribution

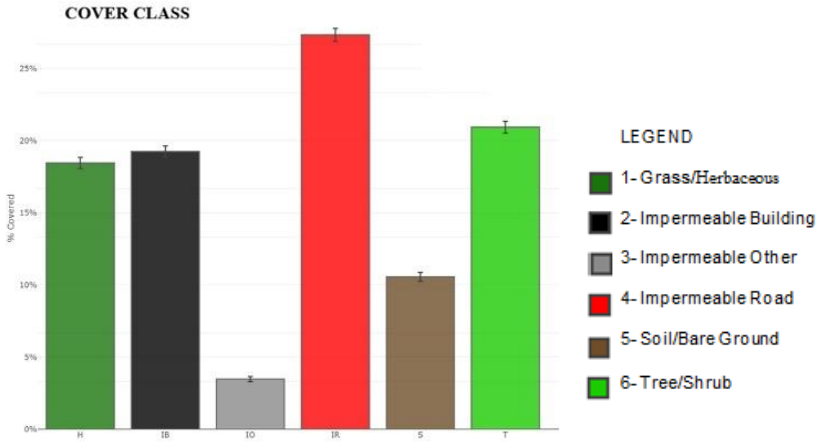

Figure 3. Distribution of total 10,000 points randomly placed within the boundaries of the campuses

Table 1. Land cover analysis results of the i-tree canopy application

Abbreviation	Cover Class	Definition	Number of Points	% Cover ± SE/Standard Deviation	Area (m²) ± CI
H	Grass/Herbaceous	Grass and herbaceous vegetation cover	1845	18,45 ± 0,39	44.839
IB	Impermeable Building	Buildings and structures	1925	19,25 ± 0,39	46.781
IO	Impermeable Other	Overhead cover, concrete walls, electrical panels, and similar areas	348	3,48 ± 0,18	8.457
IR	Impermeable Road	Asphalt, concrete, or pedestrian paths	2732	27,32 ± 0,45	66.368
S	Soil/Bare Ground	Bare soil or unvegetated ground surfaces	1056	10,56 ± 0,31	25.657
T	Tree/Shrub	Tree and tall shrub vegetation areas	2094	20,93 ± 0,41	50.828
TOTAL	-	-	10000	100	242.930 m²

In addition, the green infrastructure analysis revealed that the existing 235,087.602 m² of green areas remove a total of 405.15 kg of pollutant gases and particulate matter annually, as calculated through the i-Tree Canopy tool. According to the results, trees capture 17.15 tons of carbon per year, while the total amount of carbon stored reaches 430.71 tons. The amount of Carbon Monoxide (CO) removed from the atmosphere is 5.14 kg, and Nitrogen Dioxide (NO_2) is 25.74 kg. Ozone (O_3), which contributes to climate change and poses long-term atmospheric threats, was removed at a rate of 237.75 kg according to the analysis. This improvement in air quality represents a significant contribution to the urban environment. Another major air pollutant, Sulfur Dioxide (SO_2), was removed at a level of 25.71 kg, attributed to the extensive canopy coverage of trees within the study area. Furthermore, existing plant species were found to remove 13.53 kg of PM2.5 and 97.28 kg of PM10 particulate matter annually. These findings demonstrate the significant role of vegetation in mitigating air pollution and highlight its benefits for human health. The study concludes that the ecosystem services provided by the campus vegetation contribute a total annual economic value of $194,122 to Amasya University (Table 2).

Table 2. Ecosystem services provided by tree cover in Yeşilırmak, Hakimiyet and İpekköy Campuses

Pollutants	Quantity	±SS	Value (USD/$)	±SS
Carbon Monoxide - CO (Annual)	5,14 kg	± 0,22	2 $	± 0
Nitrogen Dioxide - NO_2 (Annual)	25,74 kg	± 1,10	1 $	± 0
Ozone- O_3 (Annual)	273,75 kg	± 11,73	35 $	± 1
Sulphur Dioxide – SO_2 (Annual)	25,71 kg	± 1,10	$ 0 $	± 0

It is stored in trees every year	17,15 ton	± 0,33	7,421 $	± 144
It is stored in trees	430,71 ton	± 8,37	186.380 $	± 3623

* The monetary values are expressed in USD and have been rounded. The standard errors of removal and benefit estimates are based on the standard errors of sampled and classified points. The amount of carbon sequestered is based on **1.365 tons (T) of carbon or 5.005 tons of CO_2 per acre per year**, rounded to the nearest value. The amount of carbon stored is based on **34.281 tons of carbon or 125.697 tons of CO_2 per acre**, also rounded. The economic value (USD) is based on **$170.55 per ton of carbon** or **$46.51 per ton of CO_2**, rounded accordingly. (English units: T = ton (2,000 pounds), ac = acre)

The proportion of tree cover and the potential regulating ecosystem services obtained for the campuses of Amasya University can be considered at a moderate level when compared with similar campus-based studies in the literature. Coşkun Hepcan and Hepcan (2017) reported that, in the Ege University Housing Campus, trees removed 289,266 kg of air pollutants annually, captured 321.57 tons of carbon per year, and stored a total of 8,107.86 tons of carbon. Dilaver et al. (2017) calculated that trees in Ankara University's Tandoğan Campus annually removed 17,935,304 kg of pollutants and stored 160,813.239 tons of carbon in total. Ersoy Tonyaloğlu (2023), in a study conducted at Aydın Adnan Menderes University Central Campus, found 77,152 kg of pollutant removal, 34.98 tons of annual carbon sequestration, and 878.44 tons of total carbon storage. Kurt Konakoğlu et al. (2024) determined that the tree and shrub cover, accounting for 31.30% of Amasya University's Hakimiyet Campus, annually removed 261.53

kg of gaseous and particulate pollutants, sequestered 36.57 tons of carbon, and stored 918.42 tons of carbon in total. Compared with these studies, Amasya University shows a certain level of potential regarding tree cover and carbon storage capacity; however, expanding green areas and increasing tree species diversity would strengthen its regulating ecosystem services. Furthermore, the high proportion of impermeable surfaces indicates the need to enhance green infrastructure, as such surfaces influence local hydrological processes, rainfall runoff, heat island effects, and overall microclimatic conditions across the campuses.

4. Conclusion and Recommendations

This study examined the green, grey, and blue infrastructure components of Amasya University's Hâkimiyet, Yeşilırmak, and İpekköy Campuses, revealing the current potential of their ecosystem services. The findings indicate that tree cover within the campuses is limited, constituting a major constraint for regulating ecosystem services. However, the existing open-green spaces and areas suitable for afforestation point to a high potential for increasing tree cover. If this potential is utilized, the campuses—and the city as a whole—could achieve enhancements in climate regulation, air quality improvement, carbon storage, and related economic benefits.

Although improving and expanding tree cover requires significant investment, the results of this study demonstrate the necessity of such analyses for campus-scale and large-area planning. Considering that campuses function as "small urban models," protecting existing trees and shrubs, increasing species diversity, and prioritizing native species are critical for supporting biodiversity and ensuring the sustainable enhancement of ecosystem services. While young trees and shrubs provide lower levels of ecosystem services compared to mature individuals, increases in their number and species diversity will raise overall contributions.

The contribution of existing vegetation to air pollution reduction and carbon storage is a fundamental component of sustainable urban development and healthy living environments. In this context, green infrastructure must be addressed not only from an environmental standpoint, but also through its social and economic dimensions. Strengthening green infrastructure systems offers significant opportunities for climate change mitigation, biodiversity conservation, ecological resilience, and the implementation of nature-based solutions.

Future studies should focus on the quantitative assessment of green infrastructure service levels, the improved integration of these services into spatial planning processes, the development of ecosystem-service-based performance indicators, and the exploration of financial incentive mechanisms. Additionally, participatory design processes that enhance cultural and social ecosystem services, the establishment of biological corridors, and the reinforcement of ecological integrity within campuses stand out as priority areas for sustainable campus management.

Abstract

Technological innovation has always played a key role in advancing architecture, providing new tools with which to solve current design industry problems. The 20th century demonstrated the impressive mechanical properties concrete can achieve when combined with steel. Similarly, the use of this material in digital manufacturing represents a promising future for the construction industry, offering the potential to transform it through the investigation of 3D printing techniques. There are currently multiple approaches to layer printing on concrete, depending on the construction system, the chemical properties, and the scale of the printing. The rapid growth of 3D concrete printing is delivering mechanical efficiency and challenging the boundaries of construction design. Printable concrete, which is made from a mixture of ordinary Portland cement, aggregates and admixtures, is attractive due to its widespread availability and low cost. Most people agree that digital and mechatronic technology is about to have a huge impact on manufacturing and industry as a whole. This paper examines the processes involved in creating different structural elements using various construction techniques with 3D printers. The purpose of this article is thus to divulge the most promising techniques and applications that have been derived from additive printing. Research conducted for this purpose has shown that, aside from pouring the entire building in one go, the columns, beams, stairs, walls and flooring elements can be poured in various ways using a multi-arm or multiple robotic system.

Keywords: Additive manufacturing, 3DC printing, printed structural elements, printing materials

1. Introduction

Concrete is utilised globally as one of the pre-eminent construction materials, both in-situ and prefabricated. There are several reasons for this. It is a construction material with a low production cost, it can be moulded into various shapes, it has high thermal resistance and it is relatively durable. Typically, reinforced concrete construction can be divided into three components: concrete, formwork, and reinforcement. The cost of formwork can account for between 35 and 54 per cent of the total construction cost, and it can take between 50 and 75 per cent of the total construction time.

The aims and benefits of smart construction are to effectively tackle the persistent issues in the construction industry, such as decreased productivity, ecological contamination, and excessive energy consumption. The implementation of sophisticated mass production, computer-based intelligence, and automation technology will lower labor requirements, enhance workplace safety, and assure construction quality and dependability (Liu et al., 2022).

The extraordinary achievements of accelerated industrial development in various regions worldwide can be credited to the automation procedures that have created a more rapid and cost-effective manner of production. However, the concrete construction industry has not experienced automation in a comparable fashion or to the same degree as other industrial domains. Over the past two decades, the traditional method of mixing and pouring concrete on-site has largely been replaced by pre-cast or prefabricated building techniques in several developed and newly industrialized nations. Nonetheless, the construction industry stands to gain significantly from the ongoing automation of procedures, leading to a decrease in labor and construction duration, improved quality, and a reduced ecological impact. The emergence

of three-dimensional printing (3DP) as a technique for rapid prototyping can be traced back to 1987 (Hull, 1986; Chua and Leong, 2014). The fundamental principle of 3DP is additive manufacturing (AM), which implies that material is added layer by layer. This contrasts with most conventional manufacturing methods, which involve the removal of material. While various 3DP techniques exist today, the core principle remains unchanged (Paul et al., 2018).

It is believed that AM and 3D printing will be significantly important in the future because they can create highly intricate items and can be modified to meet customer specifications, utilizing various materials in the process. This substantial transformation in the design and fabrication of objects presents considerable opportunities for the building and construction (B&C) sector (Gardiner, 2011).

AM processes typically utilize computer-aided design (CAD) models as molds to produce complex three-dimensional shapes in a layer-by-layer manner. The initial applications of 3DP were for modeling and prototype creation, but due to advancements in material science, it has since been employed in numerous industrial fields, including automotive, aerospace, military, and medical domains (Bak, 2003; Gibson et al., 2015). The successful implementation of this form of automated construction has been demonstrated by several 3D-printed construction initiatives (Khoshnevis, 2004; Khoshnevis et al., 2006).

Concrete is a substance characterized by its distinct properties, such as shrinkage, creep, and age-dependent strength, which differ from the characteristics of other materials. Despite thorough research on common concrete applications, the exploration of these properties in relation to 3D printing has been quite limited (Bos et al., 2016). What stands out most about 3D concrete printing (3DCP) compared to other industrial and consumer 3D printing methods is, of course, its scale. For instance, they even introduced a 12×12×12 m 3D polymer printer based on Fused Deposition Modelling (FDM) by Qindao Unique Technology (Liang and Liang, 2014). Unlike other 3D printing methods, Additive Manufacturing construction concrete techniques (AMoC) are primarily characterized by the linear deposition of filament. The filament introduces a directionality, which can represent a directional dependency—if not in the properties of the final product, then at least in the printing approach. This has a significant impact, for instance, on angles in a shape, which often appear as curves (with a minimum radius) in the tool path. Utilizing a pixel-based approach grounded in an x, y, z space with equal division in all orientations is not suitable. Moreover, the inclusion of materials like fibers further increases the directional dependence. In conclusion, we can assert that for many 3D printing methodologies, the printer head moves and rotates in the x and y directions, whereas the print surface shifts and rotates in the z direction (Bos et al., 2016).

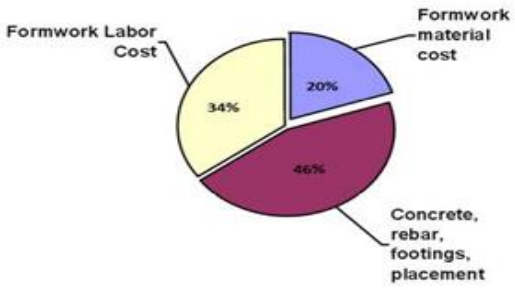

Figure 1. This is an estimate of how the cost of building a concrete structure is shared (Jha, 2012)

2. 3D Printing Production

Towards the end of the 20th century, digital production techniques began to be used in the construction industry. These techniques, which are now being used in building construction, can be examined in three groups (Hauschid, 2011):

1) Additive: Creating components by shaping a formless raw material.
2) Subtractive: Creating the desired component by removing parts from a formed raw material.
3) Transformative: Creating components through permanent shape changes while preserving the integrity of the material.

Although subtractive and transformative processes have been numerically controlled since the 1980s, the capability and ease of use of production techniques continues to improve over time. Examples of subtractive manufacturing include CNC (computer numerical control), punching, laser cutting and water jet cutting (Artuğ and Altun, 2019). CNC folding and bending, flexible roll forming and linear flow splitting are transformative production technologies, especially for steel elements (Hauschid, 2011). In the long term, additive technologies offer the greatest potential in digital production (Hauschid, 2011). "3D printing", an additive manufacturing technology, is being used in medicine, the automotive industry, education, art, textiles, and industrial products. It has recently been adopted in the construction sector and is expected to become widespread in the coming years. Various sources have offered different definitions of 3D printing. Micallef (2015), for example, defines it as a layered production system that converts digitally designed geometries into physical objects by producing them layer by layer using various materials. Kocovic (2017), on the other hand, states that 3D printing is a process that typically creates a physical object from a three-dimensional digital model by successively depositing thin layers of material.

Construction using a 3D printer is based on classic 3D printer logic. A crane equipped with a computer-controlled nozzle that dispenses concrete moves forwards and backwards, left and right, and up and down according to the programme's commands in order to produce the structure (Figure 2) (Khosnevis, 2004).

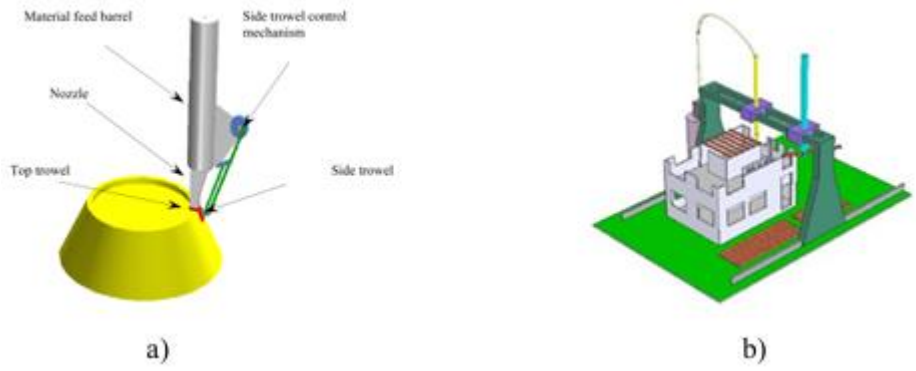

Figure 2.a) Concrete pouring nozzle tip, b) Building production using 3D printer manufacturing technology (Khosnevis, 2004)

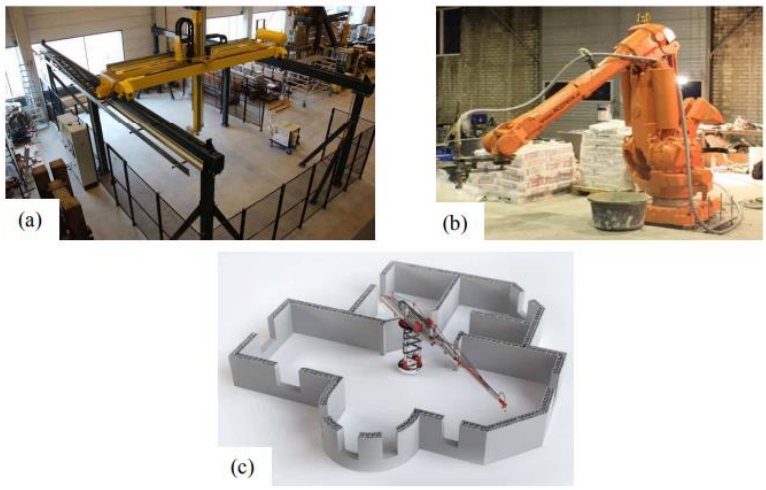
The concrete emerging from the nozzle is smoothed using a small finishing process (see Figure 3). The system works with special concrete to create a computer-generated model. The system produces structural elements that do not require moulds or moulding work. Steel reinforcement

is not used. Furthermore, surfaces ready for painting can be obtained without plastering. This results in significant labour cost savings (Çerçevik et al., 2018).

Figure 3. Structures produced layer by layer using a 3D concrete printer (Futurist Speaker, n.d.)

There are three categories of 3D concrete printers: gantry systems, robotic systems, and crane systems (see Figure 4). These printers are utilized in both academic institutions and the industry (Paul et al., 2018). One variant of crane systems is the gantry printer, which is distinguished by its fixed height, as shown in Figure 4.a. In contrast, the crane system illustrated in Figure 4.b offers vertical adjustability. The advantage of employing gantry and crane printers lies in their simplicity of scalability. On the other hand, robotic printers typically have a fixed size, making them more challenging to expand. Nevertheless, a 6-axis robot can perform numerous functions that a 4-axis gantry printer cannot achieve. This capability arises from the 6-axis robot's ability to move more rapidly and with greater versatility (see Figure 4.c).



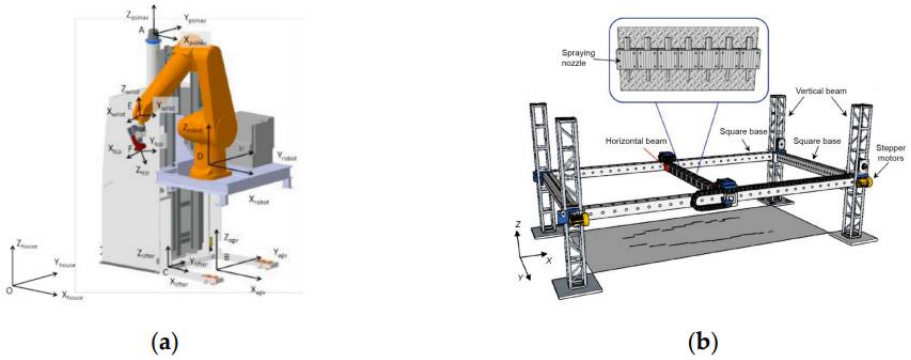


Figure 4. There are three types of 3D concrete printer: a) Four-axis gantry printer, b) Six-axis robotic printer and crane printer, c) Crane printer (Paul et al., 2018).

CyBe Additive Industries, a company based in the Netherlands, has also adopted the contour crafting (CC) technique. They have developed a mortar that achieves workable strength in just 5 minutes. CyBe has conducted experiments using a print head mounted on an imprecise 6-axis robotic arm (see Figure 5.a), which provides a wide range of printer speeds and operational strategies (Paul et al., 2018). The additional rotational axis of the robot, combined with gantry printers, grants designers greater flexibility to create complex shapes. The robotic printer's 6-meter diameter reach facilitates the rapid production of relatively large elements.

In parallel, the Russian company Apis Cor has developed a crane-type printer (see Figure 5.b) that offers a substantial printing area of up to 58 m², without significant height restrictions. As indicated in Figure 4, the printing head can be mounted on either a gantry system or a frame, and it may include one or multiple nozzles along with a binder supply tube (Relefors et al., 2019). Binder material can be supplied either through a premixed binder or via an on-site mixing container (Tay et al., 2017; Sweet, 2018). 3D printing technology presents a viable solution to address labor shortages and construction costs, making it a convenient, low-maintenance, and cost-effective method. However, it's crucial that the 3D printing robots utilize a specific blend of chemicals to ensure strength and minimize shrinkage. The use of 3D printing technology in constructing concrete structures is a compelling advancement in the construction industry, representing one of the most promising avenues for increasing automation and intelligence in this field (Liu et al., 2022).

(a) (b)

Figure 5. The 3D printer has two different types of nozzle: **a)** one nozzle on a robot arm, **b)** many nozzles on a frame (Liu et al., 2022)

The dominance of concrete in 3D printing for building structures is significant, although other materials such as ceramics, metals, and polymers are also employed for structural components. A critical requirement for 3D printing with concrete is its ability to be extruded, alongside essential properties like rigidity post-extrusion and layer adhesion, which are vital for the integrity of printed structures. Therefore, the ideal concrete mixture should exhibit high viscosity and low yield strength, promoting high plasticity and workability. Additionally, concrete must achieve quick strength gain to facilitate the construction of tall buildings efficiently (Perrot et al., 2016).
Kazeminan et al. (2017) proposed a laboratory testing-based framework for assessing the printability of concrete specifically for 3D printing applications. To meet the necessary criteria for printable concrete, Gosselin et al. (2016) developed an innovative system, illustrated in Figure 6. This system separates the concrete premix, which has high workability, from the hardening agent. The components are combined at the extrusion nozzle, thereby enhancing the rheological properties of the premix. This method ensures optimal workability and extended setting time during mixing and storage while enabling high early strength and rapid setting duration (Liu et al., 2022). This advancement represents a significant step toward improving the viability of concrete for 3D-printed construction, addressing critical operational challenges and paving the way for more sophisticated applications.

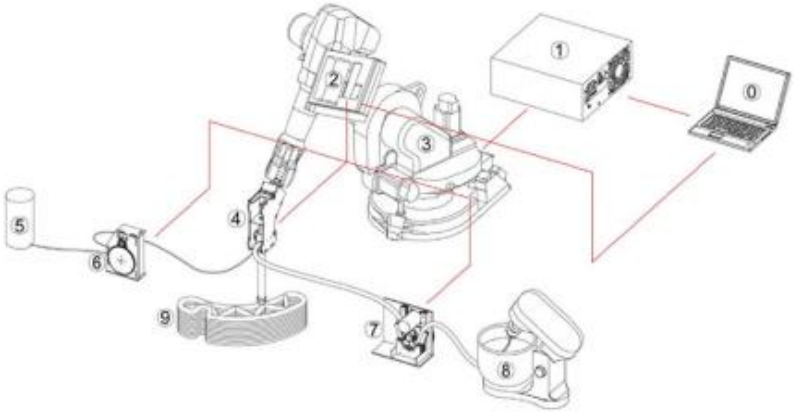

Figure 6. This is an image of a 3D concrete printing setup; 0. System command; 1. Robot controller; 2. Printing controller; 3. Robotic arm; 4. Printhead; 5. Accelerating agent; 6. Peristaltic pump for accelering agent; 7. Peristaltic pump for premix; 8. Premix mixer; 9. 3D printed object. (Gosselin et al., 2016)

There are three main approaches to where 3D printing can be conducted: on-site (direct printing), in a mini factory (indirect printing), and in a prefab factory (indirect printing). The first method refers to direct printing in situ, where the object is created without any additional handling. The second method involves printing in a controlled environment, such as a mini factory set up on the construction site, allowing for regulation of factors like temperature and humidity. The third method is traditional prefab factories, which often face challenges related to the handling and transportation of printed components (Duballet et al., 2017).

When utilizing concrete printing in a building system, certain assembly steps may be necessary. This often involves the movement of large components using machinery. Items that can be incorporated into the extruded mortar, such as polystyrene beads or fibers, are referred to as 'macroscopic elements.' In this context, it is typically accepted that the secondary robotic apparatus, or printing head, should be viewed as the primary performer of the tasks at hand, meaning it should not be considered part of the assembly process. Instead, the assembly phase is conducted either by human workers or additional robotic systems. Figure 7 illustrates the four types of assembly involved in this process (Duballet et al., 2017). This organization of tasks highlights the collaboration between technology and human effort in advancing the efficiency and effectiveness of concrete 3D printing in construction.

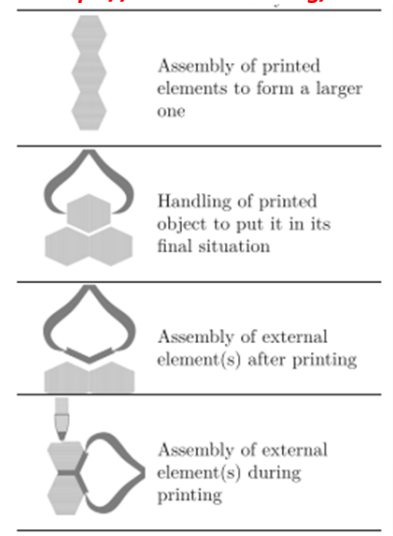

Figure 7. Variation of assembly parameter (Duballet et al., 2017)

To effectively print over an already established surface, the nozzle must navigate the contours of the surface, which involves mapping its shape prior to the printing process. Generally, this support structure is installed manually to accommodate the upcoming layers. Printing on a flat existing surface, like a reusable plank, offers a cost-effective solution; however, the true advantage of 3D printing lies in its ability to create complex, non-flat shapes. This necessitates adapting the existing surface support to match the intended design, which can be labor-intensive and time-consuming. The challenge of constructing complex surface supports can also introduce complications during printing, such as extended delays between the application of subsequent layers and the support structure (Tay et al., 2019). Figure 8 illustrates an innovative roof design that does not rely on traditional supports. This concept, first proposed by Khoshnevis in 2004, draws inspiration from ancient construction techniques. It is based on vault construction methods, where bricks and mortar are used to create a parabolic-shaped roof, inclined at about 20° to the perpendicular along the vault's longitudinal axis, as documented by Dahmen and Ochsendorf (2012). In this approach, the previous sections of the roof help support following sections, eliminating the need for extensive formwork. This unique angle facilitates the integration of the support system into the main structure. The parabolic design not only contributes to aesthetic quality but also allows for the arrangement of the bricks in a manner that puts the entire structure into compression, enhancing its overall stability and integrity.

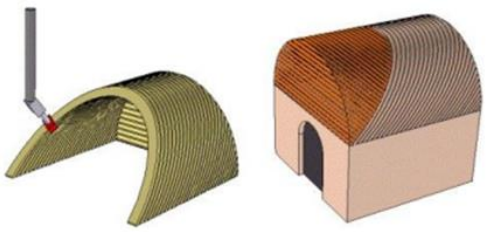

Figure 8. A method of making structures without using supports is called contour crafting (Khosnevis, 2004)

The initial phase in creating a support structure is to assess whether support is necessary for the surface in question. Once determined, the support geometry is calculated and printed using a weak infill pattern, as noted by Strano et al. (2013). Some fused filament fabrication (FFF)

techniques, as well as jetting-based additive manufacturing methods, incorporate dual-nozzle printers (illustrated in Figure 9). This design facilitates the simultaneous use of primary materials for the main structure and distinct support materials, which serve as temporary structures that can be removed during post-processing. In the context of multijet printing methods, Stansbury and Idacavage (2016) demonstrated the use of a UV-curable material that enables the production of smooth components with highly intricate geometries. Additionally, some techniques employ gel-like support materials, such as wax, which can be deposited alongside the main material and subsequently removed through heating. In contrast, Fahad et al. (2013) investigated support materials with alternative properties, specifically targeting the FFF technique with polyvinyl alcohol (PVA). This water-soluble thermoplastic dissolves easily in water, simplifying the support removal process. For jetting-based techniques, materials such as propylene glycol are favored for their ability to withstand higher temperatures, allowing them to effectively melt away during post-processing (Tay et al., 2019). These methods are particularly useful for printing multi-piece assemblies, where significant attention must be given to ensuring accessibility for the removal of residual material between components (as shown in Figure 9). The advantage of using dissolvable or meltable support materials lies in the reduction of human error, as the removal process leaves the main features of the printed structure intact and undamaged.

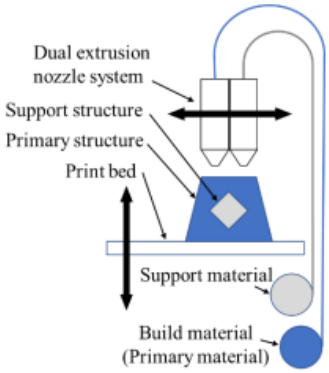

Figure 9. A system for printing with support material using a fused filament fabrication (FFF) dual nozzle (Tay et al., 2019)

The current literature lacks detailed documentation on setups for 3D concrete printing that involve the use of multiple materials. However, Zhang et al. (2018) illustrated in Figure 10 that it is feasible to employ two robotic printers to collaboratively print a single-piece structure. Each robotic printer is equipped with its own pump, allowing for synchronized printing operations. In their study, primary materials are utilized alongside support materials, such as clay, which can be integrated into one of the robots to form the necessary support structure. To prevent collisions between the robotic printers and ensure precise placement of both primary and support materials, meticulous calibration of the system is essential. The introduction of two or more nozzles significantly increases the complexity of the printing system. Nevertheless, mortar remains a cost-effective choice for the primary material in concrete printing applications. However, if the support material proves to be more expensive than the primary material, it could lead to increased overall manufacturing costs for the component. This economic consideration highlights the importance of balancing material choices to optimize both functionality and cost-efficiency in multi-material 3D concrete printing setups.

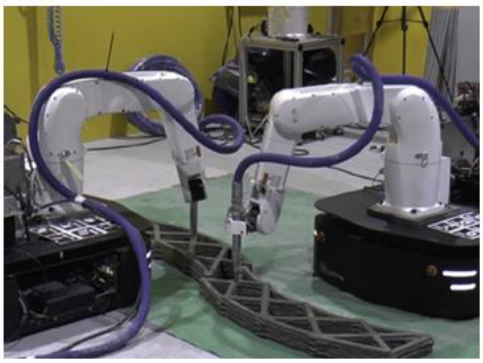

Figure 10. Two robot printers provide continuous printing (Zhang et al., 2018)

3. The Development of Three-Dimensional Printing Technology in the Construction Industry

The initial forays into automated construction by Japanese companies began in the 1980s, focusing primarily on two categories of work (Taylor et al., 2003). The first category involved the replacement of simple labor tasks on construction sites with single-task robots. These robots were utilized for various applications such as concrete floor finishing, spray painting, tile inspection, and material handling.
The second category encompassed fully automated systems capable of constructing tall buildings using steel and concrete. These structures are typically composed of pre-fabricated components assembled on-site, as illustrated in Figure 11. A notable example of this approach is the Big-Canopy system, which stands out as the first computerized building system designed for precise concrete construction. The Big-Canopy features four distinct masts that support an overhead crane, enabling the delivery of components directed by a joystick operator. Furthermore, a centralized information control system orchestrates and manages all operational tasks, ensuring efficiency and accuracy in the construction process (Khoshnevis et al., 2006; Wakisaka et al., 2000). This integration of technology in construction not only streamlines operations but also enhances the precision of building processes.

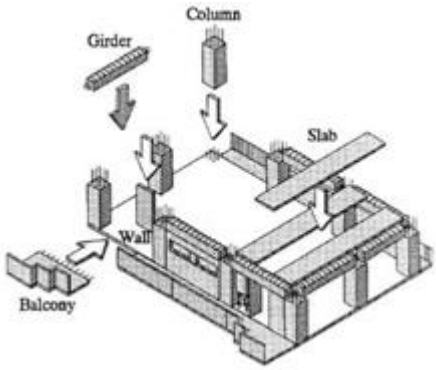

Figure 11. The use of prefabricated components in RC building (Wakisaka et al., 2000).

This text is a list of the history of 3D printing. It was written by Micallef in 2015. It talks about the most important moments in the history of 3D printing. It also talks about how 3D printing was first used to make buildings:

• The stereolithography patent was obtained by Chuck Hull in 1984. Stereolithography is the name for the process of making 3D objects using a computer-controlled laser beam that builds

the needed structure layer by layer from a liquid polymer which hardens when it touches the laser light (Kocovic, 2017).

• 1985: The technology known as selective laser sintering was first developed by two scientists, Dr Carl Deckard and Dr Joe Beaman, at the University of Texas at Austin. This is a 3D printing technique where powdered materials are heated using a strong laser (Kocovic, 2017).

• 1988: Scott Crump makes a toy frog using an old way of printing in 3D. This method was later used to make products to sell. It is called 'Fused Deposition Modelling' (FDM).

• In 1992, 3D Systems made the first 3D printer.

• 2005: The RepRap project has started. RepRap means 'Replicating Rapid Prototyper' and is a project that anyone can get involved in. It was started by Dr Adrian Bowyer, who teaches mechanical engineering at the University of Bath (UK). The objective is to develop a 3D printer that is capable of manufacturing the majority of its own components and replicating itself to a significant degree.

• 2006: Objet has engineered a machine that is capable of printing with a variety of materials.

• 8 March 2010: The initial full-scale model of a 3D-printed structure was created.

• March 2013: The first 3D-printed canal house was the brainchild of Dutch architects.

• January 2014: The building of the world's first 3D-printed home, 'Canal House', got underway.

• January 2015: WinSun has constructed an apartment complex in China employing 3D-printed panels.

Another important point to consider alongside the innovations that 3D printing technology will bring to the construction system is its potential impact on building culture and design. 3D printing technology has the potential to transform building production, and this is an area that requires comprehensive research. In general, people use three main categories of material in 3D printing: liquid, solid and powder-based. These categories include various types of materials, such as polymers, metals, ceramics and composites (Noorani, 2017). As in other fields, companies have developed different printing techniques, tools, and materials that are used on an architectural scale. Table 1 shows the 3D printing techniques that can be used in architectural construction, the materials used in production, the maximum dimensions of the produced elements, the finishing processes that can be applied afterwards, the layer height that can be produced per unit of time and the areas where 3D concrete printing technology can be used (Artuğ & Altun, 2019).

Additive manufacturing is part of the Fourth Industrial Revolution. 3D printing has the potential to transform science and technology by enabling the production of items that previously required specialised facilities using low-cost tools. While additive manufacturing will certainly not replace existing production processes entirely, it will be applied where practical and will fill gaps. For a period of time, it will be necessary to combine human labour and craftsmanship with high-tech tools (Strauss, 2016).

Table 1. Key features of different 3D printing techniques used in the architectural construction industry (Hauschid, 2011)

Technology	CNC precast concrete parts	Multi-jet modelling (MJM)	3D Printing (3DP)	Fused Deposition Modelling (FDM)	Selective Laser Sintering (SLS)	Stereo-lithography (STL)	Contour Crafting (CC) D shape	Robot-based layering

4. Production of Structural Elements Using Three-Dimensional Techniques

Building materials are the most basic natural components used to construct a building's structure, including bricks and glass. These components are then brought together or cast into moulds to form building elements such as stairs, walls, flooring and foundations. The structural elements of a building can be listed as follows: walls, floors, the roof, stairs, and joinery. A system can be defined as a more complex, integrated whole formed by interrelated or interdependent parts that serve a common purpose. A structure can be considered the physical assembly of numerous systems and subsystems that must be coordinated and integrated with each other, as well as with the three-dimensional form and spatial organisation of the structure as a whole (Ching and Adams, 2008). The systems that make up the structure are: Structural system; substructure (foundation system); superstructure (load-bearing wall, column, beam and slab system); enclosure system (roof, walls and joinery); mechanical systems (water supply system, wastewater drainage system, heating, ventilation and air conditioning systems, electrical system, vertical transport systems, fire extinguishing systems and waste control system).

Reinforcement in 3D printing of concrete (3DPC) is essential for enhancing structural performance and reliability. Prior studies have demonstrated the extrusion of strain-hardening cementitious composites (SHCC) integrated with steel bars, as depicted in Figure 11 (Van Zijl et al., 2016). Specifically, in the case of reinforced SHCC (R/SHCC), two steel bars were

extruded simultaneously with the SHCC, as illustrated in the figure. In this process, the steel bars were inserted horizontally through specially designed apertures located at the rear of the extruder. Once the bars were positioned, they were automatically drawn in and guided by a vertical piston extruder through a 90° bend. This innovative method allows for seamless integration of reinforcement into the 3D printed concrete, thereby improving the structural integrity and load-bearing capacity of the fabricated components. The use of R/SHCC signifies a significant advancement in the capabilities of 3DPC technologies, enabling the construction of more robust and reliable structures.

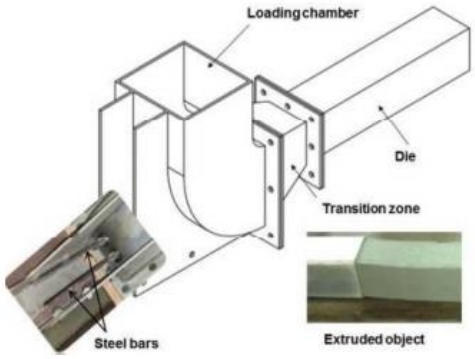

Figure 11. The process of manufacturing steel bar reinforcement in SHCC by means of extrusion. (Van Zijl et al., 2016)

The integration of reinforcement in the automated layer-by-layer 3D printing of concrete (3DPC) presents notable challenges, particularly when it comes to vertical reinforcement and its connections, largely due to the constraints of current printing technologies. To enhance the structural integrity of 3DPC structures, alternative reinforcement methods must be explored. Options such as composite fibers mixed into concrete, carbon fiber, or fiber-reinforced polymer (FRP) have potential; however, their effectiveness necessitates thorough investigation and innovative adaptations to existing 3DPC technologies. Research by Kim et al. (2003) highlights that the structural capacity and ductility of 3DPC columns and beams can be significantly improved by incorporating FRP into the design. This suggests that exploring these alternative reinforcement methods could lead to marked enhancements in structural performance. A promising solution lies in developing hybrid printing systems capable of simultaneously printing concrete and various reinforcement types in diverse configurations. Manual placement of reinforcement has already been employed in practice, as demonstrated in Figure 12 (Continuum, n.d.). This includes techniques for inserting reinforcement in intermediate layers (Figure 12.a), positioning it between filament layers (Figures 12.b & 12.c), or using extrusion through the sides of pre-tied reinforcement cages (Figure 12.d). Despite these manual methods, achieving full automation in the reinforcement process could revolutionize 3DPC. Automating the incorporation of reinforcement would enhance precision, reduce manufacturing time, lower labor costs, and minimize material waste, ultimately contributing to more efficient construction practices. Moving forward, the development of automated systems for reinforcement integration will be crucial for advancing the capabilities and applications of 3DPC.

Figure 12. Reinforcement application in 3D-printed concrete objects (Continuum, n.d.1), (Continuum, n.d.2), (3ders, n.d.), (Continuum, n.d.3).

In addition to the previously discussed methods for integrating reinforcement in 3D concrete printing (3DCP), researchers at the Singapore Centre for 3D Printing (SC3DP) are actively developing two innovative techniques, illustrated in Figure 13. The first method involves creating a new nozzle system that allows for the simultaneous extrusion of steel wire along with the concrete material, as shown in Figure 13.a. This approach requires the steel wire to possess adequate flexibility, enabling it to accommodate the dynamic movements of the printing nozzle, especially when navigating geometrical curves or transitioning between different layers of the structure. The second method introduces a robotic system tasked with automating the injection of steel fibers into an existing layer of 3DPC prior to the deposition of the subsequent layer, as depicted in Figure 13.b. This technique aims to enhance the bonding and structural integrity between layers by strategically placing reinforcement where it is most needed. Both methods are still in the preliminary stages of development, highlighting the need for further research and experimentation before they can be fully integrated into existing 3DPC processes (Paul et al., 2018). These advancements hold promise for improving the performance and durability of 3D printed structures, yet detailed investigations into their effectiveness and applicability are essential for successful implementation.

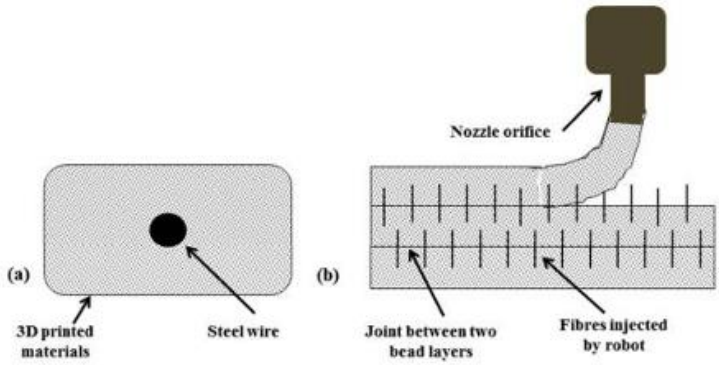

Figure 13. The following prototypes were created to show how reinforcement can be used in 3 DPPC: a) Steel wire extrusion, b) Fibre injection (Paul et al., 2018)

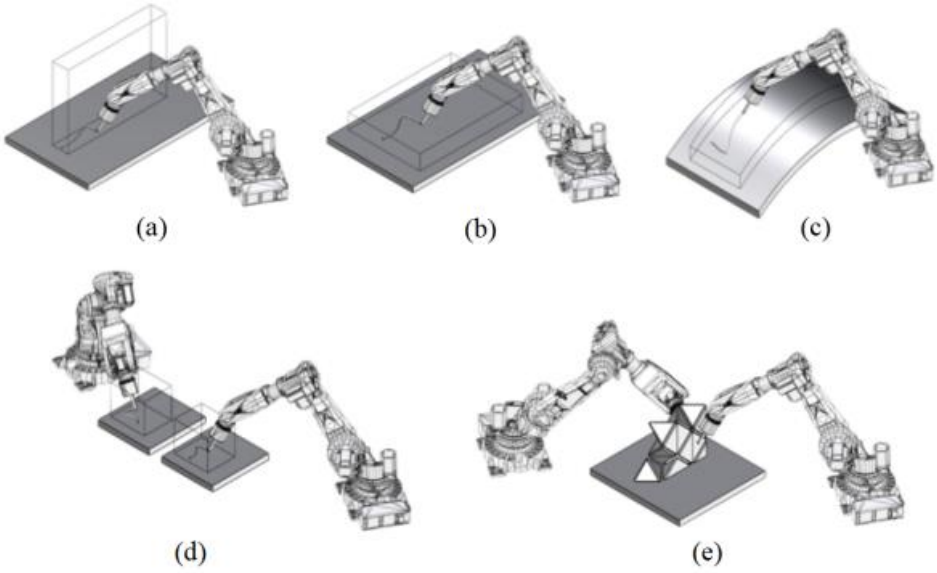

Figure 14. There are different types of external support: **a)** No support, **b)** Flat support, **c)** Curved support, **d)** Multiple supports, **e)** Assembled supports (Duballet, 2019)

External supports for 3D printing construction elements are illustrated in Figure 14, showcasing various approaches that utilize mortar extrusion controlled by a 6-axis robot. While the printing process remains consistent, the variation in external support types leads to significantly different systems and a wide range of possible forms for the printed structures. This review underscores the importance of further discussions, particularly concerning the assembly aspects of 3D printing in construction. When direct printing can occur without the need for external components or assembly elements, it simplifies the process. However, scenarios involving multiple printing instances inherently introduce an assembly step. Similarly, collaborative printing processes often necessitate an assembly phase, whereby external supports are integrated during the extrusion process. Understanding the complexities, technological challenges, and costs associated with various building systems is crucial for successful project planning. Highlighting the distinctions between these systems can enhance the anticipation of potential complications. Moreover, innovative solutions can often circumvent obstacles when the focus is on the entire building system rather than on creating overly complex processes that may hinder industrial adoption. By addressing these considerations, stakeholders can streamline the development and application of 3D printing technologies in construction, facilitating broader acceptance and implementation in the industry.

Sub-structure Production

Contour Crafting nozzle assembly and motion control system and a special method of cementitious material delivery system are employed by the method (Contourcrafting, n.d.). The substantial metal components of the tower need to be conveyed from the manufacturing facility to the wind farm for assembly (see Figure 15). They are often called "wide loads". This means that they need to be transported in a special way. Moreover, there is currently a strong impetus to construct taller towers that can reach stronger wind elevations. But the way towers are built now is limited because it costs a lot of money to build cranes that can reach higher than the current maximum height (85 to 100 metres). In addition, the construction of taller towers necessitates the use of larger base segments, which pose challenges in terms of transportation

due to limitations in road width and height restrictions imposed by overpasses. Moreover, the deployment of large cranes at wind farms requires wider roads.

Figure 15. Infrastructure work with 3D printers (Contourcrafting, n.d.)

Wall Production

a) A Block Production

In Craveiro et al., a curved external wall with a special material mix was chosen as an example. (2020) (Figure 16.a). Presently, material extrusion represents the most pervasive technology for the fabrication of homogeneous concrete structures by AM. An AM system capable of extruding functionally graded concrete was developed in this study (see Figure 16.b-c). The solitary curved block unit exhibited in Figure 17.a-b-c was printed at a deposition velocity of 25 mm/s employing cork material. A first geometrical study of the curved block unit was done after the curing period, using a 3D Systems Sense 3D scanner (resolution ~1 mm).

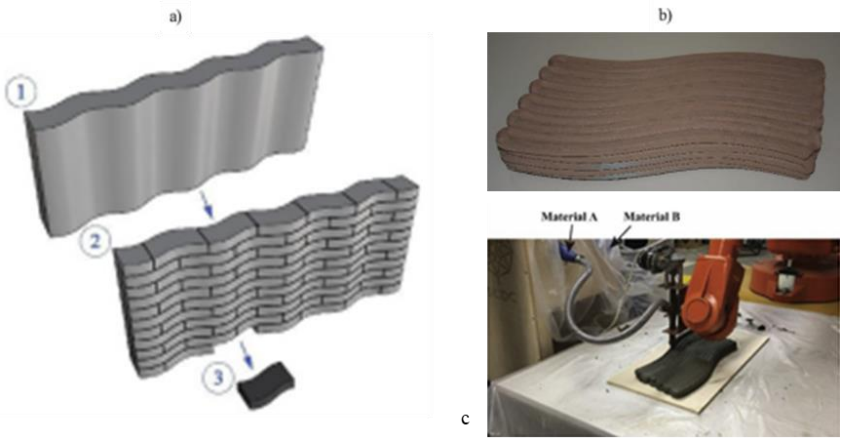

Figure 16.a) The image below shows a visual output in Rhinoceros. It includes the initial shape (1), the wall subdivided into discrete blocks (2), and one block unit extracted (3), **b)** A curved block unit produced by AM, **c)** 3D printing process (Craveiro et all., 2020)

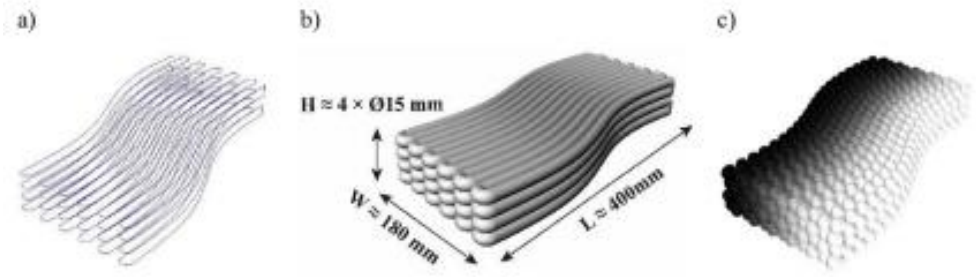

Figure 17. Curved block unit: **a)** path for the tool, **b)** computer design showing how big it is and how the filament is layered (4 layers), **c)** computer design showing the change in colour (Craveiro et all., 2020)

A block unit (Figure 16.b) made of two different concretes was produced. In this scenario, each pump reservoir contains a single material, one comprising a sand-based concrete mixture (cork) and the other a mixture in which cork granules replace 10vol% of sand (Figure 17.c). The materials were extruded through the dynamic nozzle based on the material composition and printing instructions. Each filament was 15 mm thick, and the printing speed was 25 mm/s. These values were chosen after running several tests, in an iterative process that took material flowability and hardware limitations (e.g. pump pressure) into account.

b) A Straight Wall Production

The prototype of a 'flat' wall is shown in Figure 18. Horizontal printing on the floor was the first step, followed by movement to its vertical position. A strategy like this gives you a lot of freedom when it comes to the geometry of thin 2.5 D structures. It uses the smallest dimension of the object and gets rid of the main difficulty of direct printing: height. Nevertheless, from a structural design standpoint, the loading that corresponds to the handling of the object is likely to be the worst-case scenario, and therefore to ruin the attainable lightness of the wall (Duballet et al., 2017).

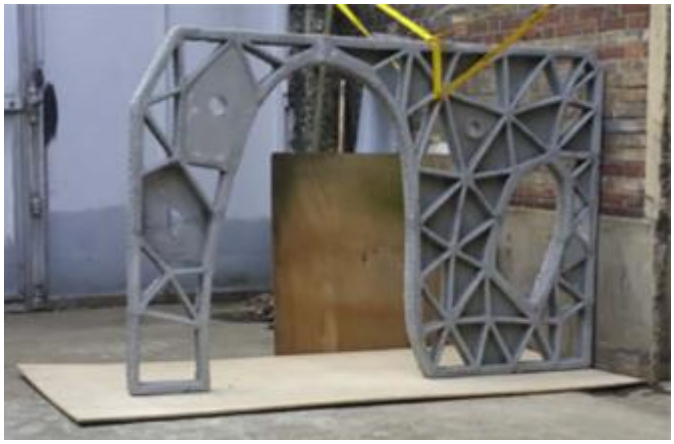

Figure 18. Flat wall (Duballet et al., 2017)

c) A Curved Wall Production

The construction of a load-bearing, steel-reinforced concrete wall using an in-situ fabrication process was carried out by Buchli et al. (2018). It is believed that one of the most comprehensive IF (in situ fabrication) processes in the building construction domain is reflected in the development and the final system. The NEST building in Dübendorf, Switzerland, was the site of the first use of robotics to build a fully load-bearing steel-reinforced concrete wall in situ (Buchli et al., 2018). The mesh mould metal (M3) process is a new way of making strong structures using steel and concrete. It is based on new ideas in materials science, structural engineering, and mechatronics (Hack, 2018). A robotic fabrication process enables the complexity of the denser mesh. This process involves a mobile robot (the in situ fabricator, or IF) guiding a special purpose tool head, which is mounted on a robotic arm, through 3D space (see Figure 19.a). The development and testing of the M3 process was a highly collaborative endeavour, involving experts from multiple disciplines working in close tandem. The subjects

involved are architectural design, structural engineering, materials science and robotics. The fundamental notion in M3 revolves around the utilisation of the reinforcement mesh as a lost formwork. The mesh is constructed with greater density than conventional steel-reinforced concrete rebar cages, thereby ensuring the concrete mix's yield stress (cohesion) prevents the concrete from flowing through the mesh (Hack et al., 2014).

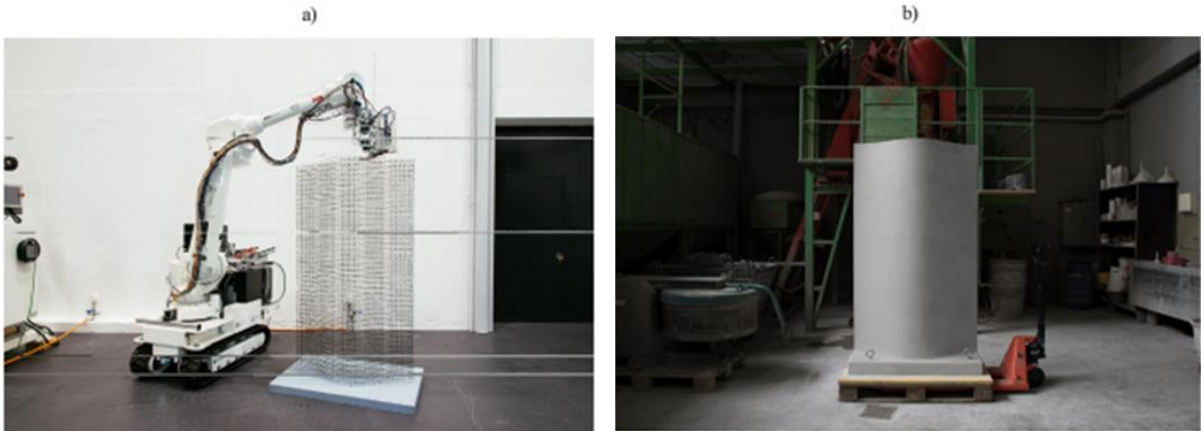

Figure 19. a) The construction of a mesh prototype, **b)** involves the creation of a filled steel-reinforced wall prototype (Buchli et al., 2018)

The M3 process is dependent on a specific concrete mixture (Hack, 2018) and the yield stress (Yahia et al., 2015) of the concrete mix to ensure it remains contained within the metal mesh. The assembly of the mesh and the filling with concrete occurs directly on the construction site, i.e. in the final position of the wall. The exterior surfaces of the meshes are subsequently overlaid with concrete, which is customarily applied by means of a spray application, followed by a manual trowelling of the surface finish (see Figure 19.b). The composition and thickness of this layer should be selected according to the expected durability and exposure conditions. The IF is equipped with additional sensors to support the building process, in addition to the process-specific M3 tooling, to facilitate the construction of the mesh. The IF must sense its position within the construction site. It must also be able to measure the mesh's contour during construction. This is in order to build the mesh accurately on-site. Using the M3 process, workers built an undulated steel-reinforced concrete wall for the DFAB house on the NEST building at EMPA in Switzerland. The wall's dimensions are 12 metres in length and 2.8 metres in height. The necessary mesh comprised over 20,000 welding points, which were constructed with an average discrepancy of 9.5 mm and a maximum discrepancy of 38 mm from the intended blueprint (see Figure 20.a, b). When finished, the wall will carry a structural live load of more than 100 t. (Buchli et al., 2018).

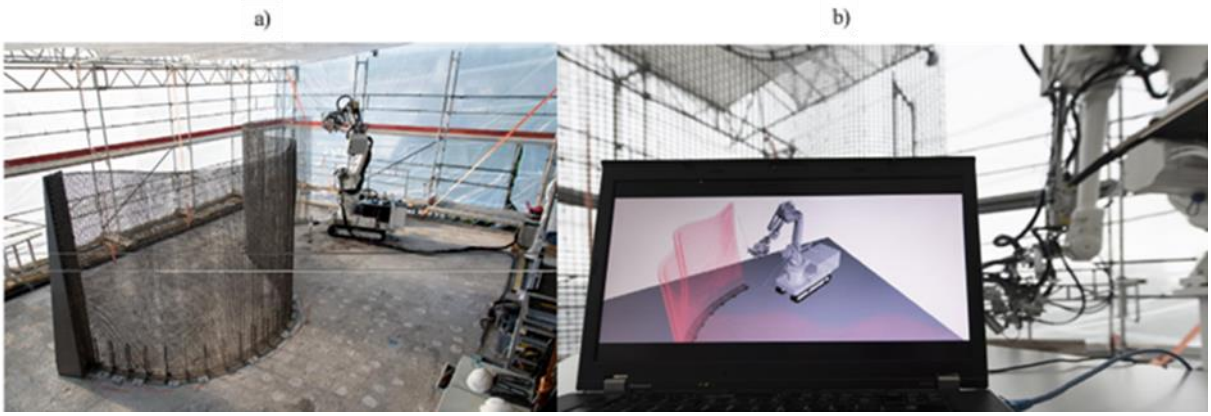

Figure 20. a) The IF assembling the metal-reinforced reinforcement mesh at the NEST building site, **b)** Screen grab of the CAD incorporation of the M3/IF manufacturing system (Buchli et al., 2018)

d) Hybrid 3D Printing & Milling for Acoustic Façades

The acoustic performance and surface precision of façade panels could be enhanced by integrating 3D concrete printing (3DCP) and robotic milling. This was the focus of the Master's thesis that Jarry Pérez López wrote at RWTH Aachen University. The design and manufacture of all prototypes was carried out at Vertico's studio in Eindhoven, using a robotic arm from ABB (model IRB 6640) and a 2K MAI-Vertico printhead (Vertico, n.d.). The study's objectives were to:

- Enhance the surface quality and geometric precision of three-dimensional printed panels.
- Find out how the speed of the printer, how thick the layers are, and the settings for milling affect how well sound is scattered.
- Establish principles for the creation of eco-friendly, sonically enhanced structural components.

Sixteen 700 mm × 700 mm concrete panels were printed in four groups, with different patterns on the surface (one-dimensional, two-dimensional, and different levels of depth) and wave height (25 mm and 50 mm). The testing of panels was undertaken within an anechoic chamber, the purpose of which was to facilitate the measurement of scattering coefficients (Figure 21) (Vertico, n.d.).

Two extra milled panels (M1 and M2) were made to compare hybrid fabrication with pure 3D printing:

- M1: 8 repetitions across two axes, changing depth, based on the top-performing B-series examples.
- M2: 12 times, with small changes in two directions, based on the C-series designs.

The highest acoustic scattering performance was achieved by two-dimensional periodic surfaces with a depth of 50 mm, especially in the case of omnidirectional noise diffusion. Milling made a big difference to geometric precision, getting rid of the staircase effect, and allowed for sharper edges and complex geometries that printing alone couldn't achieve (Vertico, n.d.). The best way to balance surface refinement with material integrity is to use green-state milling (this is a process that happens after printing and before curing). Strong potential for

urban noise mitigation was demonstrated by this hybrid manufacturing workflow, while aesthetic versatility was also offered. A seamless transition from digital concept to precisely manufactured, high-performance façade components was enabled by the combination of parametric design tools and robotic fabrication.

Figure 21. Examples of manufactured acoustic panels **(**Vertico, n.d.)

e) Masonary Wall

In 2021, an office space privacy wall was constructed by a Waterloo University team in Toronto, Canada. The structure's distinctiveness lies not only in its aesthetic appeal, but also in its remarkable method of construction. Utilising an advanced 3D printer, the structure was assembled "like a honeycomb, where the interlocking of hexagonal units forms a robust and efficient material framework" (Figure 22.a) (Prieto, 2022). The art and craft of building in clay is being reshaped by HIVE Project, which combines traditional ceramics, smart geometry and robotic precision to construct a masonry wall made up of one hundred seventy-five unique 3D-printed clay bricks. The way the wall is built plays with the opening and closing of the clay bricks, which creates a special atmosphere (see Figure 22.b). The configuration facilitates both seclusion and the diffusion of light through the partition, engendering a remarkable ambiance that compartmentalises whilst concomitantly preserving the ambience of the entire space (Figure 22.c).

Canada's first 3D-printed masonry wall was created after a complicated process of development where the team tested different materials, designs, and ways of making it before they could make it. According to the team, the project's approach aims "the spirit of traditional ceramic craft with robotic precision". This offers new avenues for material expression and geometric complexity within this field. (Prieto, 2022). One of their goals was to acknowledge the natural properties of clay. Clay is a stable and long-lasting traditional material. They assembled diverse clay mixtures. These were adaptable for an innovative 3D-printing process. The concept of 'digital craftsmanship' is introduced by HIVE as a new construction process, combining digital and analogue models.

The creation of the masonry wall involves three main steps. First, the design and best pattern for forming the wall are selected. Next, a handmade clay mixture is produced to achieve the malleability and fluidity required to shape the clay units. Finally, a robot 3D-prints the digital pattern, which has already been designed, through sliced layers of clay. The result of this work was a 2.3 m x 5.4 m 3D-printed masonry wall for a reception area (Prieto, 2022). Following extensive research and testing of various prototypes, the team developed a computer-generated design for a unit geometry that ensures the wall's feasibility. Using the association of triangular bricks composed of four hexagonal shapes, the 3D printer creates not only a stable and permeable wall, but also an artistic object with a unique pattern, texture and colour (Prieto, 2022).

A six-member research team from the University of Waterloo designed HIVE in partnership with the Investment Management Corporation of Ontario (IMCO) and the Masonry Works Council of Ontario. The project was commissioned by SDI Interior Design (Prieto, 2022), (Archdaily, n.d.).

Beam Production

a) Truss Beam

An Italian Institute of excellence, which specialises in the study of concrete mortars, received a WASP printer. A 4-metre BIGDELTA WASP was used by Domenico Asprone and some friends of the University Federico II of Naples. Figure 23 depicts an idea proposed by the WASP Project1 of using steel bars with adequately designed components for making a lightweight composite beam. The University of Naples' Stress Consortium and University of Pavia are collaborating on the research. "3D printing allows you to create curved, hollow elements or with special features that would normally require complicated wooden shapes (moulds) for fresh concrete, which is more expensive" explained Stress Consortium's Marco Iuorio. Tests on a 3-metre long test beam are planned to check the mechanical performance of the reinforced concrete elements in the Department of Engineering Structures and Architecture's laboratories (3dwasp, n.d.).

Figure 23. a) Beam, **b)** Team members: University of Naples Federico II (3dwasp, n.d.)

b) Sloped Truss Beam

A 3D-printed beam has been produced, consisting of an irregular arc (the longitudinal profile of Vesuvius volcano) measuring approximately 4.00 m in length and 0.25 m in width. The entire shape is characterised by a double-path line of printed concrete, with the exception of the hole edges (Figure 24). The connection system for the rebar is the same as the one used for the straight RC beam. Such an unconventional form has been selected to capitalise on the possibilities afforded by AM, namely the 3D printing of unconstrained concrete elements in contrast to conventional manufacturing methodologies. As you can see in Figure 24.a, each 3D-printed concrete segment is different from the others. This is because it is not necessary to produce pieces with the same shape (Asprone et al., 2018).

The final shape of the printed beam is shown in Figure 24.b. At this early stage of the work, the shape of each beam part has been made as good as possible. This has been done by using a computer to estimate the internal stress distribution for a similar arch-shaped solid concrete beam. This makes it possible to remove the concrete material from the solid beam configuration in the "ideal" way. This also makes sure that the segments are still strong and stiff enough.

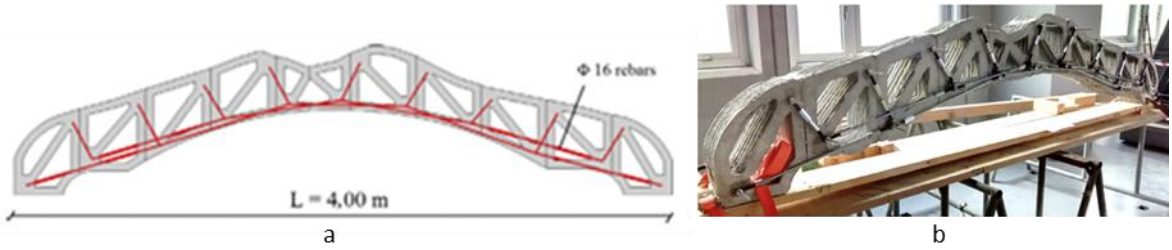

Figure 24. a) The cad design of the curved shaped truss beam, **b)** The view of the beam after printing process (Asprone et al., 2018)

c) Space Frame Production

Figure 25 shows a good way to print a concrete mould to be filled with UHPFC2, a special type of concrete. The parts between the tubes that are not used are removed afterwards, leaving only a very light, tubular, space-truss structure — in this case, a load-bearing pillar. This is called 'indirect' printing, and it shows how well concrete printing works. Although removable concrete parts can be considered printed support, Figure 25 makes no use of external support. Utilising

the same printing method (i.e. mortar extrusion directed by a 6-axis robot) and changing only the kind of outside support creates extremely divergent construction systems and achievable forms. Although direct printing does not necessitate the use of external components or assembly, multiple printing invariably involves an assembly step. In the same way, we can think of collaborative printing as including an assembly step. This is a process where external supports are added during extrusion. It is critical to point out these differences between building systems to correctly anticipate the associated complexity and technological barriers, and estimate the cost of a project. Also, you can get a good result by getting past a problem by working on the whole building system instead of making processes that are too complicated and will be hard to use on a large scale. For slipforming, the extrusion scale is usually around 1/10 of the object's size, but lower for layered extrusion (e.g. around 1/1000, as in Figures 25.a, 25.b and 25.c (R. Duballet et al., 2017). Fig. 25.c shows the structure made of two parts: the 3D-printed envelope and the core, made of conventional cast concrete. Total printing time: 15h 30m (Dirrenberger, 2019).

Figure 25. a) This is the mould for the fabrication of a space truss (XtreeE, 2016), **b)** Printed pillar location: Aix-en-Provence (XtreeE, 2016), **c)** View of school canoopy (XtreeE, 2016)

Slab Production

- **Smart Slab Formwork**

Voxeljet 3D-printed large-format formwork for the concrete casting of a smart ceiling. This was part of a research project at ETH Zurich. The project was part of the Digital Fabrication Swiss National Centre of Competence in Research (NCCR DFAB). This shows how we can create more sustainable buildings in the future. The highly complex formwork for the DFAB House research project in the NEST (Next Evolution in Sustainable Building Technologies) project of the EMPA (Swiss Federal Laboratories for Materials Science and Technology) was created by Voxeljet AG using 3D printing. This involved a 78 m² lightweight concrete slab that serves as a ceiling with a clever design. For the project, the creation of 136 formwork elements was achieved using Powder-Binder-Jetting, a 3D printing technology in which layers of silica sand are bound together with an organic binder (furan resin) through polymerisation (Voxeljet, n.d.). The VX4000 from Voxeljet is the world's largest 3D printing system for sand moulds and can print formwork elements measuring 4.00 x 2.00 x 1.00 m, with the 3D-printed elements being prefabricated by Voxeljet and infiltrated with polyester resin by ETH Zurich. These elements were then assembled into seven-metre-long formwork for the slab elements and coated with a release agent. Prior to concrete casting, application of a thin layer of fibre-

reinforced shotcrete was carried out. The struts were formed using laser-cut timber formwork, and concrete casting was used to create the structure. Consequently, the completed components were conveyed directly to the construction site and assembled there expeditiously post-stripping (Figure 26.b).

The intelligent slab constitutes a pivotal element of the DFAB House, which was conceptualised and designed by the Digital Building Technologies (DBT) research group at ETH Zurich under the direction of Prof. Dr. Benjamin Dillenburger. It shows how 3D printing can reduce construction site consumption (Figure 27.a,b). Slabs use much more concrete – up to 80% of a building's weight (Voxeljet, n.d.), so the saving potential is huge. The slab is the right weight at each point at the DFAB House. Over 60% of concrete is saved compared to conventional construction methods. 3D printing with Powder-Binder-Jetting is the ideal way to produce complex, curved formwork elements. The "Smart Slab" will help the construction industry build more compact and material-efficient structures in the future. Additional features such as lamp sockets, drill holes, and sprinkler systems can be added to the 3D printing data set.

About the project, Prof. Benjamin Dillenburger said: "There are more and more buildings being built all over the world, but we don't have enough materials to do it. We can combine the advantages of additive manufacturing in creating highly complex geometries with concrete's excellent structural capacity by 3D-printing the formwork for concrete casting. This allows us to improve the design of concrete elements and use the material more efficiently." (Voxeljet, n.d.).

Staircase Production

In 2015, the Bouwbeurs 2016 trade fair in Rotterdam, the Netherlands, featured a design workshop for architects. The TU/e 3DCP production team's redesign efforts were key to the success of the workshop (see Figures 29.a and 29.b) (Bos et al., 2016). The pattern on the railing had to be changed, and a special curved print surface had to be made to get the right design. The path that the printer head follows during printing is the guiding principle in generating 3DCP geometries. Any conceivable tool path through 3D space can generally be followed by modern gantry and articulated robots, whether defined by Euclidean geometrical shapes or more complex definitions such as splines. What this also lets you do is print on any non-planar surface, as Bos and his team found out in 2016.

The reason for highlighting this issue is to set the stage for automatically generating print job files from CAD geometries, removing the need for the involvement of production and product specialists. It'd be like when you open a text processing application to print a document on paper. This is not yet a possibility in the present circumstances. Initiatives in which AMoC has been implemented have been conceived with the distinct characteristics of the production technique in mind.

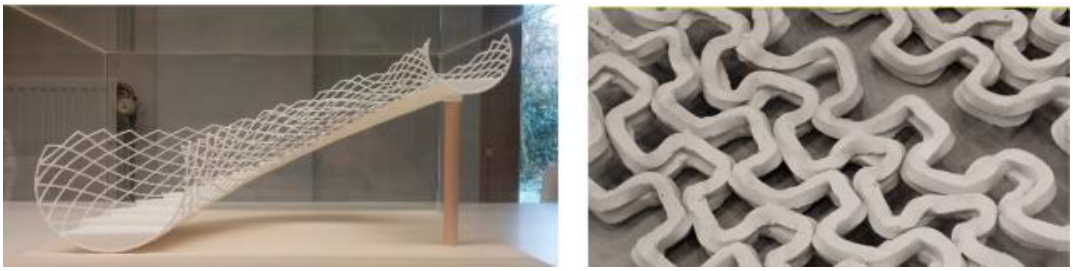

Figure 29. This is the one of the designs that was submitted to workshop, it was a staircase by BiermanHenket Architects, **a)** It is a 3D-printed scale model for this design challenge for architects back in 2015 about 3D printing concrete, **b)** A printed part of the railing (Bos et al., 2016).

Urban Furniture

İSTON has become the first company in Turkey to start producing urban furniture, such as seating, litter bins and planters, using 3D concrete printing technology. The robotic system uses mortar with a C50 concrete strength level. Products developed using ultra-high-performance

fibre-reinforced concrete offer significant material savings and greater efficiency in transportation and installation. In the garden of the Feshane Cultural Centre overlooking the sea; modern, thin-section 3D-printed white concrete seating elements and waste station boxes have been used on the grey concrete paving slabs arranged in a linear pattern, including grass-covered surfaces, creating a contrast to the building's stone masonry system (Figure 30.a). Medipol University has completed the garden landscaping design on the 4th floor with garden furniture created using 3D technology. The seating surfaces of the seating elements, which have a white concrete supporting structure, are finished with polished long wooden elements (Figure 30.b).

5. Conclusion and Discussion

This study examined the production of structural elements using 3D concrete technology. The research revealed that companies and universities from various countries have collaborated to create inspiring structural elements. While some of these remain at the research and production stage, others have been used in physical buildings. Clearly, conducting 3D concrete casting studies without the support of a company is challenging. Therefore, to conduct further studies on this technology in our country, we need to set up research companies specialising in 3D concrete casting or other materials, and support these studies. The widespread sale of robots and cranes capable of large-scale production is also necessary for the development of 3D printing technology. The significant reduction in required labour and construction time, minimal material loss and advantages such as mass customisation and design flexibility for users make this construction technology attractive (Artuğ and Altun, 2019).

Considering the instances cited earlier, it's evident that 3BCP technology facilitates the creation of intricate forms (e.g. arched beams of diverse elevations), optimisation of shapes in terms of topology, minimisation of concrete volume and weight, removal of sophisticated formwork arrangements, and straightforward conveyance and assembly. 3D printing methods have reduced concrete material waste, enabled construction with fewer teams and workers in a shorter time, made it possible to produce walls and buildings in more flexible forms, and

provided concrete elements with higher tensile and flexural strength (Şahin Diri and Yıldız, 2024). Time, materials and money are all saved by 3D printing using powder-binder jetting. Ultimately, 3D-printed formwork will change the way concrete is used in construction across many different areas, including formwork, formwork skins and facades. This'll give companies a big competitive edge by letting them create unique designs.

The use of 3D printers in construction production is increasing rapidly today. The capabilities of the concrete and devices used in this technology have improved. Consequently, 3D printers are being used in an increasing number of areas, including the production of bridges, infrastructure and buildings. Interest in NASA's project tenders, private companies' designs, and researchers' work indicates that many structures and structural elements will be produced using 3D printers in the future. It is thought that the use of 3D printers in construction will increase rapidly due to the labour, moulding and material savings compared to traditional techniques.

Abstract

Building designers and builders face material selection challenges at every stage of construction, and there's often no single, definitive criterion for selecting materials. Therefore, professionals often have to consider numerous factors when selecting materials. One of the key stages of material selection in construction is the selection of the wall system and materials. Today, curtain wall systems, panel systems, or infill wall systems constructed using adhesive mortar are used for the exterior walls of buildings. This study compared the most commonly used wall infill materials, such as brick, aerated concrete, and briquette, according to the performance criteria expected from exterior walls. For this purpose, a survey was conducted with the participation of building designers, building manufacturers, and academics. The survey evaluated and scored exterior wall performance criteria. Next, a comparison of brick, aerated concrete, and briquette was conducted using the AHP (Analytical Hierarchical Process) method. The six exterior wall performance criteria receiving the highest importance in the survey were considered in the comparison. Finally, the production and sales volumes of these materials in the construction industry were examined and compared with the selection preferences obtained from the AHP.

Keywords: Wall infill materials, material selection criteria, AHP method, material production volumes

1. Introduction

Today, sandwich wall systems, prefabricated lightweight panel systems, ightweight concrete infill or insulated precast panels, lightweight steel or aluminum curtain wall systems, or infill walls constructed using the masonry method are used on the exterior facades of builAings with reinforced concrete frame load-bearing systems.

This study examined non-load-bearing infill walls constructed using the masonry method using adhesive mortar. In the first phase, the most commonly used infill materials in these types of walls, such as brick, aerated concrete, and briquette, were compared using a survey and AHP (*Analytical Hierarchical Process*). This comparison was based on the expected properties of exterior walls and the extent to which the materials considered met these properties. Finally, the participants' preferences were compared with the production and sales volumes of these materials in Turkey.

Materials Considered, Definition, and Properties

Brick

Brick is produced by firing clay. It is a more natural material than aerated concrete and briquettes. Types include blended brick, factory brick, solid brick, and perforated brick. It is a Class A fireproof material. Its properties and types are defined in the TS EN 771-1 standard.

Bricks produced in Turkey are classified as A-quality, B-quality, and regular bricks. Class A and B bricks are produced by firing at controlled high temperatures. Class A and B bricks are more homogeneous and lighter, have lower thermal conductivity, tighter tolerances, and higher dimensional stability. Class A bricks can also be used in load-bearing wall construction. According to data from the Turkish Statistical Institute, as of 2024, there were 162 brick companies operating in Turkey (TUIK, 2024).

Aerated Concrete

Aerated concrete is a new material compared to brick. Production in Turkey began in 1965 at a facility established in Istanbul under the name Türk Ytong Sanayi A.Ş. (*Turkish Ytong Sanayi A.Ş.*). Since the 1980s, new factories have been established in various provinces, and its production has expanded. It is produced from a mixture of materials such as siliceous sand, lime, and cement. It is a Class A fireproof material. It has a porous internal structure and is notable for its low thermal conductivity and light weight. It is a breathable material, but it is also water-absorbent. It is easy to cut Easy to cut. Aerated concrete allows for a smooth wall surface, eliminating the need for a thick layer of plaster. Its compressive strength is relatively low. Because its surface strength is also low, special dowels are required for anchored connections applied to facades. According to data from the Turkish Statistical Institute, as of 2024, there were eight aerated concrete companies operating in Turkey. (TUIK, 2024)

Briquette

Briquettes are concrete-based structural elements produced from a mixture of cement, sand, and lightweight aggregate. They cure in the open air. They are a Class A fireproof material. They are also known internationally as prefabricated concrete blocks or pumice blocks. Natural pumice, a type of volcanic rock, is used as lightweight aggregate in their production, and slag, a waste product of metal separation, is used in metal separation. Because they can be recycled, they are a sustainable material. They have various uses beyond wall construction. Today, mass production can be achieved at low cost with automated machinery. According to data from the Turkish Statistical Institute, as of 2024, there were 112 briquette companies operating in Turkey. (TUIK, 2024)

Survey and AHP

The survey and AHP study were conducted based on material selection criteria for brick, aerated concrete, and briquette. Criteria affecting wall material selection include building physics, building biology, and building statics, material and labor costs, ease of access to materials, ease of construction, dimensional properties, aesthetics, environmental impacts, and sustainability.

2. Findings and Discussion

In this phase of the study, a survey was conducted with the participation of a group of building designers, building manufacturers, and academics. The survey included 140 participants, with an average age of approximately 50. Participants were given the following criteria and asked to rate them based on their importance in selecting exterior wall infill materials.

Thermal conductivity	Lightness
Vapor permeability	Cost
Water permeability/water absorbency	Environmental impacts
Sound transmission loss	Building biology/health

Earthquake resistance	Dimensional stability/surface smoothness
Fire resistance	Ease of construction
Specific heat/heat capacity	Ease of access/transportation

The criteria's resulting scores were converted to percentage weights and ranked from largest to smallest. The resulting percentage values and their columnar graph are shown in Table 1 and Figure 1, respectively.

Table 1. Percentage values obtained from the survey results (Created by authors)

Thermal conductivity	% 16.3
Cost	% 14.2
Earthquake resistance	% 12.6
Fire resistance	% 12.4
Sound transmission loss	% 10.9
Environmental impacts	% 09.8
Water permeability/water absorbency	% 05.7
Vapor permeability	% 04.8
Lightness	% 04.0
Ease of construction	% 03.2
Specific heat/heat capacity	% 02.1
Ease of access/transportation	% 01.6
Building biology/health	% 01.2
Dimensional stability/surface smoothness	% 01.2

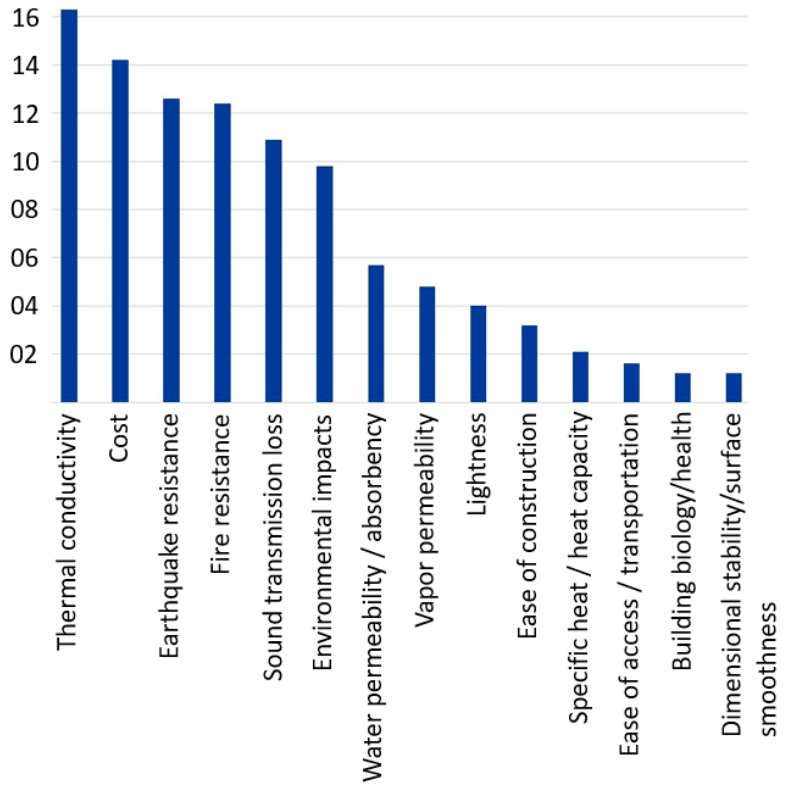

Figure 1. Columnar graph of percentage values of criteria (created by authors)

Looking at Figure 1, it can be seen that among the 14 criteria, the total weight of the first six criteria exceeds 75%, and the gap widens after the 6th criterion. These six criteria were taken into account in the AHP. These criteria are as follows, respectively:

1- Thermal conductivity	3- Earthquake resistance	5- Sound transmission loss
2- Cost	4- Fire resistance	6- Environmental impacts

Application of the AHP Method

The AHP (analytical hierarchical process) method, which began to be used in the late 20th century, facilitates choosing among multiple alternatives in multi-criteria and multi-objective decision-making situations.

This method can be used to compare and scale alternatives in complex decision-making processes involving multiple criteria. The method allows for the combined evaluation of qualitative and quantitative data.

In this method, complex decision-making processes are broken down into simpler components and evaluated through pairwise comparisons within a hierarchical structure. During the evaluations, criteria and alternatives are quantified using importance weights, and the most suitable alternative is determined through matrix calculations. Table 2 shows the AHP evaluation scale.

In summary, the process proceeds as follows: establishing the hierarchy, performing pairwise comparisons, calculating weights, finding the most suitable alternative, and conducting consistency analysis.

Table 2. AHP rating scale (created by authors)

Level of importance	Definition
1	Equally important
3	Moderately important
5	Highly important
7	Extremely important
2,4,6	İntermediate values

Firstly, the numerical values of brick, aerated concrete, and briquette corresponding to the six criteria mentioned above were determined for comparison using the AHP method.

According to TS 825 Annex E / 7.1.3.1, the numerical values, in accordance with the relevant criteria, exhibited by walls constructed with class A and B bricks compliant with the TS EN 771-1 “Masonry Units – Specifications – Part 1: Clay masonry units (*bricks*)” standard, using normal mortar, are given in Table 3. (TS 825, 2025), (TS EN 771-1, 2015)

According to TS 825 Annex E / 7.3.2, the numerical values, in accordance with the relevant criteria, exhibited by walls constructed with blocks compliant with the TS EN 771-4 “Masonry Units — Part 4: Aerated concrete masonry units (*AAC blocks*)” standard, laid with normal joint thickness and normal mortar, are given in Table 4. (TS 825, 2025), (TS EN 771-4, 2015)

According to TS 825 Annex E / 7.5.1.1, the numerical values, in accordance with the relevant criteria, exhibited by walls constructed with lightweight concrete blocks with holes compliant

with the TS EN 771-3 "Masonry Units – Specifications – Part 3: Concrete masonry units (*dense and lightweight aggregates*)" standard, are given in Table 5. (TS 825, 2025), (TS EN 771-3, 2015)

Carbon dioxide equivalent release per m^3 was used as the numerical value for environmental impact, and specific strength was used as the numerical value for earthquake resistance. The comparison of the numerical values of the materials according to the criteria is given in Table 6.

Table 3. Numerical values of walls built with A, B class bricks according to the criteria (TS 825, 2025; TS EN 771-1, 2015; Greenhouse, 2024; TUIK)

Thermal conductivity	:	$\lambda = 0.38 – 0.39$ W/mK
Unit volume weight	:	$\Delta = 750 – 800$ kg/m^3
Compressive strength	:	$\sigma = 8 – 10$ MPa => [N/mm^2]
Specific strength	:	$\sigma_s = 10.7 – 12.5$ kJ/kg
Fire resistance	:	T = 3 – 4 hours (*20 cm thickness*)
Sound transmission loss	:	$R_w \approx 51$ dB (*20 cm thickness*)
Carbon footprint	:	$W_c \approx 180$ kgCO_2eq/m^3
Current price	:	F ≈ 560 TL/m^2 (*20 cm thickness*)

Table 4. Numerical values of walls made of aerated concrete blocks according to the criteria (TS 825, 2025; TS EN 771-1, 2015; Greenhouse, 2024; TUIK)

Thermal conductivity	:	$\lambda = 0.23 – 0.24$ W/mK
Unit volume weight	:	$\Delta = 550 – 600$ kg/m^3
Compressive strength	:	$\sigma = 3 – 4$ MPa => [N/mm^2]
Specific strength	:	$\sigma_s = 6.5 – 7.2$ kJ/kg
Fire resistance	:	T = 3 – 4 hours (*20 cm thickness*)
Sound transmission loss	:	$R_w \approx 48$ dB (*20 cm thickness*)
Carbon footprint	:	$W_c \approx 250$ kgCO_2e/m^3
Current price	:	F ≈ 1050 TL/m^2 (*20 cm thickness*)

Table 5. Numerical values of walls made of lightweight concrete blocks with holes according to the criteria (TS 825, 2025; TS EN 771-1, 2015; Greenhouse, 2024; TUIK)

Thermal conductivity	:	$\lambda = 0.36 – 0.41$ W/mK
Unit volume weight	:	$\Delta = 700 – 800$ kg/m^3
Compressive strength	:	$\sigma = 6.5 – 7.5$ MPa => [N/mm^2]
Specific strength	:	$\sigma_s = 9.3 – 9.4$ kJ/kg
Fire resistance	:	T = 2 – 3 hours (*20 cm thickness*)
Sound transmission loss	:	$R_w \approx 50$ dB (*20 cm thickness*)
Carbon footprint	:	$W_c \approx 200$ kgCO_2e/m^3
Current price	:	F ≈ 300 TL/m^2 (*20 cm thickness*)

Table 6. Comparison of numerical values of materials according to criteria (Created by authors)

	Brick	Aerated concrete	Briquette
Thermal conductivity	Moderate ●●●○○ 0.38 – 0.39 W/mK	High ●●●●● 0.23 – 0.24 W/mK	Moderate ●●●○○ 0.36 – 0.41 W/mK
Cost (*20 cm thickness*)	Moderate-low ●●●●○ ≈ 560 TL/m^2	Moderate-high ●●○○○ ≈ 1050 TL/m^2	Low ●●●●● ≈ 300 TL/m^2
Specific strength	High ●●●●● 10.7 – 12.5 kJ/kg	Moderate ●●●○○ 6.5 – 7.2 kJ/kg	Moderate-high ●●●●○ 9.3 – 9.4 kJ/kg
Fire resistance (*20 cm thickness*)	High ●●●●● 3-4 hours	High ●●●●● 2-4 hours	Moderate-high ●●●●○ 2-3 hours
Sound transmission loss (*20 cm thickness*)	High ●●●●● ≈ 51 dB	Moderate-low ●●○○○ ≈ 48 dB	Moderate-high ●●●●○ ≈ 50 dB
Carbon footprint	Moderate-low ●●●●○ ≈ 180 $kgCO_2eq/m^3$	Moderate-high ●●○○○ ≈ 250 $kgCO_2e/m^3$	Moderate ●●●○○ ≈ 200 $kgCO_2e/m^3$

Then, pairwise comparison matrices were created. The pairwise comparison matrix of the criteria is given in Table 7, and the pairwise comparison matrices of the materials according to the criteria are given in Table 8.

Table 7. Pairwise comparison matrix of criteria (Created by authors)

Criteria	Thermal cond.	Cost	Spec. strength	Fire resistance	Sound tr. loss	C. footprint
Thermal conductivity	1	2	3	4	4	5
Cost	1/2	1	2	3	3	4
Specific strength	1/3	1/2	1	2	2	3
Fire resistance	1/4	1/3	1/2	1	1	2
Sound transmission loss	1/4	1/3	1/2	1	1	2

Briquette	1/2	2	1

The normalized eigenvectors of the matrices given in Table – 7 and Table – 8 were found and from here the weight matrix of the criteria and the weight matrix of the materials according to the criteria were created (*Table 9 and Table 10*).

Table 9. Weight matrix of criteria (Created by authors)

Criteria	Weights
Thermal conductivity	0.3657
Cost	0.2311
Specific strength	0.1357
Fire resistance	0.1357
Sound transmission loss	0.0803
Carbon footprint	0.0515

Table 10. Weight matrix of materials according to criteria (Created by authors)

Criteria	Materials =>	Brick	Aer. Concrete	Briquette
Thermal conductivity		0.2000	0.6000	0.2000
Cost		0.3196	0.1220	0.5584
Specific strength		0.5278	0.1396	0.3325
Fire resistance		0.4000	0.4000	0.2000
Sound transmission loss		0.5584	0.1220	0.3196
Carbon footprint		0.5396	0.1634	0.2970

The general weight matrix of the materials was found by multiplying these two matrices (*Table 11*).

Table 11. Percentage weight matrix of materials (Created by authors)

Material	Percentage weight
Brick	% 34.55
Aerated concrete	% 33.90
Briquette	% 31.54

Consistency analysis

In the consistency analysis, the consistency rate was determined and checked to see if it was below 10%. The consistency rate is the ratio of the consistency index to the random consistency index (*CR = CI / RI*).

To find the consistency index, the maximum eigenvalue (λ_{max}) was first calculated using the formula λ_{max} = avg (*C.w/w*). (*C => comparison matrix, w => weight vector*). Then, the consistency index (*CI*) was calculated using the formula CI = (λ_{max} - n) / (n-1). The random consistency index (*RI*) was taken from Saaty's table.

$$C = \begin{vmatrix} 1 & 2 & 3 & 3 & 4 & 5 \\ 1/2 & 1 & 2 & 2 & 3 & 4 \\ 1/2 & 1 & 2 & 2 & 3 & 4 \\ 1/3 & 1/2 & 1 & 1 & 2 & 3 \\ 1/4 & 1/3 & 1/2 & 1/2 & 1 & 2 \\ 1/5 & 1/4 & 1/3 & 1/3 & 1/2 & 1 \end{vmatrix} \quad w = \begin{vmatrix} 0.3657 \\ 0.2311 \\ 0.1357 \\ 0.1357 \\ 0.0803 \\ 0.0515 \end{vmatrix}$$

$$C.w = \begin{vmatrix} 2.2208 \\ 1.4037 \\ 0.8240 \\ 0.8240 \\ 0.4875 \\ 0.3130 \end{vmatrix} \quad C.w/w = \begin{vmatrix} 2.2208 / 0.3657 \\ 1.4037 / 0.2311 \\ 0.8240 / 0.1357 \\ 0.8240 / 0.1357 \\ 0.4875 / 0.0803 \\ 0.3130 / 0.0515 \end{vmatrix}$$

Maximum eigenvalue => λ_{max} = avg (C.w/w) = 6.0732

Consistency index => CI = (λ_{max} - n) / (n-1) = 0.0146

Random consistency index => RI = 1.24 (*6x6 matris için*)

Consistency rate => CR = 0.0146 / 1.24 ≈ 0.012 => % 1.2 (*is within the acceptable range*)

Production volumes of materials in Turkey

According to data from the Turkish Statistical Institute, brick, aerated concrete, and briquette are ahead of brick in Turkey in terms of number of companies and production volume. Based on data obtained from the material production indicators in the 2024 Construction Materials Sector Report of the İMSAD (*Construction Materials Industrialists' Association*), the annual production quantities of brick, aerated concrete, and briquette in tonnes are presented in Table 12, and the production quantities in m^3 are presented in Table 13. Graphical representations of these tables are also provided in Figure 2 and Figure 3.

Table 12. Production quantities of bricks, aerated concrete and briquettes in Türkiye in tonnes by year (İMSAD 2024 report)

	Brick	Aer. Concrete	Briquette
2019	18.367.500	1.259.446	5.026.711
2020	16.281.975	1.732.294	6.690.690
2021	15.492.250	2.205.141	7.125.327
2022	13.507.475	2.270.424	6.742.349
2023	15.965.000	1.911.698	8.594.352
2024	16.444.725	2.002.649	9.449.724

Table 13. Production quantities of bricks, aerated concrete and briquettes in Türkiye in m^3 by year (İMSAD 2024 report)

	Brick	Aer. Concrete	Briquette
2019	23700000	2190341	6702281
2020	21009000	3012685	8920920
2021	19990000	3835028	9500436
2022	17429000	3978563	8989799
2023	20600000	3324692	11459136
2024	21219000	3482868	12599632

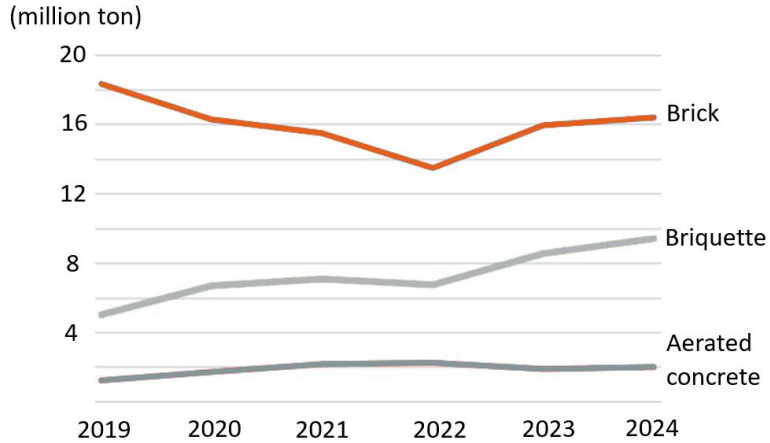

Figure 2. Production quantities of bricks, aer. concrete and briquettes in Türkiye in tonnes by year (İMSAD 2024 report)

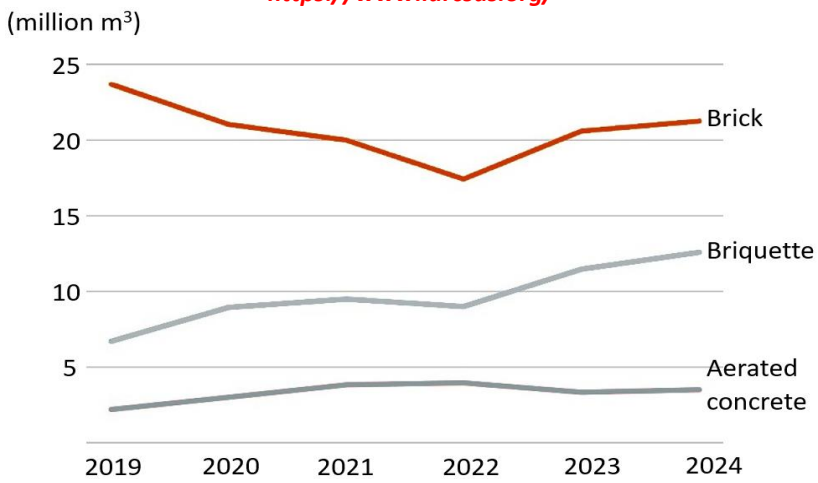

Figure 3. Production quantities of bricks, aerated concrete and briquettes in Turkey in m^3 by year (İMSAD 2024 report)

According to Table 12 and Table 13, between 2019 and 2024, the most produced material was brick, with a total of approximately 96 million tons (*124 million m^3*). Briquettes came in second with approximately 44 million tons (*58 million m^3*), and aerated concrete came in third with approximately 11 million tons (*20 million m^3*).

3. Conclusion and Recommendations

In this study, a survey was conducted with professionals and academics in the Turkish construction sector. The survey identified the criteria that participants considered important regarding exterior walls and ranked them by significance. Using the AHP method, brick, autoclaved aerated concrete (AAC), and briquettes were compared based on these criteria. In this comparison, brick's advantages were its environmental friendliness, strength, and sound attenuation. Aerated concrete's advantages were its low thermal conductivity and light weight. Cost, while an advantage for bricks, was a disadvantage for aerated concrete.

In the AHP, the relative importance of materials in pairwise comparisons was determined based on the numerical values of the materials according to the criteria. The AHP result was determined by the importance ranking of the criteria based on the scoring in the survey, and the numerical values of the materials according to the criteria. The fact that the thermal insulation criterion ranked first in the ranking of importance among the criteria gave a significant advantage to aerated concrete. However, brick ranked first among the alternatives, albeit by a small margin, due to the positive impact of the other criteria. The fact that the cost criterion surpassed all other criteria except thermal insulation also gave the brick a significant advantage. However, the brick ranked last among the alternatives, due to the negative impact of the other criteria.

When examining the annual production volumes of materials in Turkey, two differences emerge from the rankings resulting from the survey and AHP.

1 – Brick production volume far exceeds the production volumes of the other two materials.

2 – While aerated concrete (AAC) ranks second and brick last in the rankings resulting from the AHP, between 2019 and 2024, bricks ranked second and aerated concrete last in terms of production volumes in Turkey.

Tables 12 and 13 show that brick production per ton and m^3 between 2019 and 2024 exceeded the combined production of aerated concrete and briquettes. This indicates that, in the eyes of buyers, brick, as a traditional material, continues to maintain its priority as a wall material.

The reasons for the higher production of bricks compared to aerated concrete include the fact that, in addition to wall construction, they also have applications such as industrial and infrastructure applications, landscaping and environmental planning applications, agricultural and rural applications, and the higher costs of materials, energy, fuel, and labor in the production of aerated concrete. Consequently, this is reflected in the sales price, leading buyers to prefer lower-cost bricks on construction sites where cost is a priority.

Abstract

Urban green spaces are essential urban components for sustainable and livable environments. These areas, which are important recreational spots in cities, are known to provide numerous ecosystem services. The visual quality of the natural and cultural landscape elements within urban green spaces shapes people's aesthetic evaluations of the landscape and determines their spatial usage preferences. Analyzing user preferences and expectations using scientific methods is a crucial input for urban green space planning processes. At this point, eye tracking technology comes to the fore as an alternative to traditional data collection methods. This study examines the integration of eye-tracking technology into the urban planning using the case of Tayfun Gürsoy Park in Ordu. Data were collected using a visual questionnaire and an eye-tracking application. The Green View Index values of 20 photographs were evaluated, along with the responses of questionnaire participants to seven landscape assessment variables and the relationship between the variables obtained through the eye-tracking application. The findings showed that as the proportion of greenery increases, people describe the view as more beautiful, their desire to stay in the space increases, and they tend to perceive the variety of colors and plant presence as sufficient. There were significant differences between landscape architecture students and other participants in terms of the number of fixations, total fixation time, average fixation time, and time to first fixation. This study demonstrates the importance of supporting a participatory approach with up-to-date technological tools in establishing urban green spaces with high visual quality.

Keywords: Eye tracking technology, urban green space, urban planning, green view index, visual quality

1. Introduction

The impact of urbanization is increasing worldwide. This impact is expected to grow exponentially in the future. According to the United Nations (2018), 55% of the global population currently lives in urban areas, and this percentage is expected to reach 68% by 2050. Although cities are centers of economic growth and innovation, this rapid development often leads to numerous problems, ranging from social injustices and limited access to services to air and water pollution, the urban heat island effect, and threats to public health and quality of life

(Knox & McCarthy, 2012; Kumakoshi, 2020; Yu et al., 2020). At this point, urban green spaces, which are important components of urban ecosystems, play a role in carbon sequestration and oxygen release into the atmosphere (Escobedo & Nowak, 2009; Shadman et al., 2022), the absorption of air, water, and soil pollutants (Baycan et al., 2012; Dadvand et al., 2015), absorbing noise, regulating climate (Nowak & Crane, 2002), and supporting urban biodiversity (Kong et al., 2010). Additionally, according to the World Health Organization, urban green spaces and nature-based solutions contribute to sustainable urban development, increase resilience, promote healthy lifestyles, and improve physical and mental well-being.

Urban green spaces, which are located outside the city's built structures and allow nature and greenery to be incorporated into the city, provide inviting and relaxing areas where city dwellers can experience nature (Tyrväinen & Miettinen, 2000; Li et al., 2020). These areas significantly shape perceptions of the urban environment, and the qualified and holistic planning of other structural elements that make up the landscape, such as lighting elements, seating elements, canopy elements, plastic elements, and water surfaces, contributes to urban aesthetics, visual perception, and urban identity. Visually high-quality and holistically designed urban green spaces create an environment conducive to active and passive recreational activities and provide an infrastructure that supports social and cultural events (Haase, 2022; Jabbar et al., 2022). These areas not only encourage physical interaction or provide places to relax, but also strengthen residents' sense of belonging and attachment to their city (Peschardt & Stigsdotter, 2013; Jennings et al., 2016). Recent studies show that residents tend to prefer natural landscapes such as parks, river and sea belts, and other vegetated areas over built environments (Franěk, 2023; Visintin et al., 2025).

In urban areas where land competition threatens the existence of green spaces, it is important to determine the quality of the existing landscape and improve it to meet the needs of residents (Zhang & Zeng, 2024). Regulating and planning the visual and functional quality and quantity of urban green spaces involves a collaborative process involving design and implementation professionals, such as local governments, landscape architects, architects, and urban planners, as well as citizens who use these spaces (Casprini et al., 2023; Romero-Muñoz et al., 2024; Li et al., 2025). Traditional approaches such as suggestions, complaints, and satisfaction surveys exist to ensure citizen participation in these areas. However, these practices can yield misleading results that are susceptible to manipulation, largely due to people's momentary emotional changes, anxiety and pressure in answering questions, etc. Therefore, it is crucial to adopt an objective, quantitative, repeatable, and transparent methodology through technology to effectively evaluate urban green spaces and integrate citizens' demands and expectations into planning processes (Kiss et al., 2022; Beriguete et al., 2024).

Eye tracking technologies have emerged as powerful tools that complement traditional survey applications in aesthetic perception studies. Eye movements are a direct means by which individuals acquire and process information from their surroundings. Various eye tracking technologies provide objective ways to record and analyze these movements, revealing the relationships between visual attention, scene perception, and environmental cognition. Research has shown that eye fixations and eye movements such as pupil index are related to attention and relaxation (Li et al., 2022; Sankar et al., 2025). Additionally, studies using eye-tracking technologies have investigated spatial familiarity, landscape preferences, differences in visual attention and engagement between natural and urban scenes, and viewing patterns in response to landscape complexity (Wu et al., 2021; Sugano et al., 2022; Evans & Chamberlain, 2024; Fleming et al., 2024).

This study is based on the initial findings of the project titled "An Innovative Approach to Urban Green Space Planning: Eye Tracking Technology," conducted under the TÜBİTAK 3005 Innovative Solutions in Social Sciences and Humanities Research Projects Funding Program. The study was conducted at Tayfun Gürsoy Park, one of the coastal parks located in the city center of Ordu, which features various landscape elements and attracts a high volume of visitors. Essentially, the study aims to integrate the visual perceptions of city residents into the urban green space planning process through eye-tracking technology, in addition to the traditional survey method. It seeks to determine the visual quality of urban green spaces, encourage the spread of features that enhance visual quality to other arrangements in the city, and develop recommendations for improving areas perceived as having poor visual quality.

2. Materials and Methods

The study area, Tayfun Gürsoy Park, is located in the Bahçelievler Neighborhood in the center of Altınordu District, Ordu Province, on the Black Sea coast (Figure 1). The total area of the park is approximately 8.5 ha, and its linear length along the coast is approximately 1.290 m. The park, which is one of the important recreational center for the residents of Ordu, offers various recreational facilities such as bicycle and running ways, playgrounds, cafes, car parking areas, and sports facilities (Civelek & Yeşil, 2024).

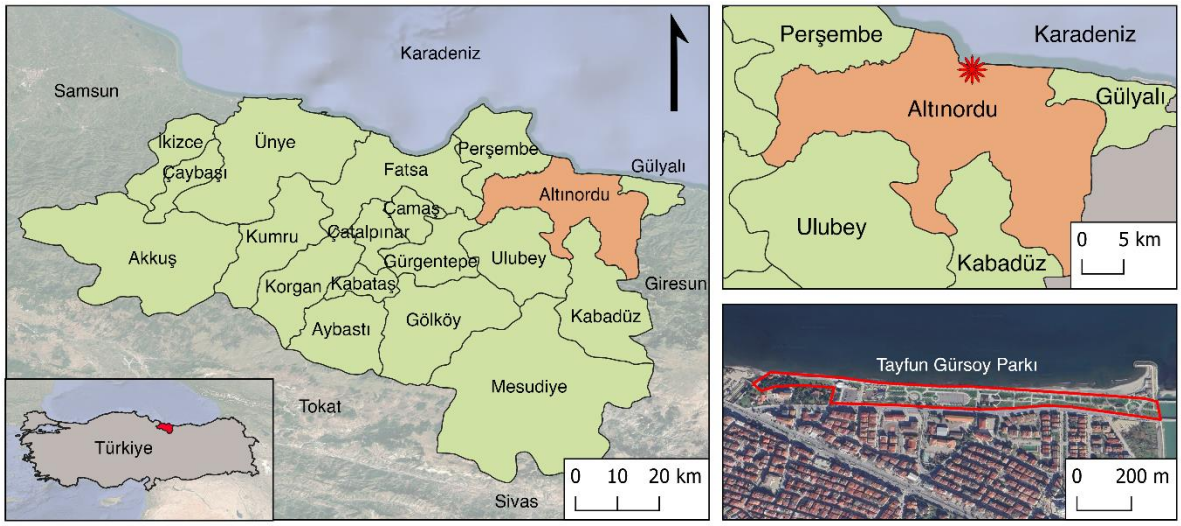

Figure 1. Location of the study area

A seven-stage method was followed in the study (Figure 2). First, photographs to be used in the eye-tracking and survey applications were taken. The Green View Index (GVI) values of all photographs were then calculated, and the photographs to be evaluated were selected. These photographs were then segmented according to landscape elements, and the proportions of these elements in the photographs were calculated. Participant characteristics were determined for the eye-tracking and survey applications, and the eye-tracking and survey applications were conducted. Finally, all data obtained in the study were analyzed using statistical methods, and the findings were evaluated.

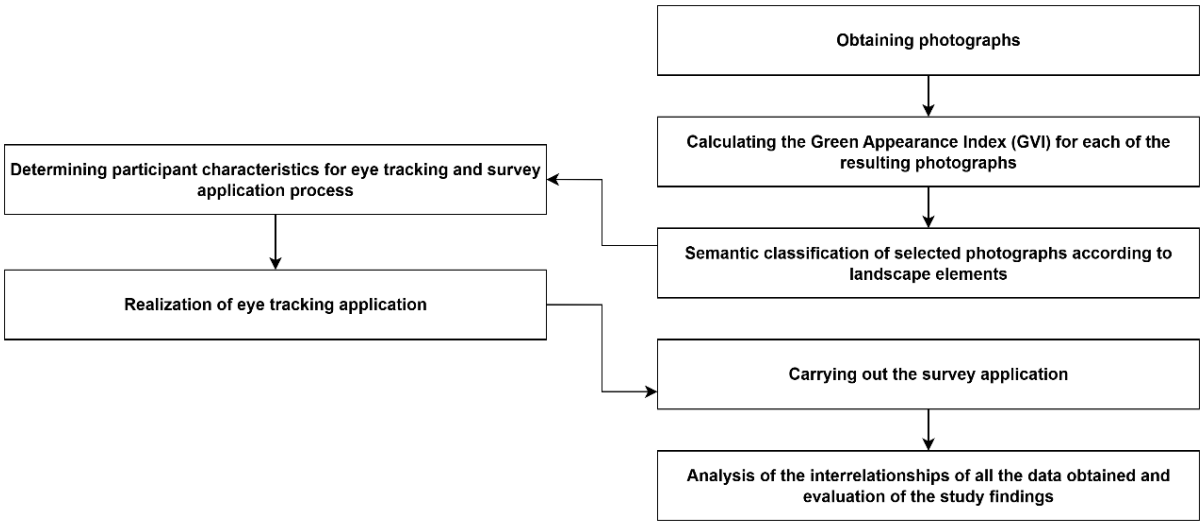

Figure 2. Methodology of the study

The photographs shown to participants in the eye-tracking and survey applications were taken at Tayfun Gürsoy Park between 8:00 and 10:00 a.m. on August 12, 2024, using a Nikon D5300 digital camera and a 67 mm lens. A tripod, set at 1.7 m, was used to stabilize the camera to ensure a standard viewing height for all photographs. All photographs were taken at a resolution of 6000x4000 pixels. A total of 616 photographs were obtained from the park, each containing at least one landscape element such as urban amenities, recreational areas, or water surfaces.

Then, the GVI values of all photographs were calculated. GVI is a parameter that measures the perceived greenness of landscapes from a human perspective. The index is obtained by multiplying the ratio of the number of green pixels corresponding to vegetation in an image to the total number of pixels in the image by 100. This method, first developed by Yang et al. (2009), was later used in many studies at the scale of urban green spaces (Wu et al., 2020; Ki and Lee, 2021).

$$GVI = \frac{Number\ of\ green\ pixels}{Total\ number\ of\ pixels} \times 100$$

After obtaining the GVI values for the photographs, the photographs were divided into four categories (0-25%, 26-50%, 51-75%, and 76-100%) based on their GVI values. Five photographs were selected from each categories using stratified random sampling, reducing the total of 616 photographs to 20. Using the smart selection tools in Adobe Photoshop CC 2014, the photographs were divided into six categories: trees, shrubs, herbaceous plants, hardscape, water surface, and other elements (urban fixtures, signs/panels/banners, fountains, etc.), and the proportions of these landscape elements in the photographs were calculated.

Certain criteria were sought in the selection of volunteers to participate in eye tracking and survey applications. The basic conditions were determined as the participants not wearing glasses, not having color blindness, normal blinking frequency, and not having excessive watery eyes. Additionally, attention was paid to the fact that the participants were healthy individuals between the ages of 18-40 and had lived in the city of Ordu for at least five years. For the applications, an environment isolated from distracting sounds and images was created at the Department of Landscape Architecture, Faculty of Agriculture, Ordu University. Gazepoint GP3 device was used for the eye-tracking application. The device was placed below

the 23.7 inch monitor, and the participants' eye calibrations were provided simultaneously with the monitor using the Gazepoint Analysis UX Edition software on the laptop (Figure 3). During the application, 20 selected photographs were projected on the monitor in random order for 10 seconds and data for a total of 4 variables were collected for each photograph through the software: the number of fixations, total fixation duration, average fixation duration, and time to first fixation. After the eye-tracking application, the participants were asked to look at the same photographs; An online survey, designed on a 5-point Likert scale, was administered to measure variables such as landscape beauty (LB), harmony of landscape elements (HL), plant presence (PP), color variety (CV), maintenance and cleaning (MC), meeting recreational needs (MR), and desire to be in the place (DP). After eliminating data that did not meet the criteria and were deemed incorrect, data from a total of 26 participants were evaluated to assess the preliminary results of the study. The GVI values obtained in the study, the proportions of landscape elements in the photograph, eye-tracking variables, and the scores assigned to the landscape evaluation variables were combined and statistically evaluated.

Figure 3. Eye tracking application

3. Findings and Discussion

3.1. Findings on Landscape Assessment Variables Using the Green View Index (GVI)

According to the results obtained, five of the landscape assessment variables show a positive correlation with GVI (Table 1). In particular, the relationship between the Plant Presence (PP) variable and GVI is quite strong ($r = 0.365$, $p < .001$). This finding means that as the proportion of green space in the scenes shown to participants increases, participants perceive greater plant richness. In addition, significant and positive relationships were also found between GVI and the variables of Landscape Beauty (LB), Harmony of Landscape Element (HL), and Color Variety (CV). This situation shows that the perception of green appearance may be related not only to the perceived presence of plant material but also to the aesthetic integrity of the

composition and color diversity. On the other hand, no significant relationship was observed between GVI and the variables of Maintenance and Cleaning (MC) and Meeting Recreational Needs (MR). Accordingly, it is understood that a landscape with a high green appearance ratio does not, on its own, give participants the impression of a well-maintained or functional area.

Table 1. Correlation between GVI and landscape assessment variables

		Landscape Assessment Variables						
		LB	HL	PP	CV	MC	MR	DP
GVI	Pearson's r	**0.213*** **	**0.192*** **	**0.365*** **	**0.211*** **	–0.051	0.072	**0.100*** **
	p-value	< .001	< .001	< .001	< .001	0.241	0.100	< .001
	N	520	520	520	520	520	520	520

LB: Landscape beauty, HL: Harmony of landscape elements, PP: Plant presence, CV: Color variety, MC: Maintenance and Cleaning, MR: Meeting Recreational Needs, DP: Desire to be in the space

The differences in the average scores of the landscape assessment variable between the four GVI categories (0-25%, 26-50%, 51-75%, 76-100%) were tested using a one-way ANOVA (Table 2). Accordingly, it was observed that the mean scores of the questionnaire participants for MC and MR did not differ significantly across GVI categories. The averages of all other variables were lowest in photos with the least green cover, while evaluations made when GVI exceeded 25% did not show a significant difference (Figure 4). This suggests that 25% may be a psychological threshold for the proportion of green cover in the landscapes visible to participants. In photographs below this threshold, participants tended to give low scores to landscape evaluation variables. In other words, weak green texture negatively affected landscape perception and satisfaction levels.

Table 2. Results of the One-Way ANOVA test

	One-Way ANOVA			
	F	**df1**	**df2**	**p**
LB	8.38	3	285	< .001
HL	8.18	3	286	< .001
PP	34.31	3	285	< .001
CV	10.59	3	285	< .001
MC	1.16	3	287	0.325
MR	1.40	3	285	0.243
DP	7.01	3	286	< .001

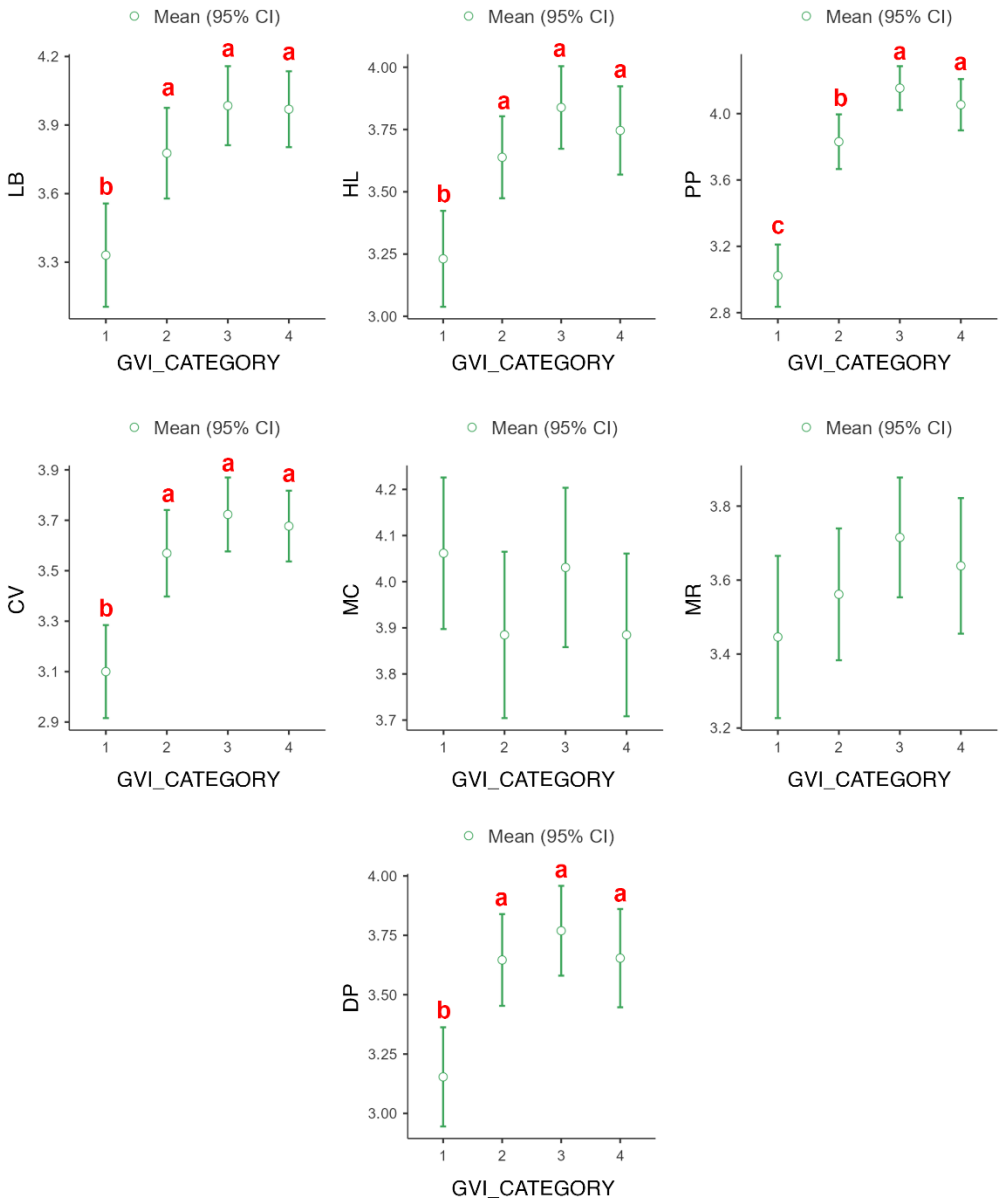

Figure 4. Differences in average scores for landscape assessment variables between GVI categories

3.2. Relationship Between Landscape Assessment Variables and the Proportion of Landscape Elements

Table 3 shows the correlation between the landscape evaluation scores of questionnaire participants regarding the photographs and the proportions of landscape elements in the photographs. The relationships between landscape elements and landscape evaluation variables are important in revealing the nature of the elements that shape participants' visual and functional perceptions.

The Landscape Beauty (LB) variable shows a significant positive correlation with the proportions of trees (r=0.094) and shrubs (r=0.104) in the photographs, and a negative correlation with hardscape (r=–0.090) and especially other elements (r=–0.169). This indicates

that questionnaire participants rated landscapes with dense vegetation as more beautiful and aesthetically pleasing. However, an increase in man-made elements such as benches, trash cans, or lighting fixtures reduced the perception of landscape beauty. The PP variable has a strong positive relationship with trees (r=0.270) and shrubs (r=0.170) and a negative relationship with hardscapes (r=–0.213) and water surfaces (r=–0.111). Participants evaluate landscapes with high tree and shrub density as rich in plant material. Hardscapes and structural elements, on the other hand, reduce the perception of plant presence. Desire to be in the space (DP) is positively correlated with shrub texture in photographs (r=0.103) and negatively correlated with other elements (r=–0.115). Participants' desire to be in a space or spend time there may increase with the continuity of the plant composition. At this point, shrubs may have served as a visual layer connecting all elements in the landscape. However, the increase in elements such as billboards or urban furniture in scenes of the park disrupted the sense of spatial integrity, reducing people's desire to be there. The Maintenance and Cleaning (MC) score showed a weak negative correlation with the tree ratio in the photographs (r=–0.096). The dense tree structure in the views seen may have created a perception of neglect by lowering the perception of visual cleanliness in people due to fallen leaves, the shading effect, or low visibility.

Generally, positive relationships are found between landscape evaluation variables and plant elements such as trees and shrubs, while negative relationships are generally observed with hardscapes or other elements. Accordingly, it is understood that participants evaluated landscapes with a plant-material emphasis and a natural character more positively in terms of aesthetics and functionality. Conversely, scenes dominated by structural landscapes were perceived with lower scores.

Table 3. Correlation between landscape assessment variables and the proportion of landscape elements in photographs

Landscape assessment variable	Tree	Shrub	Herbaceous plants	Hardscape	Water surface	Other elements
LB	**0.094***	**0.104***	0.019	**–0.090***	0.024	**–0.169*****
HL	**0.100***	**0.107***	0.025	–0.078	–0.034	**–0.089***
PP	**0.270*****	**0.170*****	0.075	**–0.213*****	**–0.111***	–0.031

3.3. Relationship Between Eye Tracking Variables and Participant Profile
